1 BricsCAD **35**

1.1 What's new in BricsCAD V21 . . . 35
1.1.1 Overview . . . 35
1.1.2 User interface . . . 36
1.1.3 Productivity . . . 45
1.1.4 Drafting . . . 74
1.1.5 Modeling . . . 79
1.1.6 Civil Tools . . . 96
1.1.7 Performance and compatibility . . . 107
1.2 Launching BricsCAD . . . 113
1.2.1 The BricsCAD Launcher . . . 113
1.2.2 Feature Comparison . . . 115
1.2.3 Setting the License Level . . . 116
1.2.4 The License Manager . . . 117
1.3 Installing BricsCAD . . . 118
1.3.1 Overview of install options . . . 118
1.3.2 Interactive Installation . . . 119
1.3.3 Silent Installation (Windows only) . . . 120
1.4 Installation & Licensing . . . 121
1.4.1 BricsCAD Migration – The BricsCAD User Interface . . . 121
1.4.2 How to roam with a network license . . . 123
1.4.3 BricsCAD License Server Setup . . . 124
1.5 Templates . . . 127
1.5.1 Command Reference V21 . . . 127
1.5.2 Command Reference Template . . . 130
1.6 Exploring the Interface . . . 133
1.6.1 The Start tab . . . 133
1.6.2 Document Tabs . . . 135
1.6.3 Choosing the Workspace . . . 136
1.6.4 The Command Line . . . 137
1.6.5 Toolbars . . . 138
1.6.6 The Ribbon . . . 139
1.6.7 The Quad Basics . . . 140
1.6.8 The Status Bar . . . 143
1.6.9 Right-click Menus . . . 144
1.6.10 Panels . . . 145
1.6.11 The Drawing Area . . . 146
1.6.12 The Clean Screen Mode . . . 148
1.6.13 Menus . . . 149
1.7 Activating and Licensing . . . 150
1.7.1 Overview of licensing options . . . 150
1.7.2 Activating a single or volume license automatically (online) . . . 152
1.7.3 Activating a single or volume license manually (offline) . . . 153
1.7.4 Activating a network license automatically (online) . . . 156
1.7.5 Activating a network license manually (offline) . . . 157
1.7.6 Activating a trial license automatically (online) . . . 158
1.7.7 Activating a trial license manually (offline) . . . 159
1.7.8 Using a network license on a client computer . . . 162
1.7.9 Roaming a network license on a client computer . . . 163
1.7.10 Proxy settings . . . 165

1.7.11 Returning a roamed network license to the server . . . 168
1.8 Installation and Licensing . . . 169
1.8.1 Minimum system requirements and recommendations . . . 169
1.8.2 Downloading BricsCAD . . . 171
1.8.3 Trial Mode . . . 172
1.8.4 Safe Mode . . . 173
1.8.5 Communicator for BricsCAD . . . 174
1.9 Interface . . . 175
1.9.1 How to navigate quickly around your drawing . . . 175
1.9.2 Maximizing the Drawing Area with Clean Screen . . . 176
1.9.3 On-screen Tips Widget in BricsCAD . . . 177
1.9.4 Tips and Tricks for Drawing Explorer . . . 179
1.9.5 Experience the Quad Cursor in BricsCAD . . . 180
1.9.6 Those Five Other Selection Modes in BricsCAD . . . 181
1.9.7 Use Layer States instead of Clicking Bulbs . . . 182
1.9.8 BricsCAD Spreadsheet Import Techniques . . . 183
1.10 Working in BricsCAD . . . 184
1.10.1 Template Drawings . . . 184
1.10.2 Entity creation settings . . . 185
1.10.3 How to draw accurately . . . 186
1.10.4 View control . . . 187
1.10.5 Selecting Entities . . . 188
1.10.6 Executing Commands . . . 189
1.10.7 Using the Manipulator . . . 191
1.10.8 Working with the Structure Panel . . . 194
1.11 Setting up a Network License Server . . . 195
1.11.1 Network license server . . . 195
1.11.2 Setting up a Windows network license server . . . 196
1.11.3 Setting up a Linux network license server . . . 199
1.11.4 Roaming . . . 200
1.11.5 Network license server administration . . . 201
1.11.6 Advanced configurations . . . 209
1.11.7 License Pooling . . . 211
1.12 Customization . . . 213
1.12.1 User profiles . . . 213
1.12.2 Customizing the Ribbon . . . 214
1.12.3 Customizing settings . . . 215
1.12.4 Customizing display settings . . . 216
1.12.5 Controlling BricsCAD Through Settings . . . 217
1.12.6 Working with Tiled Viewports in Model Space . . . 218
1.12.7 The Prompt Menu and Its Many Uses . . . 219
1.12.8 Customizing the Command Prompt . . . 220
1.12.9 Easy Menu Customization in BricsCAD . . . 221
1.12.10 Customizing shortcut menus . . . 222
1.12.11 Abbreviating Command Input with Aliases . . . 223
1.12.12 Saving Your Customizations with Partial CUI Files . . . 224
1.12.13 Customize mouse buttons to add tools to BricsCAD . . . 225
1.12.14 Customizing Tool Palettes in BricsCAD . . . 227
1.12.15 Advanced Menu Customization . . . 228
1.12.16 Clipping Attached Images and PDF Files . . . 229
1.12.17 Employing the Display Power of Layer States . . . 230
1.12.18 Clipping x-refs and blocks . . . 231
1.12.19 Joining Multiple Entities in BricsCAD . . . 232
1.12.20 Creating Custom Template Drawings . . . 233
1.13 Managing Licenses . . . 234
1.13.1 Deactivating or revoking a BricsCAD license . . . 234
1.13.2 Modifying a BricsCAD license . . . 240
1.13.3 Managing BricsCAD licenses with multiple Bricsys accounts. . . . 241
1.13.4 Migrating a license to another computer . . . 242
1.14 Drawing . . . 243
1.14.1 Drawing Accurately: Snap and Grid . . . 243
1.14.2 Drawing Accurately: Polar and Snap Tracking . . . 246

1.14.3 Tip on how to create blocks quickly on the fly . . . 252
1.14.4 Dynamic Grips and Tips . . . 253
1.14.5 Grips Editing in BricsCAD . . . 254
1.14.6 Secrets of the shift key in BricsCAD . . . 255
1.14.7 How to Align Entities . . . 256
1.14.8 Use Quick Select . . . 257
1.14.9 Using the DimBreak Command in BricsCAD . . . 259
1.14.10 Package Your Drawings with eTransmit . . . 260
1.14.11 Copying between drawings . . . 262
1.14.12 Making Smarter Drawings with Annotative Scales . . . 263
1.15 Interface . . . 264
1.15.1 Keyboard Shortcuts . . . 264
1.15.2 The BricsCAD Application Window . . . 266
1.15.3 Toolbars . . . 288
1.15.4 Properties Panel . . . 313
1.15.5 The Quad cursor menu . . . 326
1.15.6 Prompt Menus . . . 339
1.15.7 Dockable Panels . . . 341
1.15.8 Digitizing Tablet . . . 353
1.16 2D Drafting . . . 358
1.16.1 Use the Quad to simplify working with Hatch . . . 358
1.16.2 Making entities transparent . . . 359
1.16.3 Copying Layouts to Model Tab . . . 360
1.16.4 Creating and Editing Associative Arrays . . . 361
1.16.5 Transform a smartphone into a tablet . . . 362
1.17 Customization . . . 363
1.17.1 BricsCAD Startup Options . . . 363
1.17.2 BricsCAD user files . . . 365
1.17.3 Loading and unloading CUI files . . . 367
1.17.4 Understanding the Customize Dialog . . . 372
1.17.5 Creating custom tools . . . 375
1.17.6 Ribbon . . . 396
1.17.7 Tool Palettes . . . 409
1.17.8 User Profile Manager . . . 433
1.17.9 Command Aliases . . . 437
1.17.10 Settings dialog box . . . 440
1.17.11 Workspaces . . . 452
1.18 3D Modeling . . . 463
1.18.1 Making 3D surfaces . . . 463
1.18.2 Modify 3D surfaces . . . 464
1.18.3 Slice, section and interfere . . . 465
1.18.4 Extrude and revolve . . . 466
1.18.5 Slicing up 3D models . . . 467
1.18.6 Snap to 3D geometry . . . 468
1.18.7 Loft 3D Surfaces . . . 469
1.18.8 Thicken 3D and 3D entities . . . 470
1.18.9 Twist 3D solids . . . 471
1.18.10 Sweep profiles along paths . . . 472
1.18.11 Use surface modeling and deformable modeling . . . 473
1.18.12 Turning 2D Entities in Simple 3D . . . 474
1.18.13 3D Manipulator . . . 475
1.18.14 Section planes . . . 476
1.18.15 Flatten and extract faces and edges . . . 477
1.18.16 Deform faces . . . 478
1.18.17 Naming 3D parts . . . 479
1.18.18 Draw 2D Entities in 3D Space . . . 480
1.18.19 Solids, surfaces and Meshes . . . 481
1.18.20 Boolean operations . . . 482
1.18.21 3D fillet and chamfer . . . 483
1.18.22 Solid edit: part 1 . . . 484
1.18.23 Solid edit: part 2 . . . 485
1.18.24 Static UCS, Set 2D Drawing Planes in 3D . . . 486

1.18.25 3D Primitives . . . 487
1.18.26 Viewing in 3D . . . 488
1.18.27 3D Direct Modeling Basic Commands . . . 489
1.18.28 Extending onto the curve . . . 491
1.18.29 Making Beautiful Shapes from Lofts . . . 492
1.18.30 Project Geometry – Corrugate Iron . . . 493
1.18.31 3D Modeling at a Clip . . . 494
1.18.32 Generate drawing views in BricsCAD . . . 495
1.18.33 Project Geometry – Vessel . . . 496
1.18.34 Bring life to your BricsCAD models with Render Materials . . . 497
1.18.35 How to setup the 3DConnexion 3D mouse in BricsCAD . . . 499
1.18.36 Dynamic UCS, Drawing on any 3D Face . . . 500
1.19 Managing Drawings . . . 501
1.19.1 Creating a drawing . . . 501
1.19.2 Drawing Explorer . . . 509
1.19.3 Exploring the Drawing Explorer . . . 518
1.19.4 Drawing Properties . . . 540
1.19.5 Drawing Security Options . . . 544
1.19.6 Opening and saving drawings . . . 546
1.19.7 Getting drawing information . . . 551
1.19.8 Repairing a drawing . . . 552
1.19.9 Export to PDF . . . 553
1.19.10 Comparing Drawings . . . 555
1.19.11 Projects . . . 559
1.20 Images . . . 562
1.20.1 Backgrounds for visualizing your 3D models . . . 562
1.20.2 Image Geolocator . . . 563
1.21 Drawing Accurately . . . 564
1.21.1 Drawing Accurately Overview . . . 564
1.21.2 Orthogonal Mode . . . 565
1.21.3 Unit Settings . . . 566
1.21.4 Direct Distance Entry . . . 569
1.21.5 Coordinate Reference System . . . 570
1.21.6 2D Constraints Overview . . . 574
1.21.7 Using Dimensional Constraints . . . 578
1.21.8 Using Geometric Constraints . . . 586
1.21.9 Dynamic Dimensions . . . 595
1.21.10 Nearest distance . . . 602
1.21.11 Coordinate Input . . . 607
1.21.12 Using Snap and Grid . . . 613
1.21.13 Adaptive grid snap . . . 617
1.21.14 Nudge . . . 620
1.21.15 2D Entity Snaps . . . 621
1.21.16 3D Entity Snaps . . . 637
1.21.17 Entity Snap Tracking . . . 639
1.21.18 Polar Tracking . . . 642
1.21.19 Measuring . . . 646
1.21.20 Dynamic UCS . . . 650
1.21.21 User Coordinate Systems . . . 652
1.22 Printing & Plotting . . . 658
1.22.1 Output As Pdf . . . 658
1.22.2 Paper Space Layouts in BricsCAD . . . 659
1.22.3 Printing in BricsCAD: Paper Space Layouts . . . 660
1.22.4 Printing in BricsCAD: Viewports . . . 664
1.22.5 Printing in BricsCAD: Plotter Configurations . . . 665
1.22.6 Creating Plot Stamps . . . 669
1.22.7 Printing in BricsCAD: Plot Style Tables . . . 670
1.23 Viewing your Drawing . . . 673
1.23.1 View Commands Overview . . . 673
1.23.2 Layer Utilities . . . 677
1.23.3 Hide and Show Entities . . . 679
1.23.4 Redrawing and Regenerating a Drawing . . . 680

1.23.5 Zooming . . . 681
1.23.6 View manipulation using the mouse and keyboard . . . 684
1.23.7 View Rotation . . . 686
1.23.8 Panning . . . 701
1.23.9 Layer States . . . 703
1.23.10 Named Views . . . 713
1.23.11 Model Space Viewports . . . 720
1.23.12 Model space and paper space . . . 724
1.23.13 Layouts . . . 726
1.23.14 Generated Drawing Views . . . 729
1.23.15 Perspective Views . . . 740
1.23.16 Paper space viewports . . . 743
1.24 Programming . . . 757
1.24.1 Unlock BricsCAD's extra features . . . 757
1.24.2 The Case for Using LISP Today, Part 2 . . . 758
1.24.3 BricsCAD Lisp – Migrating from OtherCAD . . . 759
1.24.4 The Case for Using LISP Today, Part 1 . . . 762
1.25 2D Drafting . . . 763
1.25.1 Drawing Entities Overview . . . 763
1.25.2 Settings for Drawing Entities . . . 764
1.25.3 Current Layer . . . 767
1.25.4 Working with Layers and Linetypes . . . 769
1.25.5 Entity Color . . . 775
1.25.6 Entity Linetype . . . 780
1.25.7 Lineweight . . . 787
1.25.8 Fill Mode . . . 791
1.25.9 Transparency . . . 794
1.25.10 Lines . . . 795
1.25.11 Rays . . . 797
1.25.12 Polylines . . . 798
1.25.13 Infinite Lines . . . 811
1.25.14 Circles . . . 812
1.25.15 Arcs . . . 815
1.25.16 Elliptical Arcs . . . 818
1.25.17 Freehand sketches . . . 822
1.25.18 Rectangles . . . 824
1.25.19 Splines . . . 827
1.25.20 Polygons . . . 830
1.25.21 Ellipses . . . 831
1.25.22 Traces . . . 834
1.25.23 Solids . . . 835
1.25.24 Revision Clouds . . . 836
1.25.25 Wipeouts . . . 838
1.25.26 Hatching Overview . . . 840
1.25.27 Creating Hatches and Gradient Fills . . . 843
1.25.28 Donuts . . . 851
1.25.29 Editing a hatch or gradient fill . . . 853
1.25.30 Editing Entities . . . 861
1.25.31 Drawing with Styles . . . 866
1.25.32 Drawing Entities . . . 875
1.25.33 Points . . . 888
1.26 3D Modeling . . . 891
1.26.1 Direct Modeling Overview . . . 891
1.26.2 Direct Modeling Operations . . . 892
1.26.3 Design intent recognition . . . 912
1.26.4 Working with sections . . . 920
1.26.5 Navigate in 3D . . . 940
1.26.6 Create a TIN Surface . . . 944
1.26.7 Working with Gradings . . . 964
1.26.8 TIN Surface Edit . . . 978
1.26.9 TIN Surface Direct Modeling . . . 986
1.26.10 Create and edit Alignments . . . 1004

1.26.11 Analyzing TIN Surfaces . . . 1025
1.26.12 Modeling a Corridor . . . 1031
1.27 Parametric Modeling . . . 1050
1.27.1 Parametric Modeling Overview . . . 1050
1.27.2 Parameters Manager . . . 1053
1.27.3 3D Constraints . . . 1055
1.27.4 3D Constraints Properties . . . 1059
1.27.5 Suppression Feature . . . 1065
1.27.6 Creating a design table to drive Parametric Blocks parameters . . . 1067
1.27.7 Parameters and their Properties in Mechanical Browser . . . 1074
1.28 Point Cloud . . . 1076
1.28.1 Working with Point Clouds (V21) . . . 1076
1.28.2 Working with point clouds (V20) . . . 1094
1.28.3 Working with Point Clouds (V19) . . . 1097
1.29 Annotate . . . 1105
1.29.1 Dimensioning tools overview . . . 1105
1.29.2 Associative Dimensions . . . 1108
1.29.3 Dimension Styles explorer . . . 1109
1.29.4 Dimension Settings . . . 1112
1.29.5 Working with dimension styles . . . 1113
1.29.6 Using the dimension style tools . . . 1117
1.29.7 Creating linear dimensions . . . 1119
1.29.8 Creating angular dimensions . . . 1122
1.29.9 Creating diametrical and radial dimensions . . . 1125
1.29.10 Centerlines and Center Marks . . . 1126
1.29.11 Creating leaders and annotations . . . 1130
1.29.12 Creating ordinate dimensions . . . 1132
1.29.13 Working with Multileaders . . . 1133
1.29.14 Editing dimensions . . . 1138
1.29.15 Adding Geometric Tolerances . . . 1141
1.29.16 Editing text . . . 1143
1.29.17 Text Variables . . . 1146
1.29.18 Exploding text . . . 1147
1.29.19 Working with text styles . . . 1148
1.29.20 Creating text . . . 1151
1.29.21 Checking Spelling . . . 1159
1.29.22 Finding and replacing text . . . 1169
1.29.23 Working with Fields . . . 1173
1.29.24 Tables . . . 1178
1.29.25 Annotative Entities . . . 1190
1.29.26 Table Styles . . . 1192
1.29.27 Annotative Hatches and Gradient Fills . . . 1195
1.29.28 Link data from Excel sheets . . . 1196
1.29.29 Annotation Scales . . . 1197
1.29.30 Annotative Dimensions . . . 1199
1.29.31 Annotative Blocks . . . 1200
1.29.32 Annotative Texts . . . 1201
1.29.33 Annotative Leaders . . . 1202
1.30 Blocks, Attributes, External References and Components . . . 1203
1.30.1 Parametrize . . . 1203
1.30.2 Blockify . . . 1204
1.30.3 Working with Blocks . . . 1211
1.30.4 Block editor . . . 1219
1.30.5 Inserting Blocks . . . 1220
1.30.6 Creating Blocks . . . 1229
1.30.7 Dynamic blocks vs. 2D Parametric Blocks . . . 1233
1.30.8 Exploding Blocks . . . 1243
1.30.9 Redefining Blocks . . . 1244
1.30.10 Dynamic Blocks . . . 1246
1.30.11 Exploring Blocks . . . 1250
1.30.12 Working with attributes . . . 1253
1.30.13 Defining Attributes . . . 1254

1.30.14 Editing attributes attached to blocks . . . 1258
1.30.15 Placing blocks with attributes . . . 1262
1.30.16 Extracting attribute information . . . 1264
1.30.17 Managing Xrefs . . . 1266
1.30.18 Editing attribute definitions . . . 1267
1.30.19 Attaching an external reference . . . 1270
1.30.20 Working with References . . . 1272
1.30.21 Editing blocks and external references . . . 1280
1.30.22 Working with groups . . . 1283
1.30.23 Working with underlays . . . 1288
1.30.24 Working with external references . . . 1296
1.30.25 Components and Component Inserts . . . 1298
1.31 Managing Images . . . 1309
1.31.1 Exploring Images . . . 1309
1.31.2 Image Utilities . . . 1317
1.32 Modifying Entities . . . 1320
1.32.1 Modifying Commands Overview . . . 1320
1.32.2 Entity Modification Settings . . . 1323
1.32.3 Grips editing . . . 1325
1.32.4 Selection and grip settings . . . 1333
1.32.5 Match Properties . . . 1340
1.32.6 Quick Select . . . 1343
1.32.7 Selection Methods . . . 1350
1.32.8 Adjusting the Draw Order . . . 1354
1.32.9 Entity Manipulation . . . 1356
1.32.10 Manipulator . . . 1366
1.32.11 Moving Entities . . . 1371
1.32.12 Rotating Entities . . . 1374
1.32.13 Mirroring Entities . . . 1376
1.32.14 Aligning Entities . . . 1377
1.32.15 The Structure Panel . . . 1381
1.32.16 Changing Entities . . . 1388
1.32.17 Copying Entities in a Drawing . . . 1389
1.32.18 Copying Entities Between Drawings . . . 1392
1.32.19 Arraying Entities . . . 1394
1.32.20 Making Parallel Copies . . . 1403
1.32.21 Trimming Entities . . . 1405
1.32.22 Extending Entities . . . 1406
1.32.23 Changing the length of an entity . . . 1408
1.32.24 Stretching Entities . . . 1410
1.32.25 Scaling Entities . . . 1412
1.32.26 Joining Entities . . . 1414
1.32.27 Chamfering Entities . . . 1416
1.32.28 Filleting Entities . . . 1421
1.32.29 Converting an entity into a polyline . . . 1426
1.32.30 Opening and closing polylines . . . 1427
1.32.31 Joining Polylines . . . 1428
1.32.32 Breaking Entities . . . 1429
1.32.33 Editing polyline vertices . . . 1430
1.32.34 Changing the polyline width . . . 1435

2 BricsCAD BIM 1569
2.1 What's new in BricsCAD V21 BIM . . . 1569
2.1.1 Overview . . . 1569
2.1.2 Modeling Techniques . . . 1570
2.1.3 Building Data . . . 1581
2.1.4 Project Collaboration . . . 1594
2.1.5 Design Documentation . . . 1597
2.1.6 Point clouds . . . 1609
2.2 Getting Started . . . 1615
2.2.1 Exploring the BricsCAD BIM User Interface . . . 1615
2.2.2 How to navigate . . . 1616
2.2.3 How to use Quad Cursor & Rollover Tips . . . 1617
2.3 Getting Started . . . 1618
2.3.1 Creating a BIM Model . . . 1618
2.3.2 Exploring the Interface . . . 1621
2.3.3 Quad Cursor . . . 1644
2.3.4 Viewing Entities . . . 1652
2.3.5 Selecting Entities . . . 1659
2.3.6 Level of Detail . . . 1680
2.3.7 BIM Article Template . . . 1681
2.4 Modeling Techniques . . . 1683
2.4.1 How to create and edit sections . . . 1683
2.4.2 How to create a pitched roof . . . 1684
2.4.3 How to create wall layouts . . . 1685
2.4.4 How to detect boundaries in BricsCAD BIM . . . 1686
2.4.5 How to connect walls . . . 1687
2.4.6 How to extrude . . . 1688
2.4.7 How to create walls . . . 1689
2.4.8 How to hide and isolate objects . . . 1690
2.4.9 How to push or pull solids . . . 1691
2.4.10 How to select elements . . . 1692
2.4.11 How to use Grids . . . 1693
2.4.12 How to use linear solids . . . 1694
2.4.13 How to add eccentricities to linear solids . . . 1695
2.4.14 How to offset . . . 1696
2.4.15 How to create Curtain Walls . . . 1697
2.4.16 How to use the BIM Insert tool . . . 1698
2.4.17 How to automatically Parametrize objects . . . 1699

2.4.18 How to connect linear solids . . . 1700
2.4.19 How to create a Grading . . . 1701
2.4.20 How to use BIM Drag . . . 1702
2.4.21 How to use the MEP modeling tools . . . 1703
2.4.22 How to use Layers . . . 1704
2.4.23 How to use selection windows . . . 1705
2.4.24 How to use the Components Panel . . . 1706
2.4.25 How to use the Window Creator tool . . . 1707
2.4.26 How to use Quickdraw . . . 1708
2.5 Modeling Techniques . . . 1709
2.5.1 BIM Linear Solid . . . 1709
2.5.2 BIM Window Create . . . 1721
2.5.3 The Library Panel . . . 1733
2.5.4 Connecting Solids . . . 1741
2.5.5 Creating a Custom Window . . . 1754
2.5.6 Creating Roofs . . . 1766
2.5.7 Creating Walls . . . 1790
2.5.8 Creating Slabs . . . 1809
2.5.9 Curtain Wall . . . 1812
2.5.10 DmExtrude . . . 1826
2.5.11 DmPushPull . . . 1838
2.5.12 Editing Grids . . . 1840
2.5.13 Mass modeling with Quickbuilding . . . 1842
2.5.14 MEP Modeling . . . 1856
2.5.15 Offset . . . 1879
2.5.16 MEP Flow Connection Points . . . 1884
2.5.17 Splitting Solids . . . 1893
2.5.18 Using Drag . . . 1894
2.5.19 Inserting and editing Windows and Doors . . . 1899
2.5.20 Structural Steel . . . 1915
2.5.21 Using Parametrize . . . 1951
2.5.22 Using BIM Quickdraw . . . 1963
2.5.23 Stair Tool . . . 1984
2.5.24 Working with Parameters and Constraints . . . 2003
2.6 Building Data . . . 2015
2.6.1 How to add and create Compositions . . . 2015
2.6.2 How to add Building & Story information . . . 2016
2.6.3 How to classify BIM elements . . . 2017
2.6.4 How to create and edit Custom Properties . . . 2018
2.6.5 How to define Rooms . . . 2019
2.6.6 How to extend a Ply . . . 2020
2.6.7 How to use Classification Codes . . . 2021
2.6.8 How to use the Structure Browser . . . 2022
2.6.9 How to use the Project Browser . . . 2023
2.6.10 How to use the Profile Library for linear solids . . . 2024
2.6.11 How to use the Properties panel . . . 2025
2.7 Building Data . . . 2026
2.7.1 Analytical Model . . . 2026
2.7.2 AutoComplete BIM Data . . . 2047
2.7.3 BIM Classify . . . 2057
2.7.4 BIM Compositions . . . 2063
2.7.5 Attaching Compositions . . . 2074
2.7.6 BIM Data Structure . . . 2080
2.7.7 BIM Project Info . . . 2082
2.7.8 BIM Ply Editing . . . 2090
2.7.9 Using Python Scripts (beta) . . . 2107
2.7.10 Classification Codes . . . 2111
2.7.11 Custom Properties . . . 2117
2.7.12 Load Bearing Direction for slabs . . . 2122
2.7.13 Customizing BIM quantities . . . 2126
2.7.14 Creating and editing BIM Spaces . . . 2134
2.7.15 Project Browser . . . 2140

2.7.16 Spatial Locations . . . 2154
2.7.17 Physical Materials . . . 2163
2.7.18 Structure Browser . . . 2174
2.8 Design Assistance . . . 2183
2.8.1 Advanced Modeling with Propagate . . . 2183
2.8.2 How to automate classification with "BIMIFY" in BricsCAD BIM . . . 2184
2.8.3 How to use Propagate Linear . . . 2185
2.8.4 How to use Propagate Pattern . . . 2186
2.8.5 How to use Propagate Planar . . . 2187
2.8.6 How to use Propagate Edges . . . 2188
2.8.7 How to use Propagate Corner . . . 2189
2.9 Design Assistance . . . 2190
2.9.1 Using Bimify . . . 2190
2.9.2 Using Propagate . . . 2201
2.9.3 Propagate Linear . . . 2210
2.9.4 Propagate Pattern . . . 2213
2.9.5 Propagate Planar . . . 2216
2.9.6 Propagate Edges . . . 2219
2.9.7 Propagate Corner . . . 2222
2.9.8 Parametrize details . . . 2229
2.9.9 Details Panel . . . 2253
2.9.10 Rhino/Grasshopper Integration . . . 2268
2.10 Project Collaboration . . . 2289
2.10.1 How to do clash detection in BricsCAD BIM . . . 2289
2.10.2 How to import .RFA files . . . 2290
2.10.3 How to import & export IFC files in BricsCAD BIM . . . 2291
2.11 Project Collaboration . . . 2292
2.11.1 BIM Collaboration Format (BCF) Panel . . . 2292
2.11.2 Bricsys 24/7 Panel . . . 2299
2.11.3 IFC Import and Export in BricsCAD . . . 2306
2.11.4 Import and Underlay Autodesk® Revit® files in BricsCAD . . . 2326
2.11.5 Importing Autodesk® Revit® Families in BricsCAD . . . 2335
2.11.6 Interference Checking . . . 2342
2.11.7 Using Xrefs . . . 2346
2.12 Design Documentation . . . 2351
2.12.1 How to add tags . . . 2351
2.12.2 How to create Interior Elevations . . . 2352
2.12.3 How to create Schedules . . . 2353
2.12.4 How to extract data in BricsCAD BIM . . . 2354
2.12.5 How to generate sections . . . 2355
2.13 Design Documentation . . . 2356
2.13.1 BIM Sections . . . 2356
2.13.2 BIM Tags . . . 2370
2.13.3 Annotations in 3D . . . 2393
2.13.4 Create drawing types with Drawing Customization . . . 2406
2.13.5 Customizing Sections . . . 2455
2.13.6 Define Detailed Section . . . 2456
2.13.7 Define Reflected Ceiling Plan . . . 2464
2.13.8 Detailing with BimPatch . . . 2467
2.13.9 Editing Data Extraction Definition (.dxd) files. . . . 2474
2.13.10 Editing Generated Drawings . . . 2478
2.13.11 Elevation Hatch . . . 2485
2.13.12 Enscape Integration . . . 2489
2.13.13 Generating Drawings . . . 2502
2.13.14 Interior Elevations . . . 2512
2.13.15 Working with Point Clouds in BIM . . . 2523
2.13.16 Schedules . . . 2538
2.13.17 Spot Elevation Level . . . 2563
2.13.18 Templates for generated drawings . . . 2587

3 BricsCAD Mechanical 2603
3.1 What's new in BricsCAD V21 Mechanical . . . 2603
3.1.1 Overview . . . 2603
3.1.2 BOM Manager . . . 2604
3.1.3 Parts Libraries . . . 2611
3.1.4 Standard parts . . . 2615
3.1.5 Parameters and Constraints . . . 2616
3.1.6 Sheet Metal . . . 2617
3.2 Part Design - Workflows . . . 2625
3.2.1 Shaft support editing . . . 2625
3.2.2 Step 1. Resize . . . 2625
3.2.3 Step 2. Editing the base platform . . . 2630
3.2.4 Step 3. Copy faces . . . 2637
3.2.5 Step 4. Edge smoothing . . . 2641
3.2.6 Step 5. Update in assembly . . . 2643
3.2.7 Deflector sheave editing . . . 2645
3.2.8 Bucket tooth editing . . . 2659
3.2.9 Ball bearing creating . . . 2683
3.2.10 Step 1. Preparing for the exercise . . . 2683
3.2.11 Step 2. Design external and internal rings without grooves . . . 2685
3.2.12 Step 3. Make both rings parametric . . . 2689
3.2.13 Step 4. Add parametric groves to rings . . . 2691
3.2.14 Step 5. Add balls . . . 2693
3.2.15 Step 6. Add design table . . . 2696
3.2.16 Step 7. Insert the bearing in an assembly . . . 2698
3.3 Getting Started . . . 2700
3.3.1 Mechanical Workspace . . . 2700
3.3.2 Mechanical Browser panel . . . 2704
3.3.3 3D Comparison . . . 2710
3.4 Assembly Design - Workflows . . . 2716
3.4.1 How to work with standard parts . . . 2716
3.4.2 Introduction to standard parts . . . 2717
3.4.3 Solve inverse kinematic problems in real time . . . 2718
3.4.4 Using mass properties in BricsCAD . . . 2720
3.4.5 Exploded view of assembly . . . 2721
3.4.6 Inverse and direct analysis of kinematics . . . 2726
3.4.7 Mass properties and BOM . . . 2734
3.4.8 Assembly design using BricsCAD Communicator . . . 2739
3.4.9 Flange assembly creation . . . 2740
3.4.10 Step 1. Prepare for the exercise . . . 2740
3.4.11 Step 2. Design a flange . . . 2740
3.4.12 Step 3. Make a flange parametric . . . 2742
3.4.13 Step 4. Add parametric holes to a flange . . . 2743
3.4.14 Step 5. Create a standard part . . . 2748
3.4.15 Step 6. Create a flange assembly . . . 2751
3.4.16 Step 7. Add a design table . . . 2754
3.4.17 Step 8. Add parametric bolts to an assembly . . . 2755
3.4.18 Assembly design and kinematic analysis tutorial . . . 2758
3.5 Part Design . . . 2763
3.5.1 Thread Feature . . . 2763
3.5.2 Part Design Methods . . . 2767
3.5.3 Sketching . . . 2768
3.5.4 Solid Modeling . . . 2769
3.5.5 Surface Modeling . . . 2770
3.5.6 Freeform Modeling . . . 2771
3.6 Sheet Metal - Tutorials . . . 2772
3.6.1 User interface . . . 2772
3.6.2 BricsCAD respects your design intent . . . 2773
3.6.3 What about edges . . . 2774
3.6.4 Base flange creation . . . 2775
3.6.5 2D polyline to Sheet Metal . . . 2776
3.6.6 Lofted shapes . . . 2777

3.6.7 Associative unfolded representations . . . 2778
3.6.8 Unfold a sheet metal body . . . 2779
3.6.9 Working with hard edges . . . 2780
3.6.10 Working with reliefs . . . 2781
3.6.11 Direct editing of a sheet metal model . . . 2782
3.6.12 Working with shell . . . 2783
3.6.13 Working with bends . . . 2784
3.6.14 How to fill the gap in the corner . . . 2785
3.6.15 Split lofted bend . . . 2786
3.6.16 How to split a flange . . . 2787
3.6.17 Creating parametric sheet metal model . . . 2788
3.6.18 How to bend an existing flange . . . 2789
3.6.19 Working with form features . . . 2790
3.6.20 Smart selection . . . 2791
3.6.21 Assembly batch processing . . . 2792
3.6.22 Sheet Metal context: browser, properties & settings . . . 2793
3.6.23 Convert an imported sheet metal design . . . 2794
3.6.24 Working with ribs by trajectory . . . 2795
3.6.25 Working with junctions . . . 2796
3.7 Assembly Design . . . 2797
3.7.1 Bottom-up and Top-down Assembly Design . . . 2797
3.7.2 Assembly Design Commands and Toolbars . . . 2799
3.7.3 Component Properties . . . 2804
3.7.4 Standard Mechanical Components . . . 2820
3.7.5 Assembly mass properties . . . 2828
3.7.6 Piping in Assembly Design . . . 2831
3.7.7 Arrays of Components . . . 2833
3.7.8 Exploded Representations . . . 2837
3.7.9 Bill of Materials Manager . . . 2849
3.7.10 Multi-parametric 3D animations . . . 2898
3.7.11 Bill Of Materials . . . 2912
3.7.12 Array Properties . . . 2932
3.8 Sheet Metal - Workflows . . . 2936
3.8.1 Feature coloring in BricsCAD Sheet Metal . . . 2936
3.8.2 Split thickness faces into regions . . . 2937
3.8.3 Making a parametric workbench - Part 1 . . . 2938
3.8.4 Making a parametric workbench - Part 2 . . . 2939
3.8.5 Parametrizing sheet metal parts . . . 2940
3.8.6 Batch processing in BricsCAD Sheet Metal . . . 2941
3.8.7 Working with lofted bends of an imported model . . . 2942
3.8.8 Rework an imported model in BricsCAD Sheet Metal . . . 2943
3.8.9 Lofted bends in BricsCAD Sheet Metal . . . 2944
3.8.10 Making a parametric workbench - Part 3 . . . 2947
3.8.11 Making a parametric workbench - Part 4 . . . 2948
3.8.12 Start from an imported model in BricsCAD Sheet Metal . . . 2949
3.8.13 Sheet metal ribs . . . 2950
3.8.14 Sheet metal parametrize . . . 2953
3.8.15 Designing from scratch in BricsCAD Sheet Metal . . . 2957
3.8.16 Poor sheet metal rework . . . 2958
3.8.17 Sheet metal from solid . . . 2968
3.8.18 1. Solid creation . . . 2968
3.8.19 2. Solid to Sheet Metal conversion . . . 2975
3.8.20 3. Insert an array of Form Features . . . 2983
3.8.21 3. Creating flanges . . . 2985
3.8.22 4. Finished sheet metal model . . . 2988
3.9 Sheet Metal . . . 2990
3.9.1 Sheet Metal Design Methods . . . 2990
3.9.2 Sheet Metal Commands and Toolbars . . . 2992
3.9.3 Sheet Metal Features . . . 3000
3.9.4 Feature Coloring . . . 3007
3.9.5 Sheet Metal Global and Feature Properties . . . 3008
3.9.6 Mechanical Browser for Sheet Metal . . . 3027

3.9.7 Bend Table . . . 3037
3.9.8 K-Factor . . . 3044
3.9.9 Sheet Metal Settings . . . 3048
3.9.10 Commands . . . 3048
3.9.11 Feature Colors . . . 3050
3.9.12 Initial Parameters . . . 3052
3.9.13 Modeling . . . 3056
3.9.14 Creating Flanges . . . 3058
3.9.15 Modifying Flanges . . . 3089
3.9.16 Working with Bends and Junctions . . . 3116
3.9.17 Working with Hems . . . 3135
3.9.18 Working with Tabs . . . 3146
3.9.19 Working with T-Tabs and T-Junctions . . . 3157
3.9.20 Working with Bevels . . . 3159
3.9.21 Creating and Splitting Lofted Bends . . . 3164
3.9.22 Bend Relief and Corner Relief Feature Operations . . . 3171
3.9.23 Working with Hole Features . . . 3182
3.9.24 Unfolding Sheet Metal Parts and Exporting to CAM . . . 3188
3.9.25 Working with Form and Rib Features . . . 3197
3.9.26 Smart Features . . . 3230
3.9.27 Associative Unfolded Representations of 3D Solids . . . 3243
3.9.28 Converting to Sheet Metal and Repairing . . . 3260
3.10 Generated Drawings - Workflows . . . 3265
3.10.1 Drawing generation . . . 3265
3.10.2 1. Creating Base Views . . . 3267
3.10.3 2. Creating Section Views . . . 3269
3.10.4 3. Non-sectioned components . . . 3271

7 FAQ & Troubleshooting 6081
7.1 Error Codes . . . 6081
7.1.1 Reprise error codes . . . 6081
7.1.2 Error writing license file on Windows (error 2) . . . 6088
7.1.3 Error writing license file on OSX (error 2) . . . 6089
7.1.4 Error writing license file on Linux (error 2) . . . 6090
7.1.5 License activated as administrator cannot be used by other users (error -4) (error -1) . . . 6091
7.1.6 The license for this product is locked to another computer or is using an invalid hostid (error -4) . . . 6092
7.1.7 Terminal server disabled (Error code -46) . . . 6093
7.1.8 Error reading from network (error -105) . . . 6094
7.1.9 Cannot connect to the Bricsys License Activation Server (error -132) (error -136) . . . 6095
7.1.10 Key already used (error -1005) . . . 6096
7.1.11 Manual license activation fails with (error -1007) . . . 6097
7.1.12 Unknown error (error -1030) . . . 6098
7.1.13 BricsCAD cannot connect to a network license server (error -17) . . . 6099
7.2 Network Licenses . . . 6100
7.2.1 What is a network License file? . . . 6100
7.2.2 Add BricsCAD to an existing RLM setup . . . 6101
7.2.3 Where is the license file on a network license server? . . . 6102
7.2.4 How to move a network license to another server . . . 6103
7.2.5 Network license server : Service install failed. . . . 6104
7.2.6 Network license on Linux . . . 6105
7.2.7 How to use two Network licenses with different levels . . . 6106
7.3 Installation . . . 6107
7.3.1 Download recent and previous BricsCAD release . . . 6107
7.3.2 I cannot install / run VBA . . . 6108
7.3.3 When I upgrade to the latest build will I lose my registration info? . . . 6109
7.3.4 ROAMABLEROOTFOLDER and LOCALROOTFOLDER . . . 6110
7.3.5 I believe I got a bad install, do I have to uninstall and do a full reinstall . . . 6111
7.3.6 Silent install with MSI installer . . . 6112
7.3.7 Install more than one BricsCAD version on the same computer . . . 6113
7.3.8 BricsCAD registry structure . . . 6114
7.3.9 Registry settings and files installed by BricsCAD . . . 6115
7.3.10 Local support files (default.pgp, default.cui) are missing or out of date . . . 6116
7.3.11 Install and use BricsCAD on a Citrix server . . . 6117
7.3.12 Remove Windows Registry entries . . . 6118
7.3.13 Bricscad on 64bit Linux systems . . . 6119
7.4 Printing problems . . . 6120
7.4.1 Text not showing correctly in PDF documents . . . 6120
7.4.2 Gradient Hatches print as black fills . . . 6121
7.4.3 Images, pdf underlays or OLE objects print partially or as black filled rectangles . . . 6122
7.4.4 Printing ignores plotstyles . . . 6123
7.4.5 PRINT dialog takes a long time to open . . . 6124
7.4.6 Print has become lighter and thinner . . . 6125
7.5 Licensing . . . 6126
7.5.1 Where can I find my licenses? . . . 6126
7.5.2 How can I see which license key is in use on a computer. . . . 6128
7.5.3 How can I see which computers are using my (volume) license? . . . 6129
7.5.4 Migrate my license to another computer . . . 6130
7.5.5 How to revoke an activation after system crash? . . . 6131
7.5.6 How to try a higher license level . . . 6132
7.5.7 How to run BricsCAD in a lower license level? . . . 6134
7.5.8 Windows 10 Upgrade . . . 6135
7.5.9 Failure to add license key on Windows Vista or higher . . . 6136
7.6 Troubleshooting . . . 6137
7.6.1 Reset the user interface to defaults . . . 6137
7.6.2 Files to include when reporting crashes . . . 6138
7.6.3 Starting BricsCAD in Safe Mode, without any applications . . . 6139
7.6.4 What files are automatically loaded by BricsCAD? . . . 6140
7.6.5 Crash during startup . . . 6141
7.6.6 Failed to update the system registry . . . 6142

7.6.7 Third party application does not work . . . 6143
7.6.8 Cannot create file in Desktop.ini (error 5: access is denied) . . . 6144
7.6.9 Trailing afterimages or ghosts when dragging toolbars and dockable panels. . . . 6145
7.6.10 VBA6.dll not found . . . 6146
7.6.11 "There was a problem sending the command to the program" error . . . 6147
7.6.12 Crash in file Open or Save As dialog - ACCESS_VIOLATION (C0000005) in AcSignCore16.dll . . . 6148
7.6.13 Corrupted "default.cui" file at BricsCAD startup . . . 6149
7.6.14 Default.cui is reverted at startup . . . 6150
7.6.15 Text displays with wrong characters for certain fonts . . . 6151
7.6.16 REDSDK error . . . 6152
7.6.17 BricsCAD freezes when visual style is changed . . . 6153
7.6.18 UNDO reverts too many operations . . . 6154
7.6.19 Lost customizations after update . . . 6155
7.6.20 Some toolbar icons display as question marks . . . 6156
7.6.21 Icons on flyout toolbars are invisible . . . 6157
7.6.22 Distorted display for some hatch patterns . . . 6158
7.6.23 Toolbar position and visibility in the Customize dialog . . . 6159
7.6.24 Menus from main CUI file do not display . . . 6160
7.6.25 Toolbar icons from MNU/MNS are missing in CUI . . . 6161
7.6.26 "RLM1222.DLL" quarantined (or removed) by McAfee anti-virus . . . 6162
7.6.27 Norton Antivirus gives false positive alerts about BricsCAD . . . 6163
7.7 Customizing . . . 6164
7.7.1 Customize right-click behavior . . . 6164
7.7.2 Loading program parameters files (ICA or PGP files) . . . 6165

Chapter 1

BricsCAD

1.1 What's new in BricsCAD V21

1.1.1 Overview

BricsCAD V21 offers a plethora of new and improved tools to help maximize your productivity. This section gives an overview of all the new features and improvements in **BricsCAD V21 Core and Civil tools**: User interface (1.1.2) Productivity (1.1.3) Drafting (1.1.4) Modeling (1.1.5) Civil Tools (1.1.6) Performance and compatibility (1.1.7) For information about the new features and improvements in **BricsCAD V21 BIM**, go to the What's new in BricsCAD V21 BIM section. It contains the following articles: Overview (2.1.1) Modeling Techniques (2.1.2) Building Data (2.1.3) Project Collaboration (2.1.4) Design Documentation (2.1.5) Point clouds (2.1.6) For information about the new features and improvements in **BricsCAD V21 Mechanical tools**, go to the What's new in BricsCAD V21 Mechanical section. It contains the following articles: Overview (3.1.1) BOM Manager (3.1.2) Parts Libraries (3.1.3) Parameters and Constraints (3.1.5) Standard parts (3.1.4) Sheet Metal (3.1.6)

Release notes

Click here for an overview of the release notes.

Diagnostics and Usage Data Collection

Many of the improvements were inspired by requests and suggestions from you, BricsCAD users. At Bricsys, we continue to expand our methods of gathering user feedback with new data collection tools. When you launch BricsCAD for the second time, a dialog box displays, inviting you to participate in the Diagnostics and Usage Data Collection program (1.35.1). The data collection process enables you to share anonymous diagnostic and usage data with Bricsys to help improve BricsCAD. You can withdraw your consent and have your data removed from our databases at any time.

1.1.2 User interface

BricsCAD v21 offers a variety of user interface enhancements to help increase your productivity without disrupting your existing workflow.

BricsCAD Launcher The redesigned BricsCAD Launcher enables you to launch BricsCAD in an environment that is most relevant for your design tasks and license level. The available environment options depend on your license level. You can change the license level using the new SETLICENSELEVEL command which controls the RUNASLEVEL system variable. If you are using a trial license, you may choose any environment. Otherwise, you may choose any environment supported by the license level you purchased. For example, an Ultimate license supports all environments. Whereas, a Lite license supports only the 2D Drafting environment. The new Units option enables you to set the measurement units (MEASUREINIT system variable) that determine which hatch pattern and linetype definition files to use. This control also specifies the drawing units for new drawings created with no template file. (1.1 on the facing page)

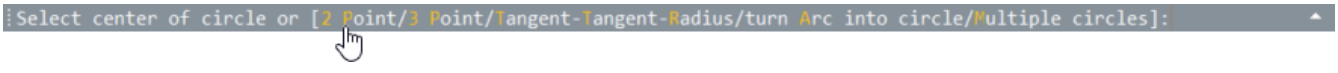
Units:
Metric
Imperial

Commands The Command window now supports clickable command options enabling you to select options at the command line without having to type at the keyboard. (1.2) The COMMANDS command allows you to look up available commands. In BricsCAD v21 it's updated to list only the commands that are available with your current license level.

Figure 1.2



Ribbon The ribbon enables you to scroll through ribbon tabs using the mouse wheel. Simply place the cursor anywhere on the ribbon and roll the wheel. The RIBBONTOOLSIZE system variable sets the size of the tool buttons in the ribbon. The options are Small, Large and Extra Large.

Toolbars New UCS and UCS Options toolbars offer easy access to UCS commands and options. You an access these toolbars by right-clicking on a toolbar, a panel, or the ribbon and expanding the Toolbars>BricsCAD menu. (1.3) (1.4 on the next page) (1.5 on the following page) The TOOLBUTTONSIZE system variable applies to toolbars only, no longer to ribbon tool buttons (see above).

Figure 1.3

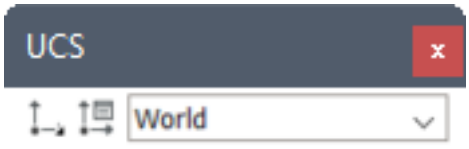


Figure 1.4

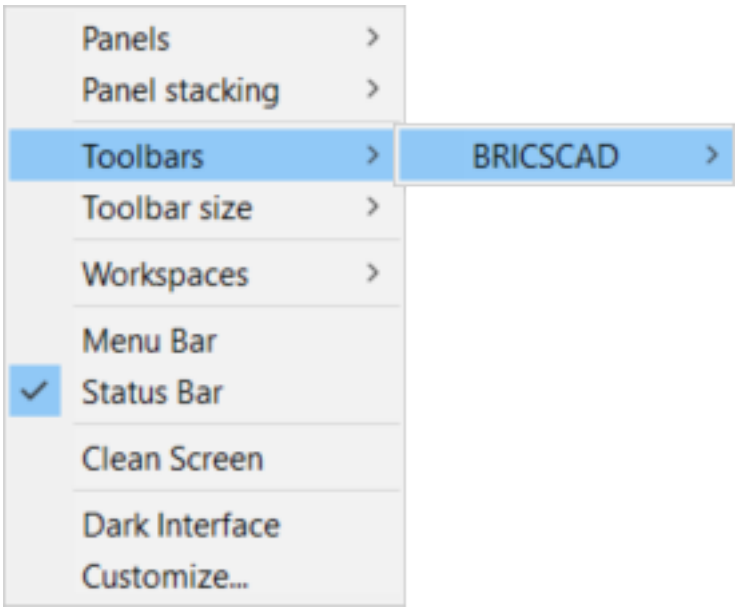
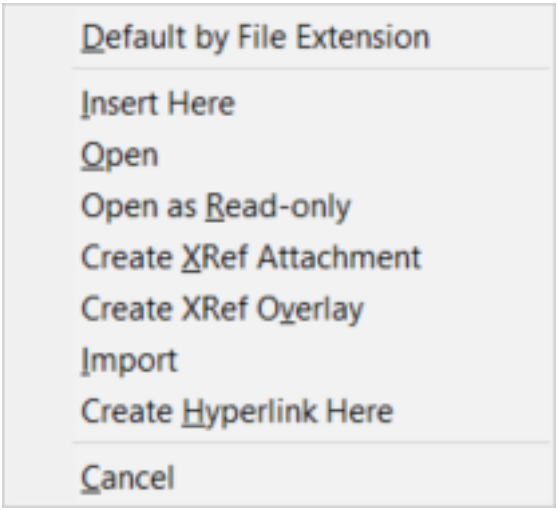
Figure 1.5



Menus The menu that displays when you drag and drop a dwg file into BricsCAD, using the right mouse button, offers a new option to Open as Read-only. (1.475 on page 549)

Figure 1.6



Layouts The Layout Manager (6.20.15) is extended to enable publishing of multiple layouts. (1.7 on the following page) When you set a layout current in the Layout Manager, the active layout tab automatically scrolls to remain visible in the layout tab list. (1.8 on the next page)

Figure 1.7

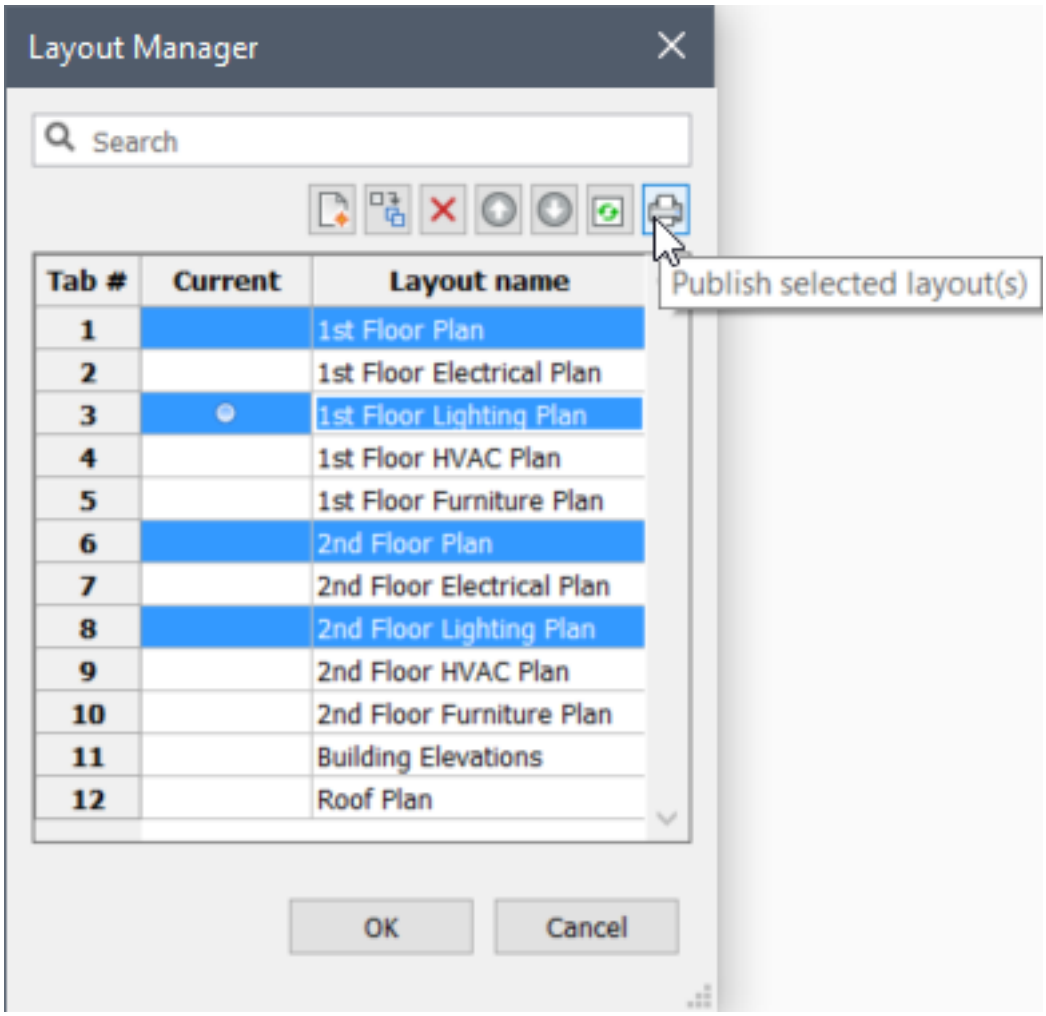


Figure 1.8

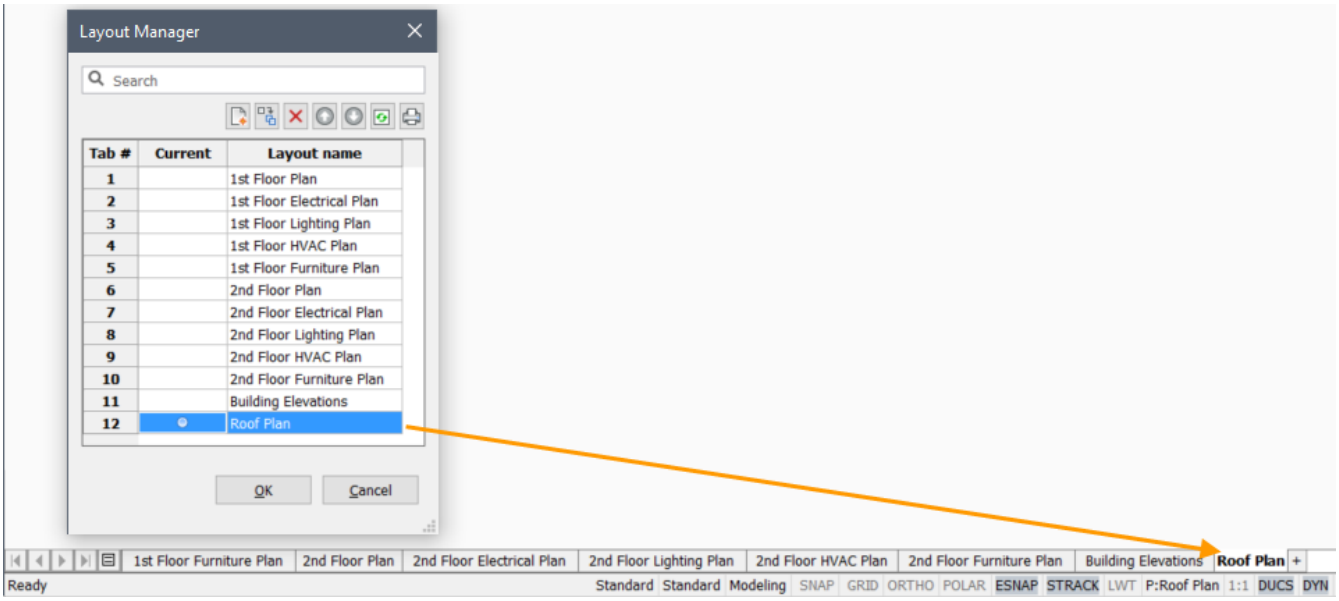

Entity Snaps The **Snap to Point** option in the Entity Snaps toolbar and menu is renamed to **Snap to Node**. (1.9) (1.10 on the next page)

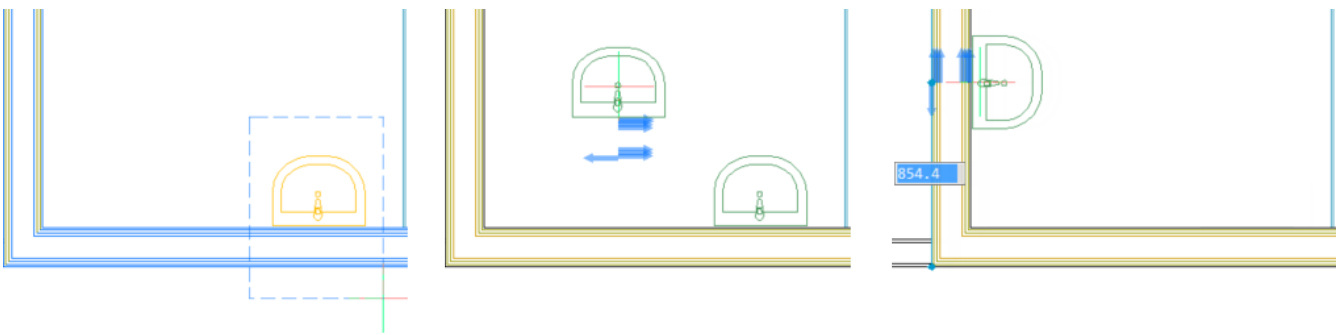
1.1.3 Productivity

Move with guide curves The new MOVEGUIDED command enables you to move selected entities using reference curves. When you launch the MOVEGUIDED command and select the entities you want to move, entities that fall completely within the selection window will be moved. Entities crossing the selection window are used as reference curves. Blue vectors on the selected entities represent the reference curves. As you move the selected entities near geometry that matches the reference curves, they automatically snap into place. Relevant geometry in the new location is automatically trimmed and geometry in the original location is automatically healed. This significantly reduces the amount of manual editing required! (1.11) For more flexibility, you can first select the entities you want to move and then launch the MOVEGUIDED command. The pre-selected entities are used for the Move selection set and you are prompted to select entities to use as reference curves.

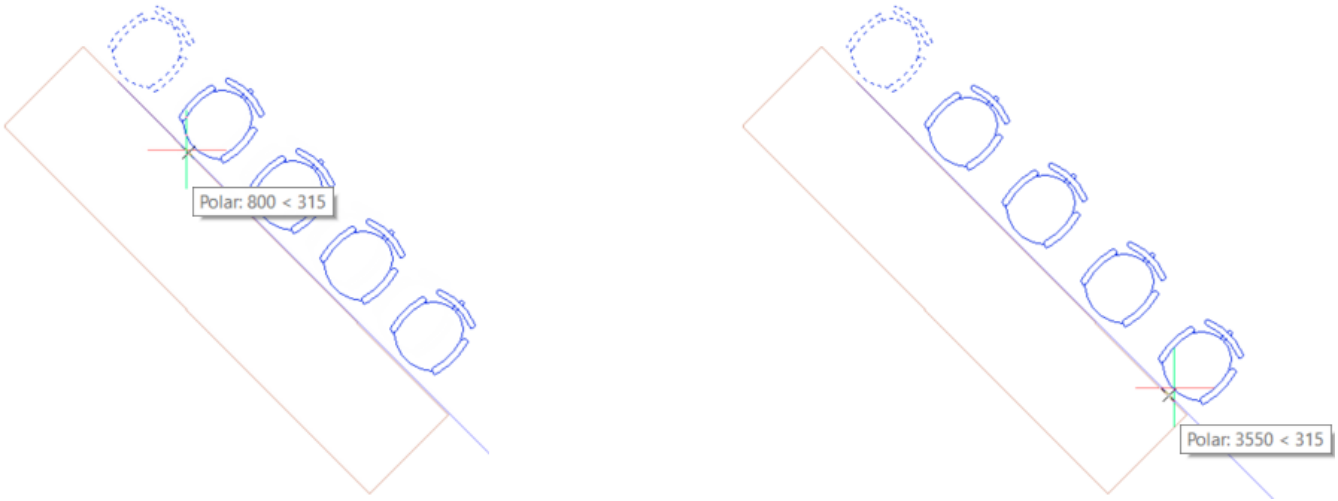
Figure 1.11



Copy in a linear array The COPY command now includes a new Array option enabling you to copy selected entities in a linear array. The new Array option is available after you specify the base point for the copy operation. (1.12) You specify the number of copies to array then pick a point to specify the distance and angle between the first two sets of entities or use the Fit option to specify the distance and angle between the first and last sets of entities. (1.13 on the facing page)

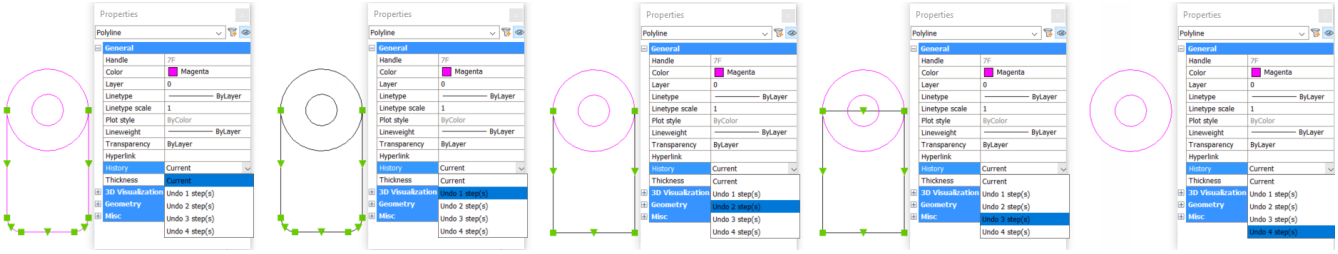
Figure 1.12

Figure 1.13



Undo per entity A new History control in the Properties panel enables you to undo editing operations for a selected entity. The History property only displays when you select a single entity. Open the History drop-down list to undo the entity back to one of the previous steps without undoing all the other commands and view operations that have been executed since. (1.14)

Figure 1.14



Manipulator Press the SHIFT key to rotate the Manipulator 90 degrees about its normal axis. (1.15) The Copy and Repeat options in the Manipulator are now visible, clickable, and localized. (1.16 on the next page)

Figure 1.15

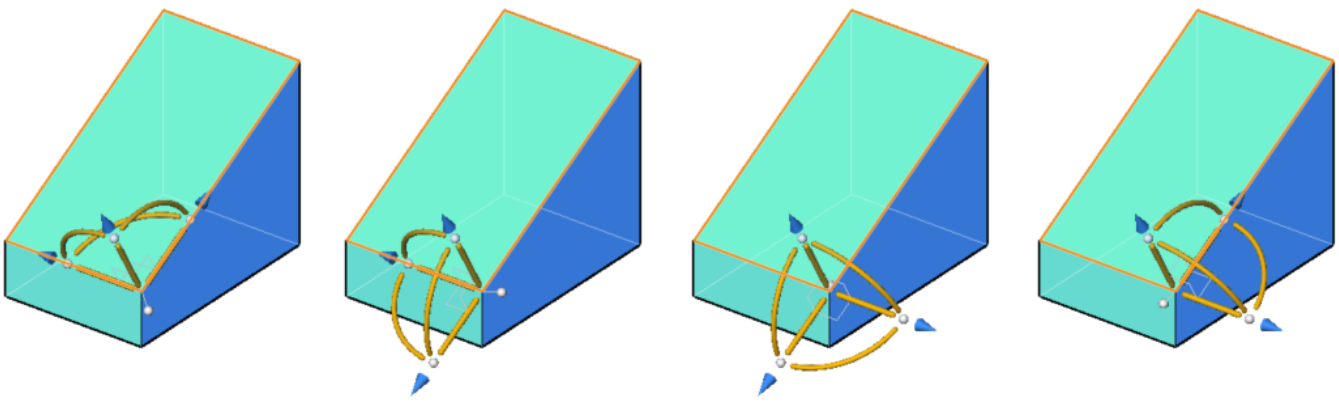


Figure 1.16

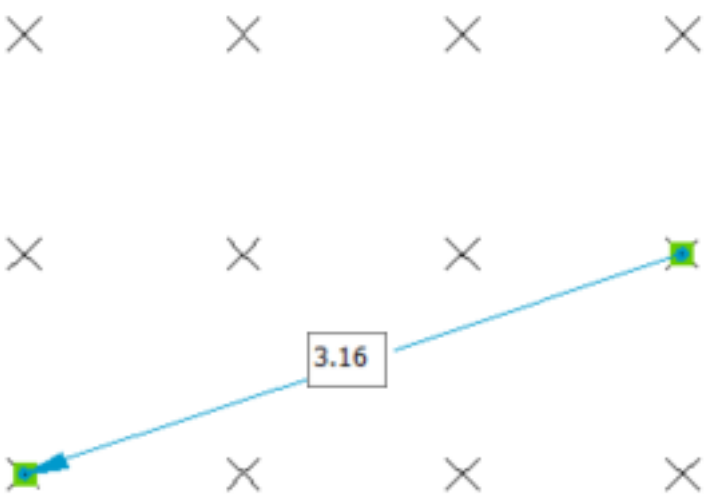
Nearest Distance The NEARESTDISTANCE command offers improved performance and behavior including support for Point entities. (1.17)

Figure 1.17



Layers BricsCAD v21 offers several layer enhancements to help increase your productivity. **Layer Translator** The new LAYTRANS command enables you quickly apply layer names and properties from another drawing file to the current drawing. When you launch the LAYTRANS command, the Layer Translator dialog displays. All the layer names in the current drawing are displayed in the Translate From list. You can specify the layers to which you want them to map by loading layer information from an existing DWG, DWS, or DWT file. (6.1412 on page 4698) You can also create new layers. Simply enter the layer name and properties to which you want to map existing layer. (6.1413 on page 4698) You can select one or more layers from the current drawing, the list on the left, to map to a layer from the list on the right. If you choose Map Same, any layer names in the current drawing with corresponding names in the list on the right will inherit the properties from the list on the right. The layer mappings you select are displayed in the Translation Mappings list. (6.1414 on page 4699)

Figure 1.18

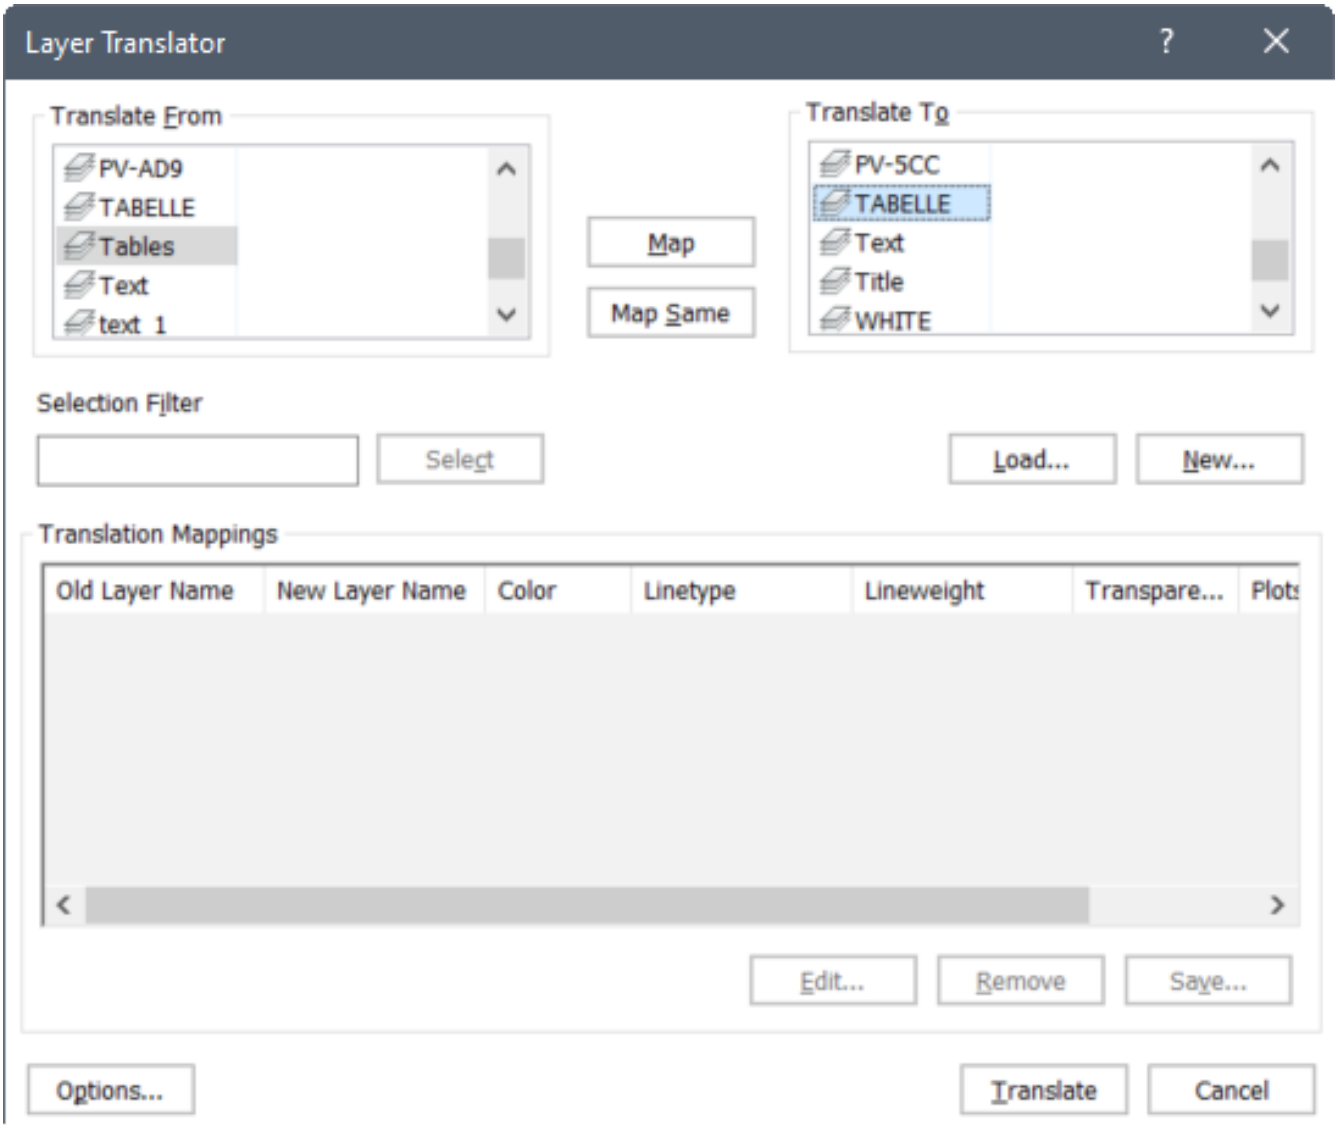


Figure 1.19

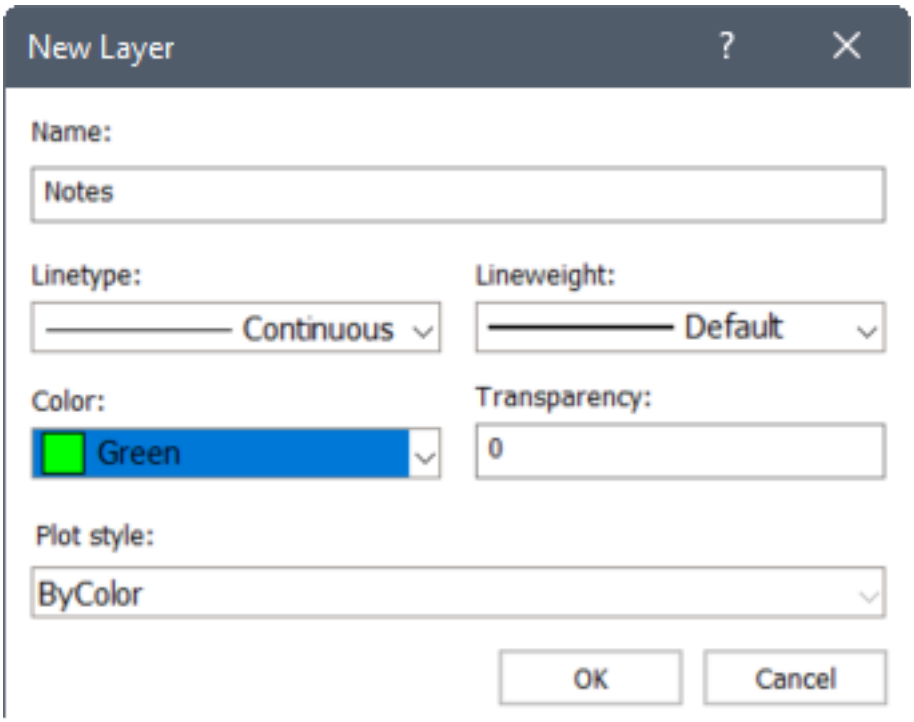

Regardless of how you add layers to the Translation Mappings list, you can modify their mapping properties. Simply double-click on a layer or choose Edit to open the Edit Layer dialog box with the same options at the New Layer dialog. You can also remove layers from the Translation Mappings list or save the mapping list to use again in the future. The Options dialog offers additional controls for layer mappings. (6.1415 on page 4699) **Set by Layer** The new SETBYLAYER and -SETBYLAYER commands enable you quickly change property overrides of selected entities to ByLayer. Use the new SETBYLAYERMODE system variable to control which properties are affected by the SETBYLAYER commands. The value is stored as a bitcode using the sum of the values of all selected options.

- 1: Color
- 2: Linetype
- 4: Lineweight
- 8: Material
- 16: Plot style
- 32: ByBlock
- 64: Blocks
- 128: Transparency

Layer properties by Viewport The VPLAYER command is enhanced in v21 allowing you to select entities on layers for which you want to apply viewport overrides. After selecting which layer property you want to modify for the viewport, you can type the name of the layer or press enter to specify the layer by selecting an entity on that layer. (1.22 on page 54)

Figure 1.20

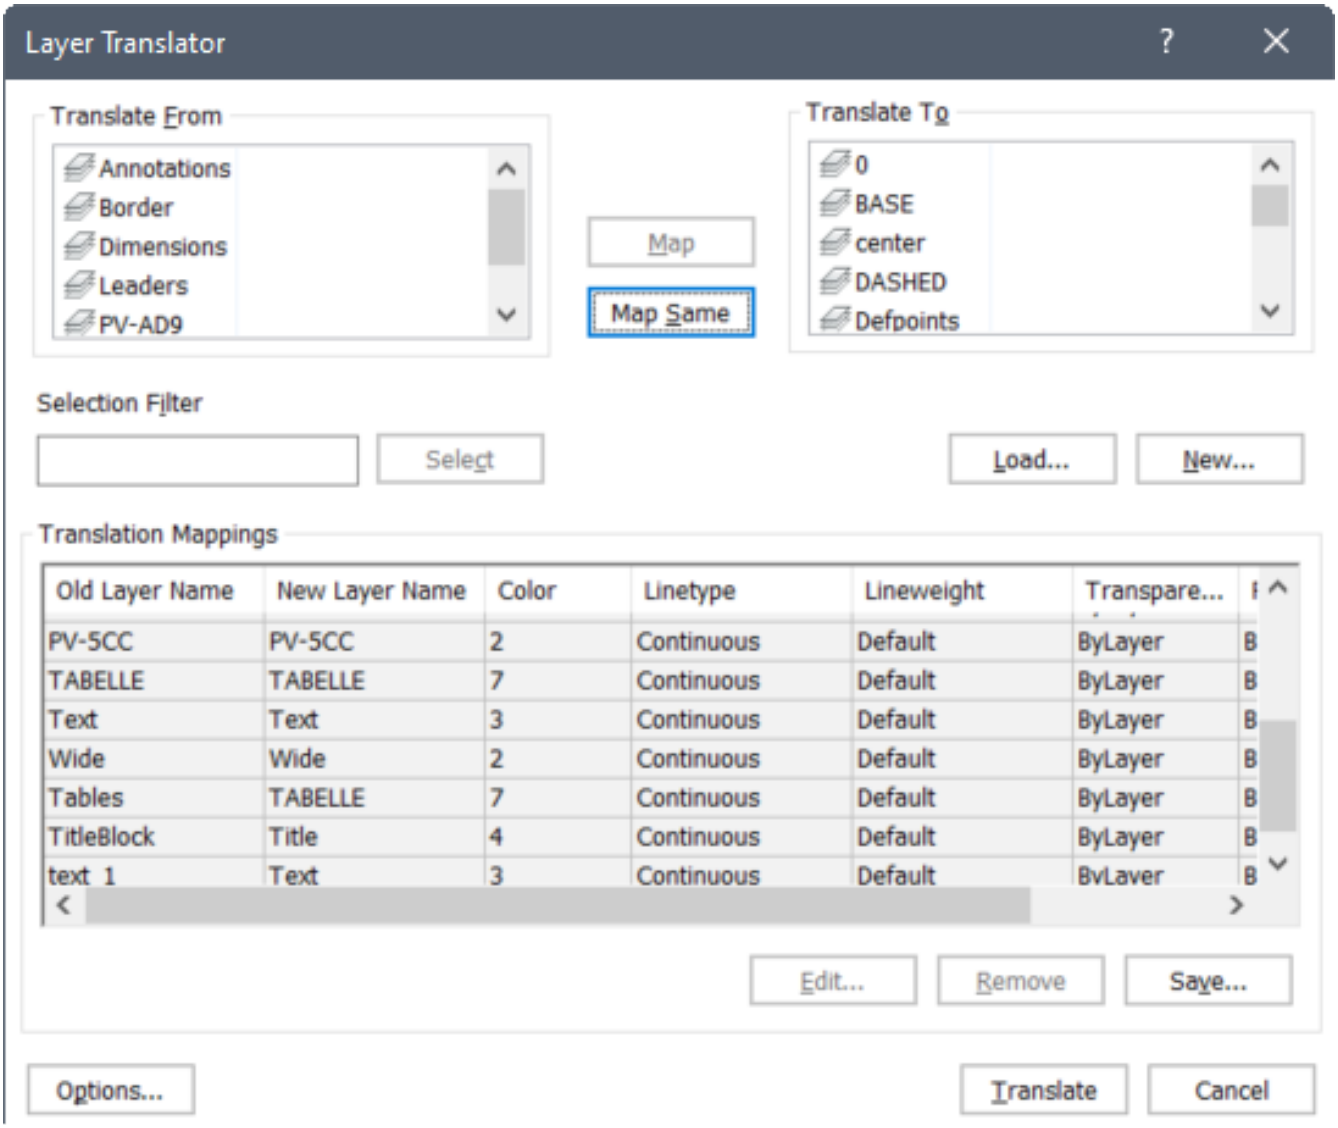

Figure 1.21

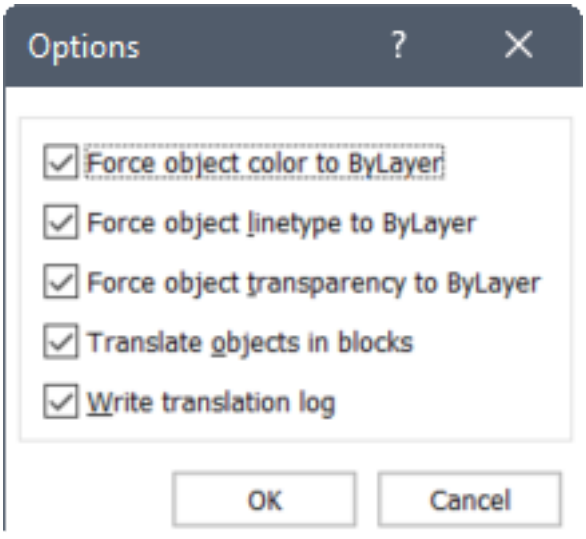

Figure 1.22

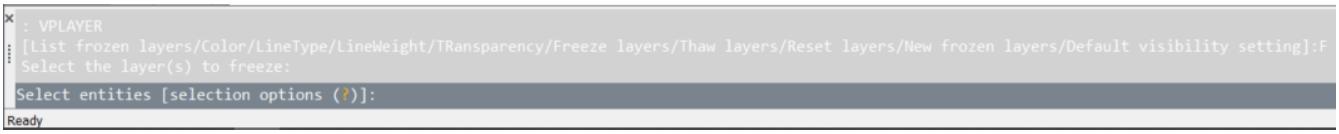
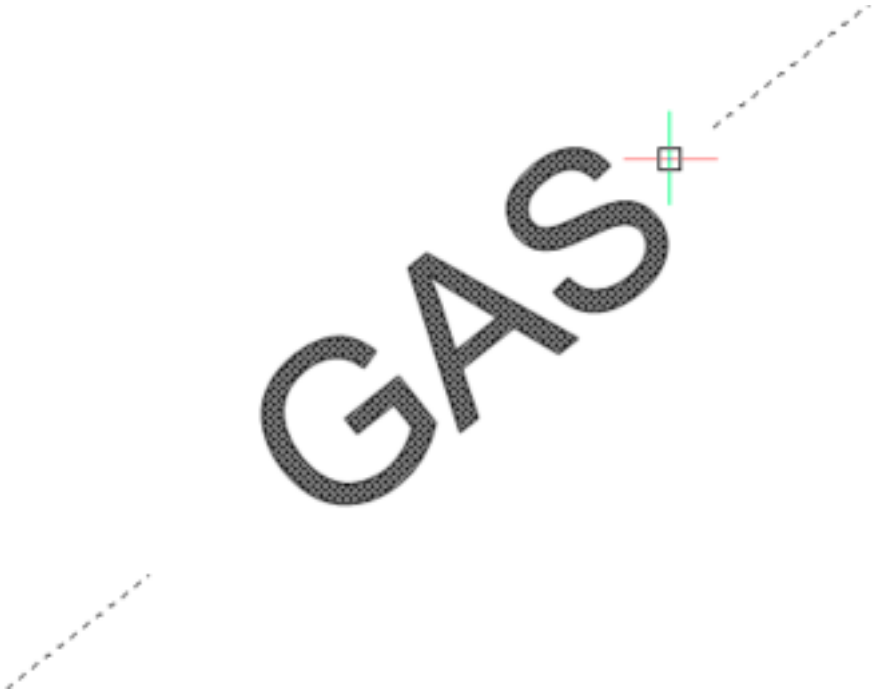
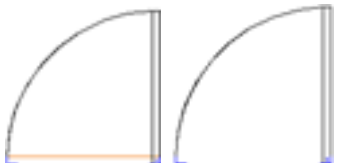


Linetypes BricsCAD now supports selection of linetype gaps with the addition of the LTGAPSELECTION system variable. With LTGAPSELECTION enabled entities are highlighted and selected even when you pick in the gap. (1.23 on the facing page)

Figure 1.23



Parameters & Constraints BricsCAD v21 offers powerful enhancements for creating parametric drawings and block definitions. **Parameters & Constraints Panel** All BricsCAD license levels now support 2D parameters and constraints. View and modify parameters and constraints in the Parameters and Constraints panel. The panel is extended to display 3D geometric constraints, 2D dimensional constraints, parametric blocks, and arrays. (1.24) The right-click menu for parameters and constraints enables you to specify if parameters are geometry-driven. Expressions for such parameters cannot be edited (you can switch geometry-driven status off to edit them) – instead they are automatically computed from 3D geometry via 3D dimensional constraints that depend, directly or indirectly, on geometry-driven parameters. Simple arithmetic expressions for such 3D dimensional constraints are solved in dynamics when you change your geometry with direct editing tools such as DMPUSHPULL or DMMOVE/DMROTATE. (1.25 on the following page) The right-click menu also enables you to control if a parameter is exposed for editing when inserted as a block. If you open a 3D parametric model with a BricsCAD Lite license, 3D constraints are shown in magenta. You can view and edit their expressions with BricsCAD Lite. However, the 3D model only reflects the changes after it's opened with a BricsCAD Pro license or above. **Automatic Constrain** The new AUTOCONSTRAIN command enables you to automatically apply 2D geometric and dimensional constraints to selected 2D geometry. BricsCAD fully constraints the geometry, ensuring not to over-constrain it. The geometric and dimensional constraints are displayed on the geometry. You can view, add, remove, and modify the parameters and constraints in the Parameters and Constraints panel. (1.26 on the next page) **Reference Curves** The new REFERENCECURVES command enables you to specify reference geometry for blocks. When you select geometry to use for reference, BricsCAD creates a REFERENCE_CURVES layer (if it doesn't already exist) and adds the selected entities to that layer. With reference curves specified in a drawing or block definition, you can automatically align the block or drawing to relevant geometry when you insert it. The number of reference curves and the distance between them determines with which geometry it can align. As the cursor approaches relevant geometry, the block can automatically flip, offering multiple insertion options. Distances between the ends of the relevant geometry and block are displayed, enabling you to enter specific values if you wish. And, if the reference curves include gaps, relevant geometry is automatically trimmed to produce matching gaps. (6.2110 on page 5292) You can also use reference curves to automatically align with corners. The following example includes 4 parallel reference curves and a single corner reference curve enabling the door block to align with geometry that matches the four parallel lines and single perpendicular line. (6.2111 on page 5292) **Visibility States** The new VISIBILITYSTATES command enables you to define visibility parameters and states. You can create multiple visibility parameters in a drawing or block definition. And, you can create multiple visibility states in each visibility parameter. When you insert the drawing or block, you can change the visibility of each instance. For example, you might create a door block with two visibility parameters, SwingAngle and Header. The SwingAngle parameter includes 5 visibility states: Closed, 30, 45, 60, and 90. (1.29 on page 57) The Header parameter includes two visibility states:



On and Off. You create all the geometry for each of the visibility states and then select the appropriate geometry to display in each state of each parameter. Geometry that doesn't belong to a visibility state is always displayed. This door example enables 10 variations of block insertions. (1.30 on page 58)

Figure 1.25

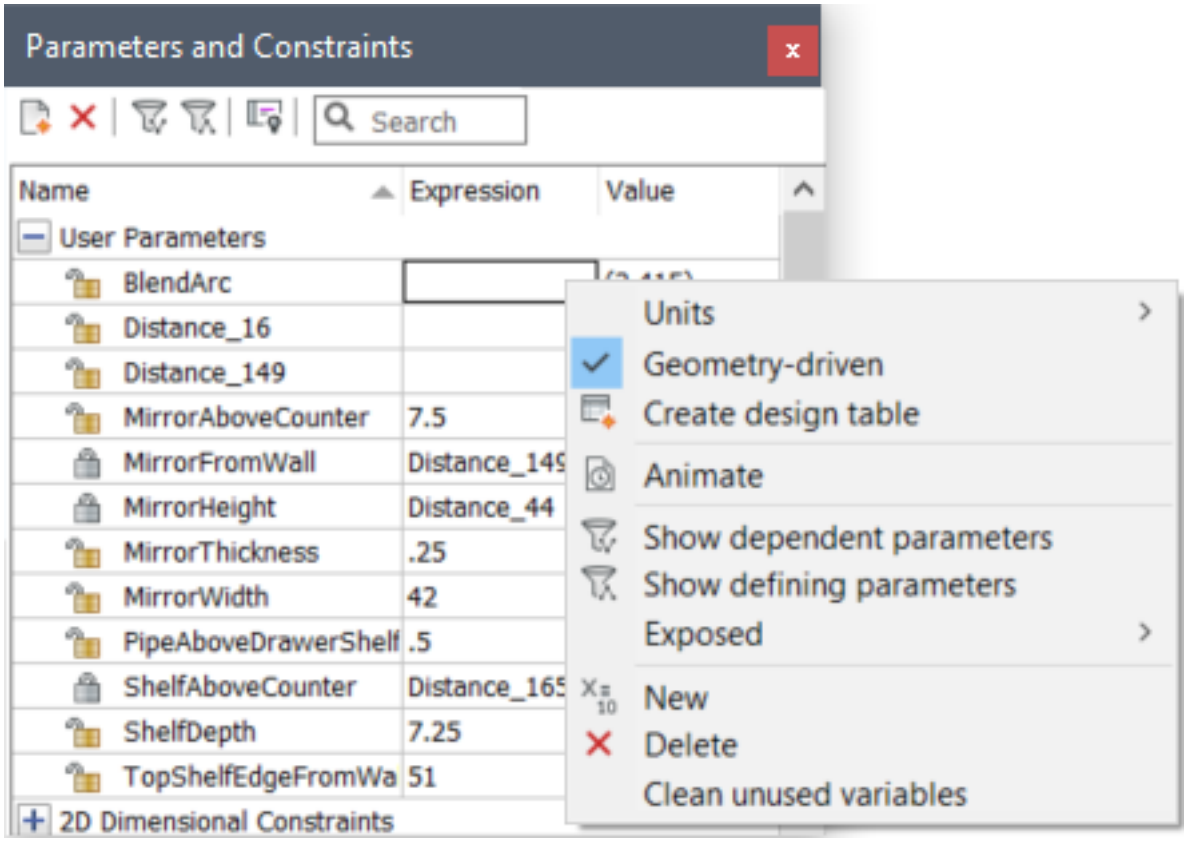


Figure 1.26

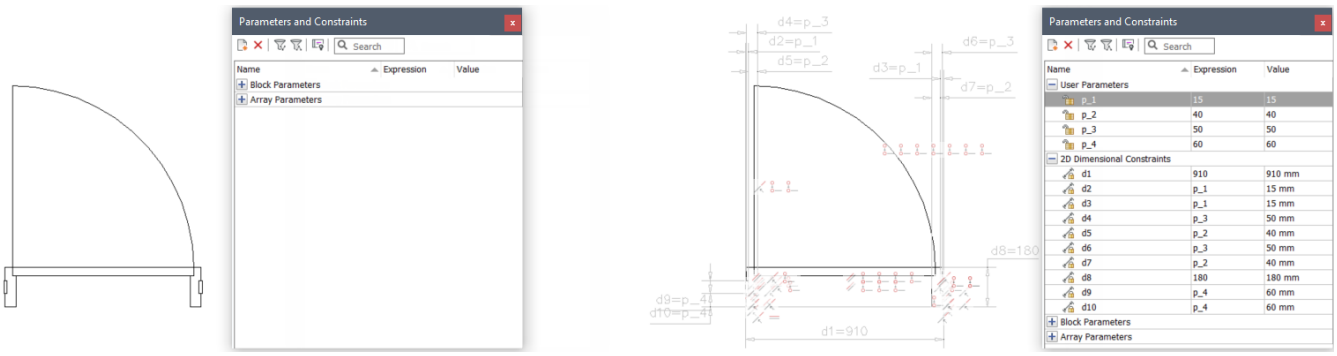

Figure 1.27

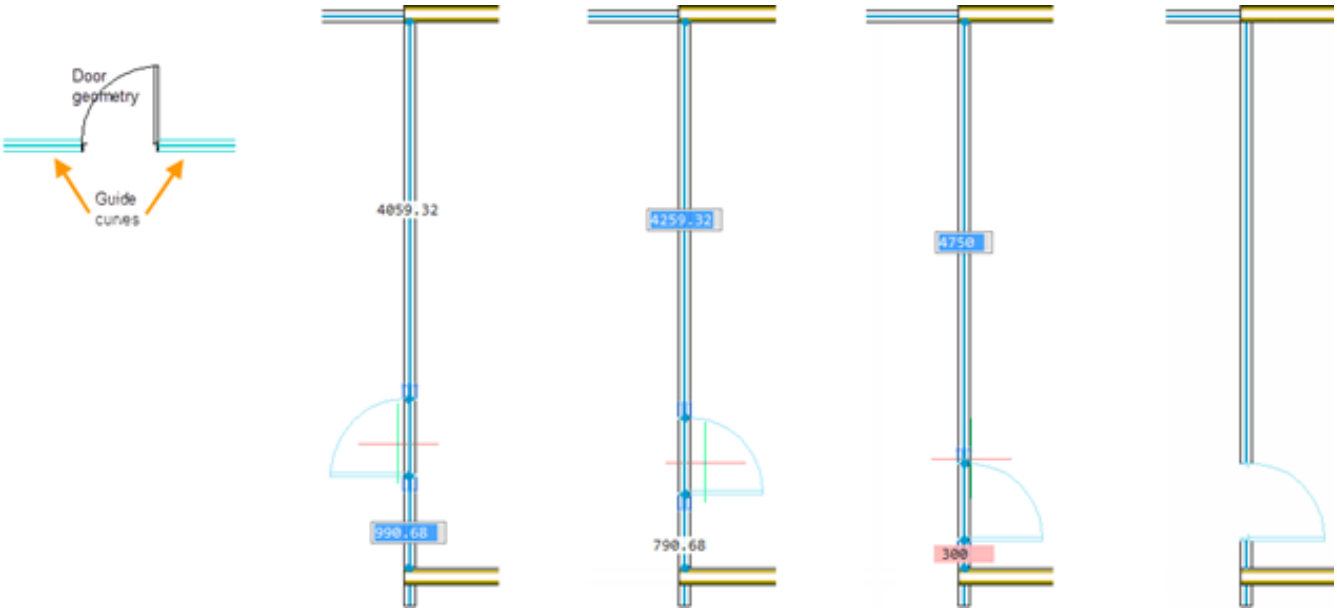

Figure 1.28

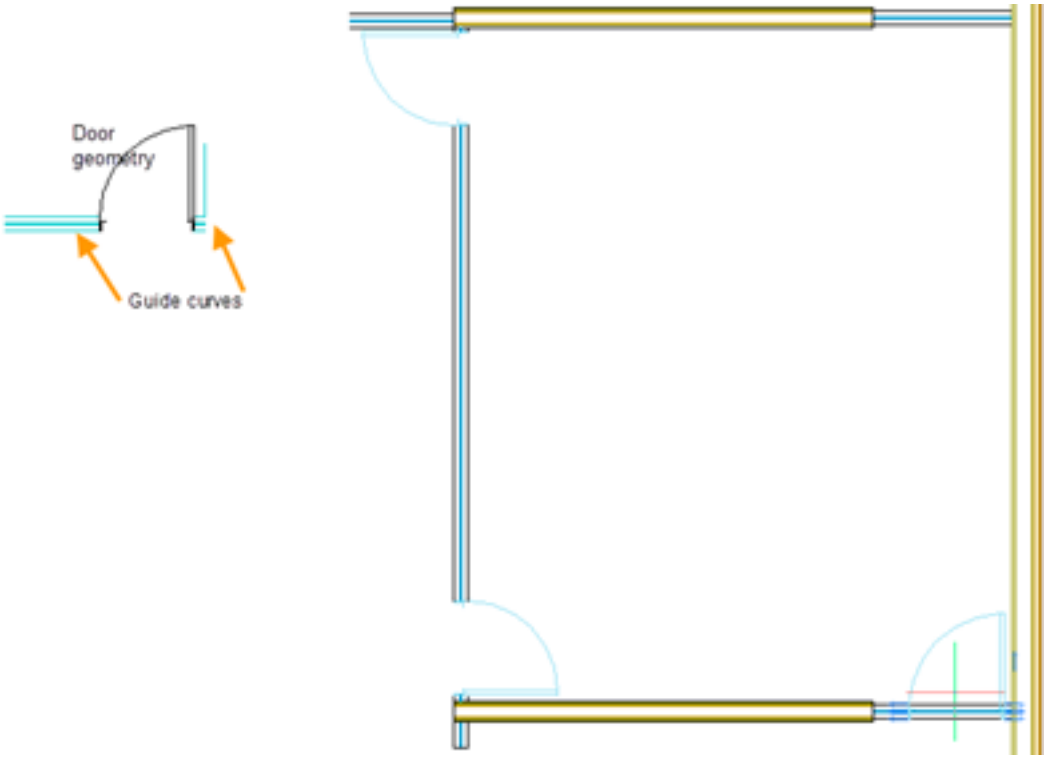

Figure 1.29

You can easily change the visibility states for a selected block insertion using the Properties panel. (1.31 on the facing page) **3D Radius Constraints** The DMRADIUS3D command enables you to create geometry-driven 3D radius constraints to measure the radius of entities inside blocks. (1.32 on the next page)

Figure 1.30

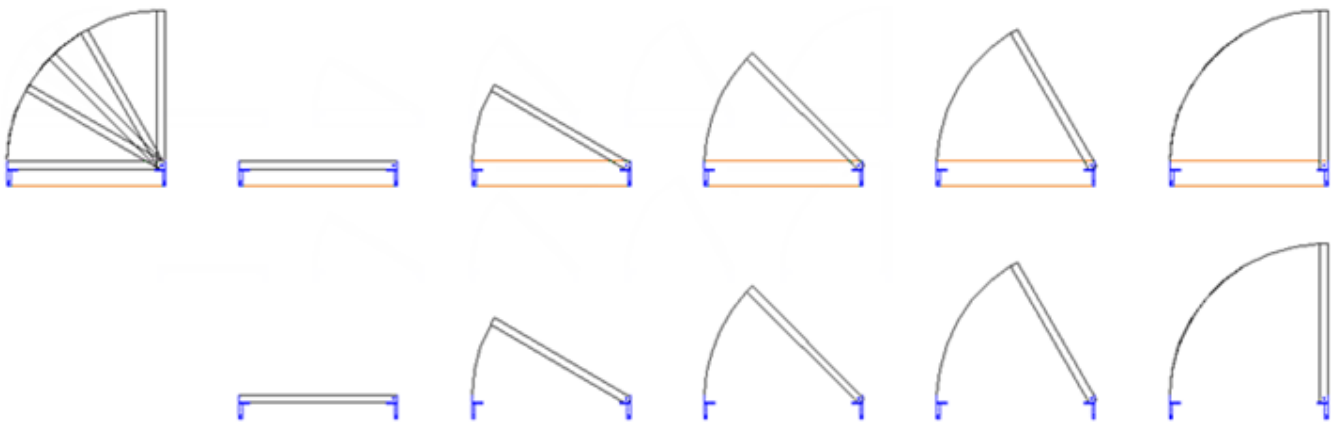

Figure 1.31

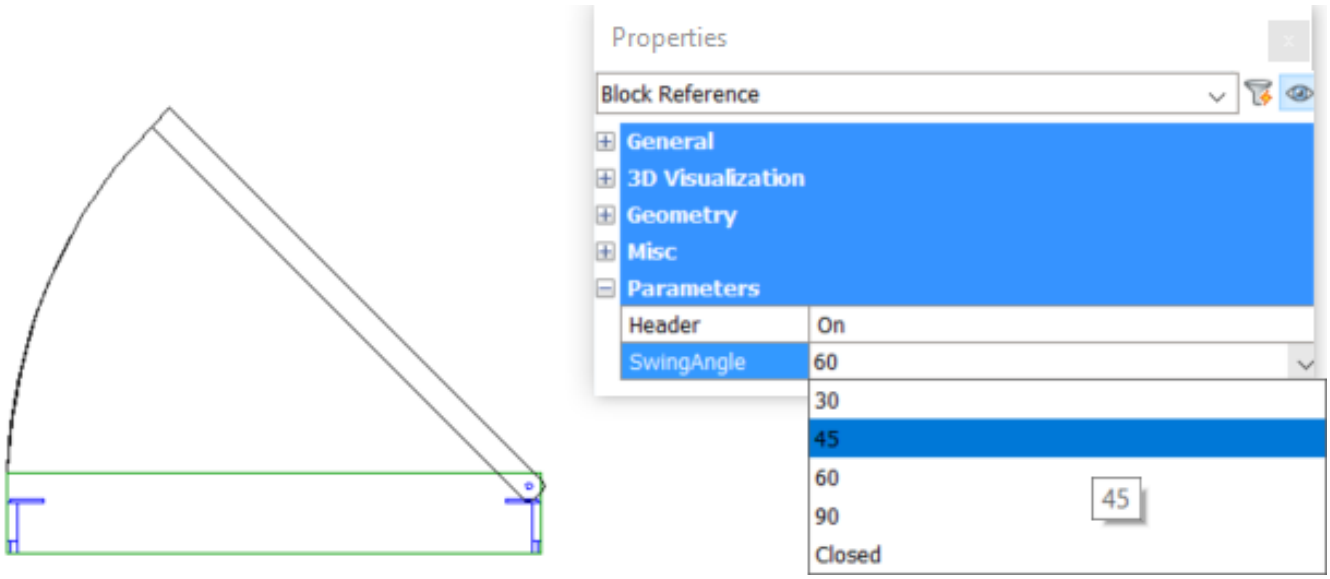

Figure 1.32

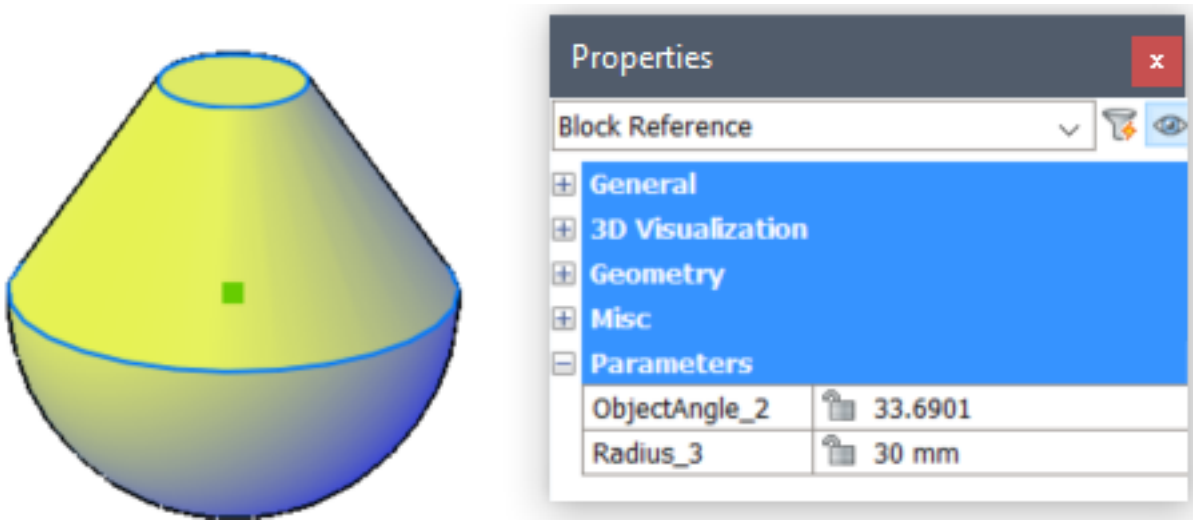

Blocks BricsCAD v21 offers many enhancements to increase your productivity when working with blocks. **Block Attribute Properties** You can now access block attribute properties in the Properties panel. This allows you to view and edit multiple attributes at the same time. Press the Ctrl key to select one or more attributes within block instances. Open the Properties panel to display the Attributes entity type with all the relevant attribute properties. (1.1152 on page 1261) **Library Panel** The new Library panel offers a central location to access 2D and 3D block libraries. It replaces both the Components and the 2D Parametric Blocks panels from previous releases. (1.34 on page 62) A menu in the upper right corner allows you to control which content is displayed in the Library panel. It may include pre-defined content from Bricsys libraries as well as the User Defined library with your own content. (1.35 on page 63) You can specify where BricsCAD looks for library content by selecting the Manage libraries option. It offers quick access to the COMPONENTSPATH setting so you can view and modify library folder locations. Another menu option automatically generates thumbnail images for any that are missing. You can search for content by typing key words in the Search box or expand a category to see all the content within that category. And you can display the content in a grid or list view.

(1.44 on page 71) (1.45 on page 72)

You can easily add new block definitions to the library using the Add button at the bottom of the Library panel. Select specific entities from the drawing or use the entire drawing. (1.36 on page 64) **Block Icons** The new BLOCKICON command creates or updates thumbnail images that enable you to preview blocks with various tools including Drawing Explorer and the Library panel. **Non-uniformly scaled blocks** The EXPLODE and XPLODE commands now honor the EXPLMODE system variable when exploding non-uniformly scaled blocks. **Insert** The INSERT command is enhanced to support parametric blocks. Block definitions containing parametric entities with exposed parameters can now be parametrically changed after insertion by the INSERT command. To insert parametric BIM and Mechanical components, use the BMINSERT command.

Drawing Optimizations A new Drawing Optimizations ribbon panel offers tools to clean up and optimize your drawings. **Simplify** The new SIMPLIFY command reduces the number of vertices of polylines and hatch boundaries without changing their general shape. Options allow you to switch between simplifying and smoothening. Additional options enable you to control the amount of deviation from the original entity. Simplified entities are easier to manipulate and can significantly reduce file size. **Purge** The PURGE command is enhanced so the Batch, All, and Orphaned data options remove more items from the drawing. **Audit** The AUDIT command is enhanced to clean up duplicate ACIS attributes. A combination of AUDIT and CLEANUNUSEDVARIABLES now cleans a drawing from multiple orphan parameters. **Delete Duplicate Entities** The OVERKILL command enables you to choose if you want to delete duplicate entities or move them to a specified layer. You can specify the layer name using the new OVERKILLLAYER setting or leave the default name, Duplicate Entities. A new option in the OVERKILL command allows you to combine duplicate block definitions. Choosing this option displays the Combine Duplicate Blocks dialog box where you can specify any block properties you want to ignore. You can specify how closely the geometry must match by entering a comparison tolerance. If BricsCAD finds more than one block definition whose geometry meets the tolerance and properties criteria, it uses the most recent definition to replace any instances of the older definitions. The older definitions become unused and you can enable the Purge duplicate blocks option to automatically purge them. (1.37 on the following page) **Optimize** The new OPTIMIZE command helps you clean up 2D lines in your drawings. It displays the Optimize 2D Lines dialog box where you can control which lines are affected. Specify which lines BricsCAD should consider for optimization. You can select specific line entities or have BricsCAD analyze and optimize all line entities in the drawing. It can find and fix lines that are within a specified angle tolerance relative to horizontal, vertical, or 45 degrees, in the current UCS. An additional option automatically closes gaps within a specified tolerance. (1.38 on the next page) The Optimize tool is useful for cleaning up any 2D lines. For example, you can use it to quickly clean up line geometry extracted from point clouds. (1.39 on page 67) (1.40 on page 67)

Figure 1.37

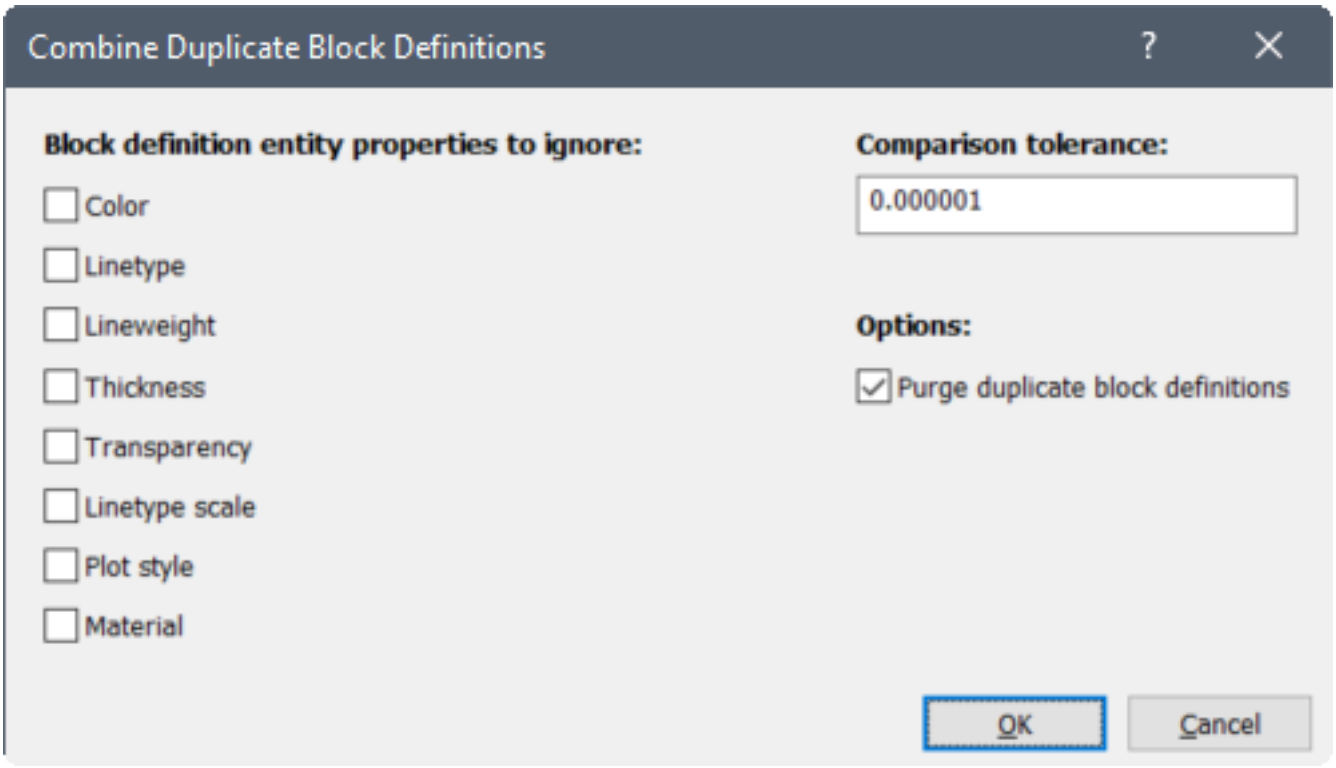

Figure 1.38

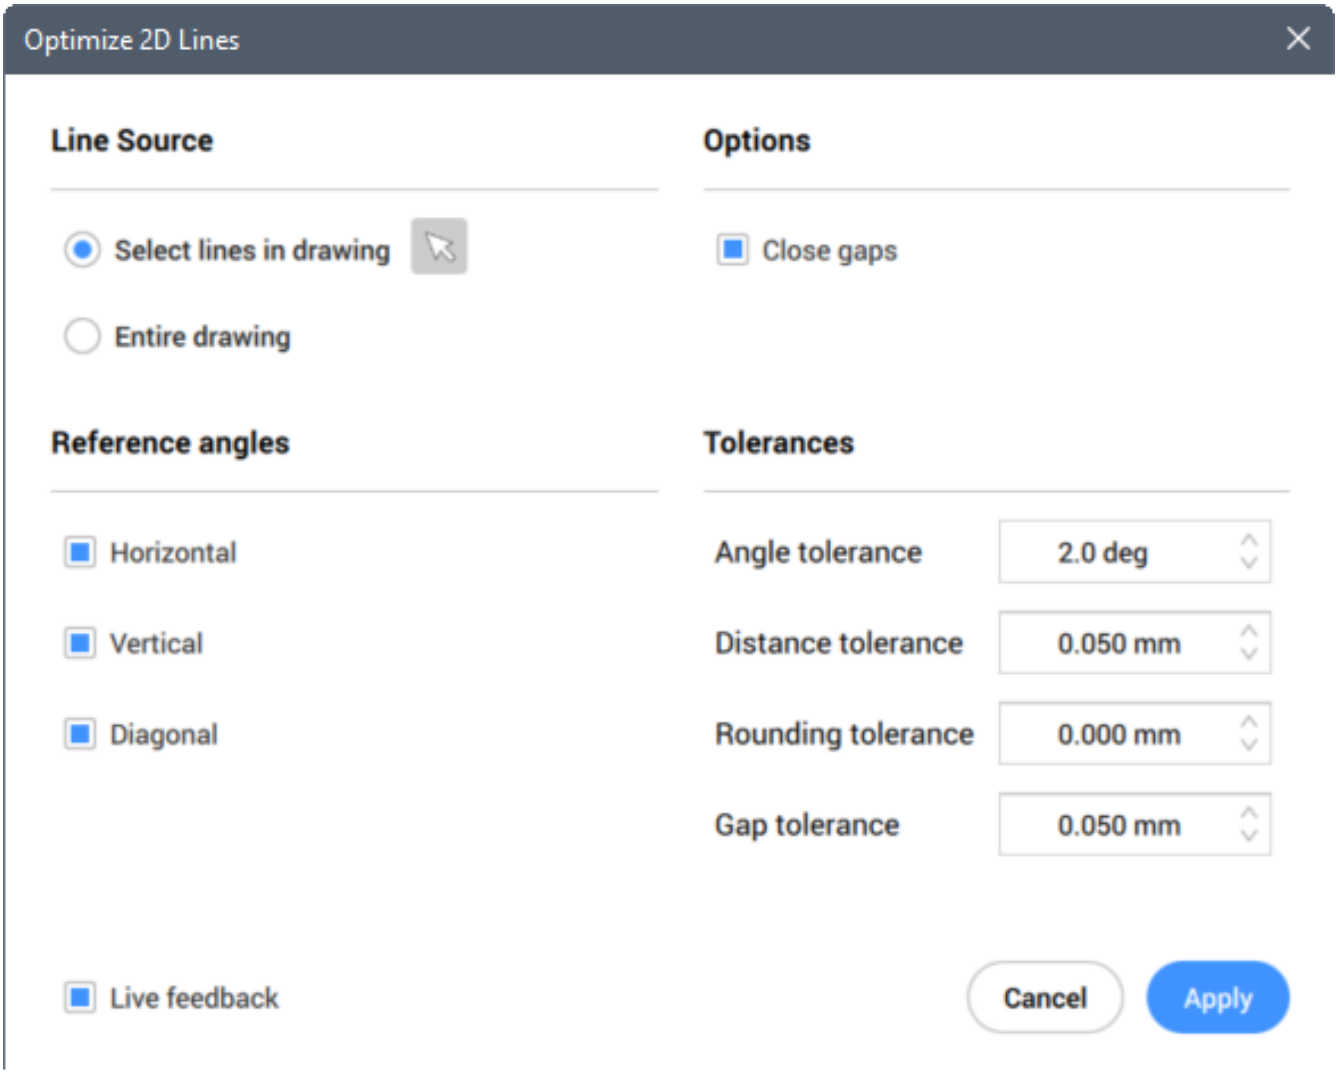

Figure 1.39

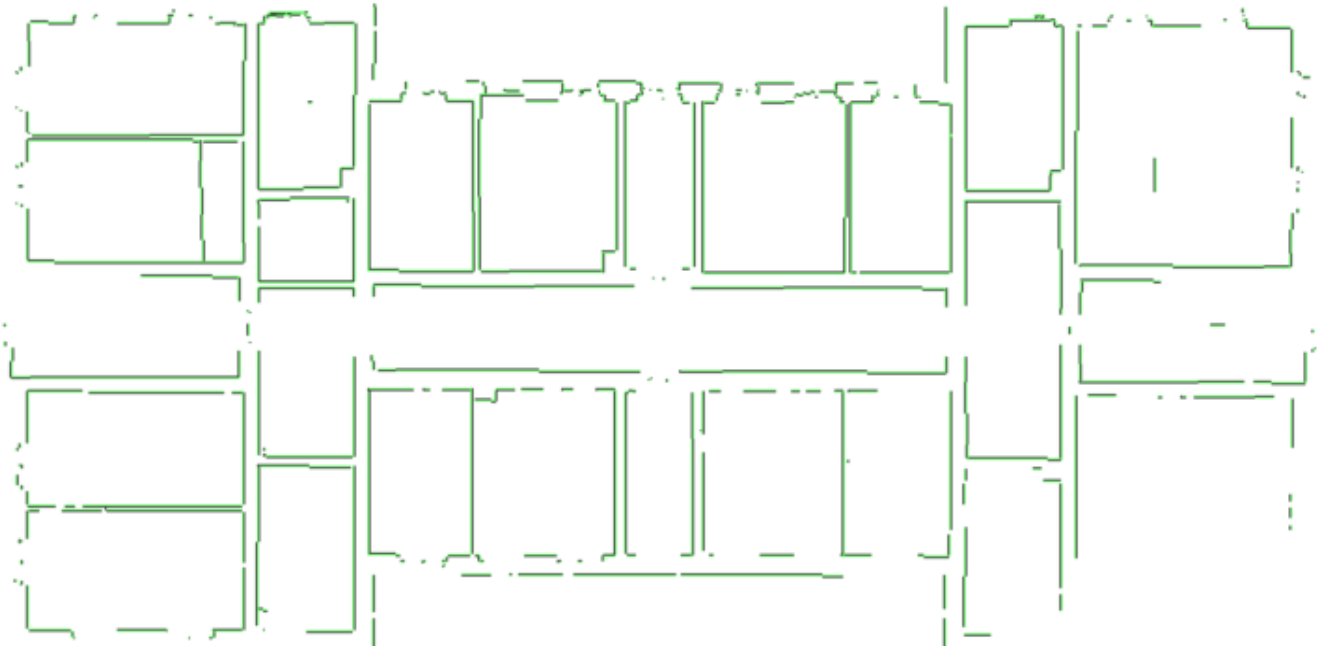
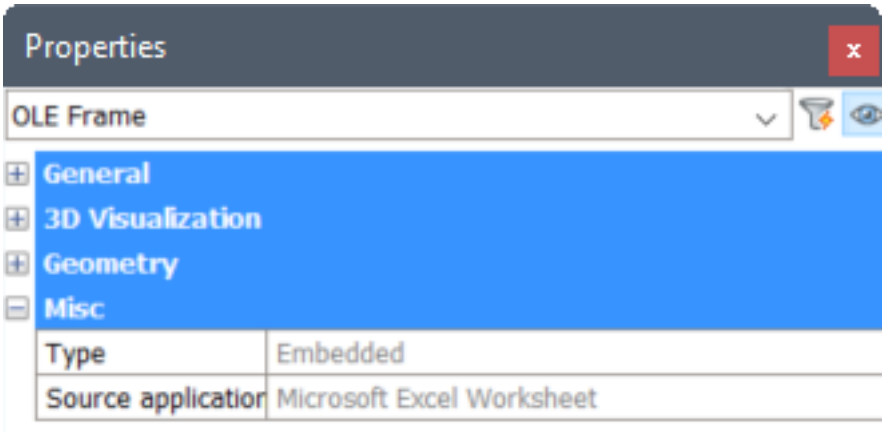
Figure 1.40



Object Linking and Embedding The Properties panel for OLE objects is enhanced to provide additional information for the selected OLE entity. The additional information may include Type, such as Embedded or Static, Plot quality, and Source application. (1.41)

Figure 1.41



Images Image manipulation is enhanced in BricsCAD v21. When you manipulate an attached image using grips and other editing tools the image content displays and updates as you edit the image frame. This enables you to position, align, and scale the image using the image content for reference. The selected image temporarily displays above any overlapping objects as you edit it.

Hyperlinks The Edit Hyperlink dialog box now enables you to link to layouts and views inside a drawing. After selecting the drawing to which you want to link, choose Target to open the Select Target View dialog box. (1.42 on the next page) The Select Target View dialog box displays a list of all named views and layouts in the linked drawing. (1.43 on the following page) To access a hyperlink, double-click on the hyperlink in the Properties panel for the selected entity or press and hold the right mouse button and choose Hyperlink from the menu.

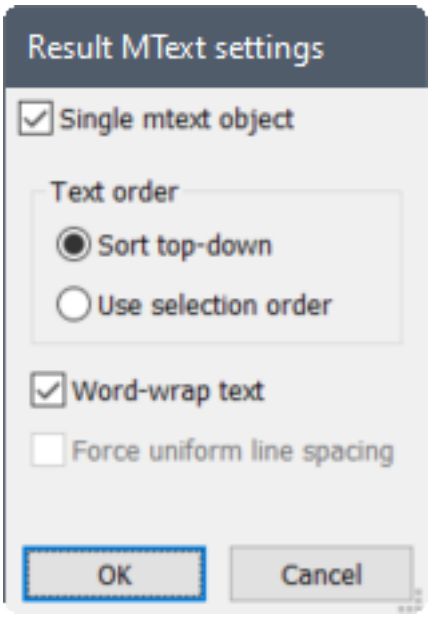
1.1.4 Drafting

BricsCAD v21 offers drafting enhancements to help increase your 2D drawing productivity.

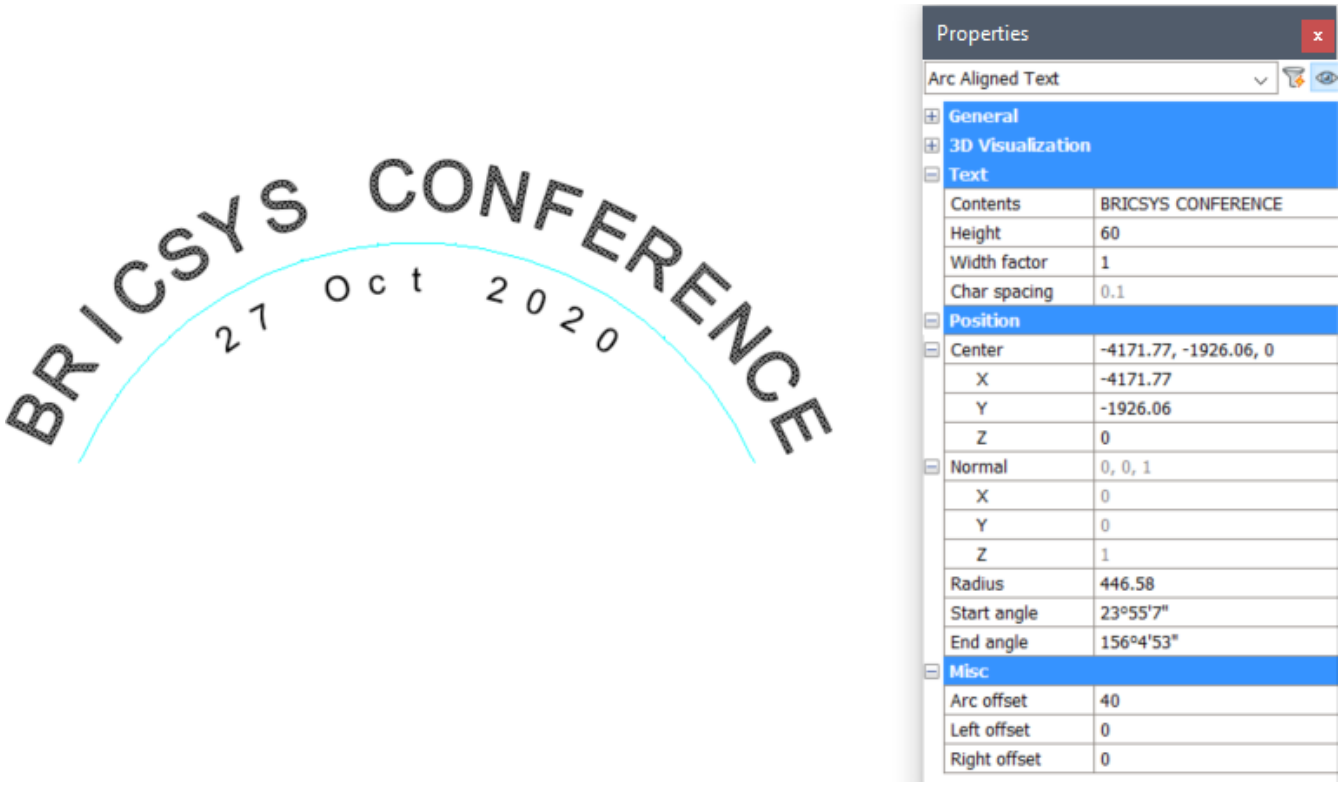
Combine Text to Mtext. The new TXT2MTXT command (alias COMBINETEXT) enables you to combine single- and multi-line text into a single MText entity. You can control the behavior for combining text in the Result MText Settings dialog box. (1.48 on the next page)

Figure 1.48



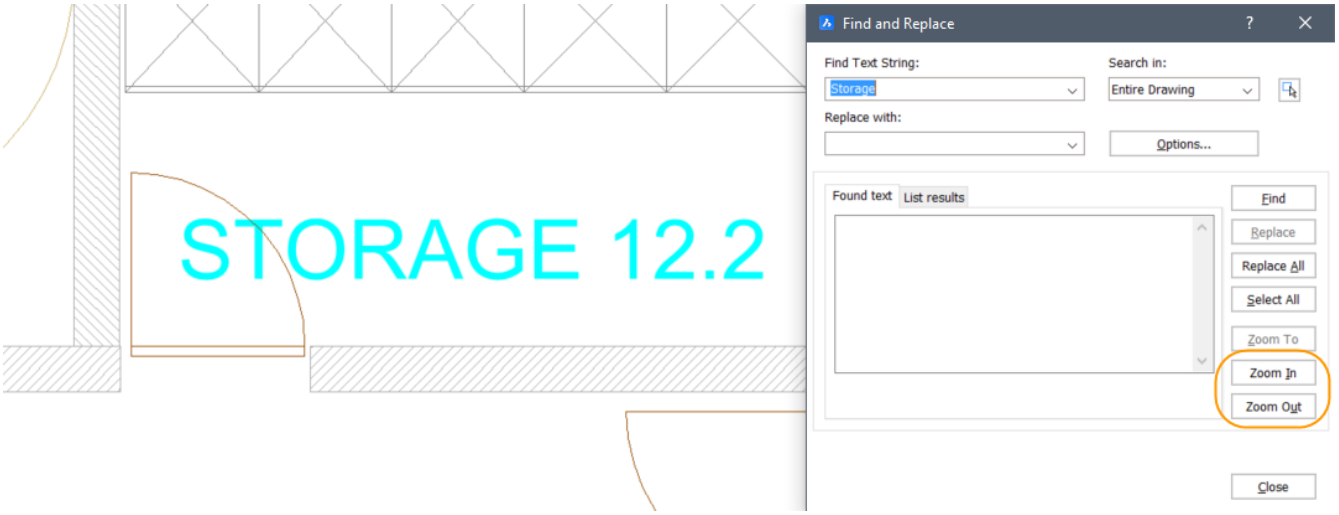
Arc Aligned Text The Properties panel enables you to view and edit properties for selected Arc Aligned Text entities. (1.49 on the following page)

Figure 1.49



Find and Replace Text The Find and Replace Text dialog box includes new buttons Zoom In and Zoom Out buttons. These enable you to take a closer look at the text within the context of the drawing without having to end the Find and Replace operation. (1.50)

Figure 1.50



Field The Field dialog box supports nested formula fields. When you right-click in the Formula field of the Field dialog box, new options enable you to Insert, Edit and Update a field. You can also convert a field to text. (1.51 on the following page)

1.1.5 Modeling

BricsCAD v21 offers many enhancements to 3D modeling tools to help simplify and automate the modeling process.

Dynamic UCS Dynamic UCS is now supported by the PLAN command. This allows you to select a face for the current UCS and immediately display it in plan view.

Direct Modeling **Threads** The new DMTHREAD command enables you to add a standard parametric thread to a cylindrical face of your 3D solid. You can edit the properties of the thread using the Mechanical Browser. (1.52 on the next page) Drawing views created with the VIEWBASE, VIEWPROJ, OR VIEWSECTION commands represent the threads following drafting standards. The following image show views of a cylinder before and after adding threads. (1.53 on the following page) **Chamfers** The DMCHAMFER command offers more flexibility with new asymmetrical, angular, variable symmetrical, variable asymmetrical and variable angular modes. (1.54 on page 81) **Fillets** The DMFILLET command offers more flexibility with a new variable radius mode. (1.55 on page 82) **Push Pull** The DMPUSHPULL command includes an option to specify subtract mode (on/off), which is also controlled by DMPUSHPULLSUBTRACT setting. It also allows you to switch the starting point of the dynamic dimensions on cylindrical faces. Press the Tab key to switch between radial and offset dimensions.

Figure 1.52

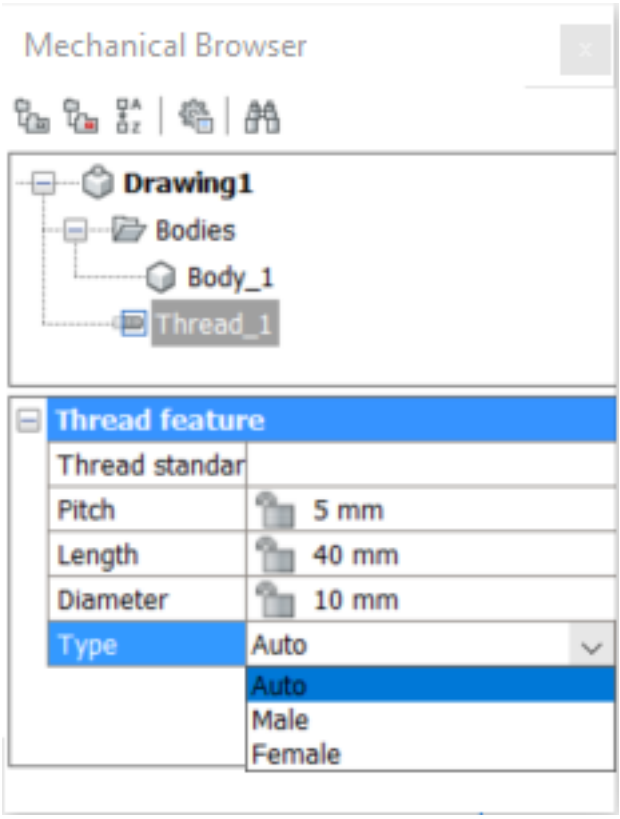

Figure 1.53

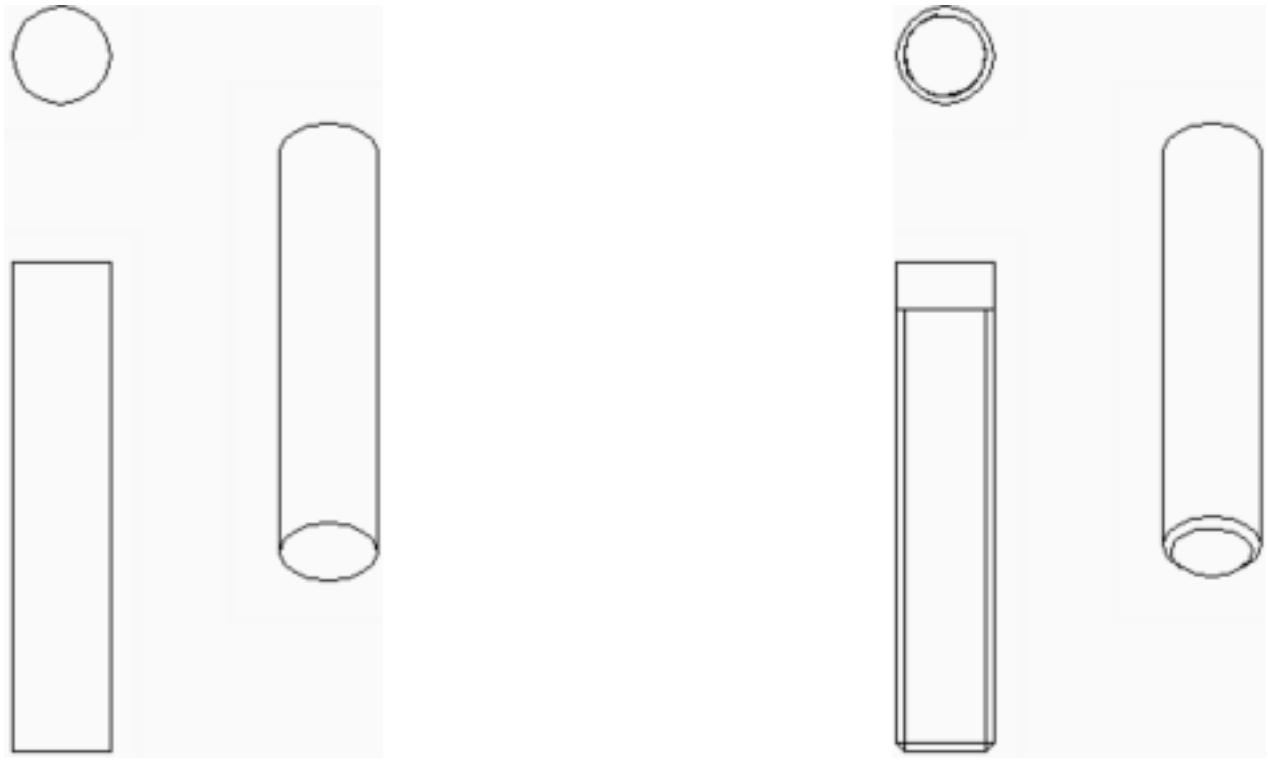

Figure 1.54

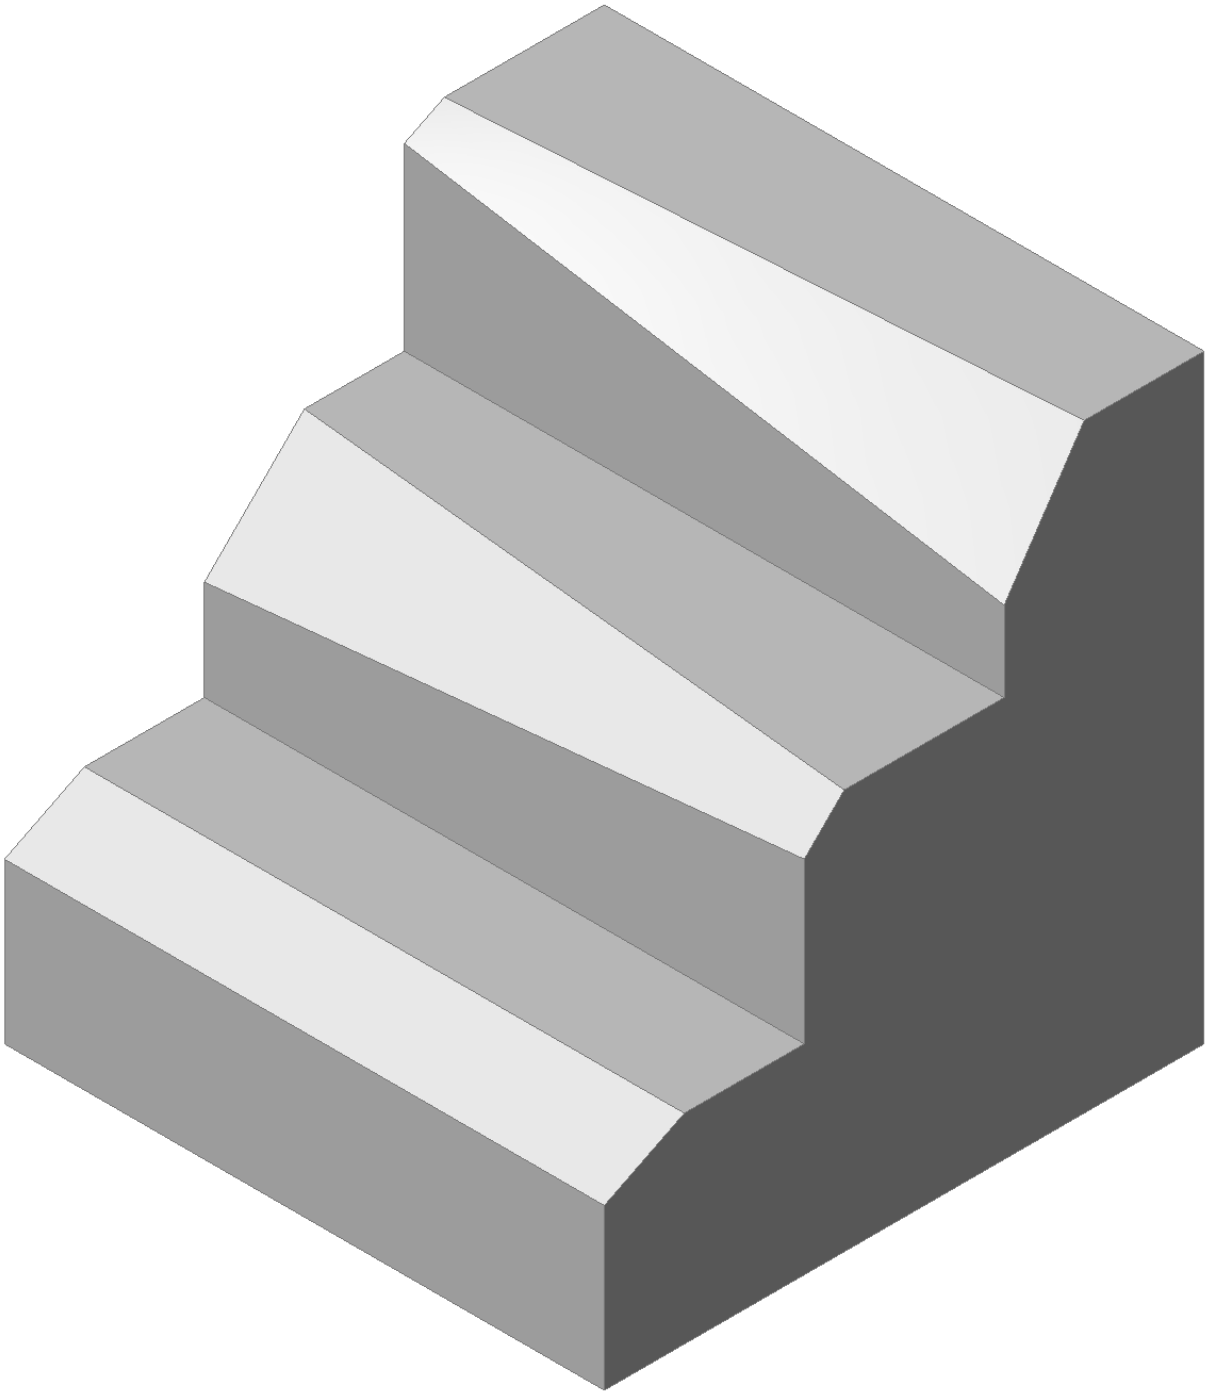

Figure 1.55

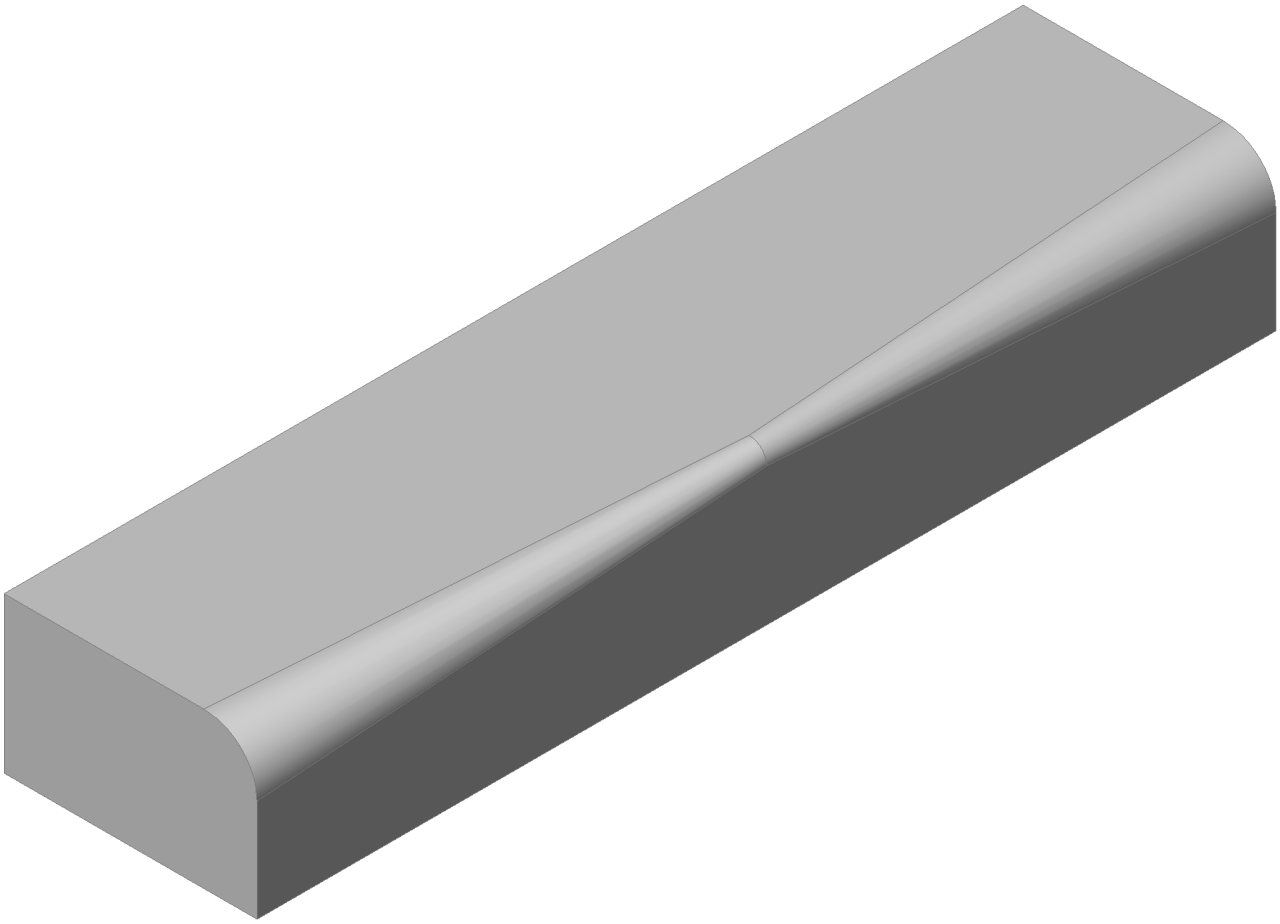

Broken Views The new VIEWBREAK command enables you to break an associative drawing view of your 3D model created with the VIEWBASE, VIEWPROJ, or VIEWSECTION commands and automatically include break symbols. You can change the appearance of a selected broken view symbol using the Properties panel. The VIEWBREAK command correctly supports dimensions you put on the drawing view before breaking. They remain associative with your 3D model and the drawing view. (1.56 on the next page)

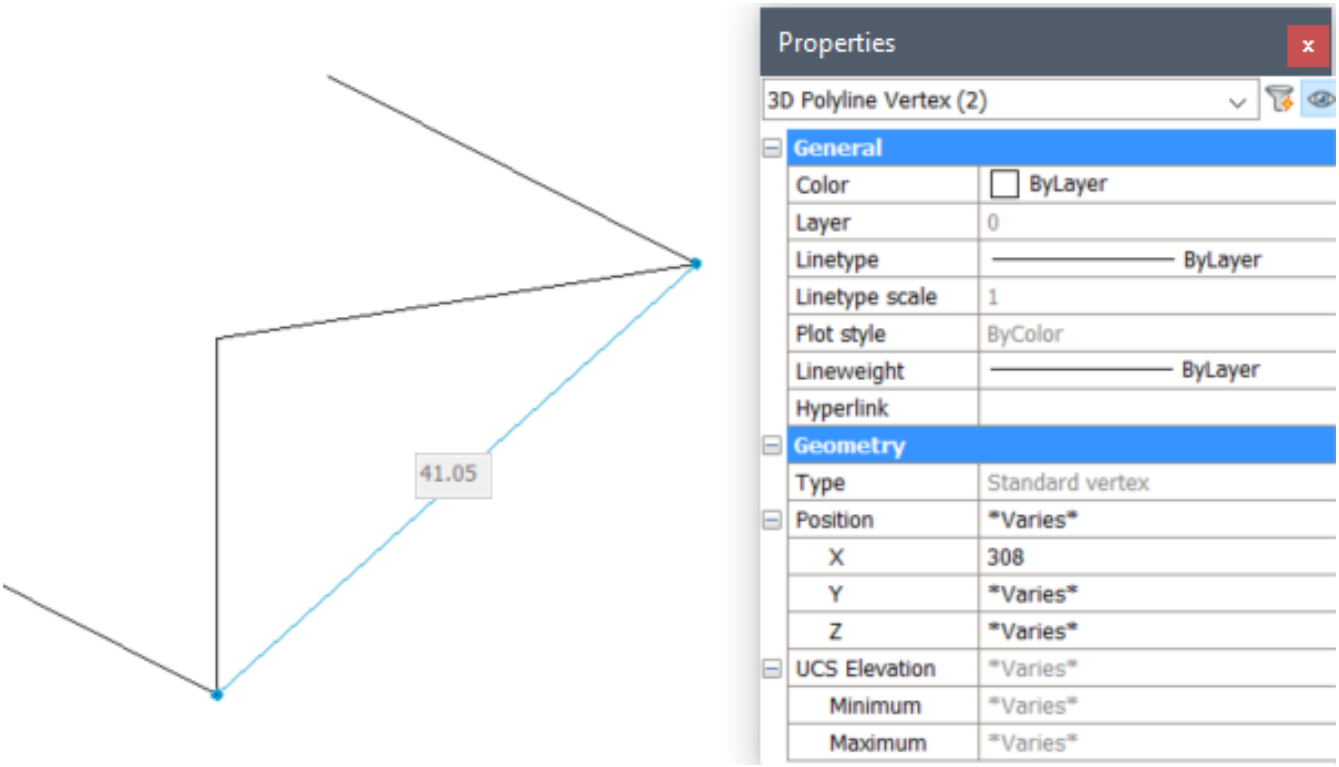
3D Entity Snaps Easily toggle 3D entity snaps on and off by pressing the F4 function key.

3D Polyline The vertices of 3D polylines now support sub-entity selection, the Properties panel, and nearest distance. (1.57 on the facing page) Additional enhancements to 3D Polylines enable you to apply 3D constraints to their vertices and edges.

Figure 1.57



Parametric Blockify The new PARAMETRICBLOCKIFY command enables you to quickly convert model entities to parametric blocks. Select a parametric block or parametrized entities as input geometry to compare against other geometry in the drawing. Matching geometry is automatically converted to parametric blocks.

3D Display Material glossiness has been adjusted to ensure entity details are distinguishable, even with glossy materials. The glossy effect is less intense for light materials and more intense for dark materials.

Solids and Meshes **Convert to Mesh** The CONVTOMESH command is optimized to triangulate planar faces only when necessary and with as few faces as possible. As an example, the original solids on the left are converted to meshes in BricsCAD v20 (center) and BricsCAD v21 (right). (1.58 on the next page) **Convert to Solid** The CONVTOSOLID command enables you to convert a mesh to an optimized 3D solid based on the new SMOOTHMESHCONVERT setting. (1.59 on the following page) When set to optimized, coplanar and adjacent faces are merged into a single face. As an example, the original mesh on the left is converted to a solid in BricsCAD v20 (center) and BricsCAD v21 (right). (1.60 on page 87) **Mesh Properties** The Properties panel offers access to additional properties for selected mesh entities. Mesh entities now include Mesh and Geometry properties including the ability to specify smoothness. (1.61 on page 87)

Figure 1.58

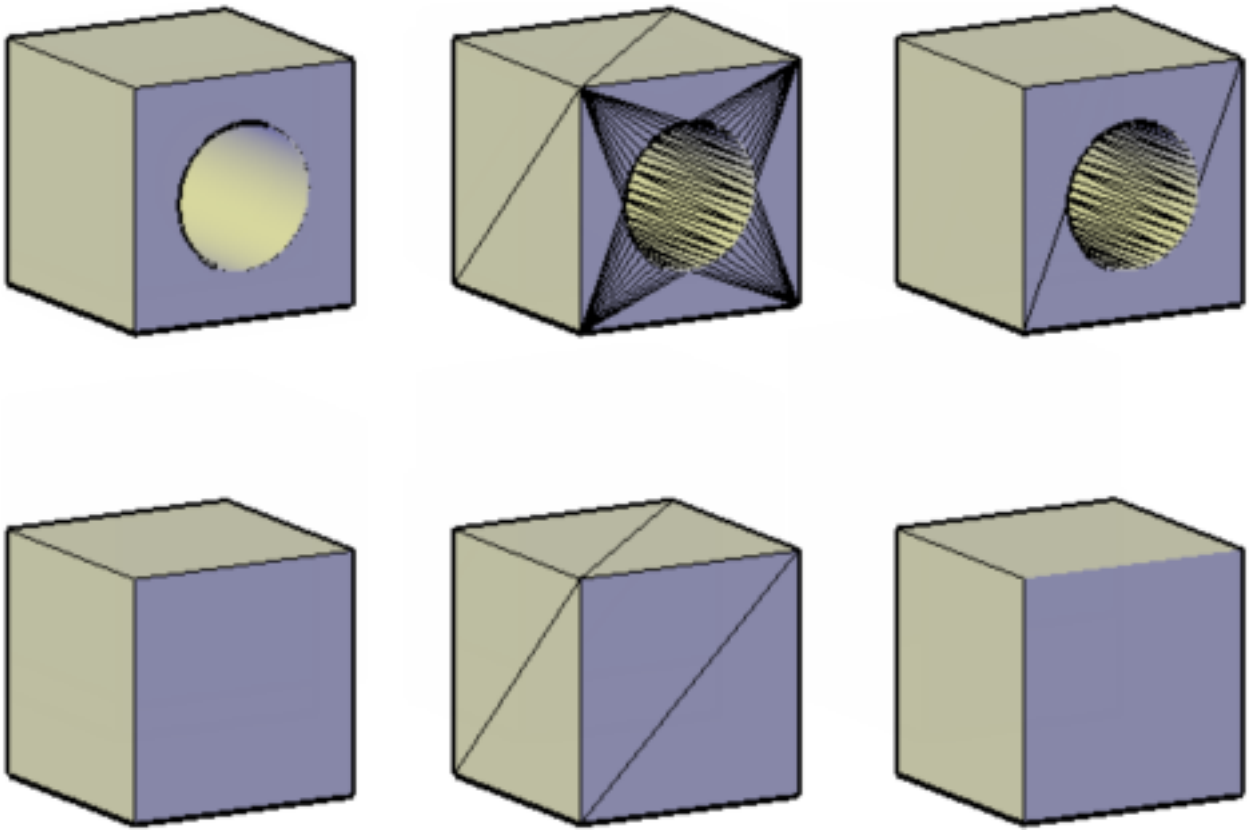


Figure 1.59

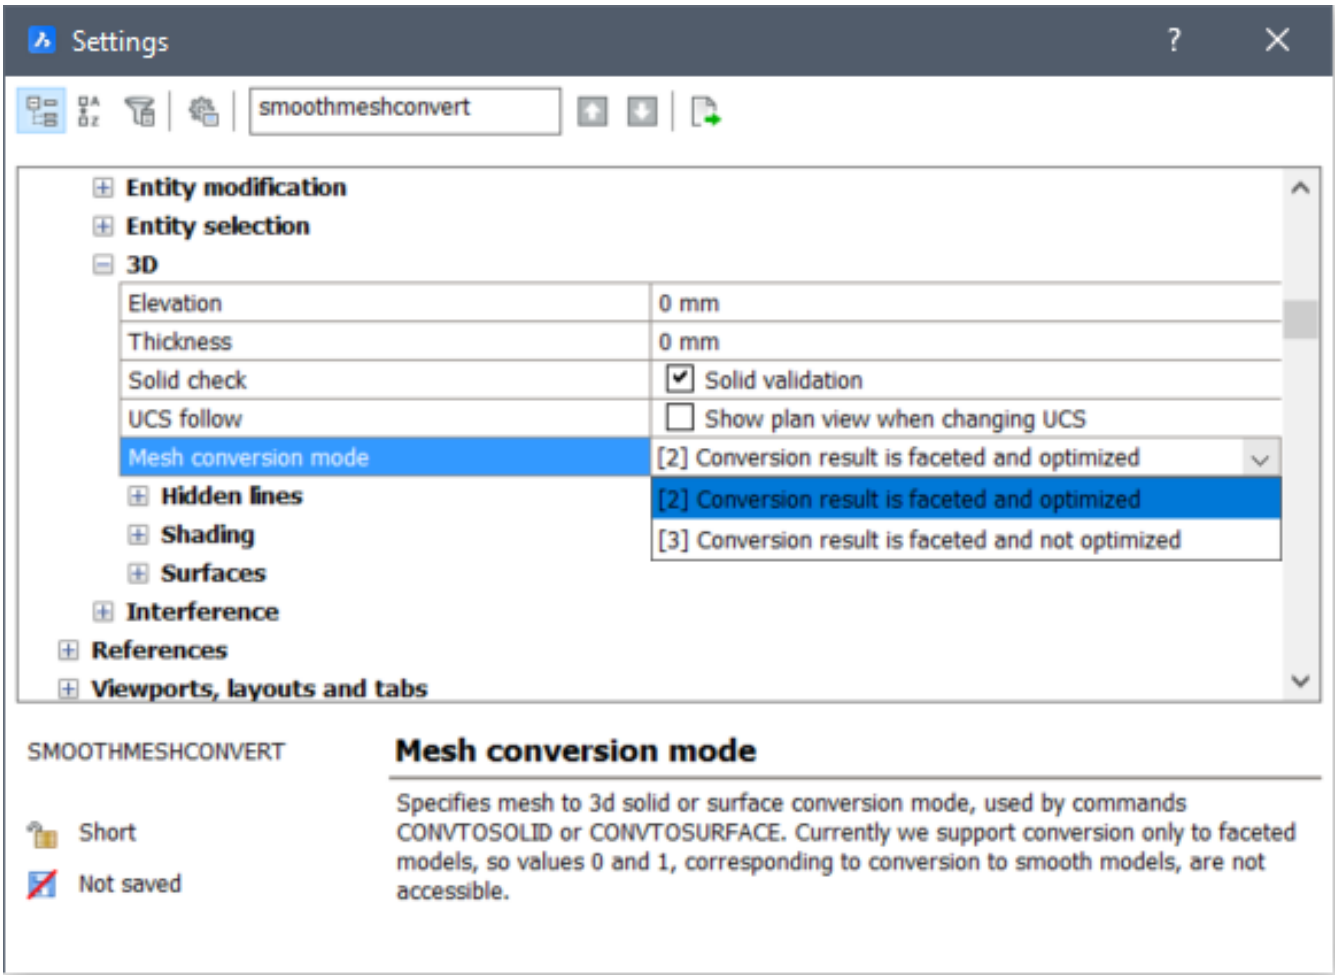

Figure 1.60

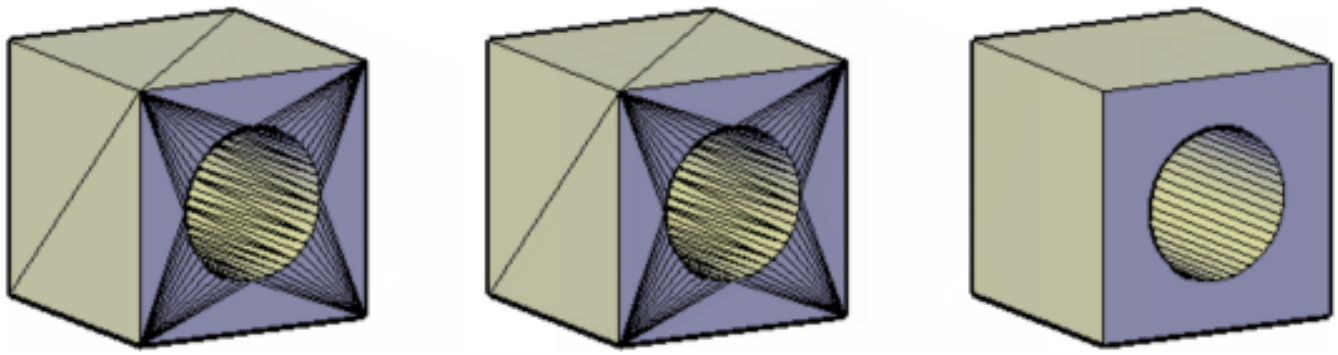

The Properties panel also supports mesh sub-entities including faces, edges and vertices enabling you to apply different levels of creasing. (1.62 on the next page)

Figure 1.61

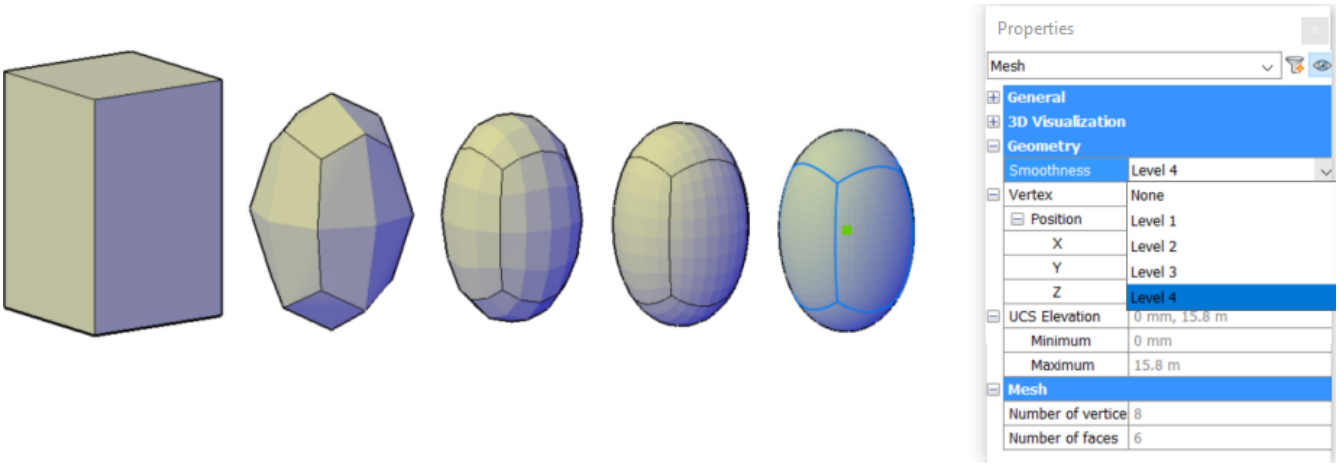

Figure 1.62

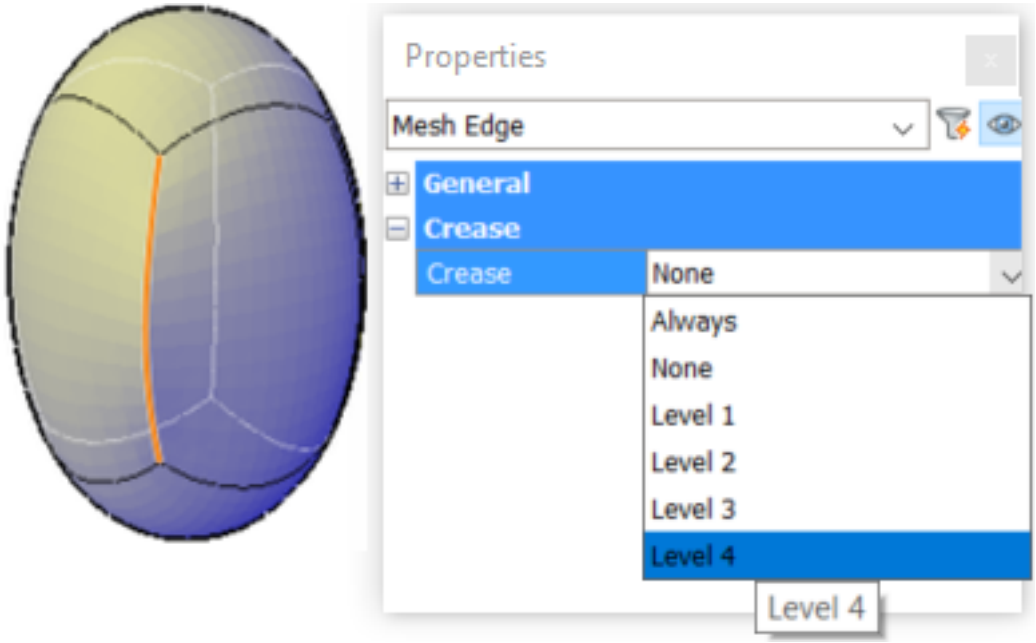

Associative Data The new GENERATEASSOCATTRS setting controls generation of associative data on 3D solids during modeling. When set to On, 3D solids contain associative data from the moment of creation. This allows BIMSECTIONUPDATE and VIEWBASE commands to produce drawings for which dimensions and tags can be automatically updated after the 3D model changes.

View Twist The Twist option is added to the -VIEW command.

Animation Editor The Animation Editor is enhanced to support the animating of exploded views in model space.

Point clouds Point cloud functionality is significantly faster and more powerful in BricsCAD v21. **Pre-processing** The E57 file format is added to the supported files for pre-processing. (1.983 on page 1077) When you attach a point cloud that requires pre-processing, it converts 5 to 8 times faster in BricsCAD v21 than in v20. A progress meter at the bottom of the display shows the conversion progress. (1.984 on page 1077) **Alignment** The new POINTCLOUDALIGN command automatically rotates a point cloud to optimally align it with the X and Y axis. To determine the best alignment it can analyze the entire point cloud or you can specify the most relevant area. (1.985 on page 1077) **Bubble Viewer** The point cloud displays bubbles at all the scan locations. It's at those locations where you will experience the most realistic visual representations. (1.986 on page 1079) Double-click one of the bubbles in model space to open the Bubble viewer. You can press the middle mouse button and move the mouse to view the point cloud in any direction from that scan location. (1.987 on page 1079) (1.988 on page 1080) Press the Tab key to cycle between three different visual modes. The first mode displays the points as their actual colors or in greyscale, depending how the data was scanned. (1.989 on page 1080) The second mode displays the points as red, green, or blue according to their normal vectors. The colors correspond to the UCS axes. (1.990 on page 1081) (1.991 on page 1081)

Figure 1.63

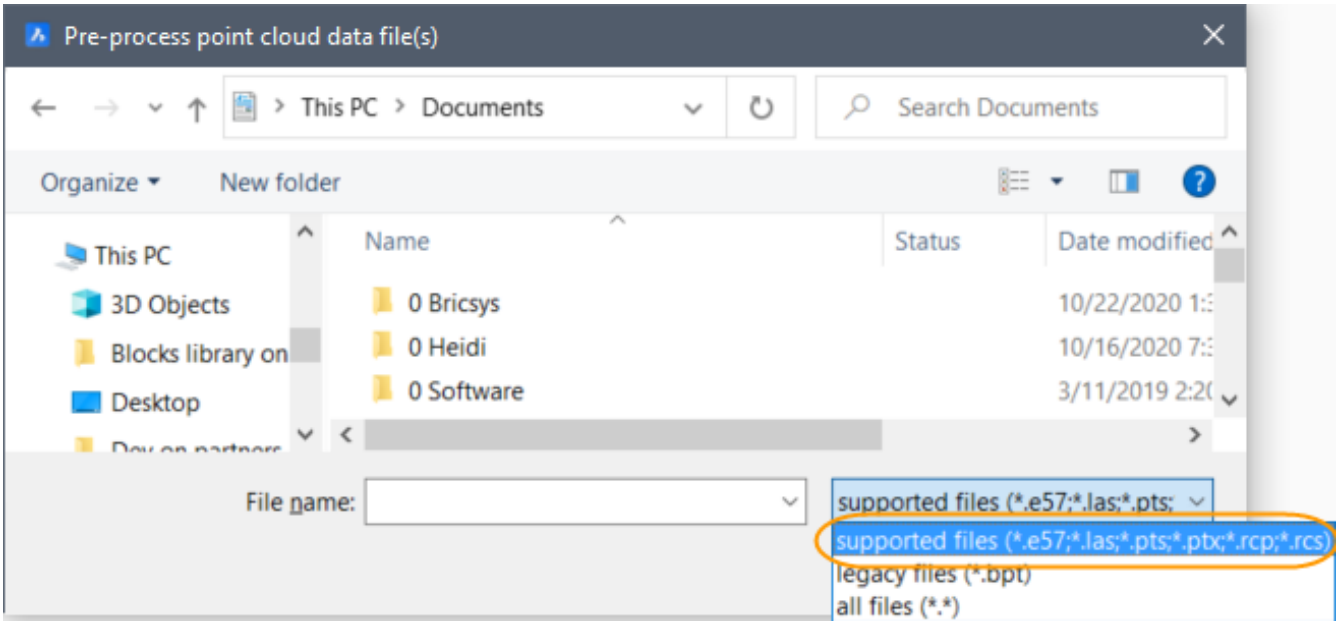

Figure 1.64

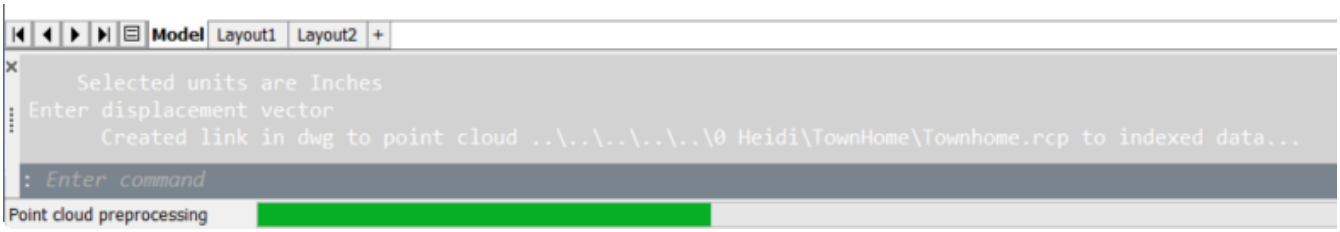

Figure 1.65

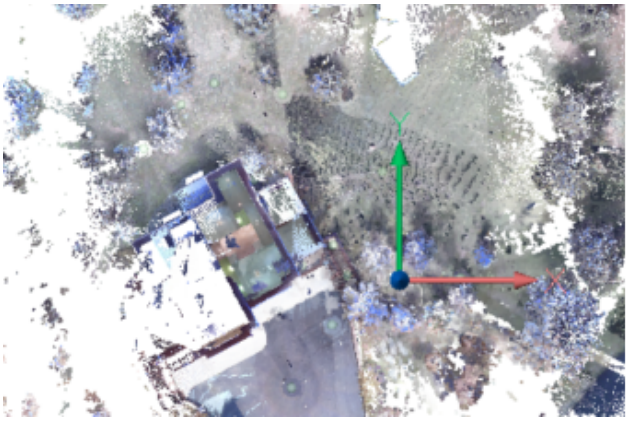

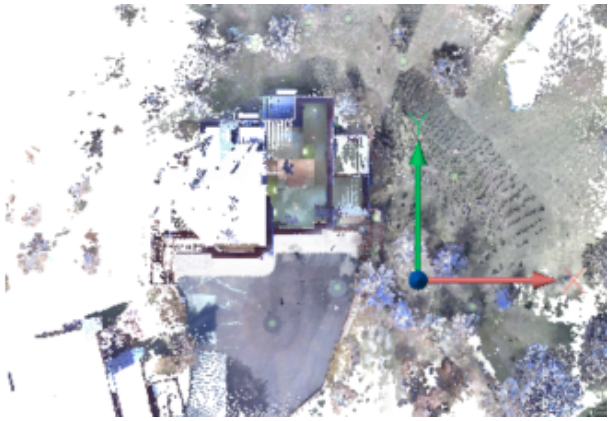

Figure 1.66

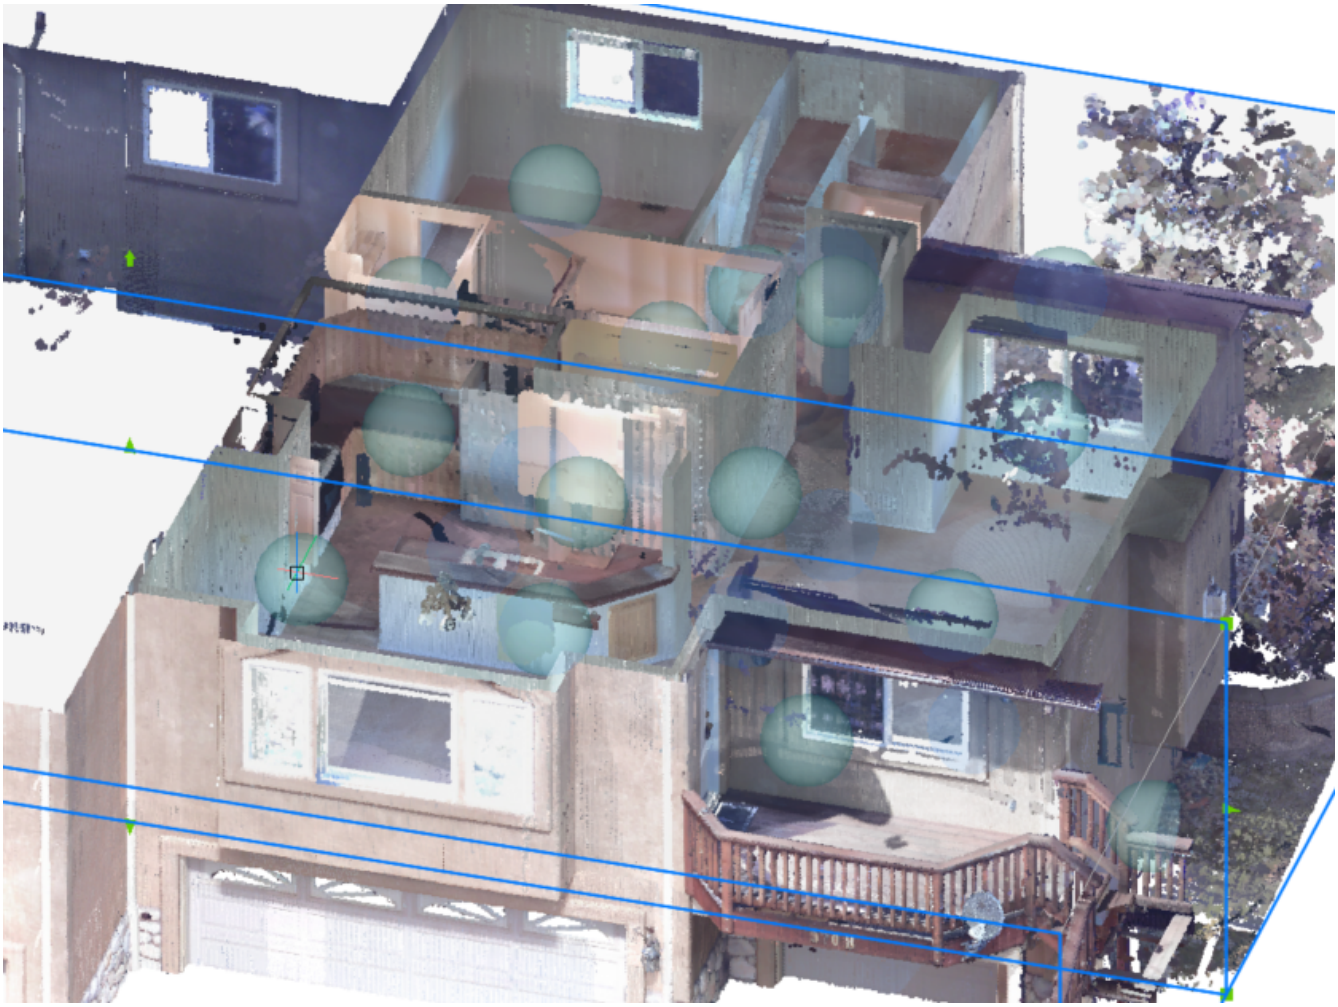

Figure 1.67

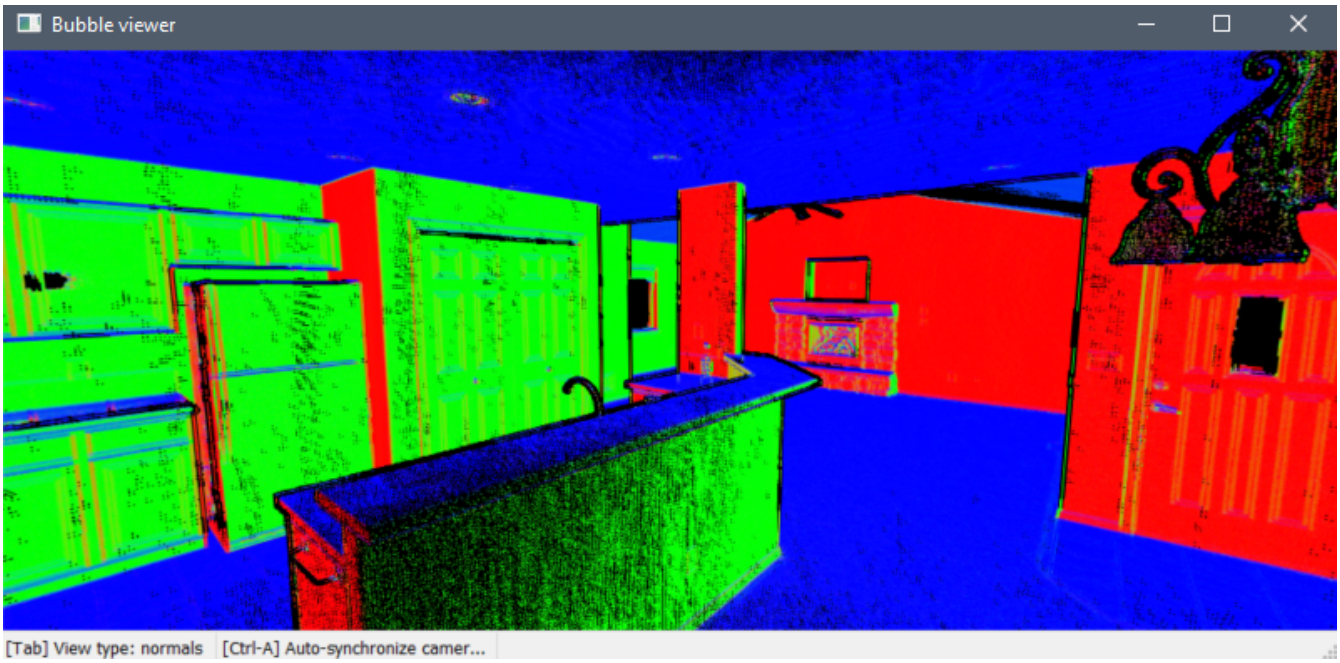
Figure 1.68

Figure 1.69

Figure 1.70



The third mode displays the points from light to dark as the distance from the scan location increases. (1.992 on page 1083) You can easily sync the drawing view to match the Bubble viewer by pressing Ctrl A. (1.993 on page 1083) **Entity snaps** The new Point Cloud Closest Point entity snap significantly improves your ability to select relevant point cloud points. It uses an imaginary cylinder from the current viewpoint toward the cursor. (1.994 on page 1085) The radius of the imaginary cylinder is defined by the Entity snap aperture box setting. (1.995 on page 1085) Enable the new Point Cloud Closest Point entity snap along with other 3D entity snaps in the Entity Snap menus, toolbar, and settings. (1.996 on page 1086) **Export** The new POINTCLOUDEXPORT command allows you to export a cropped selection of a point cloud to a .pts file.

1.1.6 Civil Tools

BricsCAD v21 offers many advanced tools for linear infrastructure modeling.

Import/Export New and enhanced tools for importing and exporting civil data help accelerate collaboration and design processes. **Civil 3D Data** The new CIVIL3DIMPORT command enables you to create multiple civil entities in your BricsCAD drawing, from an external Autodesk® Civil 3D drawing, in one operation. **LandXML Data** The LANDXMLIMPORT and LANDXMLEXPORT tools offer more flexibility. They support new alignment curves including spiral-curve-spiral combinations and parabolas for vertical alignments. Imported vertical alignments automatically create 3D Alignments. And, when importing a surface with breaklines, a new option allows you to specify whether the breaklines should be drawn as 3D polylines or not drawn at all.

Civil Entity Properties All Civil entities now include Name and Description properties in the Properties panel. Name and description are in the read-only mode in the Properties panel. They can be edited with the API. (1.77 on the facing page) Selected sub-entities of (Civil) custom entities are also displayed in the Properties panel.

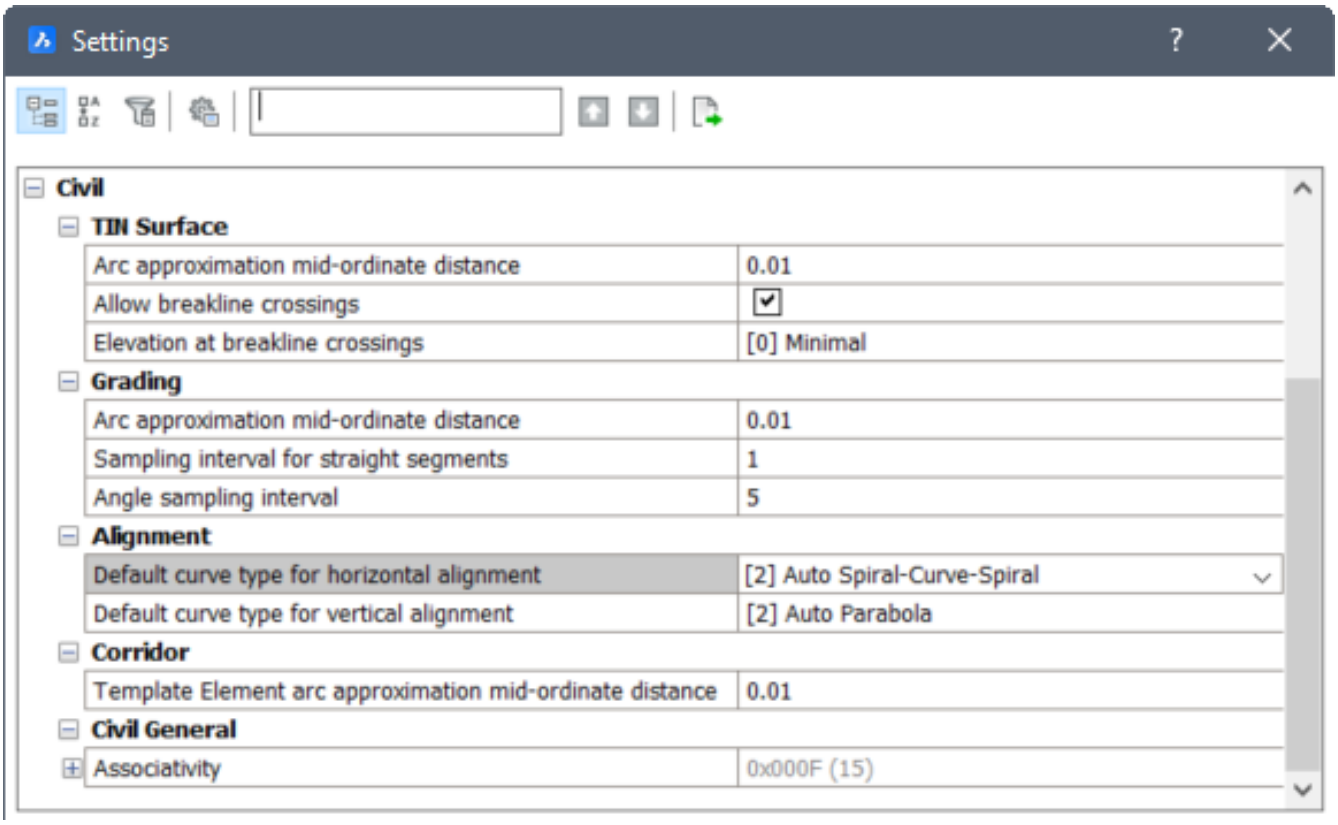
Figure 1.78



TIN Surfaces New and enhanced tools for creating and editing TIN surfaces provide more flexibility and a faster workflow. **Associativity** Points and blocks are dynamically linked to the TIN surface. If a TIN surface is created from points or blocks in the drawing and some points/blocks are moved, the TIN surface automatically updates to reflect the changes. **Clipping** A new option in TIN and TINEDIT commands enables you to clip a TIN Surface according to a given polyline boundary. (1.79) **Raster Images** The new TINASSIGNIMAGE command enables you to assign a raster image as a TIN Surface material to create a realistic site model. (6.2657 on page 5765) **Extract** The TINEXTRACT command enables you to extract faces, points, contours, and the border from a TIN surface, in addition to the previous ability to extract a mesh or solid. (1.81 on the following page) You may also extract a TIN surface from a Grading or TIN Volume Surface using the TINEXTRACT command. **Project** The new TINPROJECT command enables you to project point-based entities including points, blocks, and text or linear entities, including lines, polylines, and circles, to a TIN Surface. (6.2670 on page 5780) **Water Path** The new TINWATERDROP command enables you to draw a water drop's path from a point on a TIN Surface. (1.83 on page 101)

Figure 1.79

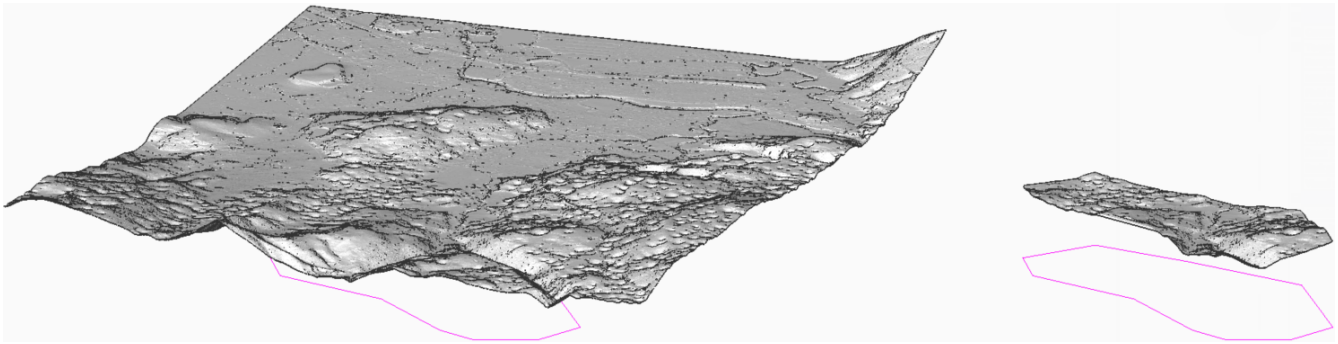


Figure 1.80

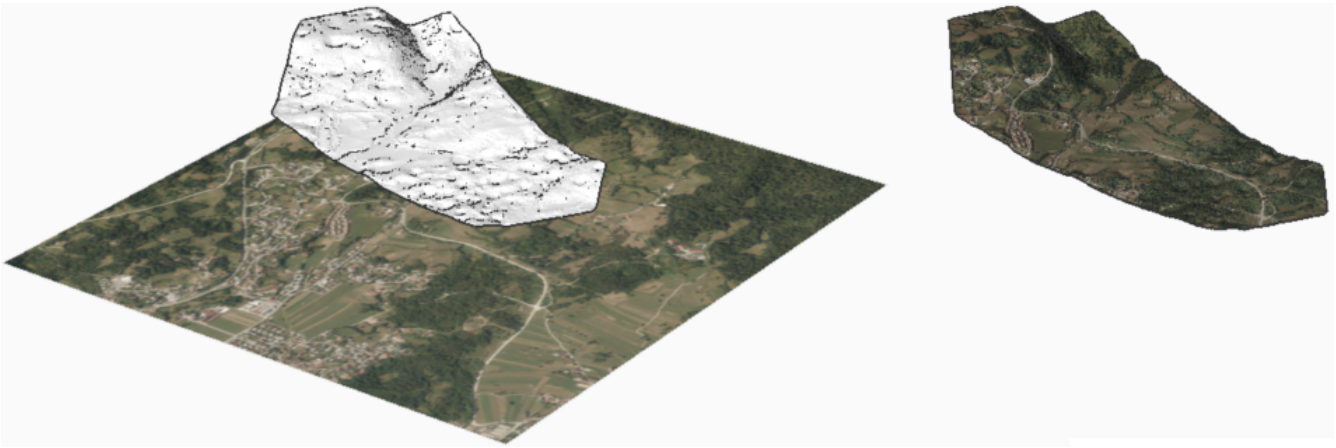

Figure 1.81

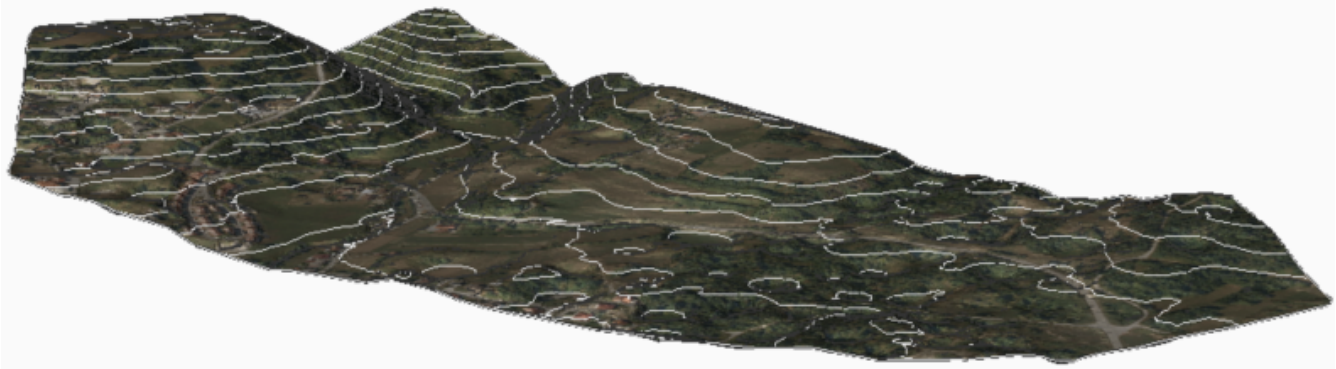

Figure 1.82

Figure 1.83

Alignments The workflow for creating alignments is simplified while still offering powerful functionality and additional flexibility. Horizontal and vertical alignment geometry is enhanced. Horizontal alignments now support spirals and vertical alignments now support parabolic curves. The new DEFAULTCURVETYPEHA and DEFAULTCURVETYPEVA alignment settings enable you to specify the default curve type for creating new horizontal and vertical alignments. (1.84 on the next page) (1.85 on page 103) The Properties panel displays properties for Spiral-Curve-Spiral or parabola elements.

Corridors Powerful corridor tools help you create a 3D model of linear infrastructure defined by a template and 3D alignment. The new CORRIDORTEMPLATEELEMENT command enables you to create a corridor template element from closed polylines. (6.740 on page 3998)

Then use the new CORRIDORTEMPLATE command to create a corridor template from template elements. (6.738 on page 3996) Finally, use the new CORRIDOR command to create a corridor from a corridor template, 3D alignment and/or TIN Surface. You can create multiple regions using different corridor templates. And, you can add or remove regions using the new CORRIDOREDIT command. (1.88 on the next page) Use the Properties panel to modify data and visual style properties of the selected region. (1.89 on the facing page) The new CORRIDOREXTRACT command enables you to extract a 3D solid, 3D mesh, or 3D polyline from a corridor to use for various purposes. For example, you can extract polylines from a corridor to use as edges for the grading. If you grip edit the alignment, the corridor and its associated geometry, such as the grading, automatically follows. (1.90 on page 106)

Figure 1.86

Figure 1.87

Figure 1.88

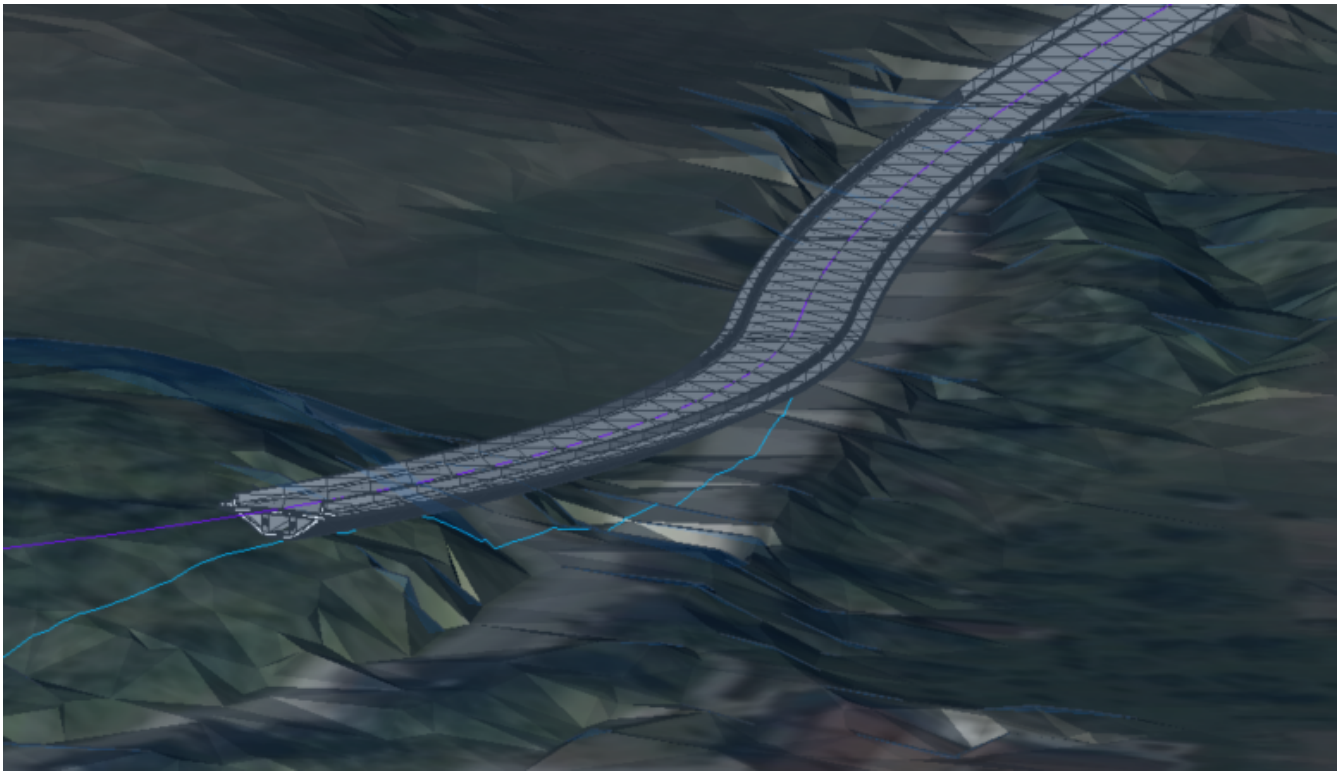

Figure 1.89

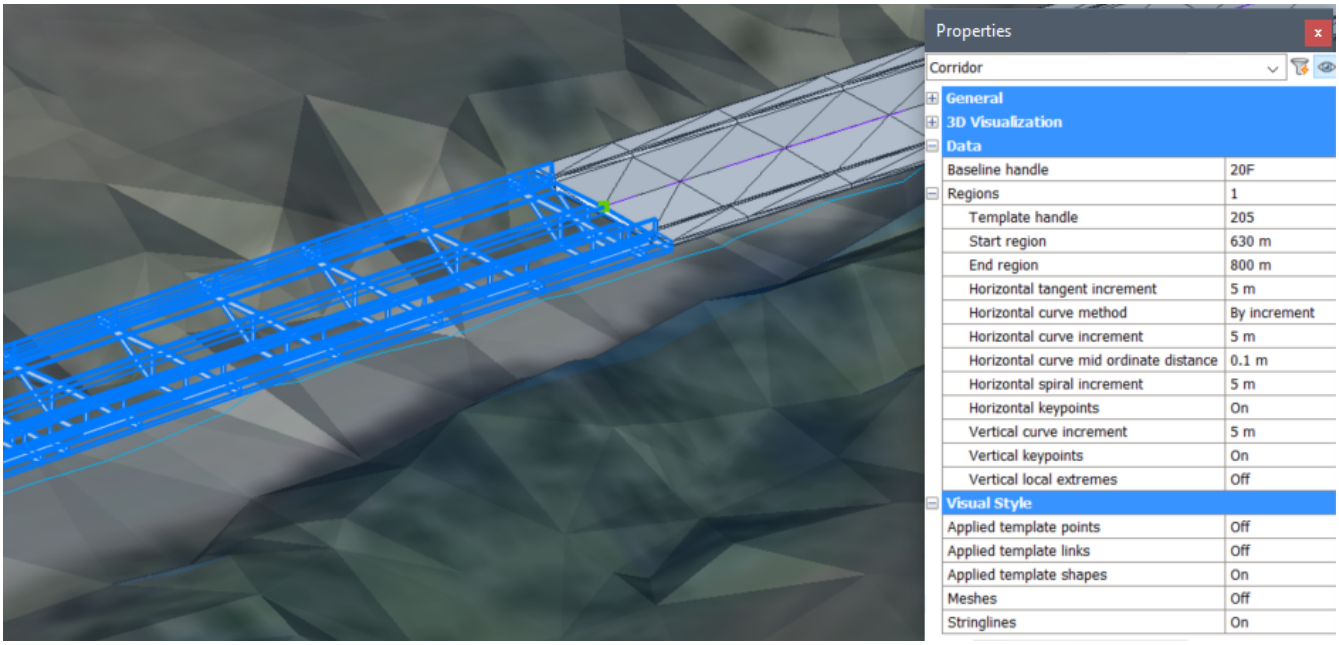

Figure 1.90

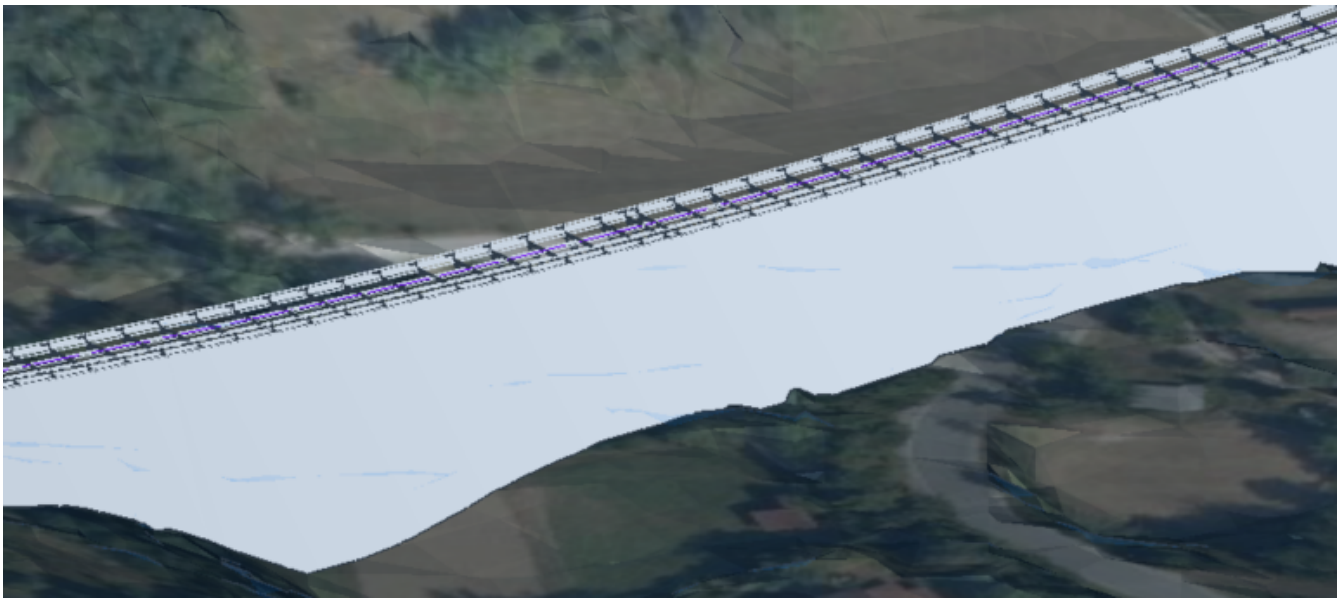

Gradings The new GRADINGBALANCE command enables you to balance grading cut and fill volumes.

TIN Volume Surfaces The ASSOCIATIVITY setting includes a new control for TIN Volume Surface associativity. TIN volume surfaces automatically rebuild when their source surfaces change.

API Samples The following API samples are provided: Horizontal alignment report, Color surface triangles by elevation, Color surface triangles by slope.

1.1.7 Performance and compatibility

BricsCAD v21 offers new and enhanced tools to improve performance and compatibility as you work individually or in a collaborative environment.

Selection Preview Selection preview highlighting is deactivated during Pan operations, resulting in a smoother user-experience.

Xref Loading A new MTFLAG is added to delay the loading of Xrefs to idle time. (1.91 on the following page)

Multiuser Version Control (BETA) BricsCAD v21 introduces new multi-user version control functionality as a beta technology preview. This functionality enables multiple users to work on the same drawings, simultaneously. Drawings are stored in the cloud using Bricsys 24/7 and checked in and out from each user's local machine. **Access** Since this is Beta functionality, you must request access by submitting a support request.

1. Log into your Bricsys account.
2. Choose New Support Request.
3. Open the BricsCAD menu and choose BricsCAD > Version Control.
4. In the Subject field enter: Access to VERSIONCONTROL Beta.
5. Fill in the rest of the fields as needed.
6. Choose Send Support Request.

VERSIONCONTROL Command The new VERSIONCONTROL command offers the following options:

- Init
- Checkout
- Checkin
- Update
- Rename

The first time you launch VERSIONCONTROL in a new BricsCAD session and choose one of the options, it prompts you to log into your Bricsys account. (6.2763 on page 5861) If your account has not been granted access to the beta functionality, it directs you to a web page with instructions to request access. If your account has access to the beta functionality, your successful login is indicated in the Command window and it prompts you to enter the name of the project on which you want to work. (6.2764 on page 5861) **Init** The **Init** option enables you to create a new multi-user project. Enter a new project name, keeping in mind project names are case-sensitive. If you enter a name that already exists, it prompts you to enter a different name. **Checkout** The **Checkout** option enables you to check out a drawing from your cloud-based projects. You must specify from which project you want to check out a drawing. Enter the project name, keeping in mind project names are case-sensitive. If you enter a project name that doesn't exist, BricsCAD displays a list of valid project names and prompts you to reenter the project name. After entering a valid project name, you must specify a version control folder for that project. The version control folder is the location on your local machine where your drawings are stored and synced with the cloud. The default location is **drive:\Users\username\Documents\Bricsys247\projectname**. However, you can specify any location. If the location doesn't exist, it's created and set under version control. If the location already exists it's set under version control. If the location is already under version control, you are prompted to specify a different location. **Checkin** The **Checkin** option enables you to check in drawings from your local, version control folder to the cloud-based project. You can check in all files in the version control folder or you can commit modified and untracked files. After specifying what to check in, you can enter a relevant Check In message. **Update** The **Update** option enables you to sync project drawings from your local folder with the cloud. **Rename** The **Rename** option enables you to rename a drawing that's under version control.

Figure 1.92

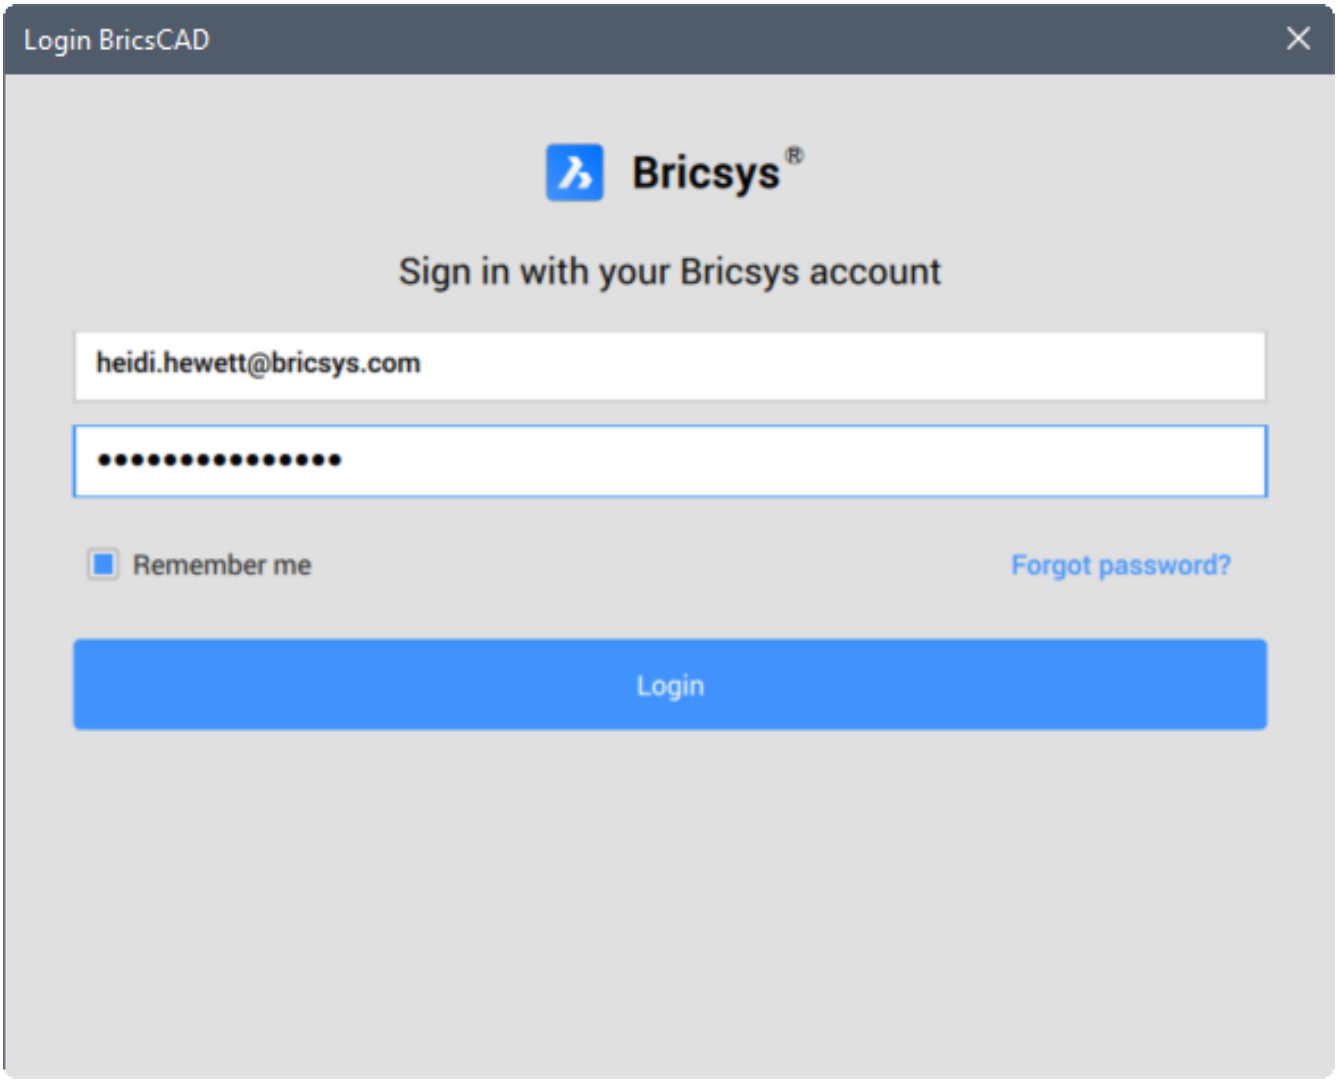

Figure 1.93

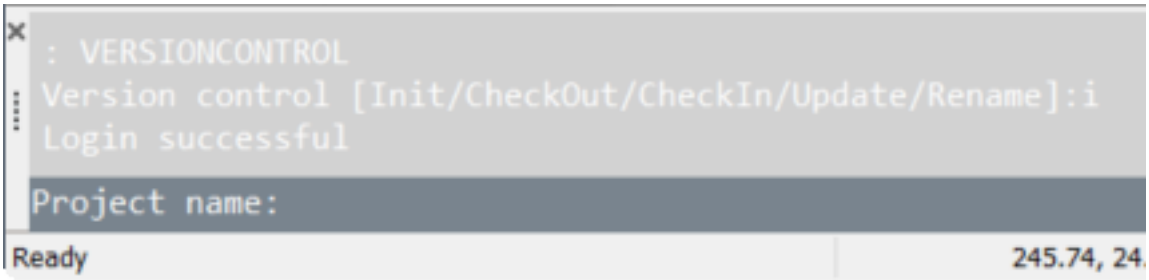
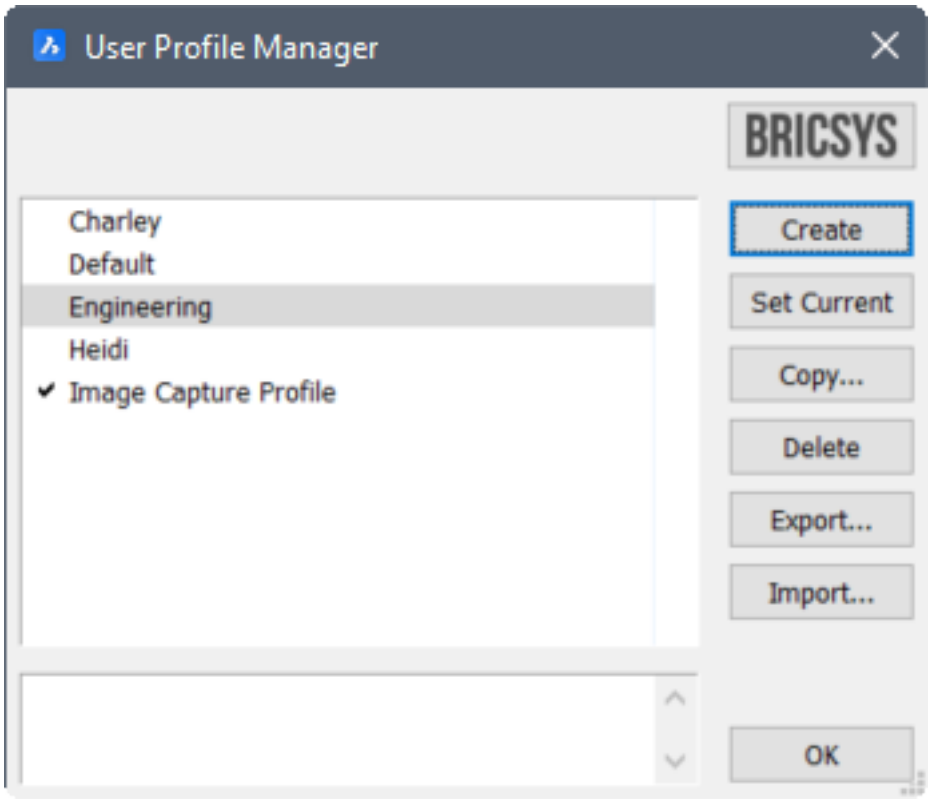


DGN Export A new DGNEXPORT command enables you to export the current drawing to DGN file format.

3D DWF Output The 3DDWF command enables you to create 3D DWF or 3D DWFx files based on the value of the new DWFFORMAT system variable.

User Profile Manager The User Profile Manager is now more powerful! It can now delete or replace existing user profiles, including the current one. Deleting the current profile doesn't completely remove it, but it does reset all settings to factory defaults. (1.94 on the next page)

Figure 1.94



Start Menu Shortcuts Start menu shortcuts now set the program folder instead of personal documents folder as the initial working directory. This change solves problems with installation under a system account where personal folders are not available.

1.2 Launching BricsCAD

1.2.1 The BricsCAD Launcher

If the **GETSTARTED** variable is ON, the **BricsCAD Launcher** dialog box displays when you launch BricsCAD. Here you can choose the Workspace for the current session. The available workspaces depend on the license level. (1.95 on the following page)

- **2D Drafting**: launches the Drafting workspace. BricsCAD Lite license or higher is required.
- **3D Modeling**: launches the Modeling workspace. BricsCAD Pro license or higher is required.
- **Mechanical design**: launches the Mechanical workspace. BricsCAD Mechanical or BricsCAD Ultimate license is required.
- **BIM**: launches the BIM workspace. BricsCAD BIM or BricsCAD Ultimate license is required.
- **Launch BricsCAD Shape**: launches BricsCAD Shape. No license is required.
- **Last used**: launches the last used workspace.
- **Don't show again**: sets the **GETSTARTED** variable to 0. To reset the display of the **BricsCAD Launcher** dialog box, type **getstarted** in the command line and choose 1 for ON.
- **Units**: sets the units for the default template drawing. Defines the **BASEFILE** system variable.

Note	The free solid modelling tool, BricsCAD Shape, is built into the single BricsCAD installer. When the BricsCAD Ultimate 30-day trial expires, it reverts to a perpetual BricsCAD Shape license, which can be converted to a full commercial license by purchasing a license key. It is not needed to uninstall BricsCAD first.

1.2.3 Setting the License Level

When running BricsCAD in trial mode, all features are available. It runs as a BricsCAD Ultimate license. The SETLICENSELEVEL (6.27.37) command allows you to select a lower license level.

Related Topics

Activating a trial license automatically (online) (1.7.6) Activating a trial license manually (offline) (1.7.7)

1.2.4 The License Manager

The LICENSEMANAGER command summarizes your BricsCAD licenses in a dialog box.

1.3 Installing BricsCAD

1.3.1 Overview of install options

- BricsCAD comes as a single download file for all license levels, including BricsCAD Shape.
- When you install a new BricsCAD version for the first time, you can run a 30-day trial mode first.
- You can install each new major version next to a previous major version.

Interactive installation

In case of a normal (non-silent) installation, the user provides the necessary installation input via dialog boxes. The user interface of Windows Installer queries the target system and displays Setup Wizard. Setup Wizard enables the user to change various options that affect the installation.

Silent installation

In case of a silent or quiet installation, the Setup Wizard user interface is disabled and the actions during the user interface sequence are not performed.

Related Topics

1.3.2 Interactive Installation

1. Double click the installer file.
2. Click **Next**.
3. Select the check box to accept the License Agreement.
4. Click **Next**.
5. Do one of the following:
   - Accept the default installation folder.
   - Click the **Change...** button and select an installation folder.
6. Click **Next**.
7. Click **Install** to start the installation.
8. Choose whether or not to add a shortcut on the desktop and/or to display the release notes when the installation process has finished.
9. Click **Next**.
10. Click **Finish** to finish the installation process.

BricsCAD is installed.

Related Topics

Overview of install options (1.3.1) Silent Installation (1.3.3)

1.3.3 Silent Installation (Windows only)

For silent installation, you need admin rights.

1. Open **PowerShell** or **Command Prompt** and change the directory (cd) to the location of the **BricsCAD®** installer .msi file. **Note**: In Windows 10, you can access the **Open PowerShell window here** context menu when you shift-right-click a folder in **Explorer**. This allows you to open PowerShell in the current window without having to change the directory.
2. Type **msiexec /i** and do one of the following:
   - Type the file name of the BricsCAD installer (e.g. BricsCAD-V20.2.09-1-en_US(x64).msi.
   - Drag the BricsCAD installer file from the Windows Explorer dialog to the command window.
3. Type **/qn** at the command prompt.
4. (option) Add **ADDDESKTOPSHORTCUT=""** to suppress the addition of a desktop shortcut.
5. (option) Add **SHOWRELEASENOTES=""** to suppress the display of the Release Notes when the installation completes.
6. (option) Add **APPLICATIONFOLDER="your_app_folder"** to install BricsCAD in a custom folder.
7. (option) Add **BRXLICENSEDESTFILE="path_to_lic_file"** to specify a folder for the license file if any of the properties **BRXLICENSEKEY**, **BRXLICENSEFILE** or **BRXLICENSESERVER** are defined. Default is **APPLICATIONFOLDER\BricsCAD.lic**.
8. (option) Add **BRXLICENSEKEY="your_license_key"** to activate the license and store it in the folder specified by **BRXLICENSEDESTFILE**.
9. (option) Add **BRXLICENSEFILE="your_license_file"** to copy the license file to the folder specified by **BRXLICENSEDESTFILE**.
10. (option) Add **BRXLICENSESERVER="host"**, or **BRXLICENSESERVER="port@host"** (*) to create a license file in the folder specified by **BRXLICENSEDESTFILE**, containing the server host specification. (*) If your license server is using a different port than default port 5053.
11. (option on 32 BIT only) Add **INSTALLVBA="0"** or **INSTALLVBA=""** to not install VBA. The complete entry in the command prompt can be: **msiexec /i "BricsCAD-Vxx.x.xx-x-en_US(x64).msi" /qn ADDDESKTOPSHORTCUT="" SHOWRELEASENOTES=""**.
12. Press **Enter** to launch the installation.

Notes:

- For more options, type: **msiexec /?** at the command prompt**.**
- On the Microsoft website, you can find more information about the **msiexec** command.

1.4 Installation & Licensing

1.4.1 BricsCAD Migration – The BricsCAD User Interface

The BricsCAD User Interface

What's different versus AutoCAD®? You may have heard phrases like "**muscle-memory compatible**" to describe the BricsCAD user interface (UI), with regard to AutoCAD's. The command syntax is almost identical. Your scripts and menus generally work in BricsCAD without modification, and your AutoLISP routines just load and run. And of course, if you're a LISPer, you'll be excited to meet BLADE, the BricsCAD LISP Advanced Development Environment. There are some advances in BricsCAD® that might confuse a long-time AutoCAD user. Let's talk about them up front, to simplify your migration journey. First: did you download the free eBook, BricsCAD for AutoCAD Users? If not, please do this right now. It's written for Bricsys by Ralph Grabowski, who is very fluent in both products.

The BricsCAD Start Screen

The simplified startup screen in BricsCAD makes it easy for new users to get going. The BricsCAD "Get Started" dialog sports a simple, single-pane layout. It lets you select an existing drawing, or create a new one from a template. You can also select your drawing units from the start screen. Wondering what's new in the latest release? It's easy to get to our (comedy) award-winning Release Notes and our on-line tutorials from the startup screen, too. Don't like it? Turn it off or on with the GETSTARTED setting.

Inside the Main Window

Are you one of those "**left hand on the keyboard, right hand on the mouse**" CAD users? The BricsCAD command prompt uses a simple ":" character to tell you that it's ready for your input. You can change the BricsCAD setting "CMDLNTEXT" to any text string you want. BricsCAD's prompt menu is a floating menu box that pops up whenever a command supports additional options. You can use it to pick command modifiers (or simply key-in the modifier, as you would in AutoCAD). You can control the display of the prompt menu – go to SETTINGS, search for "Prompt menu", or just type in PROMPTMENU. I set it to "4", so that the prompt menu appears near my command window. The biggest UI enhancement in BricsCAD has to be the Quad cursor. It's a fully customizable, context-sensitive "head-up" tool palette. The Quad brings relevant commands directly to your cursor. For more information on the Quad, go to Chapter 2, Page 57 of the Grabowski book (you **DID download** it, right?). – or check out the extensive HELP on "The Quad Cursor Menu" in Chapter 1 of the BricsCAD User Guide.

The BricsCAD SETTINGS Dialog Box

All 954 BricsCAD Settings (options + "sysvars") live here!

All BricsCAD User Interface options and settings are controlled from a single dialog box, named… SETTINGS. The search function in the SETTINGS dialog is like magic. Type in the first few letters of a setting's name, title or description and your cursor will jump to that setting automatically. More than one? Move to the next using the arrows next to the search text box. The search box changes color to show when you've typed an invalid string (or run to the end of the options). In BricsCAD, you can export all of your current settings to a CSV file by clicking a button in the SETTINGS dialog. A comprehensive overview of the SETTINGS dialog is in "BricsCAD for AutoCAD Users", Chapter 2, starting on page 60. I recommend Ralph's guided tour so that you are savvy with this important BricsCAD feature. Once you use this powerful tool, you'll be smitten!

"Panels" versus "Palettes" The menu elements called "palettes" in AutoCAD are called "panels" in the BricsCAD user interface. Some of your favorite AutoCAD palettes appear to be missing in BricsCAD, until you discover that they have been centralized into the BricsCAD Drawing Explorer. This tool gives you all the necessary information about your open drawing(s), and the ability to copy data between drawings via drag and drop. Just type "EXPLORER" at the command prompt or invoke a related command like "LAYER" or "XREF". The Properties panel in BricsCAD lets you discover data about entities, or edit entity properties. You can turn on the Properties Bar by entering "PROPERTIES" at the command prompt, or right-clicking in any toolbar (or the ribbon) and selecting "Properties".

Rollover Tips

It's important to know that, in the BricsCAD user interface, the Properties panel isn't the only way to get information on the entities in your drawings. Rollover Tips in BricsCAD appear on your cursor when activated (via the "RT" switch in the Status Bar). You can use the CUSTOMIZE (CUI) tool to set up the properties displayed in the rollover tip for each entity type. Tool palettes in AutoCAD and tool panels in BricsCAD operate very similarly, but customization works a bit differently. For more info, see Chapter 4 of Ralph's book, starting on page 121. While AutoCAD tool palettes use a file extension of "ATP", BricsCAD palette bars use "BTP". They are both stored as XML data, and you can import ATP files into BricsCAD.

More on the BricsCAD User Interface Next installment, we'll pick up with the differences in Sheet Sets between AutoCAD and BricsCAD. In the meantime, please feel free to "read ahead" in Ralph's book. The more you know, the more you'll like BricsCAD. You can never know too much about the world's best CAD software. Try BricsCAD Today!

1.4.2 How to roam with a network license

https://www.youtube-nocookie.com/embed/98zt4duxRlI

Book your BricsCAD license out

If you're running BricsCAD with a network license, then you have the option of roaming. Roaming allows you to book your BricsCAD license out, providing you a way to continue using BricsCAD without a network connection. This video will show you how to do this. Back to Tutorial Overview

1.4.3 BricsCAD License Server Setup

https://www.youtube-nocookie.com/embed/WvCh0tjDEGg

Overview on setting up BricsCAD's network license server

The video explains how to set up a BricsCAD network license server and what advantages comes with it.

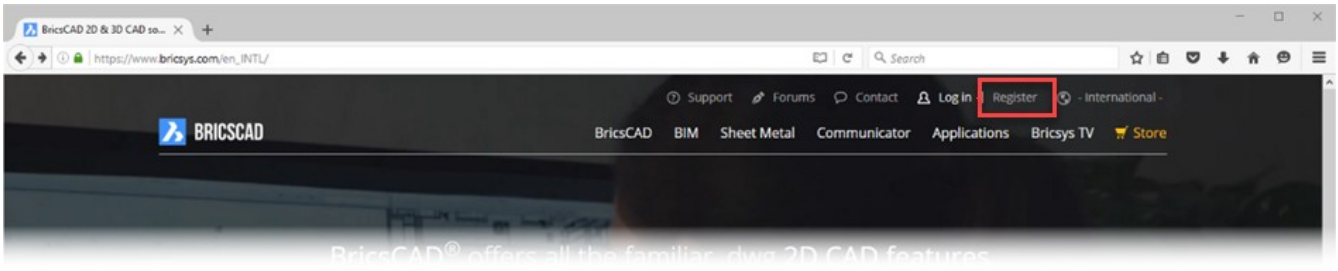
Share BricsCAD with multiple users You can run a network license server allows BricsCAD to be shared amongst multiple users. This is a great option for people that need to utilise CAD as part of their work process. It is also extremely cost effective.

A Bricsys account provides you two key advantages If you're not the License owner, then it's recommended that you first create a user account with Bricsys. This will provide you with two key advantages:

1. Firstly, It will allow the license holder to assign you as the licence manager, meaning you can manage their BricsCAD license on their behalf;
2. Secondly, should you strike any issues with administering the network license, you will be able to directly access next business day support from Bricsys.

(1.96)

Figure 1.96



License servers for Windows and Linux There are license servers available for Windows and Linux. Details on how to set the server up can be found in the online help (1.11.1). This also includes links to download the server installer. (1.97 on the following page) Back to Tutorial Overview

1.6 Exploring the Interface

1.6.1 The Start tab

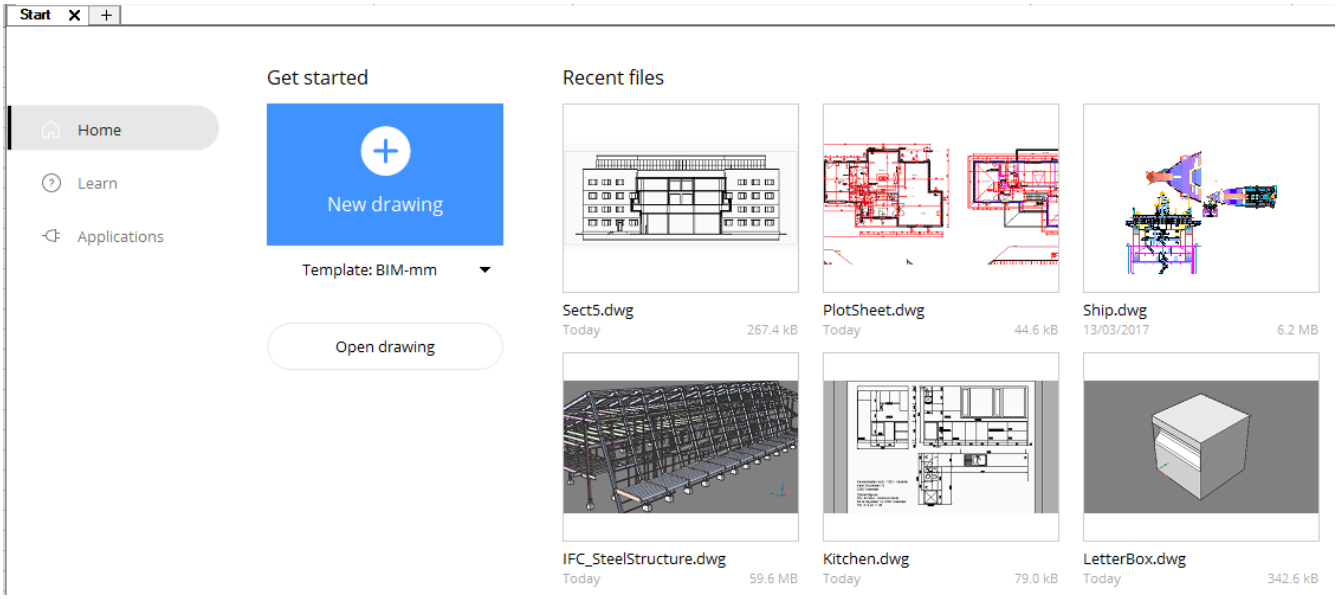
The **Start** tab sits on top of the drawing area, before the document tab(s). In the Start tab you can:

- **Open a recent drawing** Click the thumbnail image of a recent file. The number of available recent files is controlled by the value of the RECENTFILES (1.17.10) system variable.
- **Create a new drawing** Click the **New Drawing** tile to create a new drawing using the current drawing template. Optionally, open the **Drawing Template** list to select a different drawing template.
- **Open a drawing** Displays the **Open Drawing** dialog box.

(6.1247 on page 4517) The **Start** tab is active by default. If you accidently closed the tab, you can reopen it with the **Ctrl+Home** keyboard shortcut or with the GOTOSTART (6.15.18) command. **Notes**:

- When using the Ctrl+Home keyboard shortcut, make sure to turn off Num lock.
- The **SHOWDOCTABS** system variable needs to be ON to display the Start tab.

Figure 1.115



Related Topics

Document tabs (1.6.2) GOTOSTART command (6.15.18)

1.6.2 Document Tabs

For each currently open drawing, a document tab sits on top of the drawing area. Document tabs allow you to:

- Easily switch between all open drawings.
- Create a new drawing: click the **+** button on the right of the tabs.
- Close a drawing: click the **X** in the document tab.

Related Topics

1.6.3 Choosing the Workspace

Default workspaces are:

- **Drafting**: uses the ribbon.
- **Drafting (toolbars)**: uses menus and toolbars.
- **Modeling**: requires a BricsCAD Pro or higher license level; uses the ribbon.
- **Modeling (toolbars)**: requires a BricsCAD Pro or higher license level; uses menus and toolbars.
- **Mechanical**: requires a BricsCAD Mechanical or BricsCAD Ultimate license level.
- **BIM**: requires a BricsCAD BIM or BricsCAD Ultimate license level.

The current workspace configures the overall layout of the BricsCAD application window. A workspace defines the content of:

- Menus (1.6.13)
- Toolbars (1.6.5)
- Panels (1.6.10)
- Ribbon (1.6.6)
- Quad (1.6.7)

You can set the current workspace in:

- The BricsCAD Launcher (1.2.1) dialog box.
- The **Current Workspace** field in the Status bar (1.6.8).
- The Workspaces toolbar.
- The WORKSPACE (6.33.14) command.

Related Topics

Customize the user interface of BricsCAD (6.9.47) Workspaces (1.17.11)

1.6.4 The Command Line

The command line is an optional dockable panel that sits at the bottom of the drawing area by default. The command line is a fast and efficient method to launch commands and to set system variables and user preferences. BricsCAD prompts for user input in the command line and reports the results of commands such as DIST (6.10.36), AREA (6.4.18) or LIST (6.20.34) here. When the command line is closed, keyboard entries and command prompts display in the Status bar (1.15.2).

Related Topics

1.6.5 Toolbars

Toolbars are used by default in the **Drafting (toolbars)** and **Modeling (toolbars)** workspaces, but can be used in any workspace.

- You can choose small (16 x 16), large (32 x 32) or extra large (64 x 64) icons on toolbars. See: To set the toolbar icon size. (1.15.3)
- On some tool buttons, a small black arrow at the bottom right corner of the icon indicates a flyout is available. A flyout holds a group of related tools. Press and hold the left mouse button to expand the flyout and choose one of the flyout tools. The tool that was last chosen remains visible in the collapsed toolbar. See: Toolbar flyouts (1.15.3) and To tear of a flyout toolbar (1.15.3).
- You can open or close toolbars at any time. See: Opening a toolbar (1.15.3) and Closing a toolbar (1.15.3).

Related Topics

Workspaces (1.6.3) The Ribbon (1.6.6) Menus (1.6.13) The Quad (1.6.7) The Command Line (1.6.4) Executing Commands (1.10.6)

1.6.6 The Ribbon

The ribbon is a set of tabbed toolbars, filled with tool buttons and other graphical control elements, grouped by functionality. The content of the ribbon depends on the current workspace. The Drafting, Modeling, Mechanical and BIM workspaces use the ribbon by default. Use the RIBBON (6.26.32) and RIBBONCLOSE (6.26.49) commands to open or close the ribbon.

Related Topics

Figure 1.116

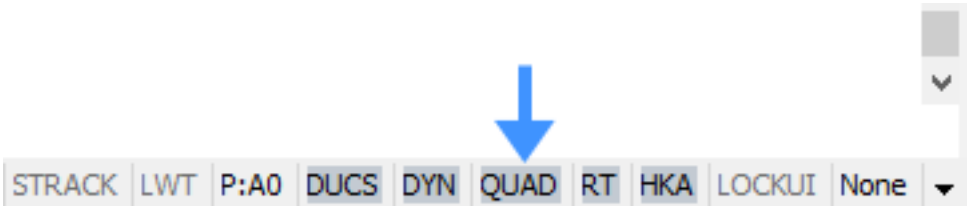

Figure 1.117

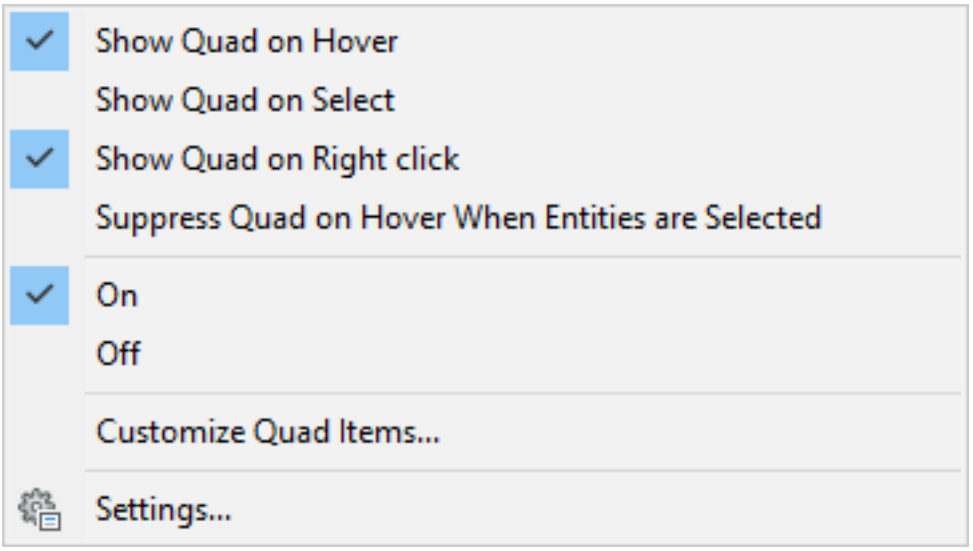

1.6.7 The Quad Basics

The Quad is a complete command system located directly at the mouse cursor. When you move the cursor across the screen or when a selection set exists, the Quad detects the entity type and presents commands that work on this entity or selection of entities. When no entity is detected or selected, you can use the Quad to create entities, insert blocks, attach underlays, or open the **Settings** and **Drawing Explorer** dialog boxes.

- To toggle the display of the **Quad**, click the Quad field in the Status bar (1.6.8) at the bottom of the BricsCAD application window. (1.116)
- Right-click the **Quad** field to define the Quad settings in a context menu. (1.197 on page 284)

Basic procedure to edit entities using the Quad

1. Move the cursor over the entity. The entity highlights and the Quad displays the most recently used command with this entity type. 

If Rollover Tips (2.2.3) = ON, the properties of the entity under the cursor display in the Quad. (1.318 on page 329)

Figure 1.118

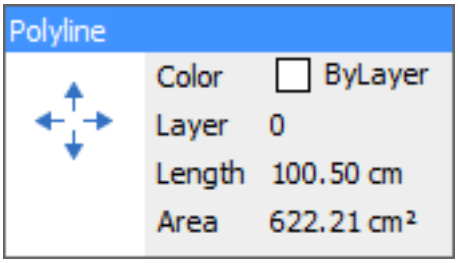

Figure 1.119

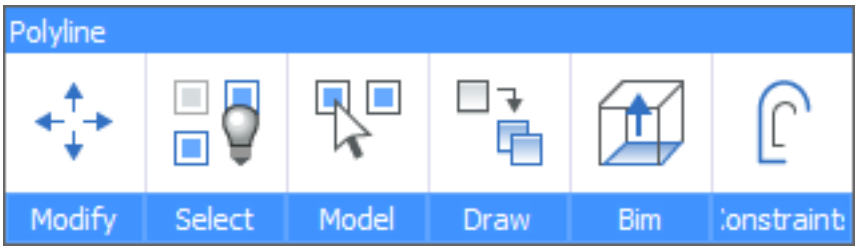

Figure 1.120

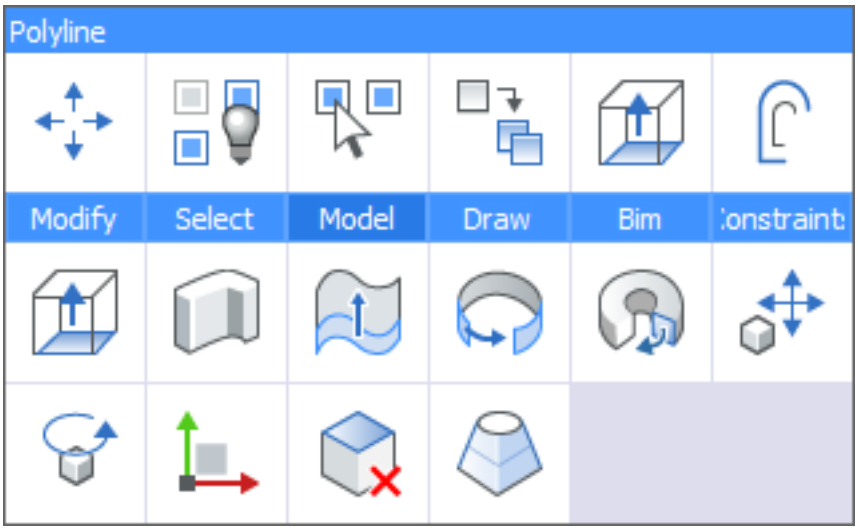

2. Move the cursor to the Quad to display the most recently used commands with this entity type. A number of command category tabs display at the bottom. (1.322 on page 331)
3. Move the cursor over the tabs to expand the command group under the cursor. (1.323 on page 332)
4. Click an icon to launch the command.

Using the No Selection Quad

Make sure the **Display the Quad on right click** option is set.

1. Do one of the following:
   - Move the cursor to a void area of the drawing window and right click.
   - When the cursor is on an entity, hold down the right mouse button longer. The **No Selection** Quad displays, showing the icons of the most recently used commands. (1.324 on page 334)
2. Do one of the following:
   - Click one of the most recently used commands.
   - Move the cursor over a command tab and select a command when it expands.
3. Execute the command.

The Quad cursor menu (1.15.5) The Ribbon (1.6.6) Toolbars (1.6.5) Menus (1.6.13) The Command Line (1.6.4) Executing Commands (1.10.6)

1.6.8 The Status Bar

The status bar sits at the bottom of the drawing area.

- It shows tool tips when you hover over a tool button on the status bar.
- It allows to enter command names and prompts command options when the command window is closed.
- It displays the current state of entity settings: layer, color, line style... and allows to edit these settings. **Note**: These are turned off in any workspace by default.
- It displays the current dim style and text style and allows to set them.
- It displays the current state of drawing aids such as entity snap and allows to toggle them on/off.
- ...

Click the small black down arrow at the right side of the status bar to manage the display of the fields.

Related Topics

Open/close the status bar (1.15.2) Working in the status bar (1.15.2)

1.6.9 Right-click Menus

Context menus or right-click menus display a list of commands next to the cursor when you right-click. When the Quad is active, hold the right mouse button a bit longer (= long right-click). The content of a context menu depends on the current entity or selection set. When the Quad is not active and nothing is selected, a right-click repeats the most recent command. Hold down the right mouse button a bit longer to display the context menu.

1.6.10 Panels

Panels are dockable dialogs. Available panels are: Animation Editor, Attachments, BIM BCF, BIM Compositions, BIM Profiles, BIM Project Browser, BOM Manager, Bricsys 24/7, Commandline, Content Browser, Details, Drawing Customizations, Layers, Library, Mechanical Browser, Parameters and Constraints, Properties, Render materials, Report, Ribbon, Sheet Sets, Structure, Tips, Tool Palettes

Related Topics

1.6.11 The Drawing Area

When you start a drawing session, your initial working area is called **model space**. Model space is an area in which you create two-dimensional and three-dimensional entities based on either the World Coordinate System (WCS) or on a user coordinate system (UCS). BricsCAD provides an additional work area called **paper space**. Each layout represents a sheet of paper. You can create up to 255 paper space layouts in a single drawing. Use the Model tab to view and work in model space. Click one of the Layout tabs at the bottom of the drawing area to switch to paper space.

Model Space

Model space consists of a single view that fills the screen. If needed, you can create additional views called viewports, which can show different views of your drawing or 3D model. You can manage drawing viewports with the VPORTS command. Viewports are displayed as tiles. You can work in only one of these viewports at once but all viewports are updated simultaneously. Click in a viewport to make it the current viewport.

Paper Space

Paper space represents the paper layout of your drawing. In this work area, you can create and arrange different views of your drawing similar to the way you arrange drawings on a sheet of paper. In paper space you can also add keynotes, annotations, borders, title blocks and other print-related entities which you don't want to view in model space. Each drawing has at least one **Layout** in which you can have one or more layout viewports. You can consider a layout viewport as a view window on your drawing in model space: (1.122 on the next page) You can place layout viewports anywhere in a paper space layout. Each layout viewport has its own scale and layer visibility. You can print all viewports in the same layout simultaneously. You can manage layout viewports with the MVIEW command. Paper space offers multiple advantages when printing your drawing:

- You can create multiple viewports to print multiple views. These views can each display a part of your drawing at the same or at different scales.
- You can create multiple layouts to print the same drawing with different print settings such as pen widths, printer configuration files, line weight settings, drawing scale...
- You can add print-related entities that are not essential to the model itself such as keynotes, annotations, title blocks...

Figure 1.122

1.6.12 The Clean Screen Mode

In clean screen mode, you can maximize the drawing area by dismissing user interface elements such as the menu bar, the ribbon, toolbars, panels, the command line, status bar and document tabs. You can still use the Quad to launch commands. Press and hold the Ctrl key and press the 0 (zero) key to toggle the clean screen mode on/off. Do not use the numeric keypad. On AZERTY-keyboards: do not press the Shift-key when hitting the 0 key.

Related Topics

CLEANSCREENON (6.9.17) command

1.6.13 Menus

The menu bar is hidden in all workspaces by default. The content of the menu is defined in the current workspace.

Controlling the display of the menu bar

1. Move the cursor over a toolbar or ribbon panel.
2. Right click and choose **Menu Bar** in the context menu.

1.7 Activating and Licensing

1.7.1 Overview of licensing options

License levels

There are 5 license levels for BricsCAD:

- BricsCAD Lite
- BricsCAD Pro
- BricsCAD BIM
- BricsCAD Mechanical
- BricsCAD Ultimate

BricsCAD Lite If you only create general 2D designs, BricsCAD Lite may be the right choice for you. Compared to AutoCAD LT, it also allows to view, move, copy or mirror 3D models. However, it is not possible to edit the model or create new 3D entities. BricsCAD Lite also runs Lisp routines. LISP allows BricsCAD users to load customized routines or small applications that will run inside BricsCAD.

BricsCAD Pro BricsCAD Pro includes direct 3D modeling with a full 3D constraint system, rendering with materials and lighting and access to third party applications.

BricsCAD BIM BricsCAD BIM license includes all BricsCAD Pro features. You can use your current CAD skills to smoothly move to creating real Building Information Models in record time. One product, one workflow, all in industry-standard DWG.

BricsCAD Mechanical On top of all BricsCAD Pro features, BricsCAD Mechanical includes a complete mechanical design toolkit, all in industry-standard DWG, including sheet metal functionality.

BricsCAD Ultimate BricsCAD Ultimate combines the BricsCAD BIM and BricsCAD Mechanical features.

License types

There are 2 license types for BricsCAD:

- Perpetual license.
- Rental license.

Perpetual license When you purchase a perpetual license, you own the software. BricsCAD editions run on Microsoft Windows, macOS and Linux. There are 2 maintenance options:

- The Maintenance option includes automatic upgrades and support.
- You can purchase upgrades at your discretion.

Rental license When you choose the rental option, you have access to the latest version of BricsCAD for a year. It includes Priority Support and access to all new versions that are released during the time your subscription is active.

Additional license options

Additional license options include academic, single-user, network and volume licensing.

Academic license Students, faculties, instructors, and educational institutions have free access to all BricsCAD software for 12 months. You can renew it yearly with a current student ID. Register as a student or school/teacher with your academic information.

Single user license The single user license agreement is for a single user. Each single user license allows two activations. You can install it on two machines, for example on a workstation in the office and on a laptop in the field. However, only one license can be in use at once. Single user licensing is available for perpetual or rental licensing. Academic licenses are always single-user.

Network license The network licensing agreement enables multiple users to access BricsCAD within a LAN (Local Area Network). The number of available network licenses defines the number of users who can concurrently use the software. The network license option is available for perpetual or rental licensing and includes a one-year maintenance contract. Network licensing is also available to institutions that use an academic license.

Volume license The volume licensing agreement allows you to use BricsCAD within a defined user base. You can install the software using a single license key valid for every user. The volume license option is available for perpetual or rental licensing and includes a one-year maintenance contract. It is default for institutional academic licenses.

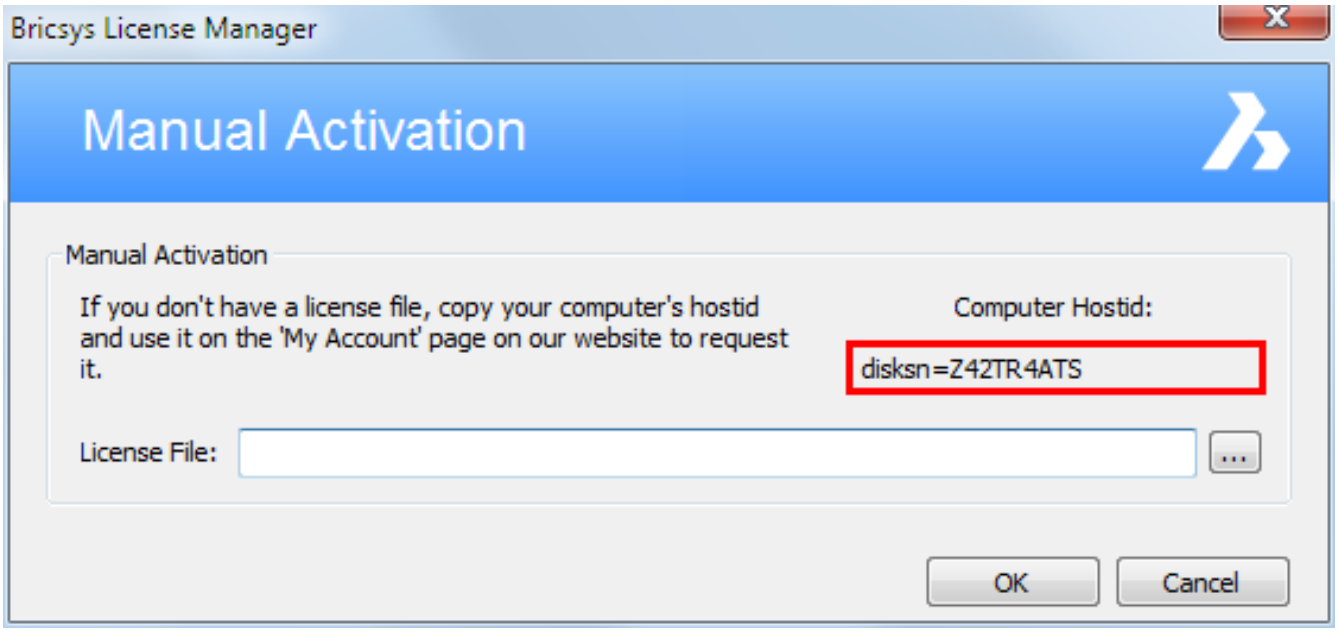
Figure 1.124



1.7.3 Activating a single or volume license manually (offline)

If your computer is not connected to the internet, you can activate the license manually via another computer that is connected to the internet. **Note**: You cannot deactivate manually activated licenses.

1. Launch BricsCAD.
2. Do one of the following:
   - If you start BricsCAD for the first time, go to next step.
   - If you start BricsCAD in trial mode, click **Enter License...** in the **Free Trial** dialog.
   - If you replace or upgrade an existing license, launch the LICENSEMANAGER (6.20.27) command, then click **Manage License** and click **Modify...** .
3. Click **Activate Manually...** in the **Activate BricsCAD** dialog box. The **Manual Activation** dialog box opens. (1.128 on page 159)
4. Copy the full content of the **Computer Hostid** field.
5. Log in to the Bricsys website with the computer connected to internet. Make sure you log in with the Bricsys account which contains your licenses.
6. Click the **My Account** icon ( ) and select **Manage Licenses** from the menu. (1.156 on page 238)
7. Hover over the license key you want to activate and click the pencil icon ( ). (1.126 on the next page)
8. The **License Details** display.
9. Click **Manual Activation**.
10. In the **Host ID** field, paste the host ID of the computer you want to install BricsCAD on.
11. Click the **Activate** button. A license file is generated and made available for download.
12. Click the **Download License File** button. The license file **BricsCADVxx.lic** is downloaded to your default download folder.
13. Copy the license file to the computer you want to install BricsCAD on.
14. In the **Manual Activation** dialog box, click the browse button ( ). Open the folder where you copied the **BricsCADVxx.lic** license file to and select the file. (1.127 on page 155)
15. Click the **OK** button. BricsCAD is launched.

1.7.4 Activating a network license automatically (online)

The BricsCAD license activation requires an internet connection.

1. Click the **License activation** shortcut in the operating system Start menu. The **Bricsys License Manager - Activate Network License** dialog box opens.
2. Enter the new network license in the **License Key** field and click **OK**.
3. Click the **License server administration** shortcut in the operating system **Start** menu to open the **Reprise License Server Administration**.
4. Click the **Reread/Restart Servers** option in the left menu.

1.7.5 Activating a network license manually (offline)

If your computer is not connected to the internet, you can activate the license manually via another computer that is connected to the internet. **Note**: You cannot deactivate manually activated licenses.

1. Click the **License Activation** shortcut in the operating system **Start** menu. The **Bricsys License Manager - Activate Network License** dialog box opens.
2. Copy the full content of the **Computer Hostid** field.
3. Log in to the Bricsys website with the computer connected to internet.
4. Click the **My Account** icon () and select **Manage Licenses** from the menu. Make sure you log in with the Bricsys account of your company which contains the Network license. Contact your Bricsys account manager if needed.
5. Hover over the license key you want to activate and click the pencil icon (). The **License Details** display.
6. Click **Manual Activation**.
7. In the **Host ID** field, paste the computer host ID of the computer you want to install BricsCAD on.
8. Click the **Activate** button. A license file is generated and made available for download.
9. Click the **Download License File** button. The license file **BricsCAD.lic** is downloaded to your default download folder.
10. Copy the license file to the server, in the Bricsys Network License Manager installation folder (by default: C:\Program Files (x86)\Bricsys\Bricsys Network License Manager).
11. Perform **reread/restart servers** from RLM web UI: localhost:5054, in order for the Reprise license manager to use the .lic file.

1.7.6 Activating a trial license automatically (online)

The BricsCAD trial license activation requires an Internet connection.

1. Launch BricsCAD.
2. Click **Start Trial** in the **BricsCAD Launcher** dialog box. The trial license is activated over the Internet.

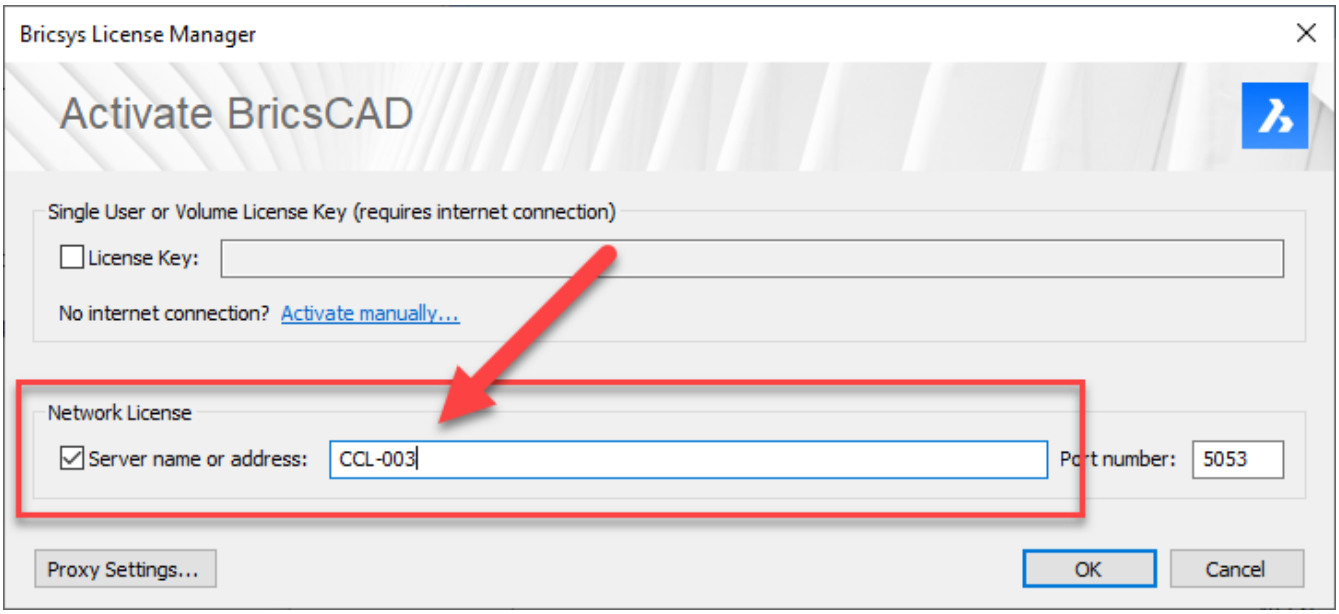
Figure 1.132



1.7.8 Using a network license on a client computer

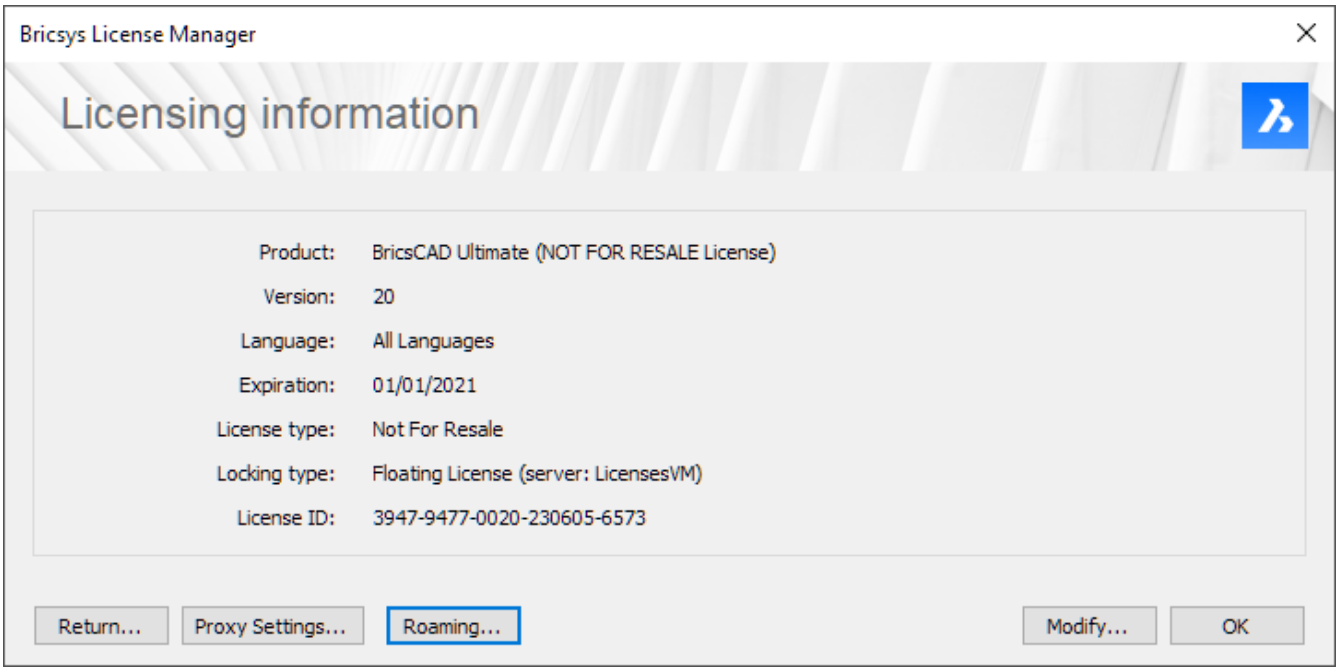
Once the Network license is activated on the license server, it can be used on client computers.

1. Do one of the following:
   - If you start BricsCAD for the first time, click the **Activate License** button in the BricsCAD Launcher (1.2.1) dialog box.
   - If you replace or upgrade an existing license, launch the LICENSEMANAGER (6.20.27) command, then click **Manage License** and click the **Modify...** button.
2. Check the **Network License** option in the **Activate BricsCAD** dialog box.
3. Type the host name or IP address of the license server in the **Server name or address** field. (1.132)
4. (optional) Type the port number in the **Port Number** field.
5. If your computer is connected to the license server through a proxy server, click the Proxy Settings (1.7.10) button to configure the proxy settings for a network license.
6. Click the **OK** button.

Related Topics

Roaming a network license on a client computer (1.7.9) Returning a roamed network license to the server (1.7.11)

Figure 1.133

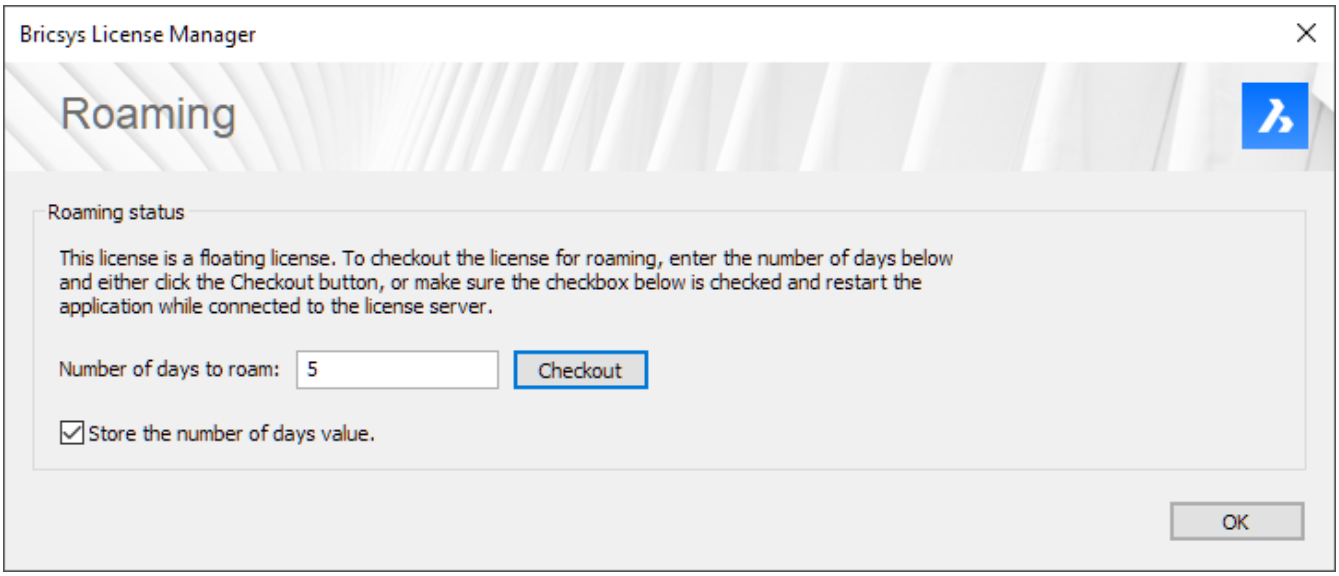


1.7.9 Roaming a network license on a client computer

A network license can be roamed in order to use BricsCAD without connection to the license server (work outside of the office, at home, ...). When a network license is used on a client computer, the **Roaming...** button is displayed in the Licensing Information (6.20.27) dialog box. (1.133)

1. If your computer is connected to the license server through a proxy server, click the Proxy Settings (1.7.10) button to configure the proxy settings for a network license.
2. Click the **Roaming...** button. The **Roaming** dialog box opens. (1.134 on the next page)
3. Enter the number of days you want to check out the license for roaming and click the **Checkout** button.
4. (Optional) Select the check box if you want to automatically refresh the roaming period whenever your computer is connected to the server.
5. Restart BricsCAD to apply the changes.

Figure 1.134



Related Topics

Using a network license on a client computer (1.7.8) Returning a roamed network license to the server (1.7.11)

1.7.10 Proxy settings

Some computers are connected to a network or to the internet via a proxy server. Therefore, the proxy settings should be configured before activating or deactivating a license.

Configuring the proxy settings

1. Click the **Proxy Settings...** button in the **Activate BricsCAD** or the **Licensing Information** dialog box. (1.135 on the following page) (1.136 on the next page) The **Proxy** dialog opens.
2. Complete the necessary fields in the **Proxy** dialog box. (1.137 on the following page)
3. Click the **OK** button to continue.

NOTE	The proxy settings configuration remains active for the current **BricsCAD®** session only. If you need to reactivate or deactivate a license in future session, you will have to reconfigure the proxy settings.

Figure 1.135

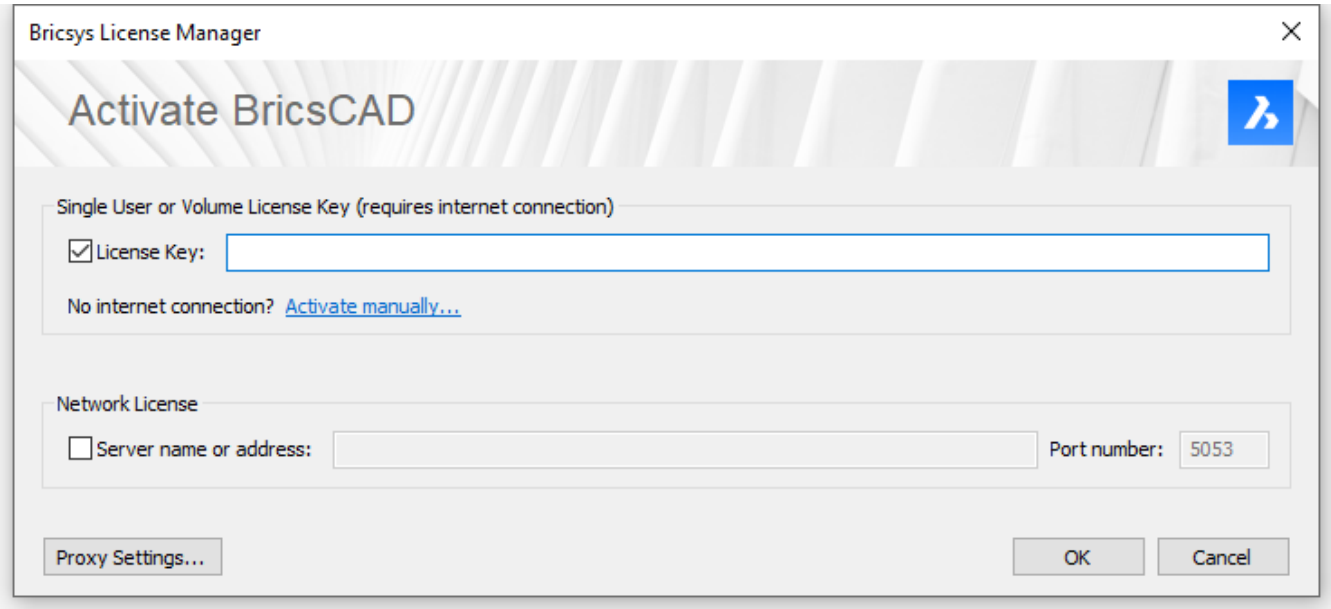


Figure 1.136

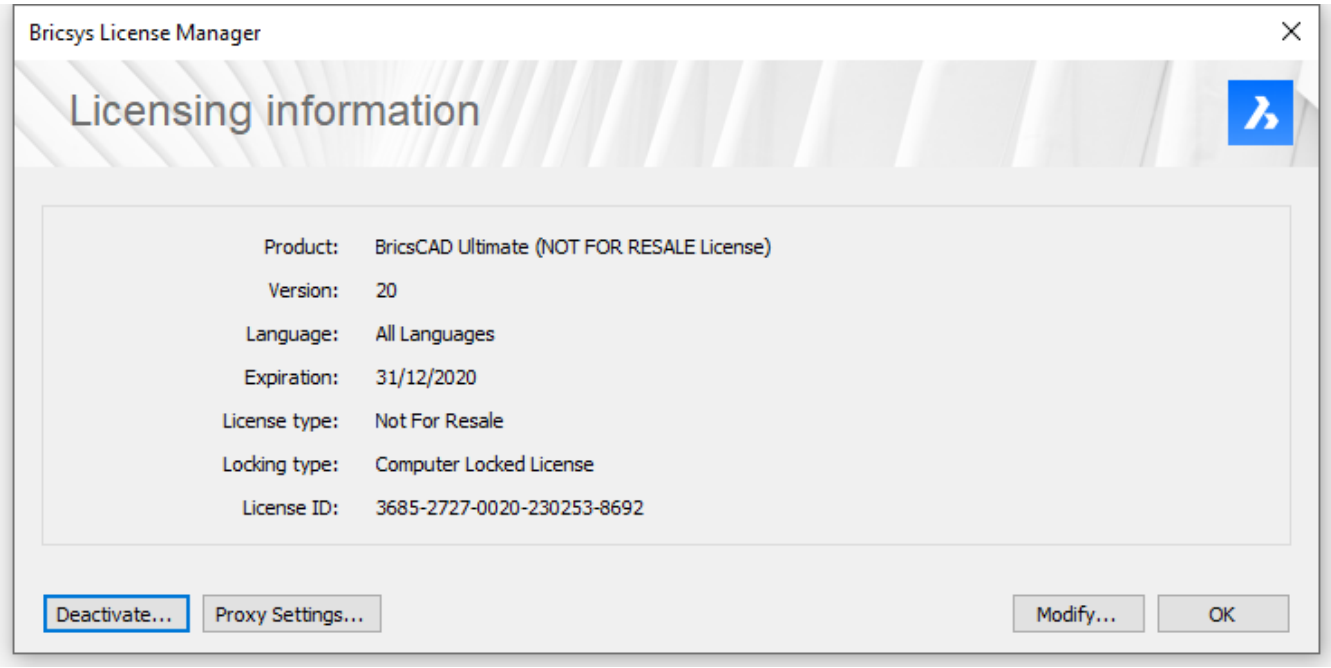

Figure 1.137

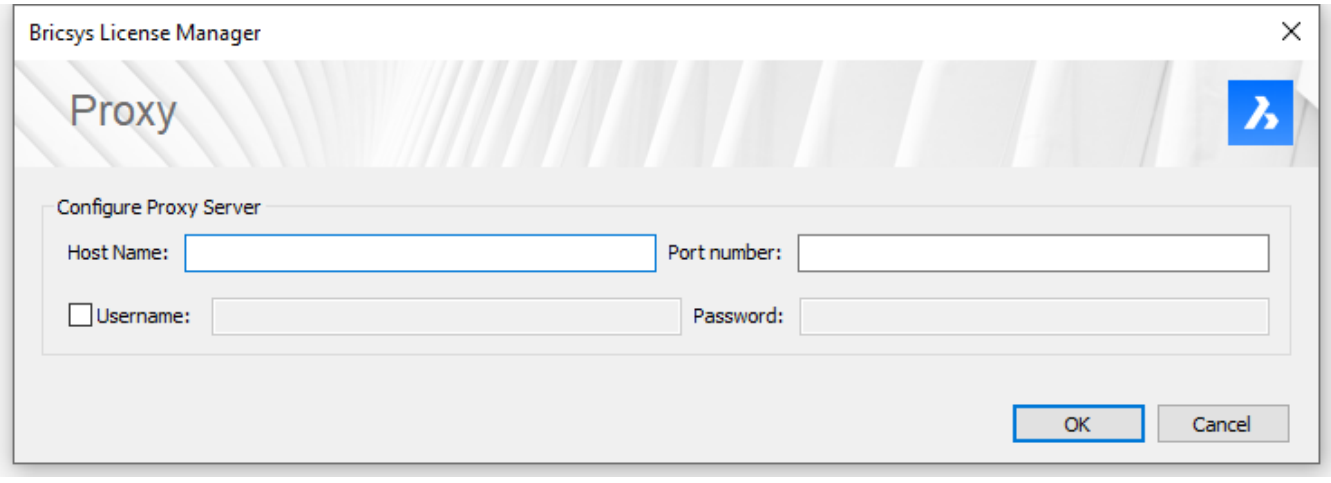
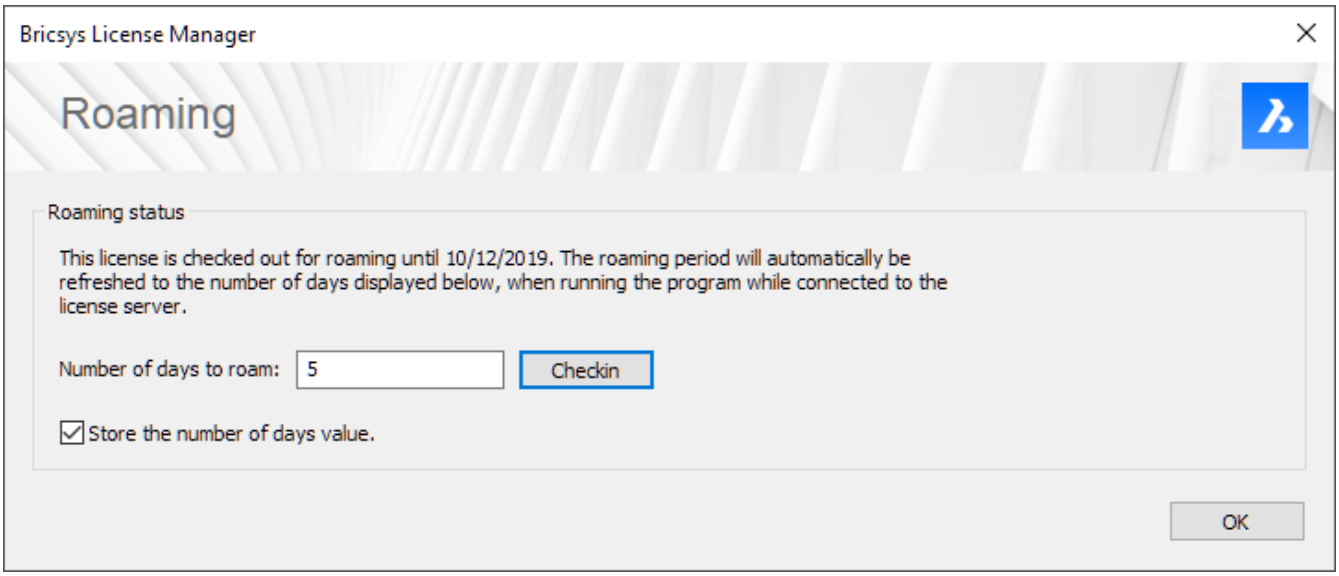


Configuring the proxy settings permanently for network license use

If you use a network license, BricsCAD needs to connect to the license server each time a session is opened. Therefore, the proxy settings should be configured permanently. Proceed as follows on the computer where BricsCAD is running:

1. Create the **HTTP_PROXY** system variable: HTTP_PROXY=[LicenseServer]:[PortNumber]
2. (Optional) If the proxy server supports basic authentication, create the **HTTP_PROXY_CREDENTIALS** variable: HTTP_PROXY_CREDENTIALS=[UserName]:[Password]

Figure 1.138



1.7.11 Returning a roamed network license to the server

If you are connected to the license server, you can return a roamed license to the server.

1. Click the **Roaming...** button in the Licensing Information (6.20.27) dialog box. The **Roaming** dialog box opens. (1.138)
2. Click the **Checkin** button.
3. Restart BricsCAD to apply the changes.

Related Topics

Using a network license on a client computer (1.7.8) Roaming a network license on a client computer (1.7.9)

1.8 Installation and Licensing

1.8.1 Minimum system requirements and recommendations

For Intel and AMD-based Microsoft Windows & Linux PCs, and Intel-based Apple Macs:

Supported Operating Systems	• Windows 10 (x64) • Windows 8.1 (x64) • Ubuntu V18.04 or higher • openSUSE builds, later than April 2018 • Fedora builds, later than April 2018 • Mac OSX 10.13 or higher	**Note**: Windows 8.1 will reach the end of Microsoft's Extended Support program on 10 January 2023. **Note**: Mac OSX is supported only on Intel-based hardware at this time.
Deprecated Operating Systems	• Windows Server 2008 R2 • Windows Server 2008 (with SP2 or higher) • Windows 7 (x64)	**Note**: we do not recommend running mission-critical CAD software on unsupported operating systems, as your PC may become more vulnerable to security risks. • On 14 January 2020, Microsoft ended support for Windows Server 2008 and 2008 R2. • On 14 January 2020, Microsoft ended the Windows 7 Extended Support initiative.

Minimum CPU: • Intel® Core™ i5 • AMD Ryzen™ 5 • 2.5 GHz or higher	**Recommended CPU:** • Intel® Core™ i7 • Intel® Core™ i9 • AMD Ryzen™ 7 • AMD Ryzen™ 9 • 3.0 GHz or higher	The CPU with the highest single-thread performance rating will always excel with BricsCAD. Additional CPU cores can be a bonus, because BricsCAD supports the concept of 'helper threads' for many data- and calculation-intensive tasks. **Note about Intel® Xeon® and AMD Ryzen™ Threadripper™ CPUs**: these top-tier workstation CPUs support large on-chip memory cache, more PCIe® I/O lanes and multi-channel, high speed memory architectures. Will they help BricsCAD run faster? Maybe. You will need to do testing in your specific environment, to determine if the additional cost of these systems is justifiable.

Minimum System Memory: 8 GB	**Recommended System Memory:** • 16 GB • 32 GB	For maximum performance, determine the memory configuration of your PC and ensure that each **memory channel** on the motherboard is populated with at least one memory module (SIMMs/DIMMs). **Note**: the number of available memory channels may not correlate 1:1 with the number of RAM sockets on your PC's motherboard. Questions? Please check with your hardware supplier before you buy system memory.
Minimum Disk Space: 2 GB for BricsCAD Ultimate, installed	**Recommended Disk Space:** (As needed)	We recommend Solid-State Drives (SSDs) as system drives, for both BricsCAD and Windows. Drawings and support files can reside on slower mechanical hard disk drives, if necessary. **Note**: solid-state disks can be up to 10x faster reading and 20x faster writing data than a mid-range hard disk drive (e.g. Seagate Barracuda 5.4k RPM, SATA 6.0).
Minimum Display System: • 1920 x 1080 True Color display and a graphics card with 1 GB VRAM • Apple Mac Displays	**Recommended Display System:** • Multiple 3840 x 2160 (4k) True Color displays, with a PCIe® graphics card w/GPUs and 4 GB VRAM • Apple Mac Retina (4K & 5K) Displays	On Microsoft Windows systems, most graphics cards & GPUs from NVIDIA, AMD and Intel® are supported. On Linux systems, most graphics cards & GPUs from NVIDIA and AMD are supported. On Mac systems, native Apple display hardware is supported. BricsCAD's non-wireframe display modes are generated by RedSDK technology from Redway3D®. For maximum RedSDK performance in these modes, a GPU is required. **Note:** We suggest that you install the latest drivers available for your display hardware, as recommended by the manufacturer. **Note to Linux users:** Hardware acceleration of 3D graphics on Linux systems is NOT supported on: • Intel® graphics chipsets / cards • Laptops with dual graphics adaptors. However, recent driver developments by NVIDIA show promise in this area. For more information about supported graphics hardware for BricsCAD, see the Redway3D GPU chipset reference page.

1.8.2 Downloading BricsCAD

Downloading the most recent release

1. If you have not already done so, go to the Bricsys website, **register** and **log in**.
2. Click Download.
3. Select the platform, language and version (32 bit or 64 bit).
4. Select the **I agree with the terms of use** check box.
5. Click the **Download** button.

Downloading an old release

1. If you have not already done so, go to the Bricsys website, **register** and **log in**.
2. Click Download.
3. Click the **Show old releases** link.
4. Select the platform and language.
5. Select the **BricsCAD** release.
6. Select the version (32 bit or 64 bit).
7. Select the **I agree with the terms of use** check box.
8. Click the **Download** button.

1.8.3 Trial Mode

BricsCAD can run in trial mode for 30 days. After this period, you need to activate a valid commercial license.

Running BricsCAD in trial mode

Each time you start BricsCAD in trial mode, the **BricsCAD - Free Trial** dialog opens, indicating the days left. Do one of the following:

- Click the **Continue** button to open BricsCAD in trial mode.
- Click the **Enter License...** button to activate a Single or Volume license (1.7.2) or to use a Network license (1.7.4).

Related Topics

Setting the trial mode license level (1.2.3) Activating a trial license automatically (online) (1.7.6) Activating a trial license manually (offline) (1.7.7)

1.8.4 Safe Mode

Since V20, you can launch the program in Safe Mode (7.6.3), using /safemode statup switch. This option sets the **SAFEMODE** system variable. Running BricsCAD in safe mode temporarily prevents all third party plug-in code, enablers and user lisp files from loading in the current session. Starting in a clean environment can prevent potential crash causes.

Setting the safemode startup switch

1. Do one of the following:
   - – Right click the BricsCAD shortcut.
   - – Copy the BricsCAD shortcut or create a new one, then right click the shortcut.
2. Choose **Properties** in the context menu. The **Switch <shortcut name> Properties** dialog box displays.
3. In the **Target** field add: /safemode. ("C:\Program Files\Bricsys\BricsCAD V21 en_US\bricscad.exe" /safemode)
4. Click the **OK** button.

1.8.5 Communicator for BricsCAD

If you are a designer for the manufacturing industry and you need to exchange data with other manufacturing applications, you should consider adding Communicator for BricsCAD to your BricsCAD Pro, BricsCAD BIM, BricsCAD Mechanical or BricsCAD Ultimate license. When running one of these versions, Communicator for BricsCAD imports full assemblies with embedded PMI (Product and Manufacturing Information). Communicator for BricsCAD is installed and licensed separately.

1.9.1 How to navigate quickly around your drawing

https://www.youtube-nocookie.com/embed/WhlZLmfCvXw
This video shows you how to use Views with 2D drawings, how to plot with named views, and the extra functions available for 3D models, such as setting individual visual styles, perspective mode, and backgrounds.

Views let you switch instantly between zoomed in areas of the drawing and back to the full drawing.

Back to Tutorial Overview

1.9.2 Maximizing the Drawing Area with Clean Screen

https://www.youtube-nocookie.com/embed/Xmn5F140KSw BricsCAD has a lot of user interface elements for you to access information and carry out commands -- menu bar, ribbon, toolbars, panels, command bar, status bar, scroll bars, and more. Fortunately, it provides a way to dismiss them all to maximize the drawing area. In this tutorial, you learn to press Ctrl+0 (or Cmd+0 of MacOS devices) to maximize the drawing area and then return to the normal interface. You also learn where in the Settings dialog box you control which user interface elements are hidden -- and which are shown -- in clean screen mode.

1.9.3 On-screen Tips Widget in BricsCAD

https://www.youtube-nocookie.com/embed/vGn81ExUU2o

The on-screen Tips widget

Many CAD systems – including BricsCAD – use the Ctrl key to change how a drawing or editing command operates. But how do you know when more options are available? BricsCAD provides a on-screen Tips widget that shows your options. For example, pressing Ctrl while selecting a solid changes the entities selected from the entire solid to specific faces or specific edges.

Where is the Tips widget? The Tips widget pops up during multiple actions in BricsCAD. It is available when dragging major/minor faces using DRAG (6.10.38), for POLYSOLID options or for DMEXTRUDE (6.12.14) options. In the video, Ralph Grabowski shows you how Tips can aid you during window selection. You can view all the possible actions that display Tips inside the Tips Configuration dialog box. To see this dialog, simply right-click on "TIPS" on the extreme right-hand side of the Status bar, and click "Configure". As your skill with BricsCAD increases, you may find that you don't need to see a specific Tip. Click the 'x' while the Tip is active and you'll dismiss that specific Tip for good. Of course, you can always activate it again in the dialog box. (1.139 on the following page) BricsCAD V17 introduced new Tips for polylines, multi-leaders and associative arrays. In the video, Ralph shows how the Ctrl key works when you are selecting any of these entities. While hovering over one of these entities, the Ctrl key gives you the option select the entire entity, or sub-entities within the larger entity. This functionality is consistent with the way that Windows works, and it gives you a simple way to get your work done more easily and… faster. Need more information about how Tips work in BricsCAD? You can find more about the Tips widget **at the bottom of the** User Interface page (1.15.2) in the BricsCAD On-line Help. As long as you're on the User Interface page, explore some of the other key features of BricsCAD – there's a lot there that you may not know about! Back to Tutorial Overview

1.9.4 Tips and Tricks for Drawing Explorer

https://www.youtube-nocookie.com/embed/iyTZJJmoViE

Here are a half-dozen tips for making better use of Drawing Explorer in BricsCAD.

Tip #1. Directly access sections through command names, like Layer Tip #2. Use the blue dot specific the current style or property. Tip #3. Click the Regen button to see the effects of changes. Tip #4. Layers node shows previews of each layer. Tip #5 Drag elements between drawings Tip #6. Right-click the names of blocks, layers, layer states, xrefs, and attachments to see bonus options

Bonus Trick: How to place blocks that are aligned with angled walls.

Back to Tutorial Overview

1.9.5 Experience the Quad Cursor in BricsCAD

https://www.youtube-nocookie.com/embed/j0dQ63Bd6Ng

The best UI enhancement ever – the BricsCAD Quad cursor!

Imagine an entire command system located directly on your mouse cursor. No need to dream it – we're talking about the BricsCAD Quad cursor! There's no easier way to select commands in any CAD system. Move your cursor across the screen, and the Quad detects the entity underneath the cursor. Based on this, the Quad presents commands that work on the entities you select, saving you time and effort. You can execute an entire range of commands with a single click from the **Quad-based command palette**. Ralph Grabowski's short video tutorial shows you how to use the Quad to place hatch patterns with a single click, and how to edit that hatch pattern with a double-click. He also shows you how to place dimensions and dimensional constraints on entities with a single click of a Quad icon. Finally, the single-click command concept applies to offset entities; and just about any other command that you can imagine. With the Quad, you can execute complex commands that normally require several clicks, options, and dialog boxes – simply and easily.

A lot more to the Quad cursor…

There's a lot more to the Quad cursor in BricsCAD, but the first step is just to turn it on – in BricsCAD, go down to the status bar in the lower-right corner of your screen and click "QUAD". Then go up and hover over some on-screen entities and, Bingo! If you right-click the "QUAD" box on the status bar, you'll get direct access to the Quad's Settings and Properties. You can find out more about the Quad cursor here in the BricsCAD on-line documentation (1.15.5). Once you have basic operations under control, you might want to customize your Quad cursor. Just move your cursor over any toolbar, right-click and select "Customize". Back to Tutorial Overview

1.9.6 Those Five Other Selection Modes in BricsCAD

https://www.youtube-nocookie.com/embed/0RgInrXDIVU Back to Tutorial Overview

1.9.7 Use Layer States instead of Clicking Bulbs

https://www.youtube-nocookie.com/embed/GV-z6vdLPZs

Layer States allow to switch quickly between your layers

If you are tired of clicking a lot of bulbs to switch between your drawing layers, then you will love this feature.

1.9.8 BricsCAD Spreadsheet Import Techniques

https://www.youtube-nocookie.com/embed/mfP54UP_2Bo

You have a spreadsheet. Here's how to bring it into BricsCAD!

This four-minute video is narrated by industry expert Ralph Grabowski of WorldCADAccess.com. Got spreadsheets that you want to bring into BricsCAD? This short tutorial gives you two options for importing them directly. The first method is to use the Table command's new File option. You can use this feature to import **any** spreadsheet file. The video shows how to save your existing spreadsheet as a CSV (comma-separated values) file. Then, you can import the CSV into your drawing by leveraging the TABLE command. This method is good for static data that you don't plan to change on a regular basis. If you use Microsoft Excel, the second method gives you a powerful benefit: any formulae in the spreadsheet are retained as FIELD text. To do this, you'll use your computer's copy and paste functionality. First, in the spreadsheet application, you simply copy the cells you need to the system Clipboard. Next, use the PasteSpec (Paste Special) command to insert the spreadsheet into BricsCAD as a linked object. The key benefit of the second method? You can edit the spreadsheet's contents and have those edits updated automatically in your drawing. You can test it out for yourself using this sample spreadsheet file, available via our **Bricsys 24/7** cloud collaboration service. Back to Tutorial Overview

1.10 Working in BricsCAD

1.10.1 Template Drawings

A template drawing is a drawing file with file extension DWT. It is used to create a new drawing that is a copy of the template drawing. Any drawing with extension DWT is considered a template drawing. The BricsCAD template drawings sit in the template folder(s). Use the TEMPLATEFOLDER (6.29.11) command to open the folder. If you save your customized template drawings in the template folder, they are available in the Start tab (1.6.1) to create new drawings. Using properly prepared templates is essential for a productive use of BricsCAD. A template drawing does not contain entities in model space, but contains settings according to the specific drawing and project requirements:

- Units: imperial or metric and units display.
- Layers.
- Dimension and leader styles.
- Text styles.
- Table styles.
- Multiple layouts, each with title block, paper size, printer and plot style.
- Standard blocks for notes, tables, symbols and other entities.

Related Topics

Creating a new drawing (1.19.1) The UNITS command (6.30.8) The Drawing Explorer (1.19.2)

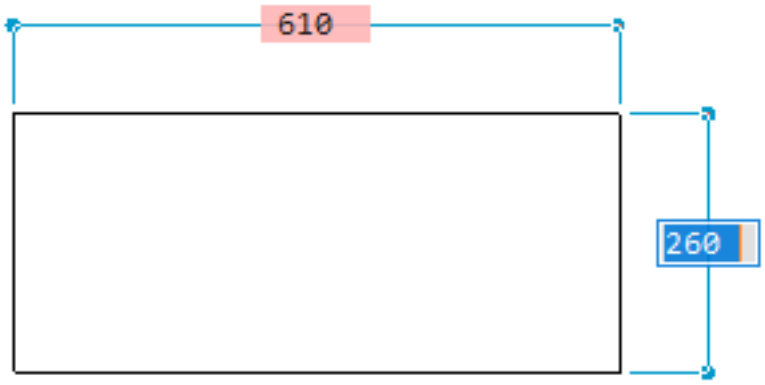
1.10.2 Entity creation settings

New entities are created on the current layer (1.25.3), using the current entity creation settings:

- Color (1.25.5)
- Linetype (1.25.6)
- Linetype Scale (1.25.6)
- Lineweight (1.25.7)
- Transparency (1.25.9)

You can define entity creation settings in the General section of the Properties panel (1.15.4). You can define all entity creation settings **ByLayer**. This means that the corresponding setting of the current layer is used. You can define layer properties in the Layer (6.13.17) section in the Drawing Explorer (1.19.2) dialog box.

Figure 1.140



1.10.3 How to draw accurately

New entities are created in the XY-plane of the current coordinate system. By default, this is the World Coordinate System (WCS). All dimensions in a DWG file are expressed in drawing units (DU). The INSUNITS (6.30.8) (Insertion Units) system variable sets the value of 1 DU. For new drawings, INSUNITS is defined in the template drawing that you selected to create the drawing. BricsCAD provides a series of Template Drawings (1.10.1) for decimal and imperial units. To draw accurately, BricsCAD provides several drawing aids:

- Entity Snaps (1.21.15) allow you to use keypoints on existing 2D entities such as endpoint, midpoint or center and the intersection. Entity snaps also allow you to draw perpendicularly, parallel or tangentially to an entity.
- 3D Entity Snaps (1.21.16) allow you to use keypoints on 3D entities such as solids.
- Dynamic dimensions (1.21.9): When dynamic dimensions are switched ON, you can enter distances and angles in dynamic dimension fields . When multiple dynamic dimension fields display, for example when drawing a rectangle, press the Tab key to switch to the next field. When you enter a value and press the Tab key, the field turns red, which indicates that the value is fixed. (1.140)
- Polar Tracking (1.21.18) forces the drawing direction to specified angles with respect to the axes (X, Y, Z) of the current coordinate system.
- Entity Snap Tracking (1.21.17) combines entity snaps and polar tracking.
- Coordinate Input (1.21.11): allows you to enter xyz coordinates to specify points.
- Snap and Grid (1.21.12): A grid is a set of evenly spaced lines or dots that serve as a visual distance reference. The cursor snaps to the grid points, which allows you to draw fast at fixed intervals.
- Drawing Limits (1.21.12) allows you to limit the drawing area, which prevents entity creation outside the drawing limits.
- Ortho Mode (1.21.2) forces the cursor to move parallel to either the X- or Y-axis of the current coordinate system.
- User Coordinate Systems (1.21.21): you can define named user coordinate systems (UCS) located anywhere in three-dimensional space. You can restore a named UCS at any time.
- Direct Distance Entry (1.21.4) allows you to enter lengths, radii, diameters and movement vectors.
- Nearest Distance (1.21.10) allows you to dynamically view and modify the distance between two selected entities or sub entities.
- Manipulator (1.10.7) is a versatile grip tool to swiftly move, rotate, scale and mirror selected entities.

1.10.4 View control

In BricsCAD, you can control the display of your drawing in the following ways:

- View control using the mouse and keyboard (1.23.6)
- Using View commands (1.23.1)
- Using the Look From widget (6.20.41)

The most frequently used view manipulations are:

Action	Mouse	Command	Look From
View Extents	Double click the scroll wheel	Zoom > Extents	Clicking a trigger zone rotates the view and zooms to the extents of the drawing.
Zoom	Scroll wheel	Zoom > In Zoom > Out	
Pan	Hold down the scroll wheel*	Pan	
Restore Plan View (Top View)		Plan > Current UCS	Click the center trigger zone

* When MBUTTONPAN = ON

1.10.5 Selecting Entities

Manipulation commands such as MOVE (6.21.29), COPY (6.9.35) and MIRROR (6.21.17) prompt you to select one or more entities. If the **PICKFIRST** variable is ON, you can also compose the selection set before launching the command. BricsCAD provides several selection methods. You can combine selection methods to compose a selection set.

Selecting entities one by one

1. Move the cursor over the entity. The entity highlights. The Quad (1.6.7) appears and displays the most recently used command and a selection of the entity properties.
2. Do one of the following:
   - Click to select the entity.
   - Repeatedly press the Tab key to highlight obscured entities and click when the desired entity highlights.
3. Repeat the previous steps to select more entities or launch a command (1.10.6).

Selecting multiple entities

BricsCAD uses window selection methods to select multiple entities:

1. Click to define the corner of the selection rectangle.
2. Do one of the following:
   - Move the cursor to the right. A blue rectangle displays. The **circle inside the rectangle** icon indicates all entities that lie completely within the selection rectangle will be selected.
   - Move the cursor to the left. A green rectangle displays. The **circle overlapping the rectangle** icon indicates that all entities which either lie within or overlap the selection rectangle will be selected.
3. Click to define the opposite corner of the selection rectangle.

Removing entities from a selection set

Hold down the shift key when executing a selection method, to remove entities from the current selection set. Press the Esc key to clear the current selection set.

Related Topics

Working with the Structure Panel (1.10.8) Selection Methods (1.32.7) Quick Select (1.32.6) The Structure Panel (1.32.15)

1.10.6 Executing Commands

In BricsCAD you can launch commands in the following ways:

- Type the command in the Command Line (1.6.4).
- Choose the command in a Menu (1.6.13).
- Click the command tool button in a toolbar (1.6.5).
- Click the command icon in the Ribbon (1.6.6).
- Choose the command in the Quad (1.6.7).

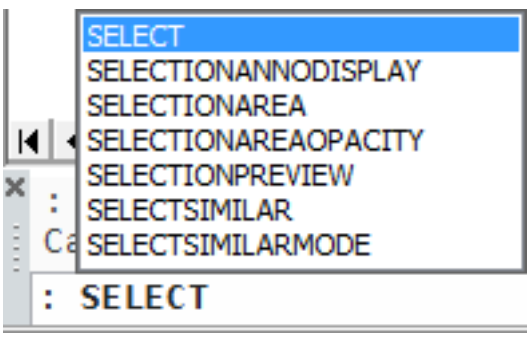
Typing a command in the Command Line

If you know the command name, you can enter it in the command line. When the command line is closed, keyboard entry and command prompts display in the Status bar (1.15.2). If the **Enable** flag of the **AUTOCOMPLETEMODE** system variable is set, command names are automatically completed when you type. All commands and/or system variables and/or user preferences that contain the current character string display in the **suggestion** list. (1.179 on page 275) Do one of the following:

- Press Enter if the currently highlighted command displays.
- Click a command in the suggestion list.

You can launch some commands with a command alias (1.17.9). For example, you can launch the LINE (6.20.31) command by entering **L** at the command prompt.

Figure 1.141



Choosing the command options

Many BricsCAD commands provide several options. These options appear in the command line or status bar (when the command line is closed) and optional also in a prompt menu (1.15.6). Do one of the following:

- Press Enter or right click to choose the default option. The default option sits at the end of the command prompt between arrow brackets (<>).
- Click the option in the command line.
- Click the option in the prompt menu (1.15.6).
- Type the capitalized letter of the option, the press Enter or right-click.

Selecting Entities (1.10.5) Using the Manipulator (1.10.7) Working with the Structure Panel (1.10.8)

Figure 1.142

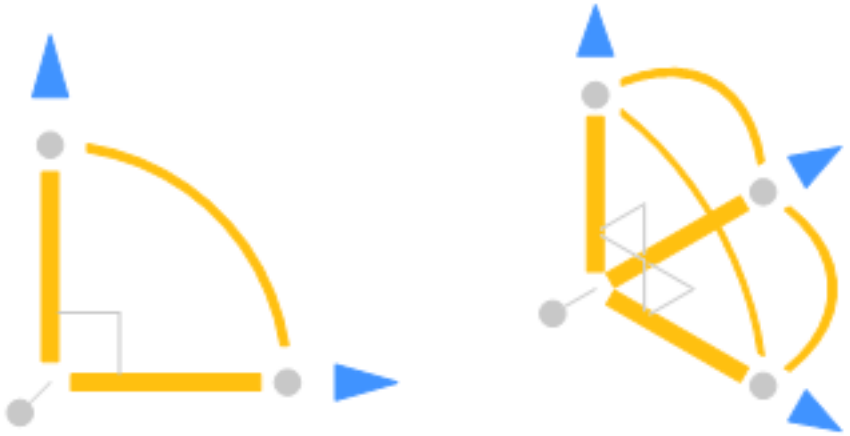

Figure 1.143

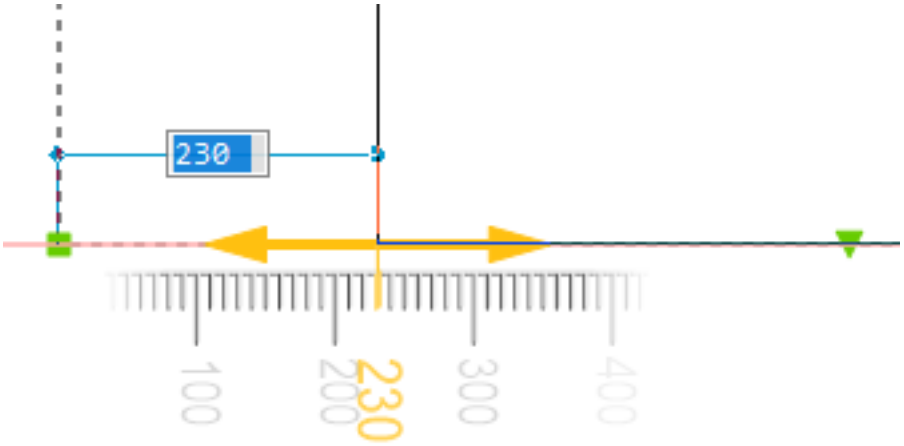

1.10.7 Using the Manipulator

The Manipulator is a versatile grip tool to swiftly move, rotate, scale and mirror selected entities. If you hold down the Ctrl key during these actions, the selected entities are copied. (1.142) By default, the Manipulator displays when selecting an entity by a long click (keeping the left mouse button down a bit longer). The anchor point of the Manipulator sits at the closest grip point, with respect to the selection point. See The location and orientation of the manipulator (1.32.10). Place the cursor over one of the trigger zones, to start an action:

- Axes, to move along the axis: (1.143)
- Arcs, to rotate: (1.144 on the next page)
- Plane swatches (= squares at the anchor point), to move freely in the selected plane (XY, XZ or YZ): (1.145 on the following page)
- Arrow heads, to mirror: (1.146 on the next page)

Note: the step size of the ruler depends on the zoom factor. Zoom in to decrease the step size, zoom out to increase.

The Manipulator (1.32.10) How to draw accurately (1.10.3)

1.10.8 Working with the Structure Panel

The Structure panel (1.32.15) displays a structured tree view of the drawing content. BricsCAD provides three configure structure tree (CST) definitions:

- **Default** displays a layer based structure.
- **BIM** displays a BIM entity based structure.
- **Mechanical** displays an entity based structure.

Click the hamburger menu () to select a definition. In the Structure panel you can:

- Click the expand (+) icon to expand a node.
- Click the collapse icon (-) to collapse a node.
- Select a node, right-click and choose **Expand All** to expand all sub nodes of the selected node. Select the drawing name and use this option to expand all nodes in the entire tree.
- Select a node, right-click and choose **Collapse All** to collapse all sub nodes of the selected node. Select the drawing name and use this option to collapse the entire tree.
- Click a node or entity in the Structure panel to select it in the drawing. **Note:** This depends on the settings in the **Structure Tree**. To configure the Structure tree, right-click in **Structure Panel** > **Configure > Options**. Hold down the Ctrl key to compose a selection set (1.10.5).
- Right-click to display a context menu, which allows to:
  - **Show**: displays the selection when previously hidden.
  - **Hide**: hides the selection.
  - **Isolate**: isolates the selection, hides all the rest.
  - **Zoom**: zooms onto the selection.

Note: Select the drawing name. Next, right-click and choose **Show** in the context menu to display the entire drawing, or choose **Show Entities** in the **General** tab of the No Selection Quad (1.6.7).

1.11 Setting up a Network License Server

1.11.1 Network license server

To make a network license available in BricsCAD on a client computer, the network administrator needs to install a network license server from Reprise Software first. Bricsys Network License Manager is a separate program which installs the server. After starting the network license server, you can configure it through a web interface. Just like BricsCAD needs a license file to run, the network license server needs a network license file that you can activate online or manually. You can activate a network license only once and it is locked to the server. Once the network license is activated and the server is started, you can use the network license in BricsCAD on a client computer. **Note**: Reprise Software doesn't offer a network license server for Mac computers. However, you can install a Windows or Linux network license server to serve licenses on Mac client computers.

Related Topics

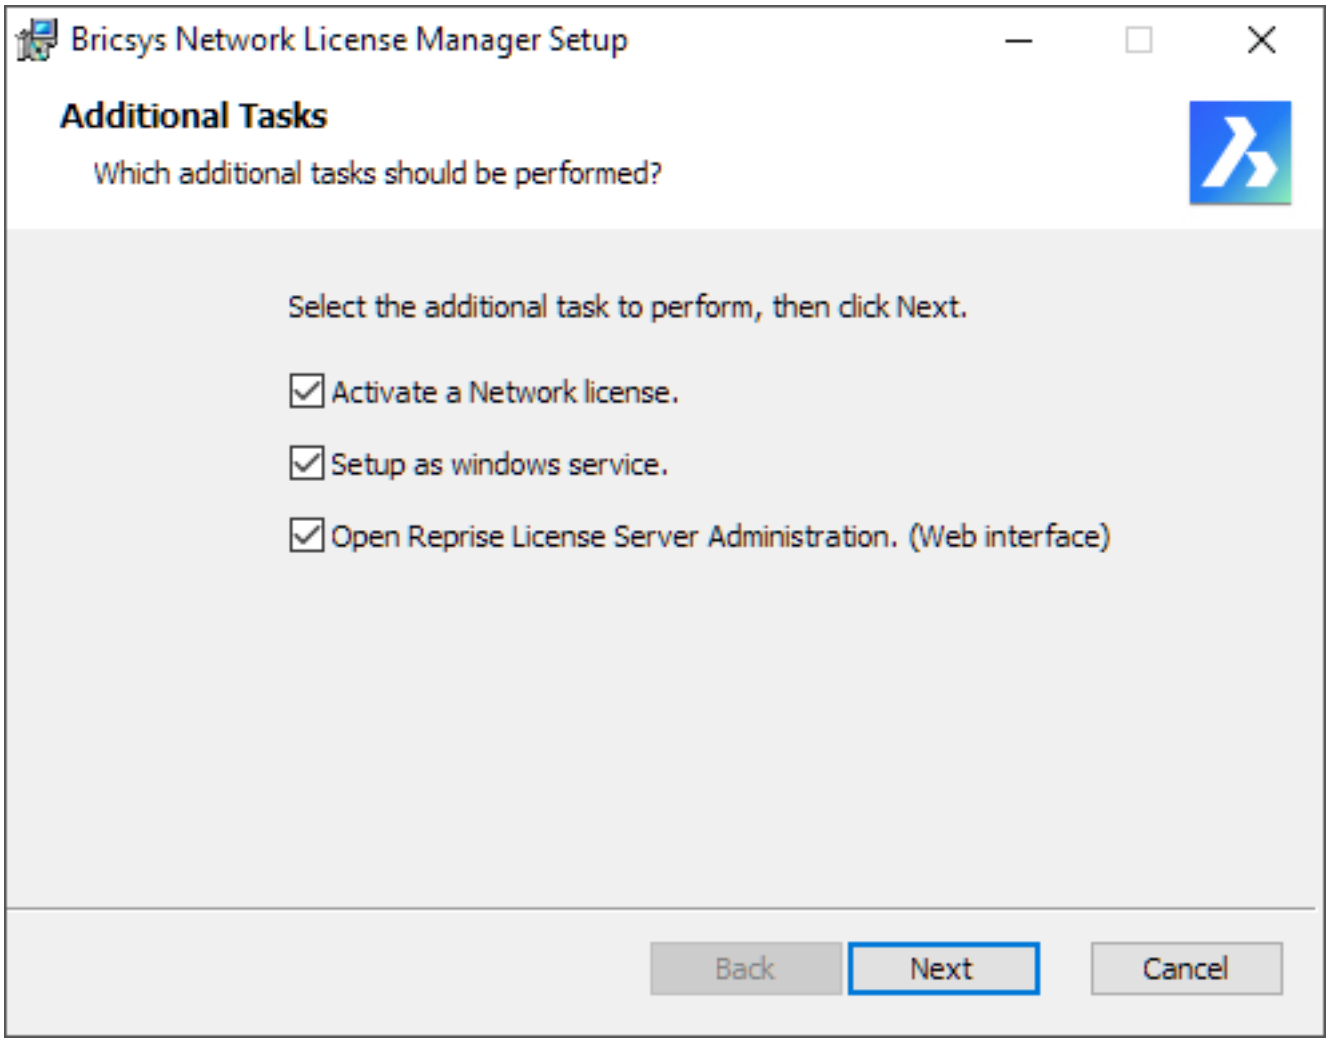
Setting up a Windows network license server (1.11.2) Setting up a Linux network license server (1.11.3) Network license server administration (1.11.5) Using a network license on a client computer (1.7.8) Roaming a network license on a client computer (1.7.9) Returning a roamed network license to the server (1.7.11)

1.11.2 Setting up a Windows network license server

Installing the Bricsys Network License Manager

1. Download Bricsys Network License Manager (Windows)
2. Double-click the installation MSI file to start the installation.
3. Accept the terms of the **End User License Agreement**.
4. Accept the **Destination** folder or click **Change...** to change the destination folder.
5. Click the **Install** button.
6. Select the check boxes next to the **Additional Tasks** that should be performed after the installation. (1.147 on the facing page)
   - **Activate a Network license** After the installation, the **Bricsys Network License Manager** opens and asks you to activate a network license. You can open the Bricsys Network License Manager later by clicking the License activation shortcut in the Start menu.
   - **Setup as Windows service** Each time you start Windows, the license server is automatically started as a service. You can do this later with the following command in the elevated command prompt: rlm.exe-dlog rlm.log-install_service.
   - **Open Reprise License Server Administration (Web interface)** After the installation, the Reprise License Server Administration web interface opens. It allows you to manage the network license. You can open the Reprise License Server Administration later by clicking the License Server Administration shortcut in the Start menu.
7. Click Next.

Figure 1.147



Bricsys Network License Manager Setup
Additional Tasks
Which additional tasks should be performed?
Select the additional task to perform, then click Next.
Activate a Network license.
Setup as windows service.
Open Reprise License Server Administration. (Web interface)
Back
Next
Cancel

New installation of the Bricsys Network License Manager

In the **Additional Tasks** dialog, make sure to select all the check boxes (see image above).

Upgrading the Bricsys Network License Manager

1. Download and install the Bricsys Network License Manager on the computer used as network license server.
2. Make sure to deselect all the check boxes next to the **Additional Tasks**.
3. The installation restarts the license server.

Installation from the command line

You can also start the Network License Manager from a command window. By default, the options **Activate a Network license**, **Setup as Windows service** and **Open Reprise License Server Administration** (Web interface) are disabled when installing via the command line. To enable these options, use the respective parameters ACTIVATELICENSE, INSTALLSERVICE and OPENWEBINTERFACE. For example, **msiexec /qb /i Bricsys-NetworkLicenseManager.ms ACTIVATELICENSE=1 INSTALLSERVICE=1** will show the activation dialog and install as a service without showing the web interface.

NOTES

- For more options, type: **msiexec /?** at the command prompt**.**
- On the Microsoft website, you can find more information about the **msiexec** command.

Starting the Network license server

The Network license server is automatically started/restarted after the installation. To check if the server has started, open Windows Services and check of the service **RLM** is running. If needed, you can manually start/stop/restart the service. You can configure the server via the Network License Server Administration (1.11.5). Once the Network license is activated and the server is started, the server is ready to serve licenses. It is now possible to use the Network license in BricsCAD on a client computer. (1.7.8)

Related topics

Network License Server (1.11.1) Setting up a Linux network license server (1.11.3)

1.11.3 Setting up a Linux network license server

Download and install the Bricsys Network License Manager on the computer that will be used as network license server.

1. Download Bricsys Network License Manager (Linux)
2. Extract **Bricsys-NetworkLicenseManager.tgz** to any folder (command line: tar xvzf Bricsys-NetworkLicenseManager.tgz
3. Start the application rlm in that folder (command line in that folder: ./rlm).
4. Open the web page **http://localhost:5054** in a browser.
5. Click the **System Info** button on the left on the web page. Copy an Ethernet host ID and use this to activate your license on the **My Account** page on the Bricsys website.
6. When you download a license file from the Bricsys website, store it in the folder where you extracted Bricsys-NetworkLicenseManager.tgz.
7. Click the **Reread/Restart Servers** button.
8. Click the **Status** button to see the server status, on the next page click the **bricsys** button in the table to view Bricsys licenses.
9. Click the **RLM Manual...** button to learn how to configure the license server in detail. Among other things, the page explains how to start rlm automatically when the server boots.

Once the Network license is activated and the server is started, the server is ready to serve licenses. It is now possible to use the Network license in BricsCAD on a client computer.

Related Topics

Network license server (1.11.1) Setting up a Windows network license server (1.11.2)

1.11.4 Roaming

With a network license, you can set a floating license to roam to a system which will subsequently be disconnected from the network. The resulting license can be used for the number of days specified when the license was set to roam. After this period, the license is checked back in automatically. If needed, you can return the roamed license to the license pool early. The license file(s) on the network license server contain(s) a parameter **max_roam_count**. This is set to the total number of seats on a network license by default.

Roaming a network license on a client computer (1.7.9)

1.11.5 Network license server administration

When the Network license server (also named RLM License server) is running, you can configure it in the Reprise License Server Administration web interface.

Opening the web interface

1. If the network license server is not running, click the **License Server** shortcut in the Start menu (on Windows Vista or higher: right-click > Run as administrator). A console window opens.
2. Open a web browser.
3. Go to **http://localhost:5054**. The **Reprise License Server Administration** web interface opens. (1.148 on the next page)

NOTES

- Do not use the **Activate License** button!
- To get an overview of all options, click the **RLM Manual...** button on the left or go to the RLM License Administration Manual.

Checking the license and server status

You can check the status of all network licenses on the server.

1. Click the **Status** button on the left. The page **Status for "rlm" on [LicenseServer] (port 5053)** opens. (1.149 on the following page)
2. Click the **bricsys** button in the **Server Status** column of the ISV Servers table to view the status of the Bricsys Network license. (1.150 on page 205)

Related Topics

Network license server (1.11.1) Setting up a Windows network license server (1.11.2) Setting up a Linux network license server (1.11.3)

1.11.6 Advanced configurations

Once the network license server is set up, BricsCAD may report error -17 when trying to connect to server. The reasons can be due to the presence of an antivirus, and/or a firewall, and/or a proxy server.

Antivirus

If an antivirus software is running on the server and blocking the license server program (**rlm.exe** on Windows, **rlm** on Linux/Mac), you need to unblock the RLM service in the antivirus. See your antivirus configuration on how to unblock services.

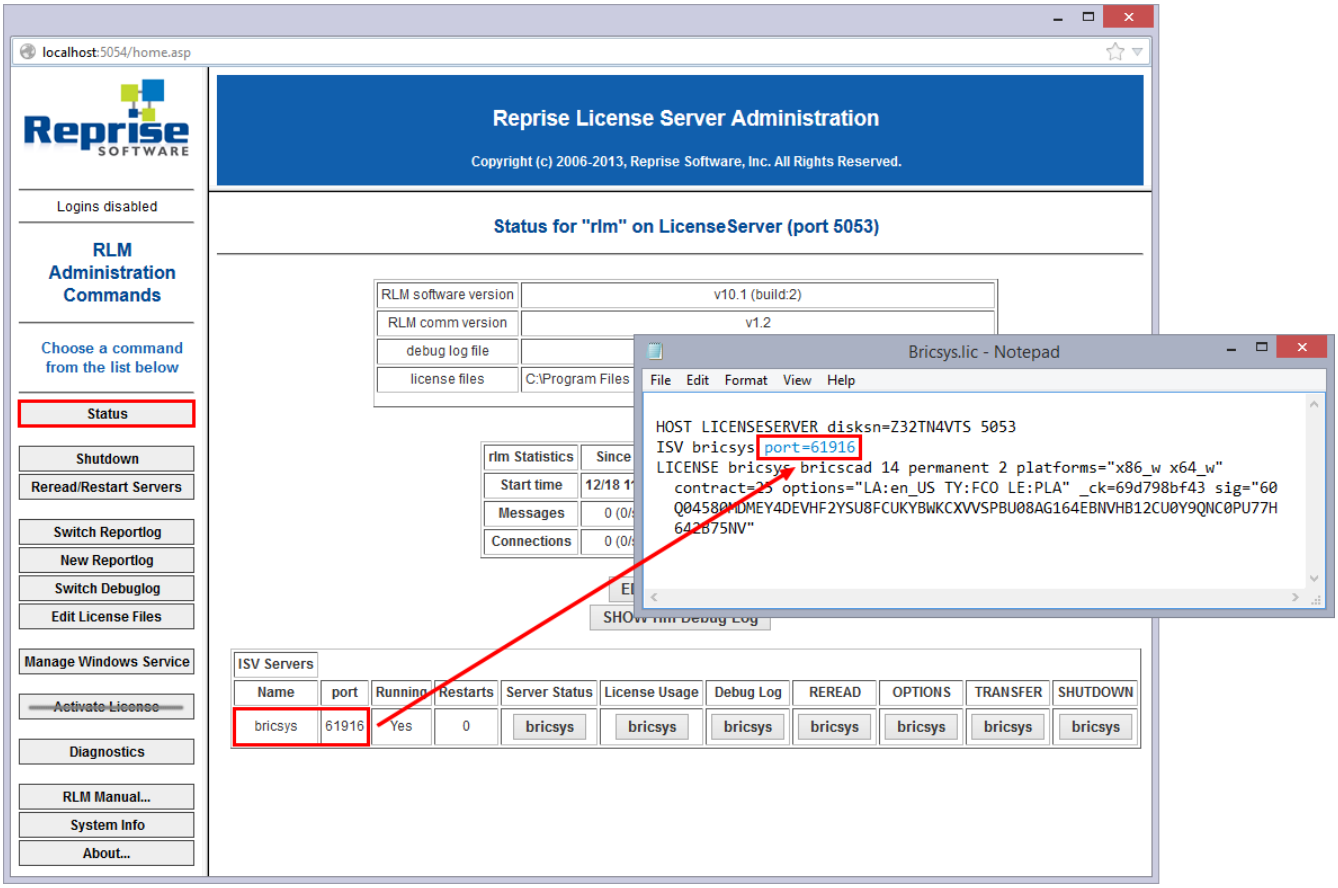
Firewall

If a firewall is installed between the server and BricsCAD, two port numbers need to be opened in the firewall: the port number 5053 and the port number assigned to the Bricsys license server. This port number is dynamically assigned when the license server starts. To open this port in the firewall, it must be first set in the Bricsys.lic file on the server:

1. Open the License Server Administration web interface at **http://localhost:5054**.
2. Click the **Status** button on the left. The **Status for "rlm" on [LicenseServer] (port 5053)** page opens.
3. In the ISV Servers table, look at the bricsys row. The port number is displayed in the second column. Copy this port number.
4. Open the Bricsys.lic file in a text editor (Notepad, Gedit, ...). The default location of the file is C:\Program Files (x86)\Bricsys\Bricsys Network License Manager. You can fix the port number by modifying the line ISV bricsys into **ISV bricsys port=[port number]** where [port number] must be replaced by port number copied from the ISV Servers table. (1.152 on the next page)
5. In the firewall, open both numbers 5053 and the port number you added to the Bricsys.lic file.
6. Shut down and restart the License Server program.

Note: If this does not solve the problem, add the license server program (rlm.exe on Windows, rlm on Linux/Mac) as an exception onto the firewall exceptions and restart the license server again.

Figure 1.152



Proxy server

If a proxy server exists between BricsCAD and the License Server, proxy settings should be configured in BricsCAD. See how to configure the proxy settings permanently for Network License use (1.7.10).

1.11.7 License Pooling

Editing the options

The options can be edited in 2 ways:

- in the bricsys.opt file, located in the Network License Manager installation folder.
- on the webinterface of the Network License Manager.
  - Browse to http://localhost:5054 on the license server.
  - Click "Status" in the menu on the left side.
  - Click "bricsys" in the OPTIONS column for the bricsys ISV row.

Once edited, Reread/Restart the license server.

Commonly used options

Groups can be used to define a list of usernames, hostnames or IP-addresses. The name can later be used to apply rules for that group. **GROUP** Defines a group of usernames. Syntax: GROUP name list-of-usernames Example: GROUP engineers userA userB userC **HOST_GROUP** Defines a group of hostnames. Syntax: HOST_GROUP name list-of-hostnames Example: HOST_GROUP firstFloor machineA machineB machineC **INTERNET_GROUP** Defines a group of IP-addresses. Syntax: INTERNET_GROUP name list-of-ip-addresses Example: INTERNET_GROUP networkGhent 192.168.1.* 192.168.2.* The wildcard character (*) can be used in IP addresses. **RESERVE** Reserve a number of licenses to a specific (group of) user(s). Syntax: RESERVE num product user|host|group|host_group|internet|intern who [id=nnn] Example: RESERVE 20 bricscad GROUP engineers **MAX** Limit the number of licenses available to a specific (group of) user(s). Syntax: MAX num product user|host|group|host_group|internet|internet_group|project who [id=nnn] Example: MAX 5 bricscad HOST_GROUP firstFloor **INCLUDE** Only allow licenses for a product to a specific (group of) user(s). Anyone not specified by the INCLUDE line is not allowed to use the product. Syntax: INCLUDE product userhost|group|host_group|internet|internet_group|project who [id=nnn] Example: INCLUDE bricscad GROUP bricscadusers **EXCLUDE** Disallow licenses for a product to a specific (group of) user(s). Syntax: EXCLUDE product user|host|group|host_group|internet|internet_group|project who [id=nnn] Example: EXCLUDE bricscad INTERNET_GROUP 1.1.*.* More options can be found in the RLM enduser manual under the paragraph "The ISV Options File"

Identifying a license file

Since V15, a new feature in the Reprise license manager allows you to add a '_id' field in your license file. With this '_id' you can identify each license file as a separate license pool. When specifying an [id=nnn] parameter for an added OPTION, that OPTION will only have effect on the corresponding license file. Usage Example: You have 2 licenses, one with 10 seats for BricsCAD Lite, and one with 10 seats for BricsCAD Pro, and want to specify which users can use which level. **THE LICENSE FILES** Lite License HOST host_name ethernet_mac 5053 ISV bricsys LICENSE bricsys bricscad 15 permanent 10 share=uh contract=1 options="LA:xx_XX TY:FCO LE:PRO" _ck=6a06665467 sig="" HOST host_name ethernet_mac 5053 ISV bricsys LICENSE bricsys bricscad 15 permanent 10 share=uh contract=1 options="LA:xx_XX TY:FCO LE:PRO" _id=1 _ck=6a06665467 sig="" Pro License HOST host_name ethernet_mac 5053 ISV bricsys LICENSE bricsys bricscad 15 permanent 10 share=uh contract=1 options="LA:xx_XX TY:FCO LE:PLA" _ck=6a06665467 sig="" HOST host_name ethernet_mac 5053 ISV bricsys LICENSE bricsys bricscad 15 permanent 10 share=uh contract=1 options="LA:xx_XX TY:FCO LE:PLA" _id=2 _ck=6a06665467 sig="" Now the Lite license is defined by id=1, and the Pro license by id=2. **THE OPTIONS** If now, for example, you would like to only allow engineers in your firm to use the Pro version, this can be done by adding the following to the options. GROUP engineers userA userB userC INCLUDE bricscad GROUP engineers id=2 Symptoms I want to adjust the way my licenses are pooled. More information http://www.reprisesoftware.com/RLM_Enduser.html

License pooling by RLM_PROJECT

The following applies to cases where multiple levels network licenses are activated on the same RLM server, so the users are able to decide what license level to acquire when activating BricsCAD. The user can obtain a specific BricsCAD license level, based on the RLM_PROJECT environment variable which should match the ISV server options. The license seats will be reserved on the ISV server for the specific PROJECT users by an IDentifer. Note: Please be aware that the following actions are to be executed by an IT department person.

1. RLM server actions

1. Add _id=<number> identifier to license files, just before the _ck=xxxxxxx string: ……contract=999-9999-9999-8888 options="LA:xx_XX TY:NFR LE:PRO _id=1 _ck=4b07efdd90…. ……contract=999-9999-9999-9999 options="LA:xx_XX TY:NFR LE:LIT _id=2 _ck=4b07efdd90…..
2. Add RESERVE option for PROJECTs and license IDs to ISV server, for all the seats of the licenses: RESERVE 5 bricscad PROJECT bc_pro id=1 RESERVE 5 bricscad PROJECT bc_lite id=2

2. BricsCAD user actions

1. Create a script that SETs a temporary environment variable RLM_PROJECT on the user machine, which will allow BricsCAD to negociate with the RLM server the PROJECT license pool.
2. Executing a specific script will allow BricsCAD to pull the desired license level It can be *.CMD (command prompt) files:
   - @echo off set RLM_PROJECT=bc_lite call "C:\Program Files\Bricsys\BricsCAD V21 en_US\bricscad.exe"
   - @echo off set RLM_PROJECT=bc_pro call "C:\Program Files\Bricsys\BricsCAD V21 en_US\bricscad.exe"
   - or *.PS1 (powershell) files: $env:RLM_PROJECT = "bc_pro" Start-Process -FilePath "C:\Program Files\Bricsys\Bric V21 en_US\bricscad.exe"
   - $env:RLM_PROJECT = "bc_lite" Start-Process -FilePath "C:\Program Files\Bricsys\BricsCAD V21 en_US\bricscad.

Since all license seats are RESERVED in the RLM options, BricsCAD will not be able to acquire a license when the RLM_PROJECT variable does not exist, or when it has a value which does not match the ISV server options. Raising the available seats above 5 or lowering the RESERVE count below 5 would let some licenses be available freely. The RLM_PROJECT also works with the other (EXCLUDE/INCLUDE/…) options so a lot of configurations are possible.

1.12 Customization

1.12.1 User profiles

https://www.youtube-nocookie.com/embed/mEPm7aelSs8 The user profiles customizes BricsCAD for the way you like to have it; such as what toolbars you want to see, the color of the screen etc.. After you customize the way BricsCAD works and looks, you can copy the settings to other computers so that BricsCAD works and looks the same way there for you. After completing this video, you will be able to:

- Understand the role of user profiles in BricsCAD.
- Create your own user profile(s).
- Know how and when to employ user profiles.
- Export and import .arg profile files.

1.12.2 Customizing the Ribbon

https://www.youtube-nocookie.com/embed/HSTdIIdFeqY The ribbon is the most prominent element of BricsCAD's user interface, but customizing it is not as straight-forward as, say, a toolbar. After completing this video, you will be able to:

- Identify the parts of the ribbon.
- Add a button to a panel.
- Add a panel to a tab.

1.12.3 Customizing settings

https://www.youtube-nocookie.com/embed/jvGu8CmjrQs Many commands have default settings that you can change in BricsCAD. After completing this video, you will be able to:

- Use Settings dialog to change BricsCAD's workings.
- Access settings quickly through the status bar.
- Modify settings of editing commands.
- Change the way dynamic input works.

1.12.4 Customizing display settings

https://www.youtube-nocookie.com/embed/wzkGnJ90REI BricsCAD lets you change many aspects of its look, from the color of the drawing area to the sizes of UI elements. After completing this video, you will be able to:

- Use Settings dialog to change BricsCAD's look.
- Change the background color.
- Modify the look of the Quad.
- Adjust the color and linetype of the rubberband.

1.12.5 Controlling BricsCAD Through Settings

https://www.youtube-nocookie.com/embed/fKWpnys7Q8k BricsCAD allows you to change the way it works and looks, and most of these changes are made through the Settings dialog box. After completing this video, you will be able to:

- Use the Settings dialog box effectively.
- Change the pickbox size in Settings.
- Set variables at the command line.

1.12.6 Working with Tiled Viewports in Model Space

https://www.youtube-nocookie.com/embed/bVxlrON1ffo

Working with Viewports in BricsCAD

The drawing window in model space can split into two or more viewports. This lets you see the same drawing in several different ways, for example, zoomed-in in one viewport, and with different layer settings applied in another. We will show you how to create and delete viewports, draw entities that start in one viewport and end in another, switch between multiple, create a new viewport inside an existing viewport, and merge adjoining viewports together. Viewports are created with the VPORTS command. Default options let you create 2, 3, or 4, and you can orient them vertically or horizontally. The dominant (active) viewport is surrounded by a heavy dark line. That's where the cursor appears and where things happen when you enter a command. Want to switch between them? Simply click in another viewport or press Ctrl+R to cycle between them.

2D Drawings Get an overview of your drawing in one viewport and a detailed view of your plan in another. Also, you can draw from one viewport to another. Start a line in the zoomed-in detail, and end it in another viewport.

Tips for Viewports and 3D Drawings When you are modeling in 3D, you can easily create 4 views – top, front, side and isometric – with the VPORTS command. Control your view angles using the "Look from" widget. Each viewport can display its own different visual style.

Want more than 4? Select the dominant viewport and enter the VPORTS command. You can save the viewport layout if you like the set up. Enter the VPORTS command, and then enter the 's' sub-command and type in a name for your viewport setup. You can **join multiple viewports**. Enter VPORTS command, enter 'j', select the dominant one and select the viewport you wish to join it with.

Cancel the viewports Enter the VPORTS command, enter 'SI' and you're back to one, single view of your model.
Back to Tutorial Overview

1.12.7 The Prompt Menu and Its Many Uses

https://www.youtube-nocookie.com/embed/It9t2eAylu0

Using the Prompt Menu for accessing command options

The Prompt Menu is found in a few CAD systems like BricsCAD but not AutoCAD. This video shows when the Prompt Menu shows up automatically, why it is useful, and how to change its settings through the Settings dialog box. Back to Tutorial Overview

1.12.8 Customizing the Command Prompt

https://www.youtube-nocookie.com/embed/e_C5C-zMEM8

For its command prompt, BricsCAD uses a simple ':' to indicate it is ready for you to enter a command. You can change what BricsCAD displays through the Settings dialog box. Older releases of AutoCAD used 'Command:', and newer releases use 'Type a command'. You can change what BricsCAD displays through the Settings dialog box. Command prompt customization is not available in AutoCAD. Back to Tutorial Overview

1.12.9 Easy Menu Customization in BricsCAD

https://www.youtube-nocookie.com/embed/-gtsGPlpMRc

How to make simple changes to the BricsCAD's menus

The menu bar and menus can be completely customized in BrisCAD. In this video, you learn how to make a new menu to the bar, add commands to the menu, and then to rename and remove menu items. Back to Tutorial Overview

1.12.10 Customizing shortcut menus

https://www.youtube-nocookie.com/embed/-6ihKCNPjHc

Choose the commands you want to have within reach

BricsCAD has the ability to customize your shortcut menu when you right click* on an entity. You can edit them by right clicking on your toolbar and choose Customize. Then you'll find the Context menu in the Menu tab, where you can change your shortcut menu per entity. (*) When the Quad curser menu (1.15.5) is active, hold the right mouse button down a little longer to display shortcut menu and overrule the Quad. Back to Tutorial Overview

1.12.11 Abbreviating Command Input with Aliases

https://www.youtube-nocookie.com/embed/qwcuK6zixHo BricsCAD lets you enter abbreviations for command names, such as L for drawing lines and E for erasing them. This video tours you through using a variety of aliases in BricsCAD, and then shows you how to create your own. Back to Tutorial Overview

1.12.12 Saving Your Customizations with Partial CUI Files

https://www.youtube-nocookie.com/embed/ecmKyfjtCos

Load UI elements independently of BricsCAD's default settings

This video shows you how to customize with partial CUI files instead of the main one, as well as to share your customizations with other BricsCAD users. When you customize BrisCAD through the default.cui file, you can lose all of your work! Unless you use partial CUI files instead; these files are not overwritten when you need to reset the system or install an upgrade. Back to Tutorial Overview

1.12.13 Customize mouse buttons to add tools to BricsCAD

https://www.youtube-nocookie.com/embed/FWk79sNscmk

Customize mouse buttons in BricsCAD easily

Like almost everything else in BricsCAD, you can customize mouse buttons to increase your productivity. The left mouse button, of course, performs the most important CAD function – selecting entities. Because of this, you can't customize your left mouse button. Never fear though – the middle and right mouse buttons are fully customizable. Also, using combinations of the CTRL, Shift and CTRL+Shift keys while clicking, you can get a total of eight commands from the middle and right mouse buttons.

How does BricsCAD identify the mouse buttons? (1.153) **Left button = 3 (not customizable – as it's always used to pick things) Middle button/roller wheel = 2 Right button = 1**

Figure 1.153

Customize mouse buttons with the CUI Right-click any User Interface (UI) element (menu, toolbar or panel), or just type in "CUI" at the command prompt to access the UI customization dialog box. Select customize and go to the Mouse tab. There you can program the middle and right mouse buttons for click, CTRL-click, Shift-click and CTRL-Shift-click options. The customization of BricsCAD doesn't end here, this is just the start! Take a few minutes to watch this video that will show you how to customize BricsCAD's tool palettes.

Want the full scoop? We have an eBook for you The author of this video tutorial on how to customize mouse buttons is Ralph Grabowski, industry expert and long-time CAD author. Ralph has written a comprehensive eBook that tells the complete story for current AutoCAD® users moving to BricsCAD®. You can get a free copy of this incredible eBook for no charge on our website. Read through it at your leisure and discover what makes BricsCAD the best value in .dwg-based CAD today. Back to Tutorial Overview

1.12.14 Customizing Tool Palettes in BricsCAD

https://www.youtube-nocookie.com/embed/YvG_wcm9xSQ

It's easy to customize BricsCAD Tool Palettes!

What are tool palettes? They are dockable, graphical panels that contain commands, hatch patterns, or blocks for insertion – or all three! To use a palette object, click the tool and move your cursor to the graphic screen. Does this sound simple enough? It gets better – it's almost as easy to customize your own tool palettes, and add your own commands or custom insert-able blocks. In this short video lesson, Ralph Grabowski gives a brief overview of Tool Palettes and how they work. The content of each button (icon) in the palettes can be fully customized to meet your needs. Ralph will give you the basics on how to create your own custom commands in the video, also.

What are the commands to access tool palettes?

- Type "**ToolPalettes**" at the command line to open the Tool Palettes bar
- Type "**ToolPalettesClose**" to close the Tool Palettes bar
- The "**TPNavigate**" command displays a specific named tool palette or a tool palette group

You can open a tool palette by right-clicking any user interface element. From the the context menu, select "**Tool Palettes**".

How do you customize commands in your tool palettes? First, right click on a command icon in a tool palette. Then click "Properties". You can change the "command string" (a.k.a. "macro") of an existing icon, or create a new one. In this lesson, Ralph builds a macro by typing this text in the command string text box: "**^C^C_line;1,1;2;2**". When Ralph clicks on the modified command icon, BricsCAD draws a line from (1,1) to (2,2). In macros, the semi-colon (;) acts like you are pressing Enter, or hitting the space-bar. In the video's first example, a single trailing semi-colon is implied. You'll see that this causes the line command to continue. You can end the line command macro by adding "**;;**" – two semi-colons – at the end of the command string.

Customizing entity properties with tool palettes You can customize the style and properties of various BricsCAD entities easily, also. In the video, Ralph edits the Revision Cloud command to change its properties. First, he makes a copy of the Revision Cloud icon in the Draw palette, and pastes it into the Command Tools palette. Then he goes back to the icon's properties to customize the way that the revision cloud appears in the drawing upon insertion. Need more? Click this link to access the BricsCAD on-line help for creating and modifying Tool Palettes (6.29.28)!
Back to Tutorial Overview

1.12.15 Advanced Menu Customization

Youtube This video explains the parameters and metacharacters that control each menu item: Title, Diesel, Tool ID, Help, Command, and Image. It also gives some tips on what to do, and what to not do. Back to Tutorial Overview

1.12.16 Clipping Attached Images and PDF Files

https://www.youtube-nocookie.com/embed/bRo0b0f-dAg Sometimes photographs, scans, and PDF files show more data than is needed for the drafting task at hand. This video shows you how to cut out parts of these attachments, both using a rectangular and a polygonal (irregular) clipping border. You learn how to turn clipping on and off, and find out why PDF files sometimes do not display. Back to Tutorial Overview

1.12.17 Employing the Display Power of Layer States

https://www.youtube-nocookie.com/embed/vAQD69pZrSs Layers have always been used to segregate information, and now layer states lets you instantly switch the drawing display between various layer combinations. A layer state freezes the layers you don't want to see; it can also change the color and other layer properties in an instant. This video shows you how to name and create Layer States with the Drawing Explorer, and then how to create a toolbar that lets you quickly switch the drawing between layer states.

Use Layer states to switch between the display of different groups of layers

Back to Tutorial Overview

1.12.18 Clipping x-refs and blocks

https://www.youtube-nocookie.com/embed/5a1CXEVX_-M

XCLip Command

This video shows you how to use the XCLip command to cut away a portion of a block and an xref. It demonstrates doing this with a rectangular shape, an irregular polygon, and with a curved shape.

> **Clipping is like cutting out part of a photograph, but in the case of BricsCAD the process can be reversed.**

When blocks and/or xrefs (externally-referenced drawing files) are placed in drawings, you can have BricsCAD show a portion of them — by hiding parts through "clipping." Back to Tutorial Overview

1.12.19 Joining Multiple Entities in BricsCAD

https://www.youtube-nocookie.com/embed/m_JroUT4two

Joining multiple entities is simple with JOIN

In this short video, BricsCAD expert Ralph Grabowski shows you the power of the JOIN command. He discusses joining multiple entities, like co-linear lines and concentric arcs, into single objects. Ralph goes into detail with regards to multiple entities with different properties. Which one will "win" the properties "battle" (**beware – spoiler!** It's based on how you pick)? He also explores the conditions under which entities of different types can be joined together into one, and the resultant entity types. This is powerful, especially in drawings that have been imported, or drawings that have been through multiple editing sessions. Depending on technique, there are scenarios where polylines will come in as lines and arcs. You can use the PEDIT command to turns them back into polylines. However, there is a better method when joining multiple entities. The JOIN command can make two or more lines into a single line, a connected line and arc into a polyline, two or more arcs into a single arc, and even convert a line and a helix into a spline. JOIN is another great tool in your CAD toolbox, and Ralph shows you how to make it work for you – on your command. Back to Tutorial Overview

1.12.20 Creating Custom Template Drawings

https://www.youtube-nocookie.com/embed/nc0vXt-COqY

How to start new drawings faster by pre-loading them with content

When you start new drawings in BricsCAD, they are quite a barebones effort: just one layer, no special line types, no nothing. When you start a new drawing project, you typically need to add in the office layer standard, the line types, dimension styles, and other material. You can start new drawings with all that in place through template drawings. This video shows you how to access template drawings, how to add content, and then how to save a drawing as a .dwt template file with the SaveAs command. Back to Tutorial Overview

1.13 Managing Licenses

1.13.1 Deactivating or revoking a BricsCAD license

Use this procedure to:

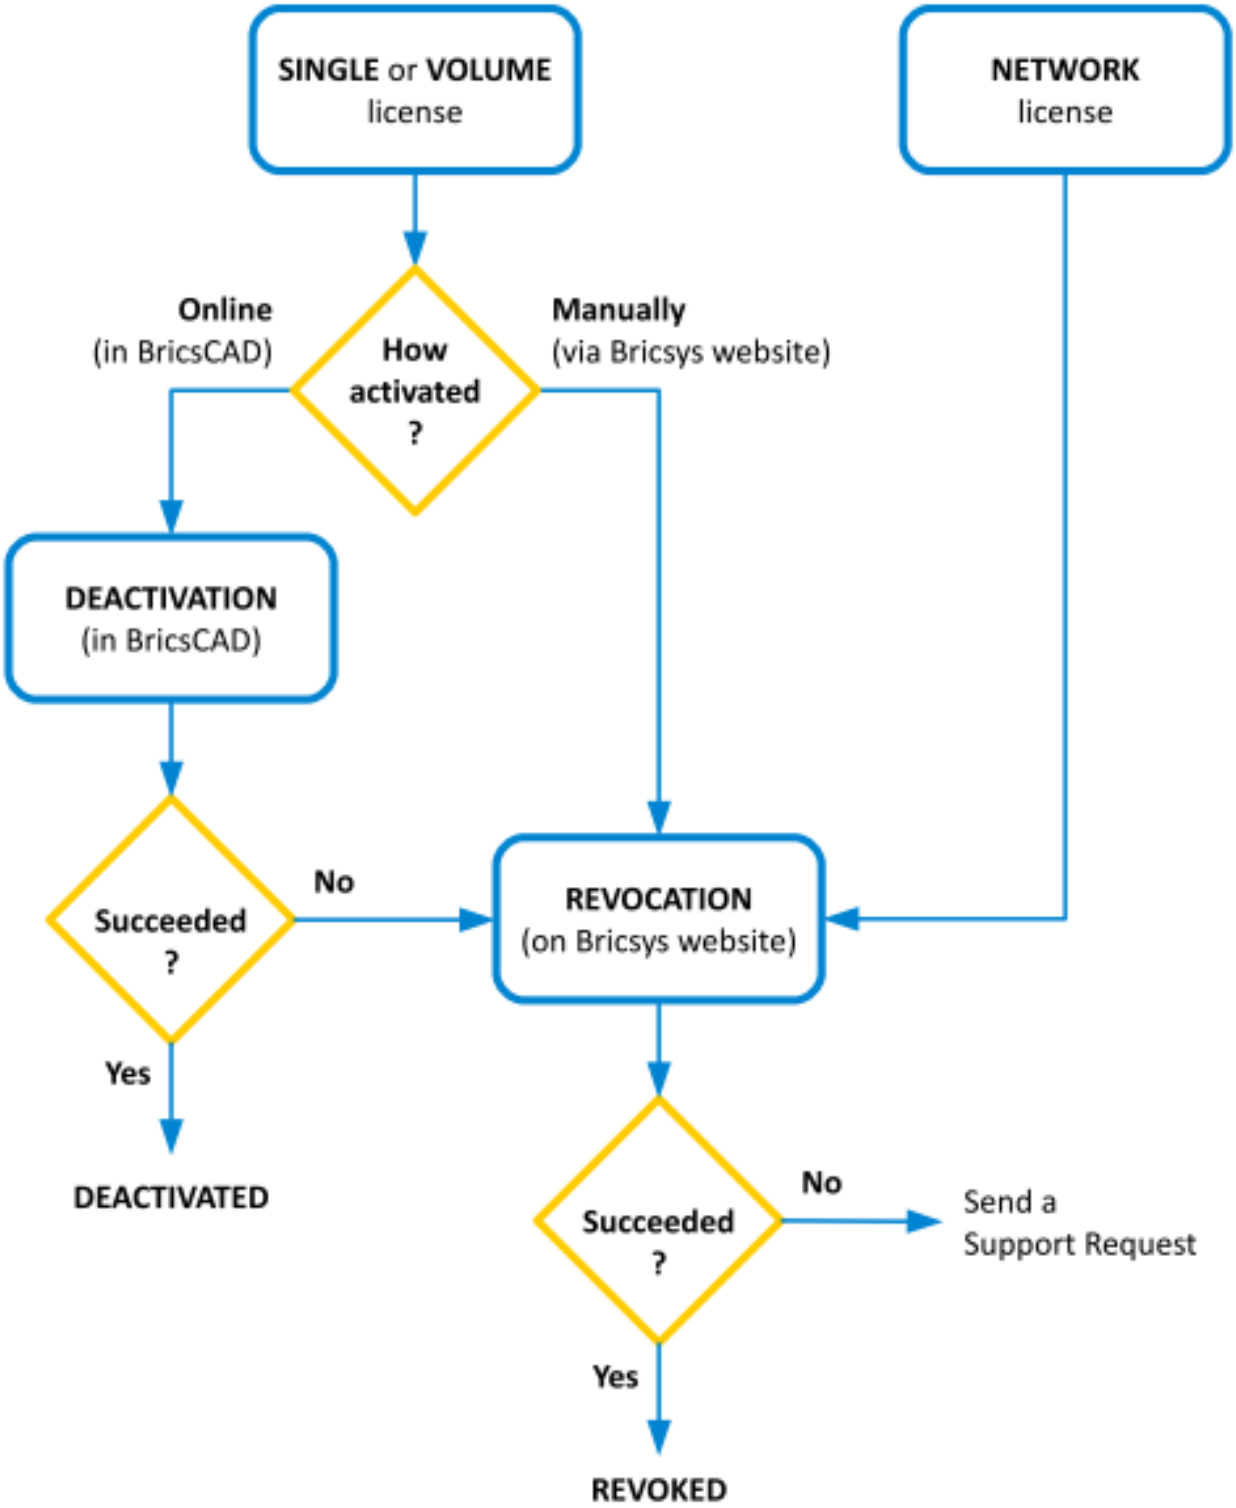
- Migrate a license to another computer.
- Permanently remove BricsCAD from a computer.
- Reactivate BricsCAD after installing a new hard disk, changing partitions or upgrading the operating system.

To deactivate a BricsCAD license, an internet connection is required. You cannot manually deactivate a license via another computer that is connected to internet. You cannot deactivate:

- Single and volume licenses that are manually activated.
- Network licenses.
- Trial licenses.

The chart below explains how you can deactivate a BricsCAD license. If it is not possible to deactivate a BricsCAD license, you can revoke the license. (1.154 on the next page)

Figure 1.154



SINGLE or VOLUME license

Succeeded ?
No
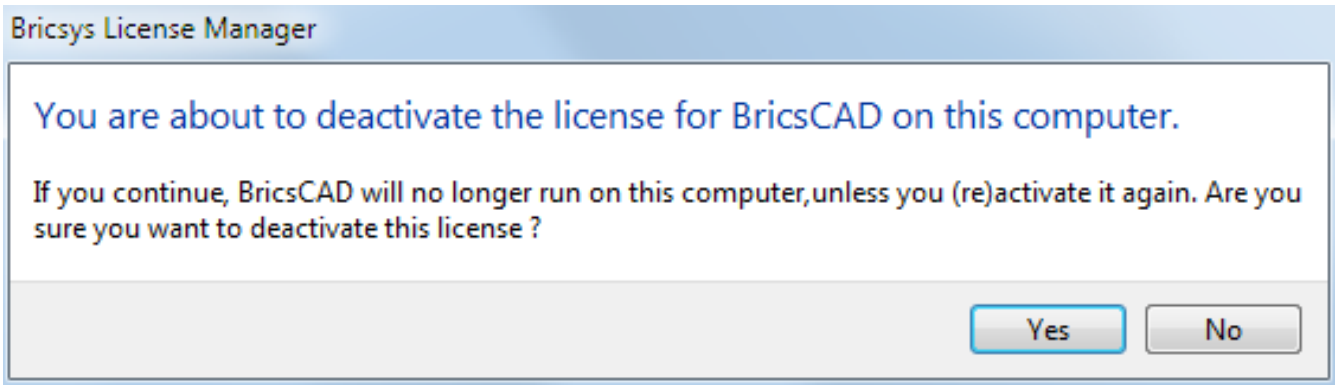
Send a Support Request
Yes
REVOKED

Deactivating a license

1. Launch the LicenseManager (6.20.27) command, then click the **Manage License** option on the **Bricsys License Manager** dialog box. The **Licensing Information** dialog box displays.
2. If your computer connects to the license server through a proxy server, click Proxy Settings (1.7.10) to configure the proxy settings.
3. Click **Deactivate...** (1.155)
4. Click the **Yes** button on the confirmation dialog box to deactivate the license. The license is deactivated now and is available to be activated on another computer.

Figure 1.155



Revoking a license

Only revoke a license if deactivation is not possible. Use this procedure to:

- Deactivate a network license or a single or volume license manually that is manually activated.
- Reactivate BricsCAD after a hard disk crash.
- Reactivate BricsCAD after installing a new hard disk, changing partitions or upgrading the operating system.
- Migrate a license to another computer.
- Permanently remove BricsCAD from a computer.

1. Log in to the Bricsys website. Make sure you log in with the Bricsys account containing your licenses.
2. Click the **My Account** icon (), then choose **Manage Licenses** in the menu. (1.156 on the next page)
3. Hover over the license key of the license you want to revoke and click on the pencil icon (). (1.157 on the following page)
4. Scroll down and click the **X** icon to revoke the license. (1.158 on the next page)

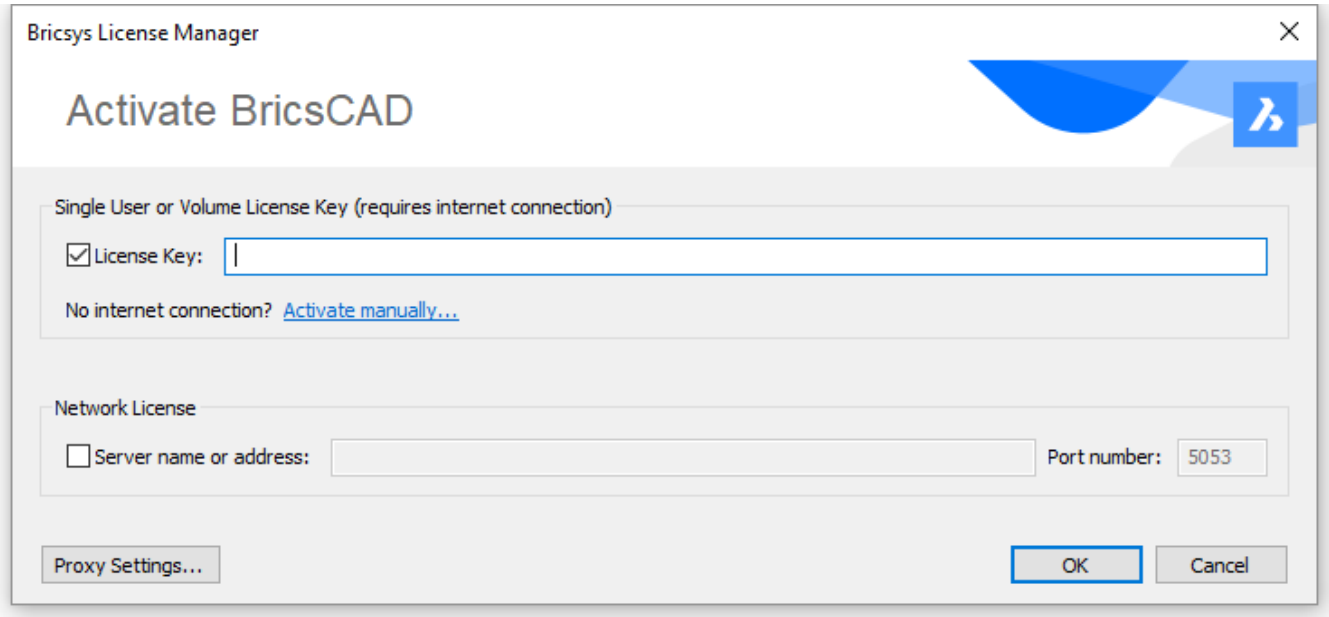
Modifying a BricsCAD license (1.13.2) Migrating a license to another computer (1.13.4)

Figure 1.159



1.13.2 Modifying a BricsCAD license

Use this procedure to upgrade or replace a license.

1. Launch the LICENSEMANAGER (6.20.27) command. The **Bricsys License Manager** dialog displays.
2. Click **Manage License**. The **Licensing Information** dialog displays.
3. Click the **Modify** button. The **BricsCAD License Manager** - **Activate BricsCAD** box displays/ (1.159)
4. Paste your license key in the **License Key** field.
5. Click the **OK** button.
   - Your license key is registered over the internet.
   - A dialog displays when the license key is successfully activated.
6. Read the text on the dialog box and click the **I understand** button.

Related Topics

Deactivating a BricsCAD license (1.13.1) Overview of licensing options (1.7.1)

1.13.3 Managing BricsCAD licenses with multiple Bricsys accounts.

You can share licenses with one or more other Bricsys accounts to allow them to view, activate and revoke your license(s). Do the following:

1. Logon to the Bricsys website.
2. Click on your user name and select **Manage Licenses** in the drop-down menu.
3. Hover over the license you want to share and click the **Pencil** icon (). The **LIcense** page displays.
4. Under **Managers**, click **Add Manager**.
5. Type the login email address* of the new manager, then click the **Plus** icon. The new manager is added. An email is sent to inform the new manager. The **X** icon after the name allows to remove the manager.

* Managers must have a Bricsys account.

1.13.4 Migrating a license to another computer

All your valid licenses can be found on the Bricsys website (login required): https://www.bricsys.com/protected/account/licenses. **Step 1**: Deactivate the license on the old computer. See: Deactivating a license (1.13.1) **Step 2**: Launch BricsCAD on the new computer. **Step 3**: Activate the license on the new computer. See: Activating and Licensing (1.7.2)

1.14 Drawing

1.14.1 Drawing Accurately: Snap and Grid

https://www.youtube-nocookie.com/embed/JRjBDLXAAks

Using snap allows to specify points at fixed intervals. The Grid command displays a grid pattern in the current viewport. Synchronize snap and grid spacing The 'Snap' option of the Grid command forces the grid spacing to be in sync with the snap spacing. When you then change the snap spacing, the grid follows. (1.160 on the next page) **Control the appearance of the grid** The appearance of the reference grid is controlled by a series of system variables. (1.161 on page 245) Back to Tutorial Overview

1.14.3 Tip on how to create blocks quickly on the fly

Youtube

Ever find yourself in the middle of a project with deadlines to meet, need to create a block, but hate how can disrupt your workflow? Or would like to collect some objects together so you can manipulate them easily? Then this video tip on how to create blocks quickly, on the fly is for you! Forms, don't you hate them? Wouldn't you rather just get on and get the drawing done? I've always found block creation really disruptive to my workflow. By the time I've mucked around and filled in the form to create the block, I've often forgotten what I needed it for in the first place.

> "There is a solution for real time, not a form in sight, block creation, and best of all it's built right into BricsCAD."

Back to Tutorial Overview

1.14.4 Dynamic Grips and Tips

https://www.youtube-nocookie.com/embed/2941QC44G-4

How to manipulate the special grips of dynamic blocks

As of BricsCAD V15, we can manipulate the special grips of dynamic blocks directly. Previously, this was possible only through the Properties palette. This video explains what the different grip icons mean, how they operate to change the block, and then provides a few tips on using dynamic blocks. Attached to this post is dyngrips.dwg, the drawing used in the video. Back to Tutorial Overview

1.14.5 Grips Editing in BricsCAD

https://www.youtube-nocookie.com/embed/RyMKZeWP_pE

Drag grips to stretch, move, mirror, rotate or scale entities.

Most people know about grip stretching, but there is much more. When you stretch a grip point and then repeatedly press the space bar, the selected entities are moved … rotated … scaled … or mirrored.

> **Each grips editing command has a Copy option which keeps the original entities.**

Back to Tutorial Overview

1.14.6 Secrets of the shift key in BricsCAD

https://www.youtube-nocookie.com/embed/8yyr8chvBIM

It does more than just capitalising text.

Everyday we use the shift key to write big letters or to select files, but in BricsCAD it does a lot more. Jan Bergmann will show you how you can use the shift key in BricCAD.

First secret: Deselect Objects SHIFT + Left Mouse Click Everyone knows how to select objects, but sometimes you've selected that extra object you didn't need. There's no need to select again. You can be very precise and deselect the redundant objects while holding the shift key.

Second secret: Temporary Ortho mode or Free draw mode Hold SHIFT when drawing a line When you draw a line and you need to switch between the Ortho mode or the Free mode, press and hold SHIFT and you'll see your mode changing temporarily.

Third secret: Switch between trim and extend Hold SHIFT when in Trim or Extend mode Trim what you want in the Trim mode. If you need to extend some lines, press and hold SHIFT and you switch to a temporary extend command. It also works the other way around.

Fourth secret: Snap menu sideways to the mouse Press SHIFT + Right Mouse Click If you have selected an object and want to move it. Press the SHIFT key + right click and the snap menu appears. Choose the action you want and it will be executed with the next mouse click.

Fifth secret: Real Time Motion Press and hold Shift + Middle Mouse Button You can now move your drawing like a satellite around the earth. Back to Tutorial Overview

1.14.7 How to Align Entities

https://www.youtube-nocookie.com/embed/aEIL3uVzEkw

Forget move, scale and rotate. Use the align command.

Sometimes you get some drawings from third party companies which are wrong in location and wrong scale. With this command you can correct it very fast. Back to Tutorial Overview

1.14.8 Use Quick Select

https://www.youtube-nocookie.com/embed/TqSIV9tKN4s

Use smart filters to compose a selection set

Quick Select allows you to specify filters, such as entity type, color, line type or any other entity property to compose a selection set. **Start Quick Select** In BricsCAD the Quick Select tool is integrated in the Properties panel. Click the Quick Select button to switch between Properties mode and Quick Select mode. (1.165 on the following page) **Quick Select Modes** After applying the filter criteria you can choose to add the entities to the current selection set, remove the matching entities from the current selection or create a new selection set. Optionally, Quick Select applies either to the entire drawing or to the current selection set. (1.166 on the next page) Back to Tutorial Overview

1.14.9 Using the DimBreak Command in BricsCAD

https://www.youtube-nocookie.com/embed/W72PI-UEa7Q

DimBreak helps improve drawing clarity

If you draw in BricsCAD, you probably need DimBreak. Have you noticed how quickly dimension and extension lines can get crossed up? It's a common situation as you add additional dimensions to your drawing sheets. Also, you'll find that some dimension annotations will lie on top of drawing geometry. When this happens, drawing clarity suffers – and that's the last thing that a designer wants! You need to ensure that the fabricators or builders who will use your drawings get the correct data from those sheets. This short video by Ralph Grabowski will show you how to clean up these unwanted overlaps. Ralph uses the DimBreak command in BricsCAD to break and heal dimension and extension lines that cross each other. Next, he'll show you how to clean up dimensions that obscure other entities. What happens when your drawing changes and a specific break is no longer needed? Well, the DimBreak command can also heal existing breaks one at a time, or across the entire drawing. Finally, Ralph shows you how to properly leverage the Auto option of the command. The dimensioning tools in BricsCAD are very powerful, and better yet, quite familiar. Do you want to learn more about dimensioning in BricsCAD, and DimBreak in particular? Click on the links below to access these specific on-line help pages at bricsys.com:

1.14.11 Copying between drawings

https://www.youtube-nocookie.com/embed/Cr0ktFdYzEE When copying entities from one drawing to another you can either paste the entities using a default base point, paste with a user-defined base point, paste to the original coordinates or paste the selection as a block. Select the desired procedure in the Edit menu or use a keyboard shortcut. (1.168) Back to Tutorial Overview

1.14.12 Making Smarter Drawings with Annotative Scales

https://www.youtube-nocookie.com/embed/BKsyXQ0X1hQ Annotation scaling tools can help you save you hours of time previously spent calculating scale factors and text heights. While creating, editing, and managing drawing data at different scales, stored in multiple layers. Back to Tutorial Overview

1.15 Interface

1.15.1 Keyboard Shortcuts

(1.169 on the facing page) Are you avoiding a key BricsCAD performance tool? Are you a BricsCAD user who favors using menus over using the keyboard for command input? If you are, you might want to reconsider. You need to know that the most often used commands in BricsCAD have fast keyboard equivalents. These keyboard shortcuts can be a great performance enhancer, especially when toggling settings. To help you get started using them, we've created a map of BricsCAD's keyboard shortcuts. Your computer's keyboard is sitting right in front of you – don't ignore it! Using BricsCAD keyboard shortcuts can boost your productivity over using menus alone. You can do things much faster with keyboard shortcuts then you can by clicking through multiple menu panels. Don't waste any more of your precious time – get to know the time-saving BricsCAD keyboard shortcuts. At Bricsys, we're all about speeding your CAD workflow. An easy-to-print PDF version of the BricsCAD keyboard shortcut map is available here. The following keyboard shortcuts are available: **Keyboard Description** F1 Opens the BricsCAD Help. F2 Toggles the display of the Prompt History window. F3 Toggles Entity Snaps (1.21.15). F4 Toggles 3D Entity Snaps (1.21.16). F5 Sets the isoplane (see Using Isometric snap (1.21.12)). F6 Toggles the Dynamic UCS (1.21.21) feature. F7 Toggles the display of the Grid (1.21.12). F8 Toggles the Ortho (1.21.2) setting. Disables Polar Tracking (1.21.18), if on. F9 Toggles the Snap (1.21.12) setting. F10 Toggles the Polar Tracking (1.21.18) setting. Disables Ortho (1.21.2), if on. F11 Toggles the Entity Snap Tracking (1.21.17) setting. F12 Toggles the Quad (1.15.5) display. Alt+F8 Launches the VbaRun (6.32.6) command. Alt+F11 Launches the VbaIde (6.32.1) command. Ctrl+1* Toggles the Properties bar (1.15.4). Ctrl+2* Opens the Drawing Explorer (1.19.2). Ctrl+9* Toggles the display of the command bar. Ctrl+0* Toggles the display of user interface entities as specified by the CleanScreenOptions (1.17.10) system variable. Executes the CleanScreenOn (6.9.17) and CleanScreenOff (6.9.14) commands. * Do not use the numeric keypad. On AZERTY-keyboards: do not press the Shift-key when hitting the number key. Ctrl+A Selects all entities. Ctrl+B Toggles the Snap (1.21.12) setting. Ctrl+C Copies the selection to the clipboard (CopyClip (6.9.36) command). Ctrl+Shift+C Copies the selection along with a base point (CopyBase (6.9.58) command). Ctrl+E Sets the isoplane (see Using Isometric Snap (1.21.12)). Ctrl+F Launches the Find (6.14.8) command. Ctrl+G Toggles the display of the Grid (1.21.12). Ctrl+H Toggles the value of the PICKSTYLE system variable, which controls the selection of groups and associative hatches. Ctrl+I Sets the readout of the coordinate field (1.21.4) in the Status Bar (1.15.2). Ctrl+J Repeats the previously issued command. Ctrl+K Attach a hyperlink to an object or modify an existing hyperlink (Hyperlink (6.16.11) command). Ctrl+L Toggles the Ortho (1.21.2) setting. Ctrl+M Repeats the previously issued command. Ctrl+N Creates a new drawing (New (6.22.5) command). Ctrl+O Opens an existing drawing (Open (6.23.8) command). Ctrl+P Prints the current drawing (Print (6.24.51) command). Ctrl+Shift+P Toggles the Properties bar (1.15.4). Ctrl+Q Quits the application; prompts to save changes (Quit (6.25.8) command). Ctrl+R Iterates through viewports. Ctrl+S Saves the current drawing (QSave (6.25.4) command). Ctrl+T Turns the tablet on/off. Ctrl+V Pastes the contents of the Clipboard into the drawing (PasteClip (6.24.13) command). Ctrl+Alt+V Pastes the contents of the Clipboard in a specified format (PasteSpec (6.24.14) command). Ctrl+Shift+V Pastes the contents of the Clipboard as a block (PasteBlock (6.24.11) command). Ctrl+X Cuts the selection and puts it on the clipboard (CutClip (6.9.48) command). Ctrl+Y Redoes the last action undone (Redo (6.26.8) command). Ctrl+Z Undoes the last action (Undo (6.30.5) command). Ctrl+[Cancels the running command. Ctrl+\ Cancels the running command. Ctrl+Home Creates the Start tab (GoToStart (6.15.18) command) Shift+F2 Toggles the display of the command bar. Shift+F3 Turns the Status Bar on/off (StatBar (6.27.51) command). Shift+F4 Turns the Scroll Bars on/off (ScrollBar (6.27.10) command). Shift+F8 Launches the Visual Basic Project Manager (VbaMan (6.32.4) command). Shift+F11 Launches the VBA COM Add-In Manager (AddInMan (6.4.3) command). PgUp Moves the view up. PgDn Moves the view down. Shift+Left Arrow Moves the view to the left. Shift+Right Arrow Moves the view to the right. Shift+Up Arrow Moves the view up. Shift+Down Arrow Moves the view down.

1.15.2 The BricsCAD Application Window

The color theme

The COLORTHEME system variable controls the color theme of the BricsCAD application window. COLORTHEME = 0: Dark color theme: (1.170 on the next page) COLORTHEME = 1: Light color theme: (1.171 on the facing page)

Figure 1.170

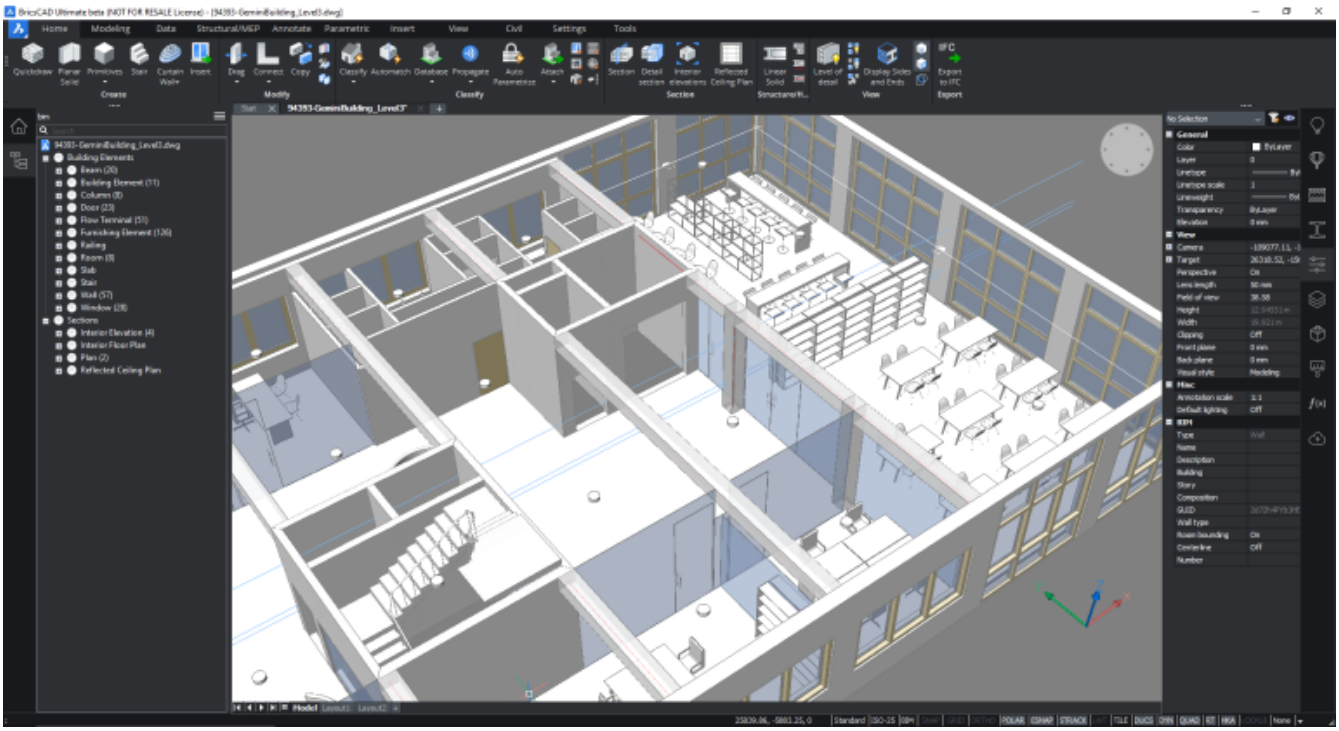

Figure 1.171

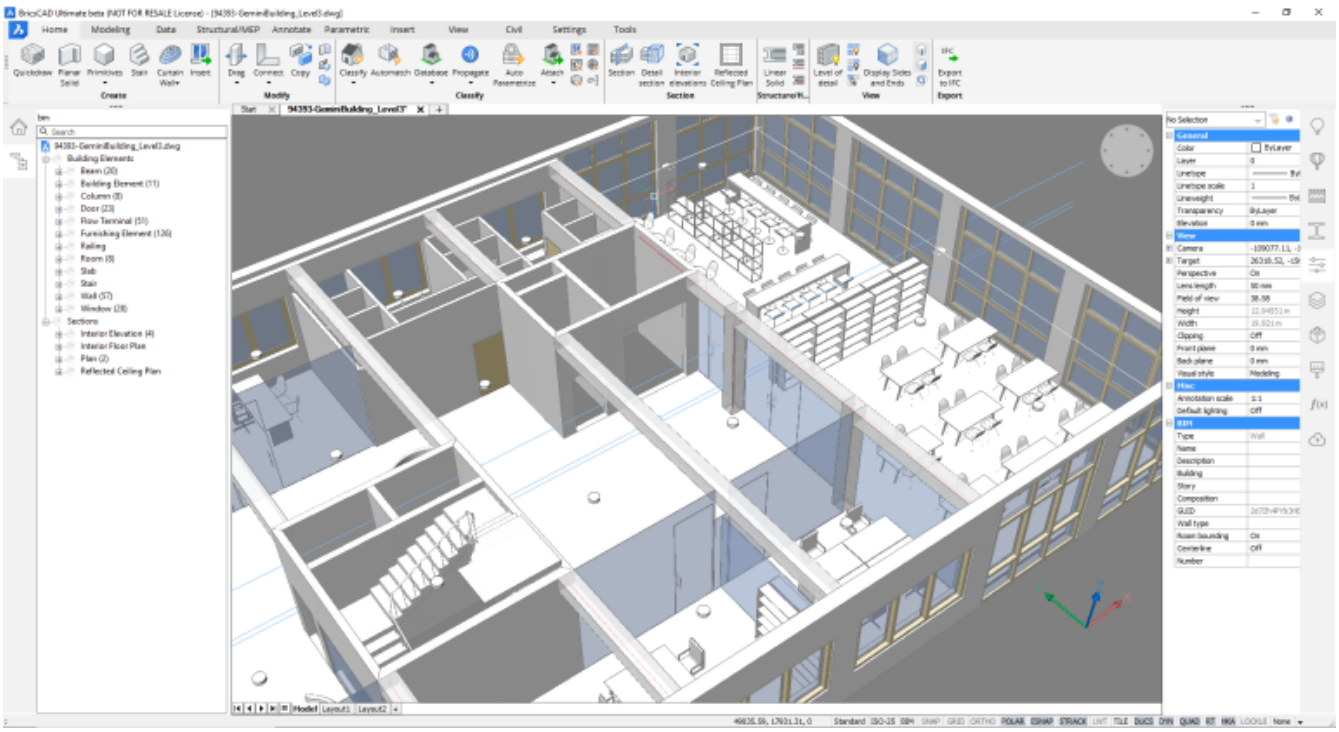

Setting the color theme Do one of the following:

- Type colortheme in the command line and choose **1** for light or **0** for dark.
- Right-click on a toolbar or ribbon panel and select **Dark Interface** in the context menu.

Understanding the BricsCAD application window

(1.172 on the next page) (1.173 on the facing page) Place the cursor over the ribbon then use the scroll wheel to select a tab.

Figure 1.172

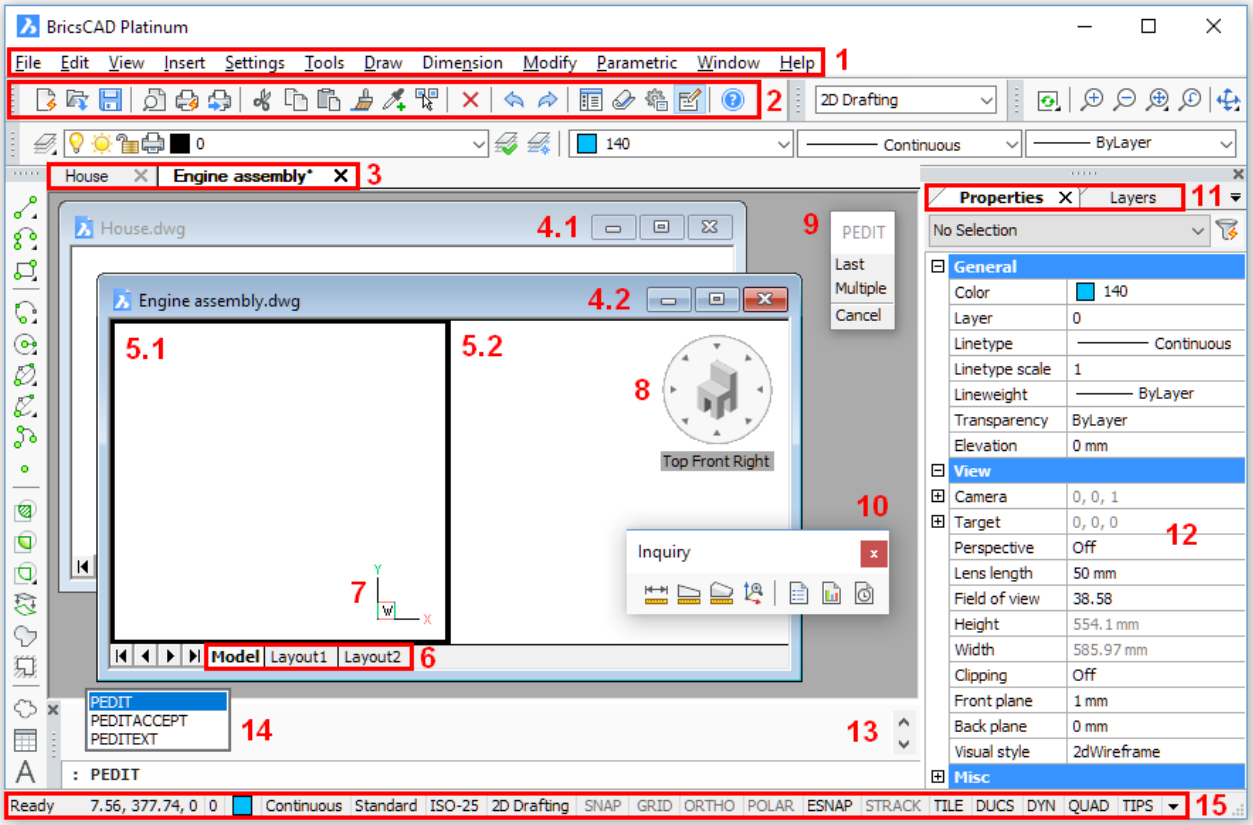

Figure 1.173

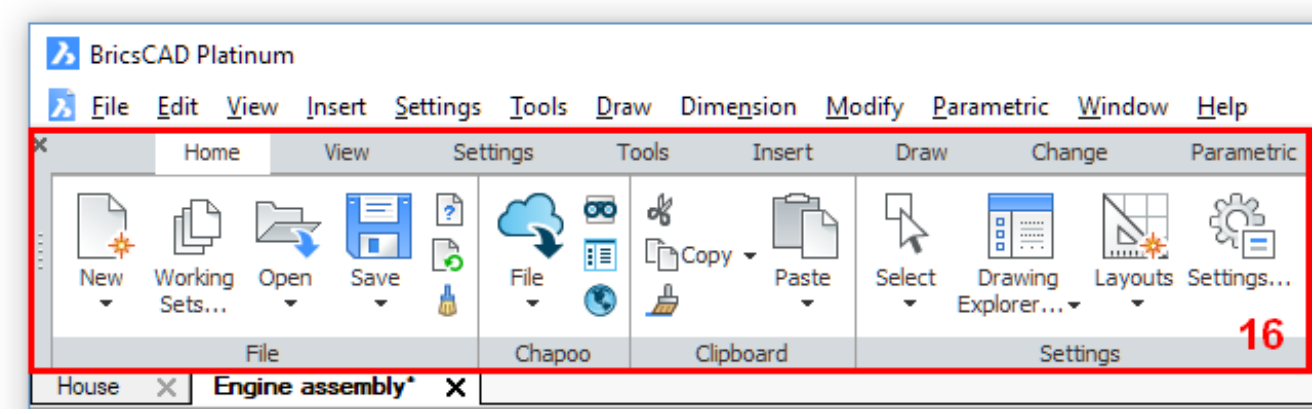

Components of the BricsCAD application window:

1. Menu Bar
2. Toolbar (docked)
3. Document tabs
4. Drawing windows
5. Drawing viewports
6. Window tabs
7. UCS icon
8. Look From widget
9. Prompt Menu

Hiding the ribbon

Do one of the following:

- Execute the RibbonClose (6.26.49) command.
- Right click an empty space in the Layout or Drawing tab area and choose **Ribbon** in the context menu.

Setting the Ribbon tool size

The size of the tool buttons in the Ribbon is controlled through the RIBBONTOOLSIZE system variable. You can choose between small, large or extra-large buttons.

Working with document tabs

Document tabs allow you to:

- Easily switch between all open drawings.
- Drag and drop the tabs to change their order.

Click the **X** at the right-hand side of tab to close it. Right click on a document tab to display a context menu: (1.175 on the facing page)

Item	Description
Close	Closes the current drawing (Close (6.9.18) command).
Close Left Tabs	Closes the drawings at the left of the current tab.
Close All But This	Closes all drawings except the current one.
Close All	Closes all drawings (WCloseAll (6.33.5) command).
Open	Displays the **Open Drawing** dialog (Open (6.23.8) command).
New	Displays the **Create New Drawing** dialog (New (6.22.5) command).
Save	Saves the current drawing (Save (6.27.1) command).
Save All	Saves all open drawings (SaveAll (6.27.2) command).
Save As	Launches the SaveAs (6.27.3) command.
Position	Lets you select the position of the document tabs. (1.205 on page 287)
Duplicate Tab	Saves a copy of the current drawing in a new tab, while keeping the original drawing open. Displays the **Save As** dialog.
Restore Last Session	Opens the drawings that were open in the previous BricsCAD session.
Open Folder	Opens the folder of the current drawing.
Cascade	Cascades the windows of the current drawings (WCascade (6.33.2) command).
Tile Horizontally	Tiles the windows of the current drawings horizontally (WhTile (6.33.13) command).
Tile Vertically	Tiles the windows of the current drawings vertically (WvTile (6.33.16) command).

The display and location of document tabs is controlled through a system variable and user preferences. In the Settings (6.27.25) dialog box, go to **Program Options > Display > Document tabs** .

- SHOWDOCTABS: controls the display of document tabs. (Default = ON)
- DocTabPosition : controls the location of the document tabs: top, bottom, left or right. (Default = Top)
- SaveOnDocSwitch: automatically save the drawing when clicking another document tab. (Default = OFF)

Opening or closing the command line

Do one of the following:

- Launch the COMMANDLINE (6.9.25) command.
- Use the Shift+F2 keyboard shortcut.
- Choose **Command Bar** in the **View** Menu.
- Move the cursor over a docked toolbar, the ribbon or a panel icon, then right-click and choose **Panels > Commandline** in the context menu.
- Double click the the far left side of the **Status Bar**.

The **Command line** closes if it was open and vice versa.

Setting the command line state

The command line can either be docked or floating. By default, the command line is docked at the bottom of the BricsCAD application window: (1.176) Click the **Close** (x) button to close the command line. Move the cursor over the dotted left hand side, then press and hold the left mouse button to make the command line floating: (1.177 on the next page) When the command line is floating, set the value of the **CmdLineUseNewFrame** user preference to 1 to minimize the command line to a single line. When executing a command a number of prompt lines display temporarily and transparently in the graphic screen:(1.178 on the facing page) When you move the command line mini-frame near the bottom of the graphic screen, it will stick there. The behavior of the new command line mini-frame is controlled through a series of variables:

- **CmdLineUseNewFrame** : controls whether the new frame is used when the command line is floating.
- **CLIPROMPTLINES:** controls the number of prompt lines in the command history. A value of zero disables this feature.
- **CmdLineFadingLogFadeDelay:** sets the display time of the prompt lines before they start fading.
- **CmdLineFadingLogTransparency:** sets the transparency of the command history lines.

NOTES

- You can modify the height of the docked command line by dragging its top or bottom edge, depending on its docking position (bottom or top).
- You can change the size of a floating command line by dragging one of its edges.
- You can browse the command history with the up arrow and down arrow keys of the keyboard.
- When the command line is closed, command options and keyboard entries display in the status bar.
- Press the F2 function key to toggle the Command History (6.29.16) window.

Figure 1.176

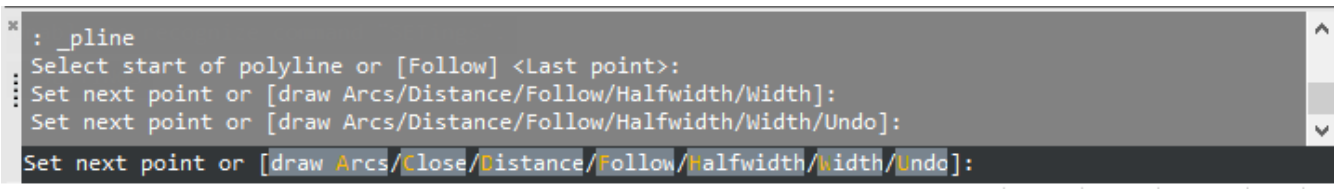

Figure 1.177

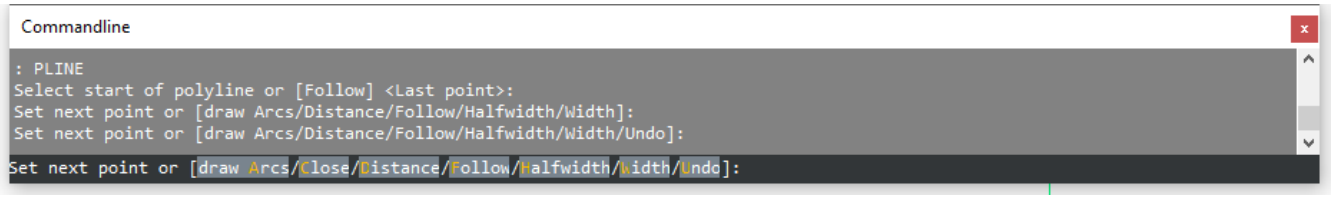

Figure 1.178

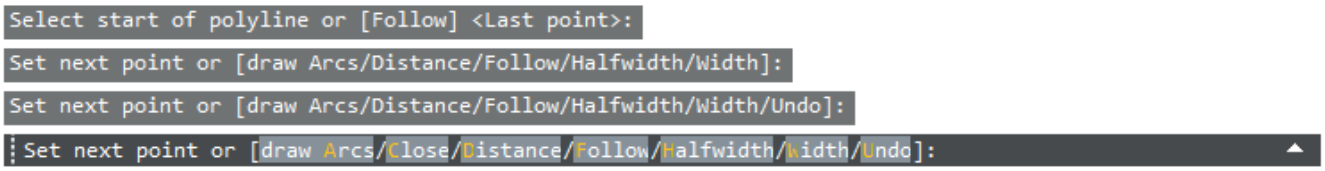

Launching a command in the command line

If the Enable flag of the AUTOCOMPLETEMODE (1.17.10) system variable is set, command entries are completed automatically as you type. All commands and/or system variables and/or user preferences that contain the current character string display in the **Suggestion** list: (1.179)

Do one of the following:

- Press Enter to choose the highlighted command.
- Use the down or up arrow key to choose a command, then press Enter.
- Click a command in the list.
- Complete the command name, then press Enter.

To choose a command option, click the option in the prompt or type the capitalized letter then press Enter. Autocomplete options are: (1.180 on the following page)

Figure 1.179

Auto complete mode	0x002F (47)
1	☑ Enable
2	☑ Auto-Append
4	☑ Suggestion List
8	☑ Display Icons (unsupported)
16	☐ Exclude the display of System Variables
32	☑ Display preference variables
Auto complete delay	0.3

Setting the command line properties

Tutorial: Customizing the Command Prompt in BricsCAD Click here to watch.

1. Open the Settings (6.27.25) window.
2. Go to **Program Options > User Preferences > Command Line.**

Opening or closing the status bar

Do one of the following:

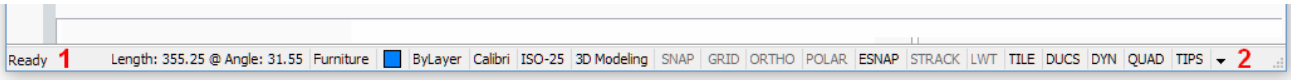
- Choose **Status Bar** in the **View** Menu.
- Press the **Shift + F3** keyboard shortcut.

The **Status Bar** closes if it was open and vice versa.

Working with the status bar

(1.181)

Figure 1.181



1. Status field:

- Displays the status of the software.
- When the cursor is in a menu or on a toolbar, it gives a brief description of the tool or menu item under the cursor.
- When the command window is closed, it displays the command prompts, tool options and keyboard entry.
- Double click the status field to open or close the **Commandline**.

2. Field List button: Click the arrow button ( ) to display a list of available **Status Bar** fields. Click an item in the list to toggle the display of the corresponding field in the **Status Bar**: (1.182 on the following page) **Cursor co-ordinate values**: displays the coordinates of the current cursor position (depending on the setting of the COORDS (1.17.10) variable).

1. Click to cycle the **Coordinate** setting. The sequence is **Geographic** , **Relative** , **Absolute, Off.**
2. Right-click and choose an option in the context menu. (1.183 on page 279)

Current Layer: displays the name of the current layer.

1. Click to open the **Layer Explorer**.
2. Right-click to select the current layer in the context menu.
3. Right-click and choose **Properties** in the context menu to open the Drawing Explorer - Layers (6.13.17).

Current Color: displays the current color.

1. Click to open the **Select Color** dialog window.
2. Right-click to select one of the basic colors. (1.184 on page 279)
3. Right click and choose **Select Color...** to select a color (1.25.5).

Current Linetype: displays the name of the current linetype.

1. Click to open the **Linetype Explorer** .
2. Right-click to select the current linetype.
3. Right-click and choose **Properties** in the context menu to open the Drawing Explorer - Linetypes (6.20.32).

Current Text Style: displays the name of the current text style.

1. Click to open the **Styles Explorer** .
2. Right-click to select the current text style.
3. Right-click and choose **Properties** in the context menu to open the Drawing Explorer - Text Styles (6.27.55).

Current Dimension Style: displays the name of the current dimension style

1. Click to open the **Dimensions Settings** dialog window.
2. Right-click to select the current dimension style.
3. Right-click and choose **Properties** in the context menu to open the Drawing Explorer - Dimension Styles (6.11.19).

Current Work Space: indicates the current workspace.

1. Click to set the value of the WSCURRENT (1.17.10) system variable in the commandline.
2. Right-click and choose the current workspace. (1.185 on page 279)
3. Choose **Customize** in the context menu to open the Customize - Workspaces (1.17.11) dialog box.

Snap: toggles the SNAPMODE (1.17.10) system variable.

1. Click to toggle Snap (6.27.41) **On** (SNAP) / **Off** (SNAP).
2. Right-click and choose **Settings** to edit the **Snap and Grid** settings. (1.196 on page 283)

Grid: toggles the GRIDMODE (1.17.10) system variable.

1. Click to toggle the display of the Grid (6.15.23) **On** (GRID) / **Off** (GRID) in the current viewport.
2. Right-click and choose **Settings** to edit the **Snap and Grid** settings. (1.196 on page 283)

Ortho: toggles the ORTHOMODE (1.17.10) system variable. Turning on **Orthogonal mode** automatically disables **Polar Tracking.**

1. Click to toggle Orthogonal mode (1.21.2) **On** (ORTHO) /**Off** (ORTHO).
2. Right-click and choose **Settings** to edit the **Orthomode** setting. (1.196 on page 283)

Polar: toggles the **Polar Tracking** option of the AUTOSNAP (1.17.10) system variable.

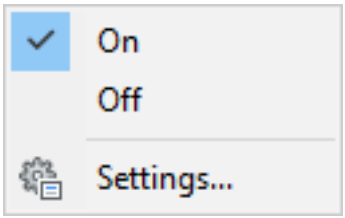

Figure 1.189

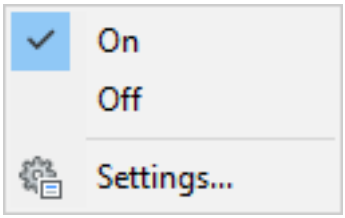

Figure 1.190

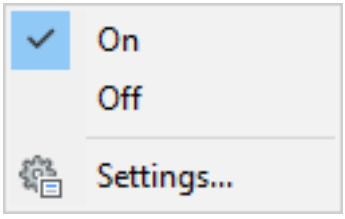

Figure 1.191

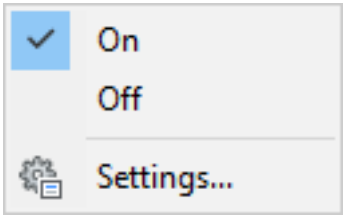

1. Click to toggle Polar Tracking (1.21.18) **On** (POLAR) / **Off** (POLAR). Turning **Polar Tracking** on automatically disables **Orthogonal mode** .
2. Right-click and choose **Settings** to edit the **Polar Tracking** settings. (1.196 on page 283)

Esnap: toggles the **Turn of all snaps** option of the OSMODE (1.17.10) system variable.

1. Click to toggle Entity Snaps (1.21.15) **On** (ESNAP) / **Off** (ESNAP).
2. Right-click and choose **Settings** to edit the **Entity Snaps** settings. (1.196 on page 283)

Strack: toggles the **Entity Snap Tracking** option of the AUTOSNAP (1.17.10) system variable.

1. Click to toggle Snap Tracking (1.21.17) **On** (STRACK) / **Off** (STRACK).
2. Right-click and choose **Settings** to edit the **Snap Tracking** settings. (1.196 on page 283)

Lineweight (LWT): toggles the LWDISPLAY (1.17.10) system variable.

1. Click to toggle the display of Line Weights (1.25.7) **On** (LWT) or **Off** (LWT).
2. Right-click and choose **Settings** to edit the **Lineweights** settings. (1.196 on page 283)

Paper/Model (1.23.12): allows you to choose between model space and paper space.

- When working in Model Space, the field reads: **Tile** (= Model space with tiled viewports). Click to switch to the most recently opened paper space layout. Right click to choose a paper space layout: (1.193 on the next page)
- When working in a layout, the field reads:
  M:Layout: Model space with floating viewports or
  P.Layout: Paper space Click to toggle between paper space and model space with floating viewports. Right-click and choose: (1.194 on the following page)
- **Paper Space**: Switch to paper space.
- **Model Space**: Switch to model space with floating viewports.
- **Model**: Switch to model space with tiled viewports.
- **Layout**: Switch to the selected paper space layout.

Figure 1.192

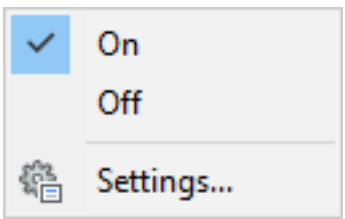

Figure 1.193

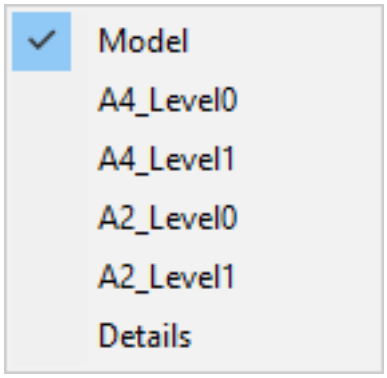

Figure 1.194

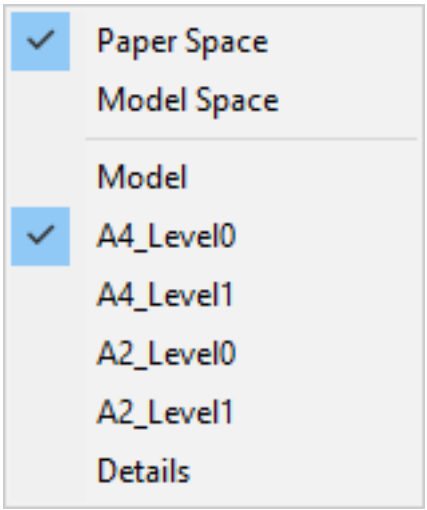

Figure 1.195

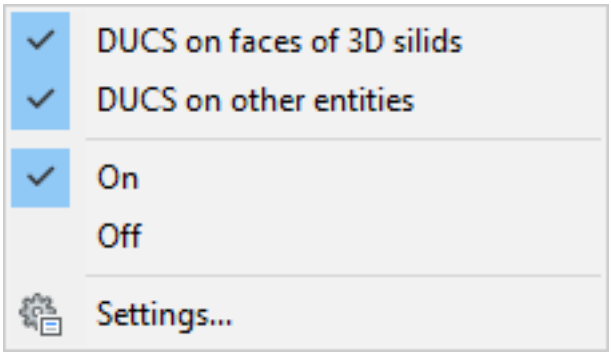

Figure 1.196

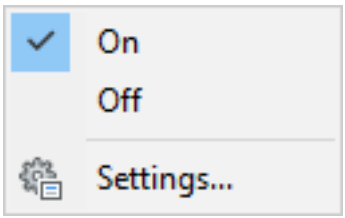

Annotation Scale: displays the value of the CANNOSCALE (1.17.10) (= current annotation scale) system variable. Right-click and:

1. Select an annotation scale in the list.
2. Choose Custom to launch the ScaleListEdit (6.27.7) command.
3. Check the **Hide Xrf scales** option to list annotation scales of the current drawing only.

Autoscale: Click to toggle the ANNOAUTOSCALE (1.17.10) system variable. **Tablet**: Initializes the use of a drawing tablet (1.15.8). **Viewport Lock** (VPLOCK): displays the Display Lock status of the current viewport or the selected viewport(s). Click the VPLOCK field to toggle the Display Lock property. The VPLOCK field only displays when one or more paper space viewports are selected or when a viewport is active (Model space with floating viewports). **Dynamic UCS (1.21.20)** (DUCS)

1. Click to toggle the UCSDETECT (1.17.10) system variable On (DUCS) or Off (DUCS).
2. Right-click to select the supported entity types: (1.195)

Dynamic Input (DYN): Toggles the **Switch all off temporarily** option of the DYNMODE system variable.

1. Click to toggle the display of Dynamic Dimensions (1.21.9) **On** (DYN) or **Off** (DYN).
2. Right-click and choose **Settings** to edit the **Dynamic Dimensions** settings. (1.196)

Quad (1.15.5): toggles the **Switch off** option of the QUADDISPLAY (1.17.10) system variable.

1. Click to toggle the display of the Quad (1.15.5) **On** (QUAD) or **Off** (QUAD).
2. Right-click and choose an option in the context menu.
3. Right-click and choose **Settings** to edit the **Quad** settings. (1.197 on the next page)

Rollover tips (1.15.5) (RT): toggles the ROLLOVERTIPS (1.17.10) system variable.

1. Click to toggle the display of rollover tips.
2. Right-click to select the display options for rollover tips: **On hovering entities** or **No rollover tips** . (1.198 on the following page)

Hotkey Assistant (HKA): toggles the HOTKEYASSISTANT system variable. When switched ON, an assistant widget at the bottom of the screen reveals options available by pressing the Ctrl key. (1.199 on the next page)

Figure 1.197

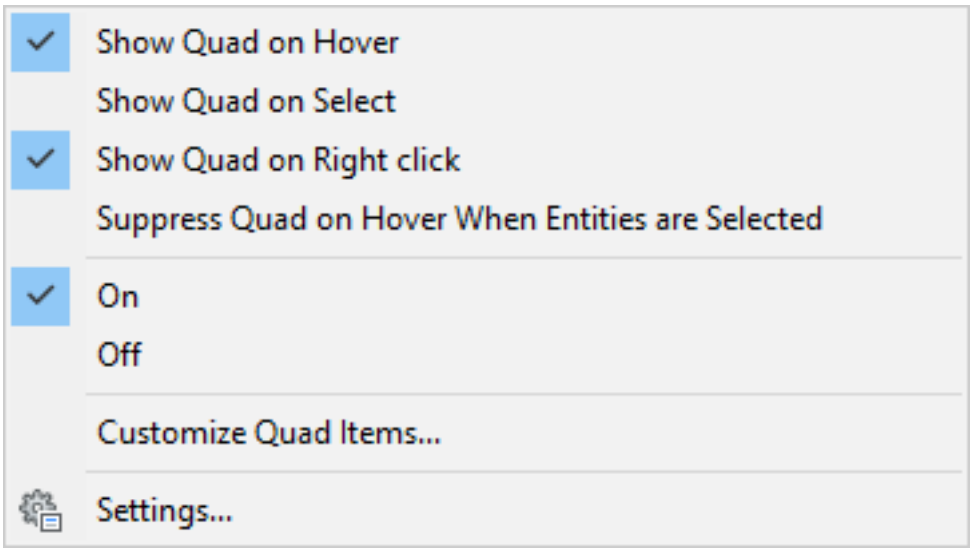

Figure 1.198

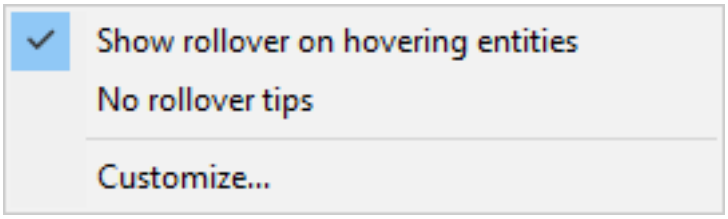

- Click to toggle the display of the HKA widget on/off.
- Right-click to display a context menu: (1.200 on the facing page)
- Click **On** or **Off** to set the display of the the HKA widget.
- Click **Configure** to display the **Hotkey Assistant Configuration** dialog. Select the commands for which you want the the HKA widget to display when HOTKEYASSISTANT = ON. (1.201 on the next page)

Lock User Interface (LOCKUI): allows you to lock the location and size of toolbars and dockable panels. Press Ctrl to override. Click the LOCKUI field to toggle the lock. Press Ctrl to override. Which user interface elements are affected is controlled through the LOCKUI (1.17.10) system variable. (1.202 on the facing page) **GIS Coordinate System**: displays the name of the current GIS coordinate system.

Figure 1.199

Figure 1.201

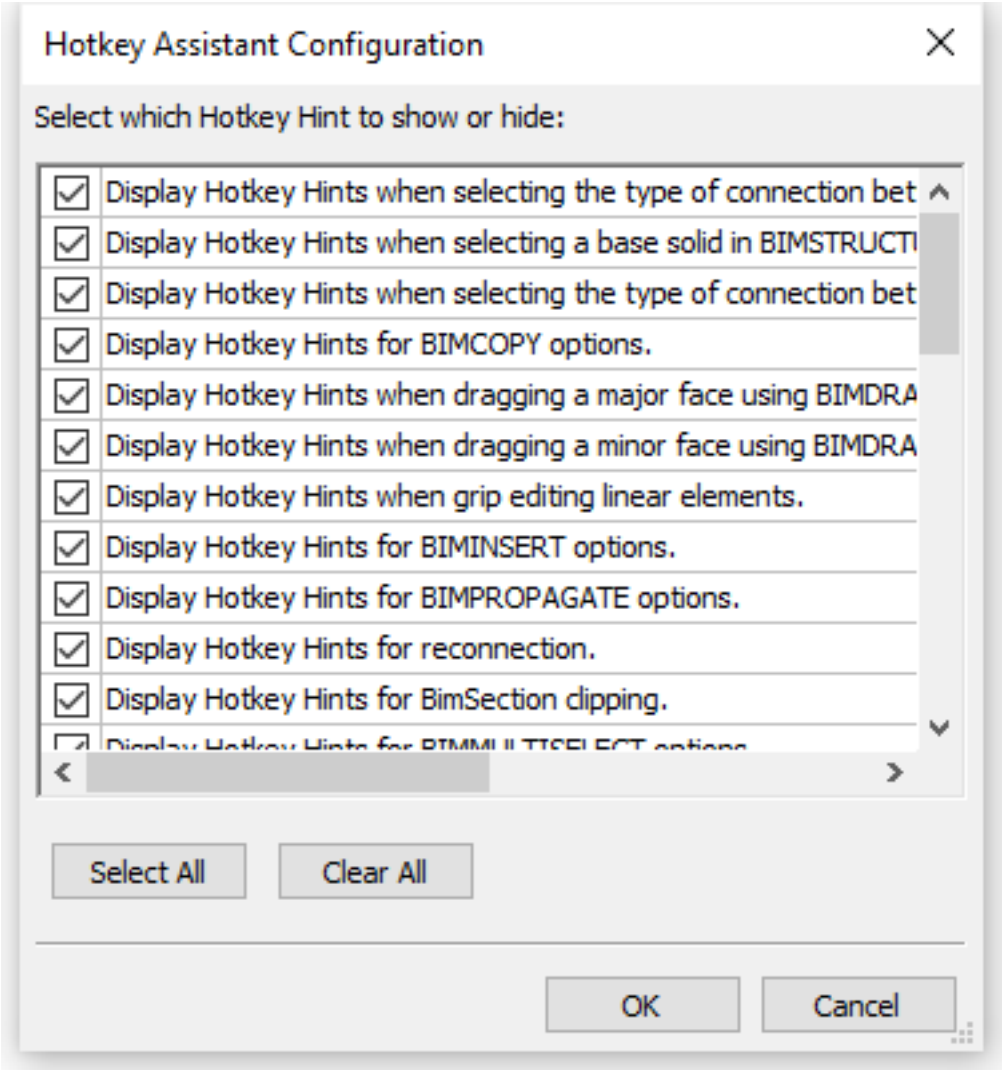

Figure 1.202

Displaying or hiding scroll bars

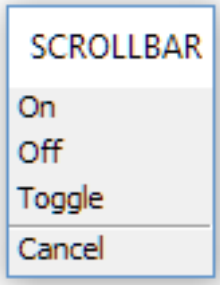
To toggle scroll bars on/off:

1. (option) Hold down the Shift key and press the **F4** function key.
2. (option) Choose **Scroll Bars** in the **View** menu. (1.203)
3. (option) Type **scrollbar** in the command bar and do one of the following:
   - type **off** in the command bar or choose **Off** in the context menu.
   - type **on** in the command bar or choose **On** in the context menu.
   - type **T** in the command bar or choose **Toggle** in the context menu. (1.204 on the facing page)

NOTE	Use the -ToolPanel (6.29.37) command to show, hide or toggle the display of the various tool panels.

Figure 1.203

Figure 1.204

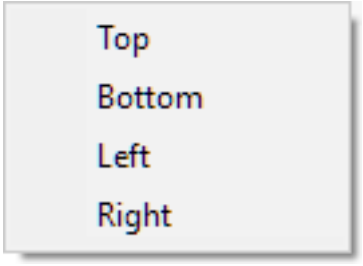


Hiding or showing a selection of user interface elements

The CleanScreenOn (6.9.17) and CleanScreenOff (6.9.14) commands allow you to hide or show a selection of user interface elements simultaneously. The user interface elements that are affected by these commands is defined by the CLEANSCREENOPTIONS (1.17.10) system variable. The Ctrl+0 keyboard shortcut toggles the display of user interface elements. On AZERTY-keyboards:

- Do not use the numeric keypad.
- Do not press the Shift-key when hitting the number key.

Figure 1.205



1.15.3 Toolbars

The availability of a command depends on the license Level (**??**) (Shape - Classic - Pro - Platinum - Mechanical - Bim - Ultimate) as indicated in the command articles in the Command Reference section of the Bricys Help Center.

To set the icon size

You can choose between small (16 x 16) large (32 x 32) or extra large (64 x 64) icons on toolbars.

1. Move the cursor over a toolbar, then right click.
2. Choose **Toolbar size** then select either **Small Icons**, **Large Icons** or **Extra Large Icons**.

Small

Large

Extra Large

The icon size is saved in the **Tool Button Size** property of the current Workspaces (1.17.11). (1.206 on the next page)

Toolbar Flyouts

On some tool buttons a small black arrow at the bottom right corner of the icon indicates a flyout is available. A flyout holds a group of related tools. Press and hold the left mouse button to expand the flyout and choose one of the flyout tools. The tool that was last chosen remains visible in the collapsed toolbar. Each of the flyouts can be opened as a separate toolbar. Drag the button of a toolbar flyout into the drawing area to open it as a floating toolbar.

Opening a toolbar

1. In **Windows** : Hover over a toolbar or a blank portion of the toolbar area, then right click. In **Linux** : Hover over a blank portion of the menu bar, status bar or toolbar area, then right click. A context menu displays. (1.207 on the next page) (1) Main CUI file (1.17.3). (2) Partial CUI file(s) (1.17.3) (3) Click here for more toolbars (4) Flyout toolbar menu
2. In the context menu choose either the Main CUI file (e.g. BRICSCAD) or one of the Partial CUI files (if any). A list of available toolbars in the selected CUI file displays. Toolbars that are already open are checked. If the list does not fit on the screen, click More (3) at the bottom of the menu. Related toolbars are grouped in a flyout menu (4).
3. Select the toolbar on the context menu. The toolbar opens.
4. (option) Dock the toolbar by dragging the toolbar by its title bar to one of the edges of the BricsCAD application window.

NOTES

- If you select a toolbar that was already open, it will be closed.
- To prevent a toolbar from docking, press and hold the Ctrl key while dragging the toolbar.
- Drag a toolbar by the grip at its left edge (when docked horizontally) () or top edge (when docked vertically) edge to undock.
- To dock a toolbar vertically in **Linux** , the **Position** property of the toolbar must be set to **Left** or **Right** .
- The LOCKUI (1.15.2) system variable allows to lock the location and size of toolbars and dockable panels (1.15.7). Press and hold the Ctrl-key to override. Click the **LOCKUI** field in the Status Bar (1.15.2) to toggle the locking of the user interface.

To tear off a flyout toolbar

1. Press and hold the left mouse button to drag the visible icon of a flyout toolbar into the drawing area.
2. Release the left mouse button to place the toolbar.

Closing a toolbar

1. In **Windows** : Place the cursor on a toolbar, then right click. In **Linux** : Place the cursor on the menu bar, then right click. A context menu displays.
2. Choose **BRICSCAD** on the context menu. Toolbars that are open are checked.
3. In the toolbar list, uncheck the toolbar you want to close.

NOTE Floating toolbar can be closed by clicking the **Close** button ().

To set the position and visible property of a toolbar

The **Visible** property determines whether a toolbar is visible when a CUI-file is loaded. The **Position** property determines where a toolbar displays when a CUI-file is loaded.

1. In the Customize dialog (1.17.4) click the **Toolbars** tab.
2. If necessary, expand the **BricsCAD** menu group.
3. Select the toolbar.
4. Choose **Position** in the **Properties** grid on the **Customize** dialog.
5. Click the settings field and choose the desired position in the list. The options are: **Floating** , **Top** , **Left** , **Bottom** , **Right**
6. Choose **Visible** in the **Properties** grid on the **Customize** dialog.
7. Click the settings field and choose either **Show** or **Hide** in the options list.

1.15.4 Properties Panel

Command: PROPERTIES (6.24.54) In the **Properties** panel you can:

- Set the current properties: **color** , **layer** , **linetype** , **linetypescale** and **lineweight**
- Edit the properties of a single entity
- Edit the shared properties of a selection set
- Edit endpoints of lines and vertices of polylines graphically
- Compose a selection set using Quick Select (1.32.6).

To open the Properties panel

Do one of the following:

- Click the **Properties** tool button () on the **Standard** toolbar. The pressed state of the tool button indicates that the **Properties** panel is currently open. Click the tool button again to close the **Properties** panel.
- Right click when the cursor is on a toolbar or ribbon panel. A context menu displays. The marked items in the context menu are currently open. Select **Properties** in the context menu. (1.307 on the following page)
- Double click an entity, such as lines, circles, arcs, 3D solids ... The **Properties** panel opens, showing the properties of the selected entity. Double clicking entities such as texts, hatches, blocks or polylines start an editing command (See the **Mouse** tab on the Customize (1.17.4) dialog). (1.308 on page 315)
- Choose **Properties** in the **Modify** menu.
- Type **properties** in the command window, then press Enter.

(1.312 on page 322) **No selection** The current entity properties, current Elevation (6.13.4), View properties and Annotation scale (1.29.29) display	(1.315 on page 325) **Single entity selected** The properties of the selected entity display	(1.314 on page 324) **Multiple entities selected** The shared properties of the selected entities display. *Varies* indicates that the shared property has different values.

NOTE	The **Properties** panel is dockable panel (1.15.7). To dock the **Properties** panel, drag it by its title bar to either the left or right hand side of the BricsCAD application window or onto another dockable panel.

NOTE	Read-only fields display in grey. The content of a read-only field can be copied though. To copy a read-only field, click the field, then press Ctrl C.

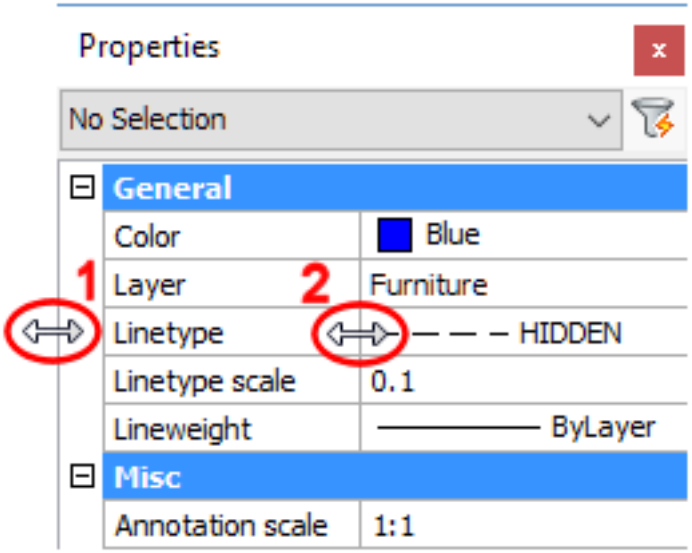
To adjust the size of the Properties panel

1. Move the cursor over one of the edges of the **Properties** (1). The cursor turns into a double-headed arrow.
2. Press and hold the left mouse button to drag the edge of the **Properties** . (1.309 on the next page)
3. Move the cursor over the boundary between the **Setting Names** and the **Setting Fields** columns (2). The cursor turns into a double-headed arrow.
4. Press and hold the left mouse button to drag the boundary.

NOTE	When docked, only the left (or right) edge of the **Properties** is adjustable.

Figure 1.309



Setting the current properties in the Properties panel

1. (option) Click on **Color,** then click the down arrow button to select a color.
2. (option) Click on **Layer,** then click the down arrow to select a layer.
3. (option) Click on **Linetype** . then click on the down arrow to select a linetype.
4. (option) Click on **Linetype scale** , then type the new value in the **Linetype scale** field.
5. (option) Click on **Lineweight**, then click on the down arrow to select a lineweight.

Restoring a previous state of an entity

1. Select the entity.
2. Select the **History** property.
3. Click the **History** field. The history of the selected entities is listed.
4. Hover over a step in the list to see the state of the entity in that step.
5. Click a step to restore a state.

Edit the properties of a single entity

1. Select the entity. The entity's properties display in the **Properties** panel.. (1.315 on page 325)
2. Click the property you want to modify. The settings field of the selected property is activated.
3. Type a new value in the settings field of the selected property or choose a setting from the list box, then press the **Enter** key or select another property. The entity is updated.
4. (option) repeat steps 2 and 3 to modify another property.
5. Press the **Escape** key to stop.

NOTES

- Properties of which the value displays in grey cannot be modified.
- Step 3: Properties (such as the General properties), which are chosen from a list are updated instantly.

To edit the endpoints of a line

1. Select the line.
2. In the **Properties Bar**, under **Geometry**, do one of the following:
   - Select the X-, Y- or Z- field, then enter a value

To edit the vertices of a polyline

1. Select the polyline.
2. On the **Properties Bar** under **Geometry** , select **Vertex**.
3. Click the **Next/Previous** arrow buttons to select a vertex. (1.311 on the following page) An X indicates the vertex being edited.
4. Do one of the following:
   - Select the X- or Y- field, then enter a value.
   - Under **Vertex** select **Position** and click the **Pick Point** button (), then specify the point in the drawing.
5. Press the **Escape** key to stop.

Edit the shared properties of a selection set

1. Select the entities. The shared properties display in the **Properties Bar**.
2. Click the property you want to modify. The settings field of the selected property is activated.
3. Type a new value in settings field of the selected property or choose a setting from the list box, then press the **Enter** key or select another property. All selected entities are updated simultaneously.
4. (option) Repeat steps 2 and 3 to modify another property.
5. Press the **Escape** key to stop.

NOTES

- *Varies* displays for shared properties which are defined differently. If you edit such property, all entities in the selection set will be equally defined for this property.
- Step 3: Properties (such as the General properties), which are chosen from a list are updated instantly.

1.15.5 The Quad cursor menu

The Quad cursor menu, aka the Quad is an alternative to grip-editing of entities, offering a (much) richer set of editing operations while requiring fewer clicks, without cluttering the screen with loads of grip-glyphs. The Quad can be used to:

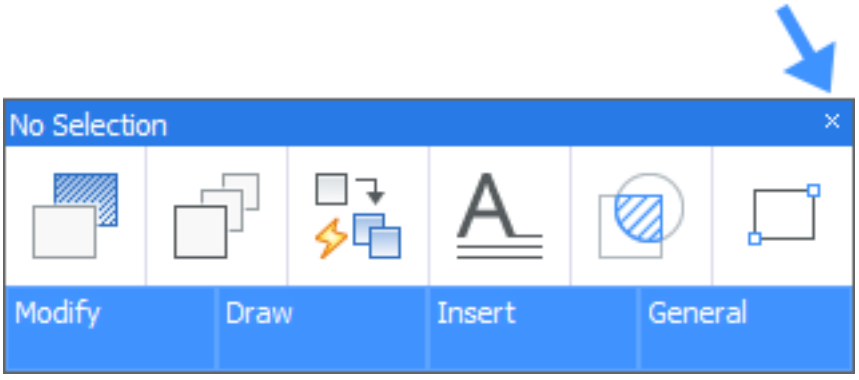
- Easy and fast editing of entities.
- Creating entities.

To activate the Quad

Activation of the Quad is controlled by the QUADDISPLAY (1.17.10) system variable. To toggle the Quad On/Off, do one of the following:

- Click the QUAD (1.15.2) field in the Status bar (1.15.2).
- Press the **F12** function key.
- Edit the **QUADDISPLAY** system variable in the Settings (1.17.10) dialog.
- Type **QuadDisplay** in the command bar, then choose an option.
- Click the **Close** button (x) at the top right corner of the Quad. (1.316)

Figure 1.316



Editing the Quad settings

1. Right click the **QUAD** field in the Status bar (1.15.2), then choose **Settings** in the context menu. The **Settings** dialog opens, showing the **Quad settings** : (1.317 on the following page)

   - **Quad display:** Determines when the Quad displays.
     - Negative: Switches the Quad off.
     - 1: When the cursor is over an entity. The entity under the cursor highlights.
     - 2: When entities are selected
     - 4: On right click when no entities are selected and there is no entity under the cursor.
     - 8: Suppress the quad when hovering over entities that are not in the current selection set; set Show **Quad on right click** ON to display the Quad.
   - **Quad default command launch** : Sets the action to launch the default Quad command.
     - 0: Click the button.
     - 1: Right click
   - **Quad popup corner** : Controls the popup position of the Quad relative to the cursor position: **Upper** , **Center** or **Middle Right** .
   - **Quad width** : Defines the number of commands in a row. Default = 6 commands.
   - **Quad icon size** : Small icons (16 x 16 pixels), Large icons (32 x 32 pixels) or Extra Large icons (64 x 64 pixels).

(1.331 on page 338) Small Icons (1.329 on page 338) Extra Large Icons	(1.328 on page 337) Large Icons

   - **Quad icon space** : Defines the space around the Quad tool buttons: narrow, normal or large

(1.330 on page 338) Narrow	(1.331 on page 338) Normal	(1.332 on page 338) Wide

   - **Quad show delay** : Sets the time lap in milliseconds between the highlighting of the entity and the Quad display.
   - **Quad hide delay** : Sets the time lap in milliseconds to hide the Quad when the cursor is outside the **Quad hide margin** limit.
   - **Quad hide margin** : Sets the distance in pixels the cursor can move away from the Quad. If the cursor moves outside this limit, the Quad is hidden.
   - **Quad go transparent** : Defines whether the Quad becomes transparent when the mouse moves outside the Quad, but within the **Quad hide margin** .
   - **Quad tooltip delay** : Sets the delay time in milliseconds to display tooltips. If the value is negative, no tooltips display.
   - **Quad expand delay** : Sets the time lap in milliseconds to expand the Quad after mouse-enter.
   - **Quad expand tab delay** : Sets the time lap in milliseconds to expand a group tab after mouse-enter.
   - **Rollover tips** : Specifies whether entity properties display in the Quad while hovering (1.15.5).
   - **Rollover opacity** : Specifies the degree of opacity when the Quad is in rollover state. Values between 10 (very transparent) and 100 (fully opaque) are accepted.
   - **Rollover selection set** : Controls the content of Rollover tips when multiple entities are selected.

2. To edit a setting, select the setting then do one of the following

   - Type a new value.
   - Click the check box.
   - Choose an option.

3. Close the **Settings** dialog.

Figure 1.317

Rollover selecion set	[2] Properties shared by all selected entities

The Quad layout

The layout of the Quad cursor menu depends on:

- The entity type under de cursor or the current selection set.
- The current Workspace (6.33.14).
- Geometric events such as intersection or tangency.
- When the cursor hovers over an entity, the entity highlights and the Quad displays the most recently used command with this entity type. When multiple entities are under the cursor, hit the TAB key to highlight all entities one by one. 

If QuadCommandLaunch = 1, right click without entering the Quad to launch the command. If QuadCommandLAUNCH = 0, click the command button.
- If Rollover Tips (2.2.3) = ON the properties of the entity under the cursor display in the Quad. (1.318) If the Quad display is off, rollover tips display if:
  - SELECTIONPREVIEW (1.17.10) = 1 or 3
  - ROLLOVERTIPS = ON (1.319 on the following page)
- Click a property to edit: (1.320 on the next page)

Which properties display for each entity type is specified in the Properties tab (6.9.47) of the Customize dialog box. Select an entity type in the left pane, then check properties in the **Rollover** pane. (1.321 on page 331)

- Move the cursor to the Quad to display the most recently used commands with this entity type. A number of command category tabs display at the bottom. (1.322 on page 331)
  - The number of buttons is controlled by the **QuadWidth** user preference.
  - Which command group tabs display depends on the current Workspace (6.33.14). See To edit the workspace command groups (1.15.5) to switch closed command groups on.
  - Click an icon to launch the command.
- Move the cursor over the tabs to expand the command group under the cursor. (1.323 on page 332) Click an icon to launch the command.

Note: When the Quad is expanded, click the title bar of the Quad to display the Rollover tips.

Figure 1.318

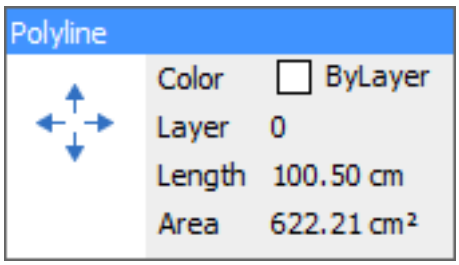

Figure 1.319

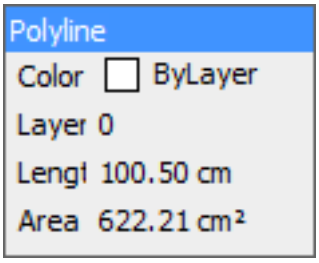

Figure 1.320

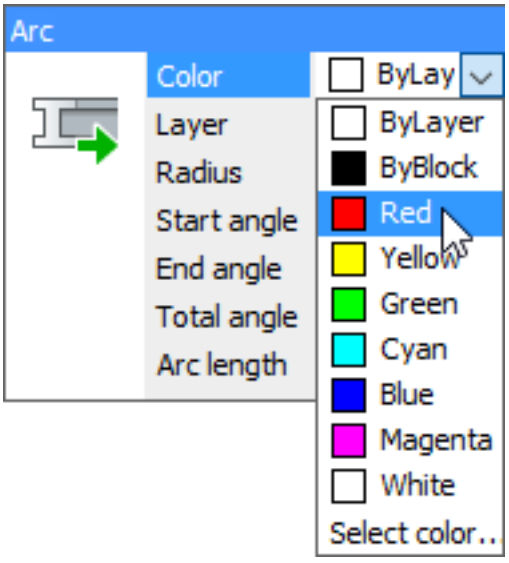

Figure 1.321

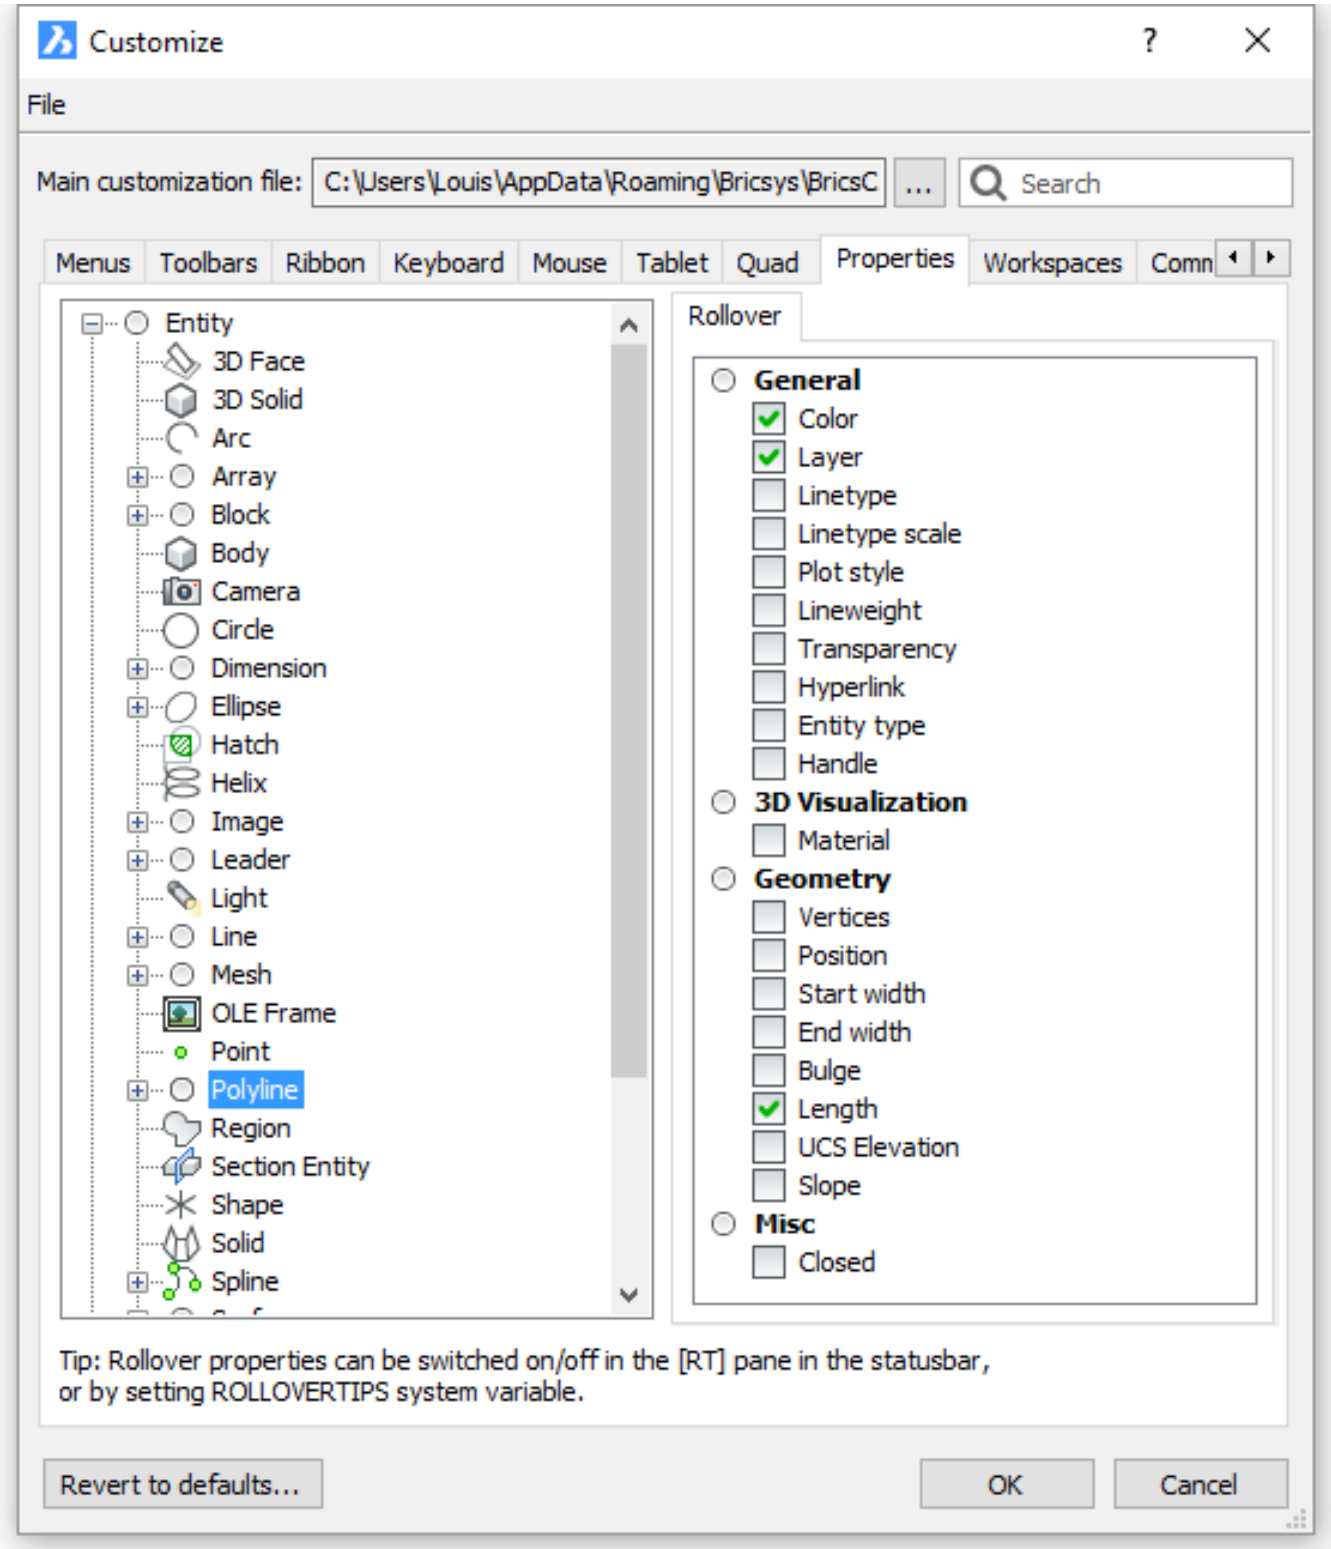

Figure 1.322

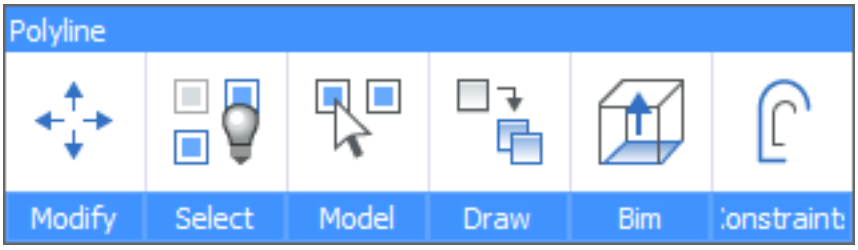

Figure 1.323

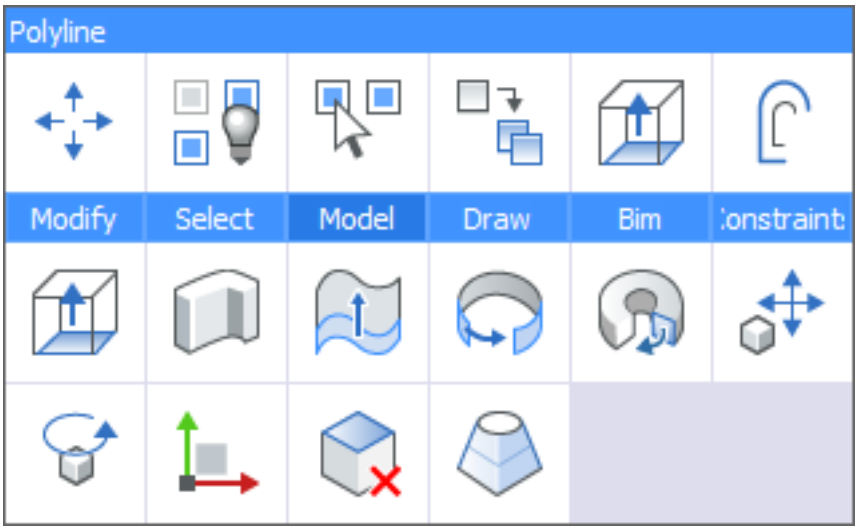


Using the Quad

1. Move the cursor to the entity you want to manipulate. The entity under the cursor highlights and the Quad displays the most recently used command with this entity type.
2. (option) Select more entities. See Selecting multiple entities.
3. Do one of the following:
   - Depending on the value of the QUADCOMMANDLAUNCH (1.17.10) system variable, either right click or click the Quad to repeat the most recently used command.
   - Move the cursor to the Quad and select a different command. See The Quad Layout.
4. Execute the command.

Tutorial: Experience the Quad Cursor in BricsCAD Click here (1.9.5) to watch

Selecting multiple entities

1. Move the cursor over the first entity, then click when the entity highlights. The entity is selected and remains highlighted.
2. Move the cursor to another entity, then click when the entity highlights. The entity is added to the selection set and remains highlighted.
3. (option) Repeat step 2 to select more entities.
4. (option) Move the cursor to a selected entity, then press and hold the Shift key and click. The entity is removed from the selection set.

NOTES

- When the Quad is active, SELECTIONPREVIEW (1.32.4) is neglected, unless a command prompts for entity selection.
- When working with solids:
  - The SELECTIONMODES (1.32.4) system variable controls which subentities are detected: edges, faces and/or boundaries. Holding down the Ctrl key inverts the current selection mode.
  - Click a button on the **Selection Modes** toolbar to toggle an option. A pressed button indicates the option is selected. (1.333 on page 338)
    -  Enable detection of 3D solid edges
    -  Enable detection of 3D solid faces
    -  Enable boundary detection
- Repeatedly press the TAB key to highlight all (sub)entities under the cursor one by one.

Selecting edges of faces or solids

Command: DmSelectEdges (6.12.26)

1. Select the faces and or solids. See Selecting multiple entities.

2. In the **Model** command group of the Quad cursor menu, click the **Select Edges** tool ( ). All edges of the selected faces and solids are selected.
3. (option) To remove edges from the selection set: press and hold the Shift key, then click the edge(s).

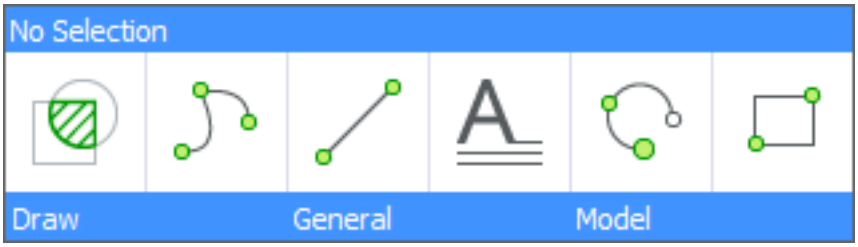
Using the Quad to create entities

If the flag 4 (= Display the Quad on right click) of the QUADDISPLAY (1.17.10) system variable is set, entity creation commands are available in the Quad (No Selection Quad). To set the **Display the Quad on right click** option: Right click the Quad (1.15.2) field in the **Status Bar** and check the option in the context menu. The available entity creation commands in the Quad are:

- The most recently used commands. The number of available commands depends on the **QuadWidth** user preference.
- A number of command group tabs, depending on the current workspace (6.33.14). (1.324)

NOTE	When the cursor is on an entity, hold down the right mouse button longer to display the **No Selection** Quad.

Figure 1.324



Customizing the Quad

To open the **Customize/Quad** dialog box, do one of the following:

- Right click the Quad (1.15.2) field in the Status Bar (1.15.2) and choose **Customize Quad items...** in the context menu.
- Run the Customize (6.9.47) command, then select the **Quad** tab.

The **Customize/Quad** dialog box has two section tabs that are involved in customizing the Quad:

- The **Quad** section: In this section, the name and content of all Quad Tabs can be specified, similar to the way Ribbon Tabs are customized. Quad Tabs can be created, copied, renamed and deleted. Manage the content of a Quad Tab by dragging buttons from the right side of the dialog, or by using the right-click context menu to add, rename, move or delete Quad Buttons. The right side of the dialog contains the full list of all buttons which can be shown in the quad. These include the tools defined in the cui file, plus all internally defined Quad Buttons, which are listed under the new 'Built-in' branch at the bottom. These built-in buttons are similar to the tools, only they can not be edited: their name, icon, command string etc.. are read-only. The condition which specifies whether a certain Quad Button will appear in the quad when the cursor hovers on an entity, is specified for each Quad Button individually in the 'Object Filter' property, similar to the way Object Context Menu Items are configured. It is not possible to modify the Object Filter of a built-in Quad Button.
- The **Workspaces** section: This section defines which Quad Tabs will be available in the Quad, in which order, and in which workspace. In this interface, you can add/move/remove entire Quad Tabs. The contents of the Quad Tabs is not shown nor editable in this section, as this is done in the Quad section of the dialog. When a new Quad Tab is created in the Quad section, this Quad Tab is automatically added to the Quad in all workspaces.

To edit the Quad tabs of a workspace

1. Move the cursor over a toolbar, then right click and choose **Customize** in the context menu.
2. Click the **Workspace** tab on the **Customize** dialog box.
3. Expand the workspace you want to edit.
4. Expand the **Quad Tabs** list. Tabs that are currently switched off display in grey. (1.325 on the next page)
5. To set the availability of a tab, select the tab then click the **Display** field in the Properties grid and choose **Yes** or **No**.
6. To add a tab do one of the following:
   - Right click the Quad Tabs node and choose Append Quad tab in the context menu to add a tab at the bottom of the tab list.
   - Select a tab, then right click and choose Insert in the context menu to add a tab above the selected tab.
   - On the **Select Ribbon Tab** dialog select the tab you want to insert and click the **OK** button. (1.326 on page 337)
7. To remove a tab, select the tab, then right and choose **Delete** in the context menu.
8. To change the tab order: drag and drop the tabs in the list.

1.15.6 Prompt Menus

BricsCAD commands often provide several options. These options appear in the status bar or command bar and also in a prompt menu, which initially displays at the top right corner of the screen. Choose an option by clicking in the prompt menu. E.g. click **Radius** in the **PLINE** prompt menu to define the radius of the current arc segment of a polyline.

(1.334 on the next page) Polyline prompt menu when drawing line segments	(1.335 on the following page) Polyline prompt menu when drawing arc segments

To control the display of prompt menus

Whether a prompt menu displays and its location is controlled through the **PROMPTMENU** system variable and the **PromptMenuFlags** user preference. Type **promptmenu** in the command bar, then type a value of 0 to 5 (see table below) and press Enter.

Value	Description
0	No prompt menus
1	Display prompt menu at user defined location (*)
2	Display prompt menu at top left corner
3	Display prompt menu at top right corner
4	Display prompt menu at bottom left corner
5	Display prompt menu at bottom right corner

(*) You can move the prompt menu by dragging it; future prompt menus will appear where you last placed it.

NOTES	The PROMPTMENU (1.17.10) system variable is saved in the registry and therefore applies to all drawings. The PromptMenuFlags (1.17.10) user preference has three options: • 1 = Show hidden options. Hidden options display in italics. • 2 = Hide the prompt menu when a command prompts to select entities. • 3 = Disable selection options in the prompt menu.

1.15.7 Dockable Panels

The following panels can be docked: Animation Editor (6.4.12), Attachments (6.4.30), BIM BCF, BIM Compositions (6.7.8), BIM Profiles, BIM Project Browser, BOM Manager, Bricsys 24/7 (2.11.2), Command Bar (6.9.25), Content Browser (6.9.32), Details (6.10.52), GPM Demo Properties, LayersPanelOpen (6.20.5), LibraryPanelOpen (6.20.23), Mechanical Browser (3.3.2), Parameters and Constraints (6.24.10), Properties (6.24.54), Render Materials (6.21.6), Report (6.8.35), Ribbon (6.26.32), Sheet Sets (6.27.38), Structure (1.32.15), Tips (6.29.27), Tool Palettes, (6.29.28)

NOTE	Use the -TOOLPANEL (6.29.37) command to show, hide or toggle the display of the various tool panels at the command line.

(1.336) Panels are docked at the left or right side of the screen as defined in the Panels property of a workspace in the Customize | (1.17.4) Workspaces (1.17.11) dialog: (1.337 on the following page)

- Panels | Stack (LDOCK) define the panels stacked a the left side of the screen.
- Panels | Stack (RDOCK) define the panels stacked a the right side of the screen.

The stack type is defined in the Customize | (1.17.4) Workspaces (1.17.11) dialog through the Stack Type property of a workspace. (1.338 on the next page) The possible stack types are:

- Fixed resizable panel set
- Collapsible panel set
- Flyout panel set

Figure 1.337

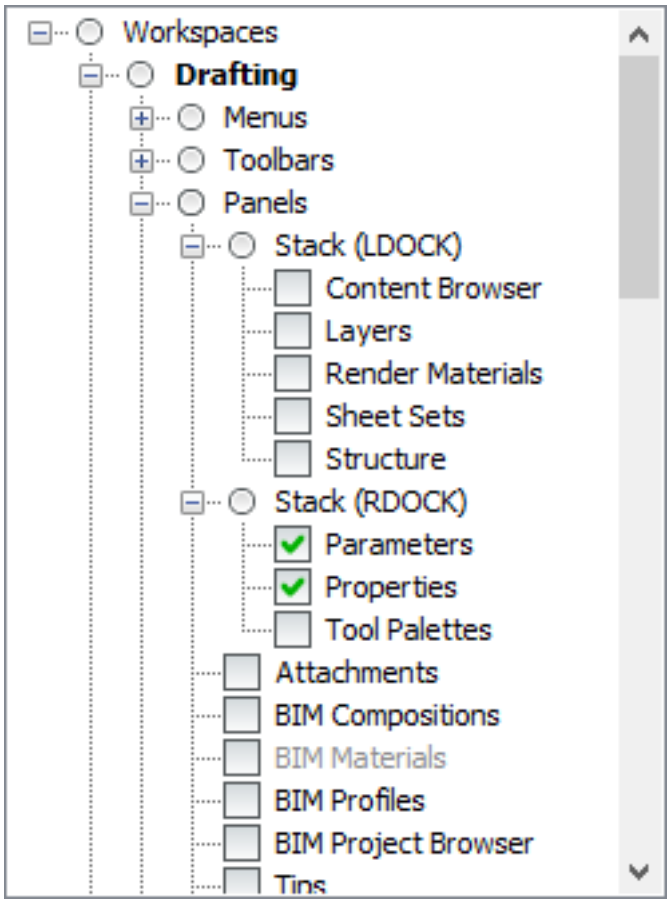

Figure 1.338

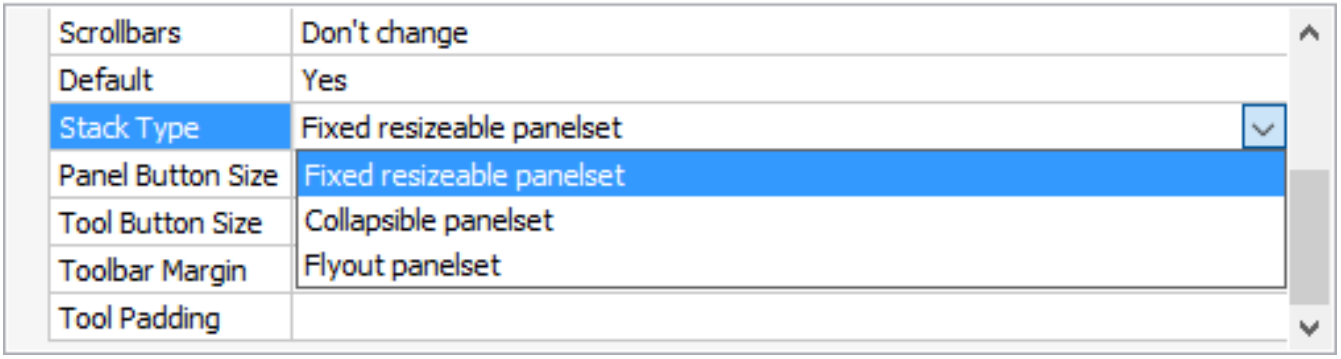
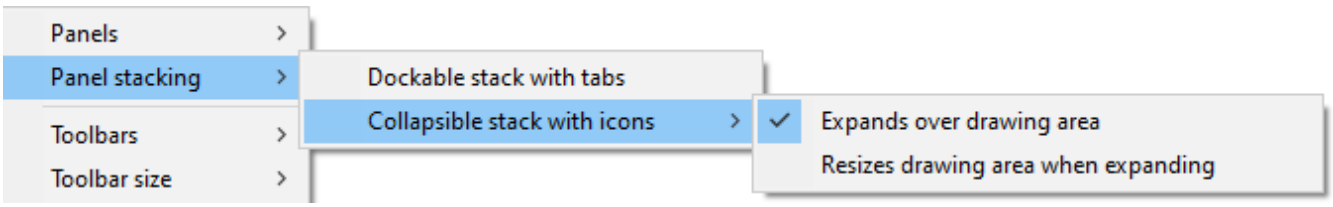


To set the stack type

1. Move the cursor over a toolbar or panel, then right click. A context menu displays.
2. Choose Panel stacking. (1.339)
3. Select the desired stack type.

Figure 1.339



Fixed resizable panelset

Panels are docked next to each other or in a tabbed panel. (1.340 on the next page)

- Click a tab to display the panel.
- Press and hold the left mouse button to drag a tab to re-arrange the tab order.
- Drag an tab into the graphic screen to make it floating.

Close

Collapsible panelset and Flyout panelset

Panels are docked at a default location in an icon strip at the left or right side of the screen. Flyout panels overlap the drawing area, thus hiding part of the drawing. Collapsible panels narrow the drawing area when expanded. (1.341 on the facing page)

- Click an icon to expand a panel. Only one panel in the same icon strip can be expanded.
- To collapse an expanded icon click its icon again.
- Press and hold the left mouse button to drag an icon to re-arrange the icon order.
- Drag the icon into the graphic screen or double click the icon to make the panel floating.

To dock a floating panel

Although panels can be docked at the top or bottom of the graphical screen, they are best placed at the left or right side. Do one of the following:

- Drag the panel by its title bar. A rectangle indicates the boundary of the panel. Release the left mouse button when the boundary rectangle is over an edge of the graphical screen.
- Double click the title bar to dock the panel at its previous location.

NOTE	The LOCKUI (1.17.10) system variable controls whether the current position docked and/or floating panels is locked or not. Press and hold the Ctrl-key to override. Click the **LOCKUI** field in the Status Bar (1.15.2) to toggle the locking of the user interface.

To move a panel to the other icon tab strip

1. Drag the icon to the other icon strip. The docking location selector displays. The blue zone indicates the selected docking position. (1.343)
2. Move the cursor over the center docking location then release the left mouse button.

LibraryPanelOpen (6.20.23) - Opens the Library panel. LibraryPanelClose (6.20.22) - Closes the Library panel.

1.15.8 Digitizing Tablet

Command: TABLET (6.29.8) **Overview**: The Tablet command configures (1.15.8) and calibrates (1.15.8) a digitizing tablet and toggles tablet mode (1.15.8). This command requires that Wintab32.dll from Wacom Technology, Corp. be installed on the computer. Download Wintab32.dll from the internet, then place the file in your system directory: C:\Windows\System32. A digitizing tablet, also called a graphics tablet, agraphics pad or drawing tablet, is a computer input device that allows you to hand-draw images and graphics, similar to the way one draws images with a pencil and paper. In a CAD program a digitizing tablet can be used to trace paper drawings into a drawing file or to launch drawing commands from a digitizing tablet overlay.

To use a digitizing tablet in BricsCAD

In order to prepare BricsCAD for using a digitizing tablet do the following:

- Install the appropriate driver for your tablet.
- Make sure Wintab32.dll exists in C:\Windows\System32.
- Download the tablet overlay and CUI files.
- Print the BricsCAD tablet overlay.
- Load the overlay CUI file.
- Start BricsCAD, then initialize the tablet.
- Configure the tablet: part of the tablet surface is used as the menu area, another part as the screen pointing area.
- Calibrate the tablet: a calibrated tablet can be used to trace the geometry of a paper drawing or image into a drawing.

To download the tablet overlay and the CUI files

Click here to download the file Tablet.zip. The ZIP file contains the following files:

- **overlay.png**: an image of the tablet overlay
- **overlay(A3).pdf**: to print the tablet overlay on a A3 paper size.
- **overlay(cm).dwg**: a DWG in which the **overlay.png** is attached as an image. The drawing contains two layouts to print the overlay using decimal units.
- **overlay(inch).dwg**: a DWG in which the **overlay.png** is attached as an image. The drawing contains two layouts to print the overlay using imperial units.
- **tablet.cui**: a partial cui file to be used with a tablet.
- **tablet(acadLike).cui**: an AutoCAD-like partial cui file to be used with a tablet.

To load the overlay CUI file

1. Extract the overlay CUI files to the **Support** folder of the **roamable root** folder (see BricsCAD User Files (1.17.2)). E.g. C:\Users\[user name]\AppData\Roaming\Bricsys\BricsCAD\V[version nummer]\en_US\Support\.
2. Load **Tablet.cui** as a partial CUI (see To load a partial CUI file (1.17.3)). The next time you start BricsCAD, **Tablet.cui** will be loaded automatically.

NOTES

- Please make sure the **overlay.png** image file is extracted to the same folder as the DWG's.
- It might be necessary to repeat the above procedure after upgrading BricsCAD.

To switch the tablet ON / OFF

Do one of the following:

- Click the **TABLET** field in the Status Bar (1.15.2).
- Press the **F4** function key to toggle the tablet mode.
- Choose **Tablet On** or **Tablet Off** in the **Settings** menu.
- Type **tablet** in the command bar, press Enter, then type **ON** or **OFF** ; or click **ON** or **OFF** in the prompt box.

Figure 1.344

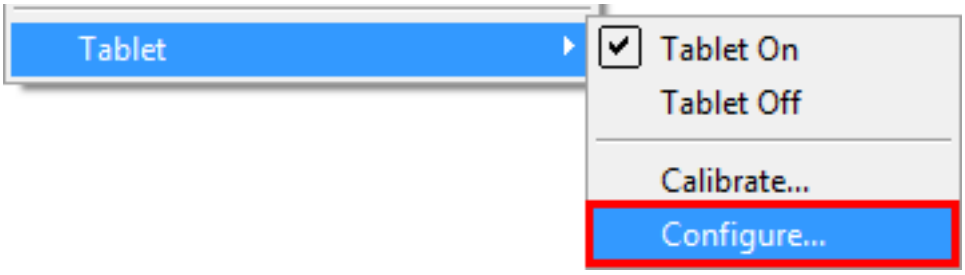

Figure 1.345

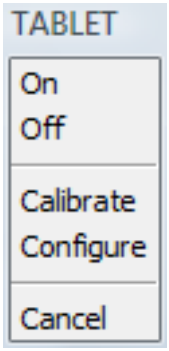
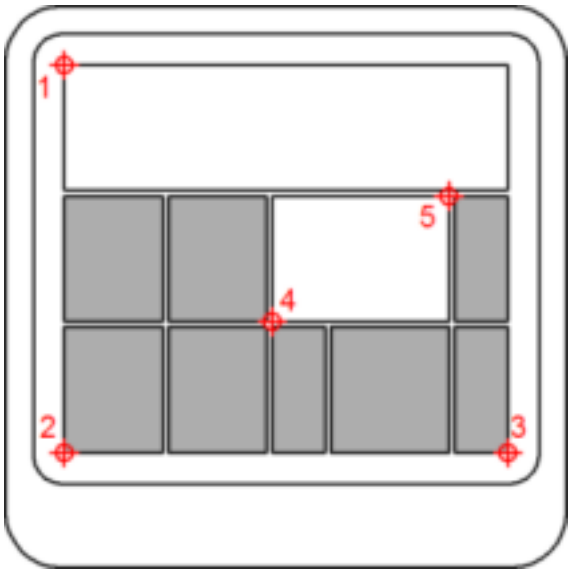


To configure the tablet

1. Do one of the following:
   - Choose **Tablet** in the **Settings** menu, then choose **Configure...** in the flyout menu. (1.344)
   - Type tablet in the command bar and press Enter. You are prompted: Tablet: ON/OFF/CALibrate/ConFiGure/<On>: a prompt menu displays: (1.348 on page 356) Type **cfg** in the command bar and press Enter or choose **Configure** in the prompt menu.
2. You are prompted: Do you want to align the tablet overlay? Yes/No/<No>. Type **Y** in the command bar and press Enter or choose **Yes** in the prompt menu. You are prompted: Digitize upper left corner of the overlay.
3. Click on the mark in the upper left corner (1) of the digitizing tablet overlay. (1.346 on the next page) You are prompted: Digitize the lower left corner of the overlay.
4. Click on the mark in the lower left corner (2) of the digitizing tablet overlay. You are prompted: Digitize the lower right corner of the overlay.
5. Click on the mark in the lower right corner (3) of the digitizing tablet overlay. You are prompted: Digitize the lower left corner of the screen pointing area.
6. Click on the mark at position (4) on the of the digitizing tablet overlay. You are prompted: Digitize the upper right corner of the screen pointing area.
7. Click on the mark at position (5) on the of the digitizing tablet overlay. You are prompted: Tablet configured.

Figure 1.346



To calibrate the tablet

To calibrate the digitizing tablet you must specify at least two points. The more additional points you specify, the more accurate the digitizing process. Additional points are particularly recommended when digitizing a non-orthogonal image, such as an aerial photograph.

1. Do one of the following:

   - Choose **Tablet** in the **Settings** menu, then choose **Calibrate...** in the flyout menu. (1.347)
   - Type tablet in the command bar and press Enter. You are prompted: Tablet: ON/OFF/CALibrate/ConFiGure/<On>: a prompt menu displays: (1.348 on the next page) Type **cal** in the command bar and press Enter or choose **Calibrate** in the prompt menu.

2. You are prompted: Digitize point #1: Click a point on the digitizing tablet. You are prompted: Enter coordinates for point #1:

3. Do one of the following:

   - Click a point in the BricsCAD drawing window.
   - Enter the coordinates (x,y) in the command bar.

4. You are prompted: Digitize point #2: Repeat step 3 to specify the following calibration point. You are prompted: Digitize point #3 (or ENTER to end):

5. Do one of the following:

   - Repeat step 4 to specify an additional calibration point. (You can specify up to 10 calibration points).
   - Press Enter to conclude the calibration process. You are prompted: When 2 calibration points are specified: Tablet calibrated. When 3 or more than 4 calibration points are specified: Select transformation type Orthogonal/Affine: Wen 4 calibration points are specified: Select transformation type Orthogonal/Affine/Projective: (1.349 on the following page)

Figure 1.347

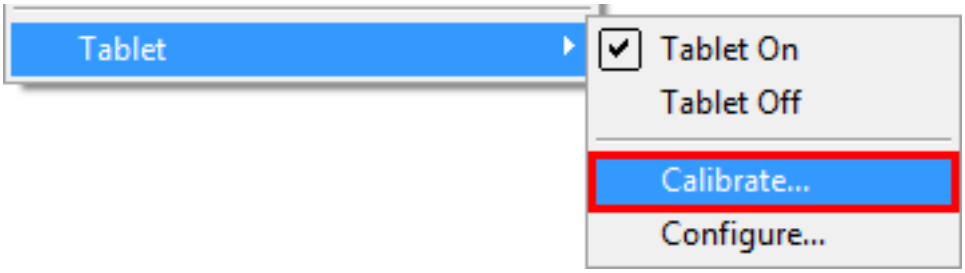


Figure 1.348

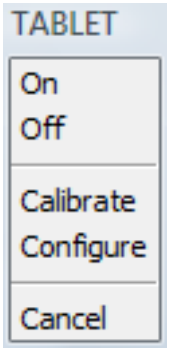

Figure 1.349

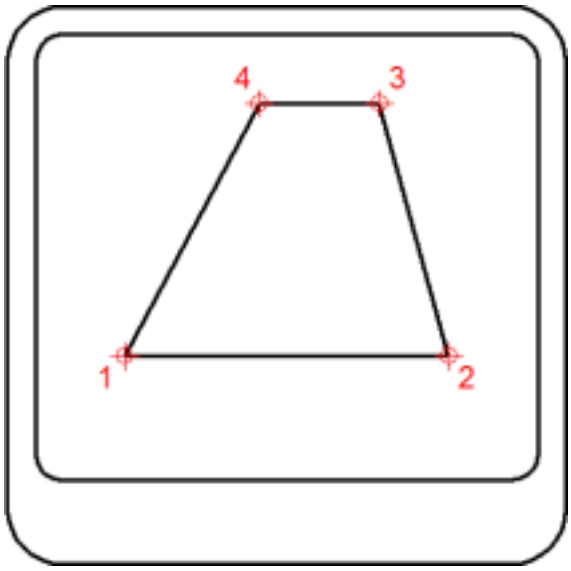

Figure 1.350

6. Select the transformation type. Transformation refers to the calculation of the points on the screen that correspond to points you digitize on the tablet. (1.350 on the preceding page)

   - **Orthogonal** (left): To be used with accurate paper drawings. Orthogonal transformation maintains all angles and preserves relative distances. If only two calibration points are specified orthogonal transformation is generated automatically.
   - **Affine** (middle): Maintains parallel lines, but not necessarily the angles between intersecting lines.
   - **Projective** (right): Does not maintain parallel lines, nor angles.

1.16 2D Drafting

1.16.1 Use the Quad to simplify working with Hatch

https://www.youtube-nocookie.com/embed/TbmCR4M1G3g BricsCAD V15 introduced a number of enhancements to editing Hatch. Coupling this with the intuitive Quad and you will speed through Hatch operations. BricsCAD V15 comes with grip editing for hatch, boundary generation, and simple hatch editing using double click. In this video we will look at these enhancements, and to speed things up we will be using the Quad, which places Hatch options at your fingertips. Back to Tutorial Overview

1.16.2 Making entities transparent

https://www.youtube-nocookie.com/embed/sWriVvS8VVU BricsCAD can display entities opaque or semi-transparent. This is done with the transparency property to individual entities, to entire layers, and to blocks. A setting in the Hatch command makes hatch patterns and fills separately transparent. This video shows you how to use the transparency property with entities, layers, and hatches. It clearly explains the difference between the Transparency command and the “CeTransparency" variable. You also learn how to change the fading of locked layers, xrefs, and references being edited. Back to Tutorial Overview

1.16.3 Copying Layouts to Model Tab

Youtube

How to use the ExportLayout command

This video shows you how to use the ExportLayout command to export a layout to .dwg file, and then how BricsCAD opens the .dwg file in model space. Sometimes it is necessary to bring layouts into the model tab. For example, some CAM programs cannot read layouts. Or you might want to save a layout and all its viewports as an independent drawing file. The ExportLayout command lets you so these things. Back to Tutorial Overview

1.16.4 Creating and Editing Associative Arrays

https://www.youtube-nocookie.com/embed/aBVlovvZAvw

How to use the ArrayPolar, ArrayPath and ArrayEdit Commands

The old Array command is a powerful way to make many copies in rectangular or round patterns. But the result is a group of independent objects, and so the arrays cannot be edited except by erasing and starting over. To the rescue are associative arrays, in which the elements of the array can be interactively adjusted during their creation, as well as after the arrays are placed in the drawing.

Interactively adjust elements of the array during their creation This video shows you how to use the ArrayPolar command to interactively create and modify polar arrays; the ArrayPath command to place objects along a path, such as a spline; and the ArrayEdit command to change the array after the fact — including replacing individual items with another object. Back to Tutorial Overview

1.16.5 Transform a smartphone into a tablet

https://www.youtube-nocookie.com/embed/o05XkMG-1FQ

Using 2D Dimensional constraints in BricsCAD

Learn how to work with 2D constraints in BricsCAD by transforming a smartphone in a tablet. BricsCAD's parametric modeling allows you to change your model easily and intelligently. To keep your design intent, you need to add some geometric constraints. The overall height of our smartphone is equal to the sum of the height of its screen and the heights of both borders (upper and lower), which are equal. We can easily specify this condition with an expression in the constraints bar. Back to Tutorial Overview

1.17 Customization

1.17.1 BricsCAD Startup Options

When starting up BricsCAD it is possible to add arguments or switches. E.g. the command line "BricsCAD.exe drawing1.dwg drawing2.dwg drawing3.dwg" will start the BricsCAD application and load the specified drawings while the command line "bricscad.exe /P MyProfile" will load BricsCAD using user profile MyProfile. "/P MyProfile" is called a command line switch. Both a slash or a hyphen are accepted to precede the switch, e.g. "-P MyProfile" will also work. The space is optional, e.g. "/PMyProfile" would also work, and the switch character is case insensitive, e.g. "-p MyProfile" is also fine.

Switch	Description
/P [userProfileName]	Starting without the /P option, BricsCAD re-uses the last used user profile (called current user profile), which is not necessarily the Default profile. If the user profile specified with the /P option doesn't exist at startup, a new empty user profile will be created with that name. If the /P argument is an .arg file the arg file is used to initialize the profile settings on the first run (See Starting BricsCAD with a specific profile (1.17.8)).
/B [scriptFileName.scr]	Runs a script (*.scr) or lisp (*.lsp) at startup. Opens all the file types that can be dragged and dropped on the application main frame window. If you pass filenames without a parameter, they are opened as if they had been passed with /B. Therefore, bricscad.exe mylisp.lsp is exactly the same as bricscad.exe /B mylisp.lsp, and bricscad.exe my.dwg is identical to bricscad.exe /B my.dwg.
/L	Suppresses the startup splash screen.
/LD [application.arx/brx/drx/lsp]	Loads an application on startup and on every new or opened drawing depending on the file extension. If the file extension is .lsp/.des/.mnl, it is treated as a lisp file and loaded in every drawing. Other file types are loaded only once at startup.
/Safemode	Prevents all third party plug-in code, enablers and user lisp files from loading in the current session. Starting in a clean environment can prevent potential crash causes. See Launching BricsCAD in safe mode (1.8.4).
/S [path]	Redefines the SRCHPATH system variable. e.g. BricsCAD.exe /S C:\BricsCAD\
/T [TemplateFileName]	Creates a new drawing based on the template drawing specified.
regserver unregserver	To register/unregister BricsCAD COM. Please note these arguments are to be used without a preceding "/".

NOTES

- Switch arguments containing spaces should be enclosed by double quotes, e.g. /P "My user profile"
- Switches can be combined, e.g. **/P MyProfile /L /S C:\BricsCAD** will start BricsCAD using the **MyProfile** user profile without the splash screen and sets the SRCHPATH system variable to **C:\BricsCAD** .
- Switches /B and /LD enable all sorts of files to be loaded, some maybe not expected. For example, .cui, .dsd, .txt, .pdf types are also processed.

Besides these switches, BricsCAD supports file names as command line arguments. Supported file types are:

- DWG - to load a drawing
- DXF - to load a drawing
- SCR - to load a script
- LSP - to load a LISP program
- DLL - to load an ADS/SDS or DRX/ARX program
- SLD - to load a slide file
- MNU - to load a menu file
- CUI - to load a menu file

If GETSTARTED = ON when you launch BricsCAD, the BricsCAD Launcher (**??**) dialog box displays, which lets you choose the workspace.

1.17.2 BricsCAD user files

Commands: SupportFolder (6.27.59), TemplateFolder (6.29.11) In BricsCAD the preferences of each user are stored in specific folders, which are called the **Local root** folder and the **Roamable root** folder. The **Local root** folder (Windows only) contains the **Templates** folder, where the drawing templates are saved. The **Roamable root** folder contains several subfolders:

- **PlotConfig**: where the plotter configuration files (*.pc3) are saved
- **PlotStyles**: where the plot style table files (*.stb) and plot color table files (*.ctb) are saved
- **Support**:
  - hatch pattern files (*.pat)
  - line style files (*.lin)
  - alias files (*.pgp)
  - unit files (*.unt)
  - custom user interface files (*.cui)
  - BIM library files (*.bsyslib) see BIMPROJECTINFO (6.7.32) command.
  - Structure tree configuration files (*.cst) see STRUCTUREPANEL (6.27.54) command.
  - Library panel configuration files (*.ccf) see LIBRARYPANELOPEN (6.20.23) command.

PointCloudCache: the point cloud preprocessing files are saved here. **Templates**: (Mac and Linux only) where the drawing templates are saved. **Platform Local / Roamable root folder Subfolders** Windows C:\Users\[UserName]\AppData\Loc \Bricsys\BricsCAD\V[Version]\en_US \Templates C:\Users\[UserName]\AppData\Roaming \Bricsys\BricsCAD\V[Version]\en \PlotConfig \PlotStyles \Support Mac /Users/[UserName]/Library/Preferences/Bricsys/BricsCAD/V[Version]/en_US /PlotConfig /PlotStyles /Support /Templates Linux /home/[UserName]/Bricsys/BricsCAD/V[Version]/en_US /PlotConfig /PlotStyles /Support /Templates

The BricsCAD user file manager

When you install an update of the software, the first time you launch BricsCAD after the update, the content of the **UserDataCache** folder (C:\Program Files\Bricsys\BricsCAD\UserDataCache) is compared with the content of the **Local root** folder and the **Roamable root** folder of the current user. If you have customized the files in these folders and if one or more of the corresponding files in the **UserDataCache** folder are more recent, the **BricsCAD user file manager** is launched asking you to keep your files or to overwrite them with the new version of these files. (1.351 on the following page)

1. Do one of the following:
   - Select a file in the file list, then click the **Yes** button to overwrite or click the **No** button to keep your file.
   - Repeat this procedure for each file in the list.
   - Click the **Yes to all** button to replace all your files with the more recent files from BricsCAD.
   - Click the **Stop Copying** button to keep all your files.
2. If you have decided not to update one or more files, an alert window displays. (1.352 on the next page)
3. Do one of the following:
   - Click the **Yes** button if you want to update one of these files later. In this case this procedure is restarted the next time you start BricsCAD.
   - Click the **No** button if you don't want to be reminded.

Figure 1.351

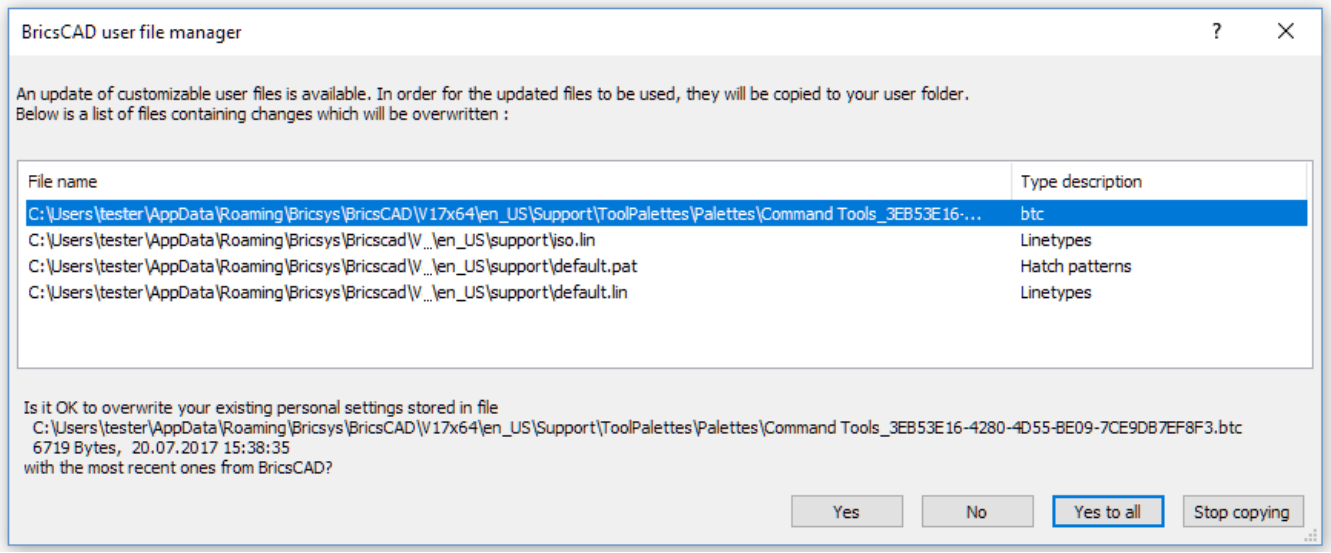

Figure 1.352

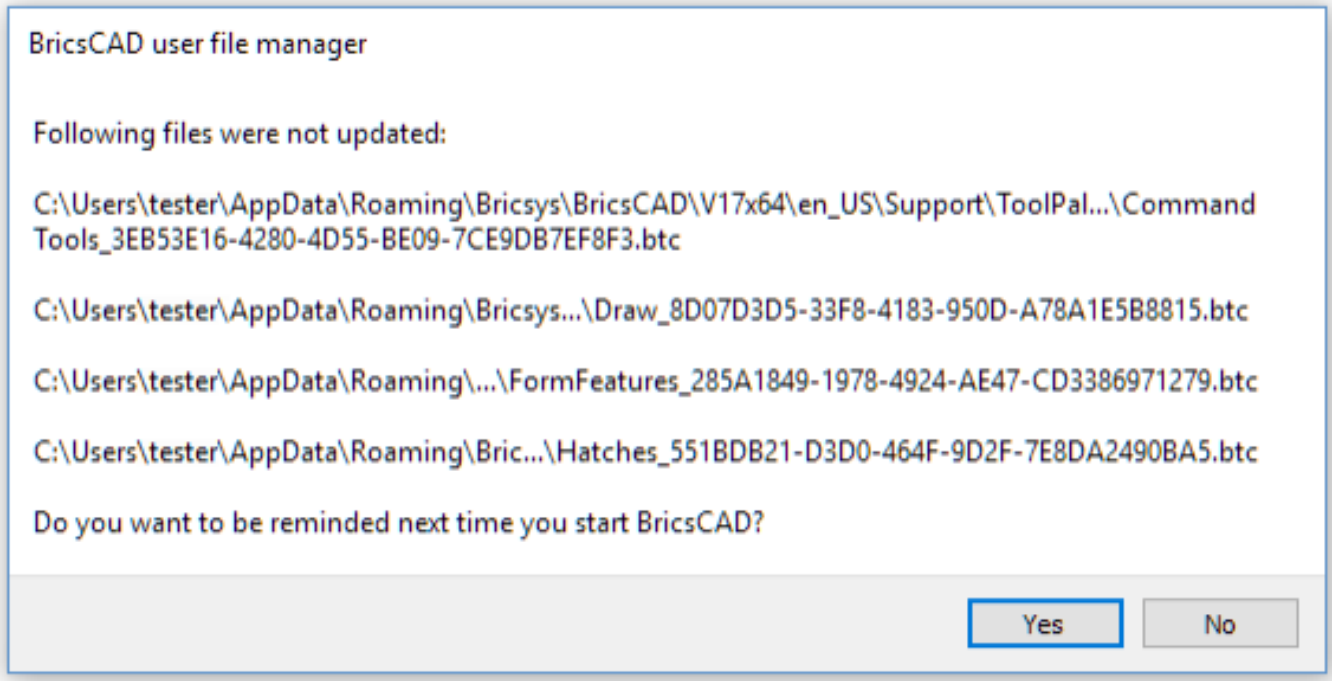


1.17.3 Loading and unloading CUI files

Commands: MenuLoad (6.21.14), CuiLoad (6.9.56), MenuUnload (6.21.13) and CuiUnload (6.9.51) When you install BricsCAD the default CUI files are copied to the **Support** folder of your Roamable root folder (1.17.2). (e.g. C:\Users\<user_name>\AppData\Roaming\Bricsys\Bricscad\Vxx.x\en_US\Support). When you launch BricsCAD the first time the **default.cui** file is loaded automatically. There are two procedures to load a CUI file:

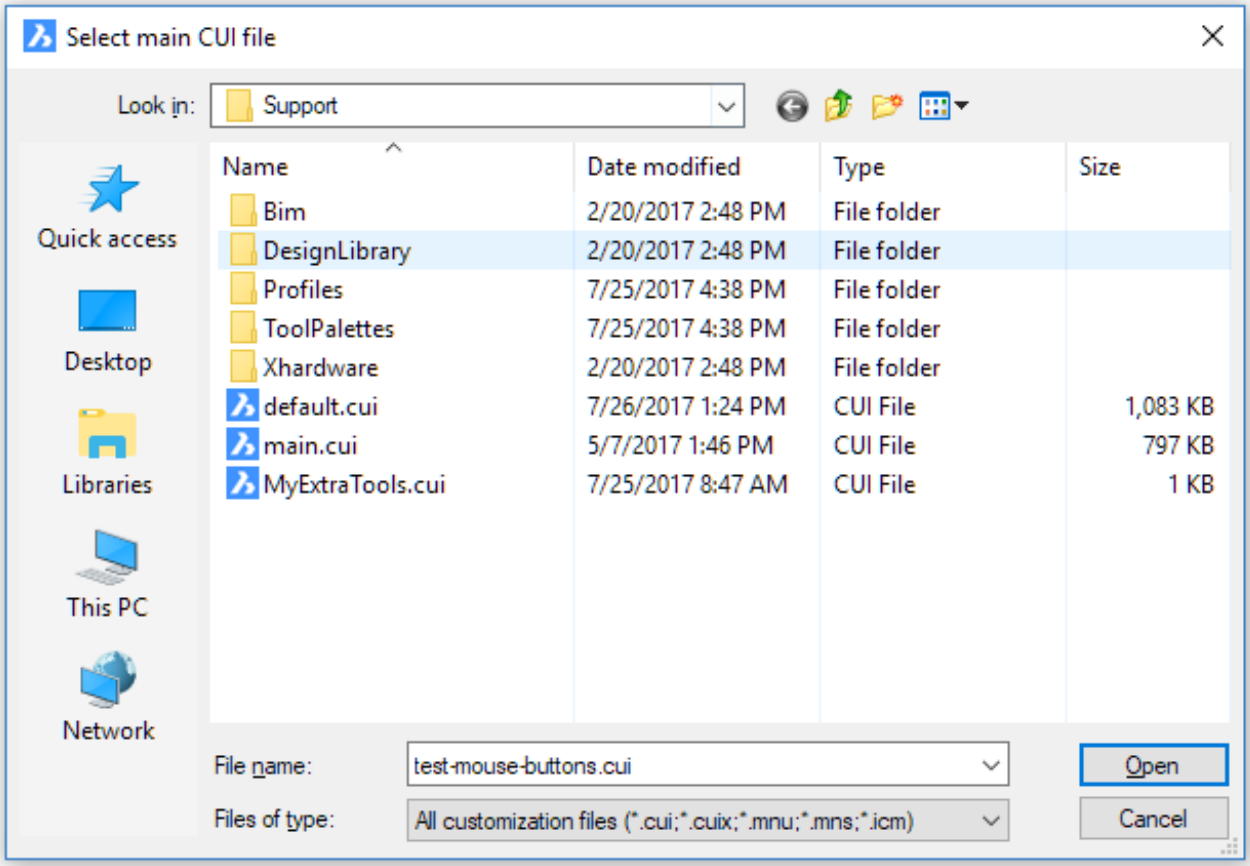
- Load main CUI file, which replaces all existing content with the content of the new CUI file.
- Load partial CUI file, which appends its content to the content of the currently loaded main CUI file.

NOTE	You can load an IntelliCAD menu file if you select **MNU files (*.mnu;*.mns)** in the **Files of Type** list box of the **Choose a Customization file** dialog in the Load main CUI file (1.17.3), Load partial CUI file (1.17.3) and Manage Customization Groups (1.17.3) procedures. The menu file will be converted to a CUI file automatically.

To load a main CUI file

1. Do one of the following:
   - Click the **Load Menu** tool button ( ) on the **Tools** toolbar.
   - Choose **Load Menu** in the **Tools** menu.
   - Type **menu** in the command bar, then press Enter.
   - Open the Customize dialog (1.17.4), then click the **Browse** button.
   - Open the Customize dialog (1.17.4), then choose **Load main CUI file ...** in the **File** menu.
2. The **Select main CUI file** dialog displays: (1.353 on the following page) Do one of the following:
   - Double click a **CUI** file.
   - Select a **CUI** file, then click the **Open** button.
3. The selected **CUI** file is loaded. Close the **Customize** dialog.

Figure 1.353



To load a partial CUI file

1. Open the Customize dialog (1.17.4), then choose **Load partial CUI file ...** in the **File** menu. The **Choose a Customization file** dialog displays.
2. Do one of the following:
   - Double click a CUI file.
   - Select a CUI file, then click the **Open** button.
3. **Optional** Repeat steps 1 and 2 to load another partial CUI file.
4. Do one of the following:
   - Click the **OK** button (

) to confirm the loading of the partial CUI file(s) and close the **Customize** dialog.
   - Click the **Cancel** button to (
) close the **Customize** dialog and unload the partial CUI file(s).

NOTE	If a CUIX file is selected in step 2 it will be converted to a CUI file on-the-fly. When a CUIX file contains bitmaps, they are copied into a .RESZ resource file, which are supported as an alternative to resource DLL (zip file containing tool bitmaps; works on all platforms). The following image formats are supported: BMP, JPG, PNG, ICO, GIF, TIFF, XBM, XPM.

To unload a partial CUI file

1. Open the Customize dialog (1.17.4).
2. In the **Menus** , **Toolbars** or **Keyboard** section select the partial CUI file you want to unload. (1.354 on the next page)

1.17.4 Understanding the Customize Dialog

Command: Customize (6.9.47)

What are the CUI files

Files with the CUI extension are Customize User Interface files for BricsCAD. These XML format files replace the previously used menu definition files (*.mnu *.mns). CUI files can be edited with the build-in interactive editor, launched by the Customize command. You can migrate CUI files between BricsCAD versions and combine them between different computers.

NOTE	The Load partial CUI file (1.17.3) ... procedure accepts IntelliCAD menu files (*.mnu *.mns) and converts them to CUI files.

Opening the Customize dialog

To open the Customize dialog do one of the following:

- Choose **Customize** in the **Tools** menu
- In Windows and OS X: Hover over a toolbar or ribbon panel or a blank portion of the toolbar area, then right click and choose **Customize** in the context menu.
- In Linux: Hover over a blank portion of the menu bar, status bar or toolbar area, then right click and choose **Customize** in the context menu.
- Type **customize** or **cui** in the command window, then press Enter. (1.356 on the next page)

The components of the Customize dialog are:

1. File menu
2. Main customization file name and location
3. Browse for main customization file button
4. Search field: type a search string then click the looking glass icon, click again for the next hit.
5. Section tabs
6. Content of the currently selected section
7. Available tools tree
8. Properties grid, displaying the properties of the selected item
9. (1.357 on page 374) Opens the customization history. Here, settings can be reverted to defaults.
10. 

Saves changes and closes the Customize dialog. 
Closes the Customize dialog, without saving changes.

1.17.5 Creating custom tools

General procedure to create custom tools

1. Create a Partial CUI file.
2. Optional: Add toolbox(es) in a Menu Group.
3. Optional: Add tools in a toolbox
4. Optional: Add main menu(s)
5. Optional: Add sub menu(s)
6. Optional: Add context menu(s)
7. Optional: Add toolbar(s)
8. Optional: Add flyout(s) to toolbar(s)
9. Optional: Add control(s) to toolbar(s)
10. Optional: Add keyboard shortcuts
11. Optional: Add existing tools to menus, toolbars or shortcuts
12. Optional: Create new tools in menus, toolbars or shortcuts
13. Optional: Change the tool order in menus and toolbars

Tutorial: Easy Menu Customization Click here (1.12.9) to watch

Tutorial: Advanced Menu Customization Click here (1.12.15) to watch

To create a Partial CUI file

1. In the Customize dialog (1.17.4) do one of the following:
   - In the **File** menu, choose **Create new partial CUI file ...**
   - Place the cursor on Menu group, then right click an choose **Create new partial CUI file ...** in the context menu.
2. The **Create a Customization File** dialog opens. By default the new partial CUI file will be created in the **Support** folder of the Roamable root folder (1.17.2).B **Optional** select a different folder to save the CUI file.
3. Type a name for the new CUI file in the **File name** field.
4. Click the **Save** button. The newly created **Partial CUI file** is loaded and a **Menu Group** of the same name is created in the **Menus** tree, **Toolbars** tree, **Keyboards** tree and **Available Tools** tree.

To add a toolbox in a menu group

1. In the Customize dialog (1.17.4) select a menu group.
2. Right click and choose **Append toolbox** in the context menu. (1.358 on the next page)
3. Type a name for the new **toolbox** in the **Title** field of the **Add toolbox** dialog. (1.359 on the following page)
4. Click the **OK** button. The toolbox is added in the **Available Tools** tree.
5. Click the **Apply** button to save the definition.

Figure 1.358

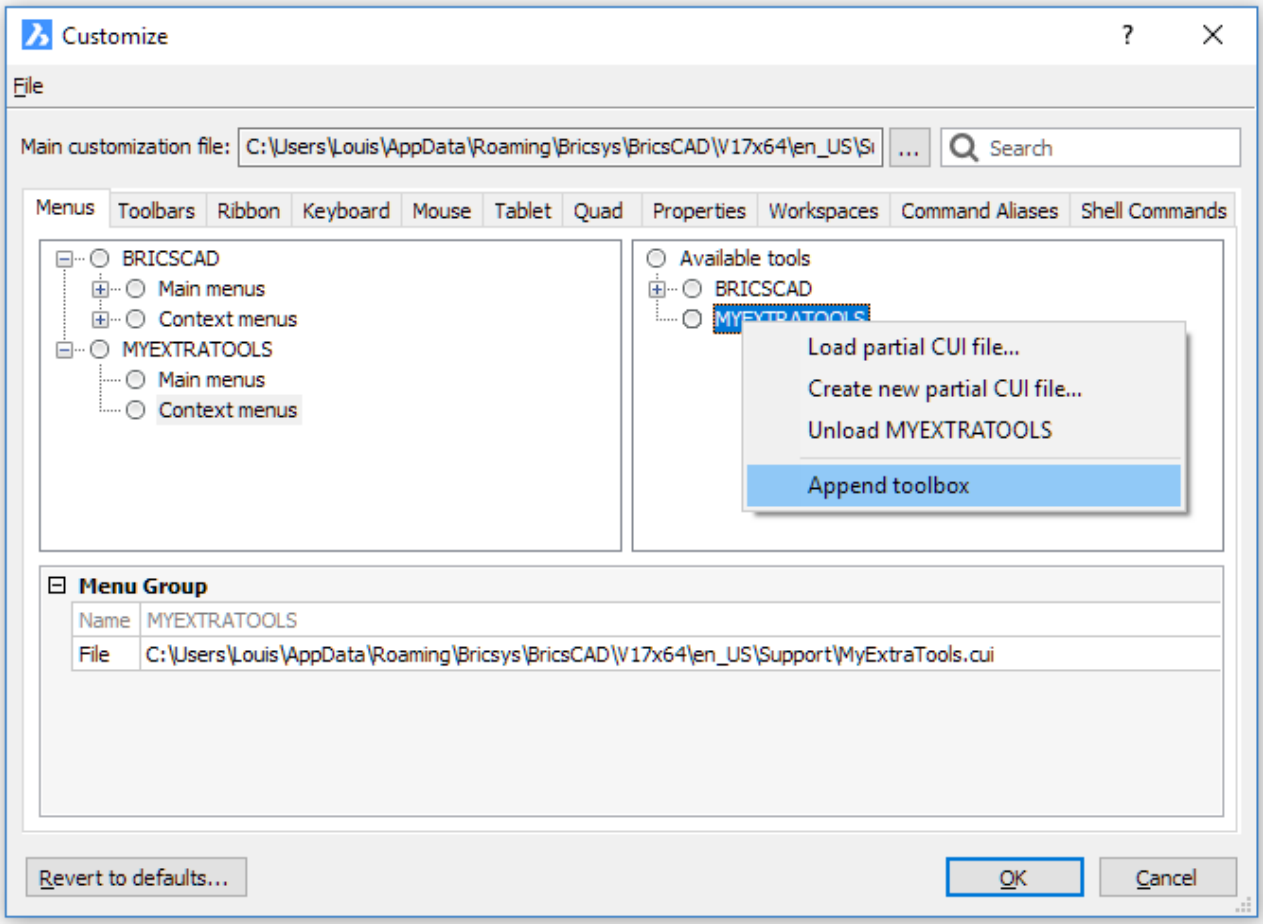

Figure 1.359

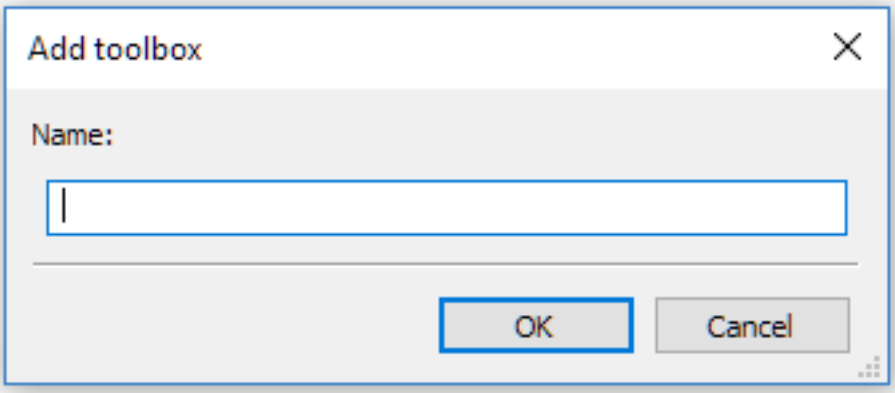

To add a tool in a toolbox

1. In the Customize dialog (1.17.4) select a toolbox in the **Available Tools** tree.
2. Right click and choose **Append tool** in the context menu. The **Add tool** dialog displays. (1.360 on the next page)
3. Type a name for the new tool in the **Title** field of the **Add tool** dialog.
4. **Optional** Type a help string in the **Help** field of the properties grid.
5. Type a command or command macro in the **Command** field of the properties grid. e.g.: ^c^c_-layer;m;InteriorWalls;;Mline
   In the above example a macro is created which makes the **InteriorWalls** layer current, then launches the **Mline** command. If the layer does not exist yet, it is created first.
6. Click the **Browse** button (…), then select an image for the new tool. Do one of the following:
   - Select **Builtin** , then choose one of the built-in icons. (1.361 on the following page) Select **Bitmap file** , and choose a bmp, gif, jpg, jpeg or png image file.
   - Click the **OK** button.
7. The tool is added in the toolbox. (1.362 on page 379)

NOTE

Syntax to create macros:

- **^c^c** is the equivalent of pressing the Esc key twice, which first ends a running command if necessary.
- an underscore (_) in front of a command name ensures that the macro still works in a non-English version of BRICSCAD.
- a point (.) in front of a command name ensures that the macro still works if this command is temporarily undefined (see the UNDEFINE (6.30.4) and REDEFINE (6.26.7) commands).
- a minus sign (-) in front of a command launches the command line version of a command, thus preventing the command dialog window to open.
- a semicolon (;) is the equivalent of pressing the Enter key
- a backslash (\) temporarily pauses the macro to allow user input, e.g. specifying a point.

Figure 1.360

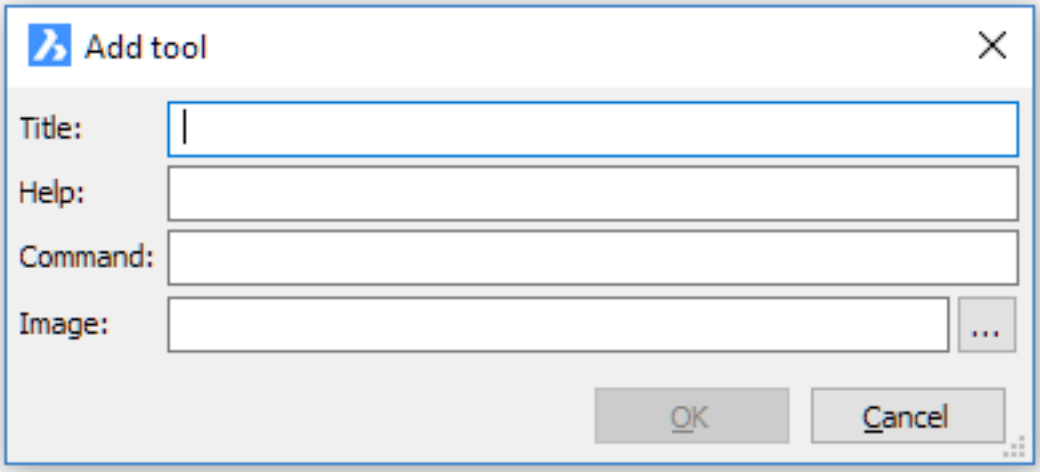

Figure 1.361

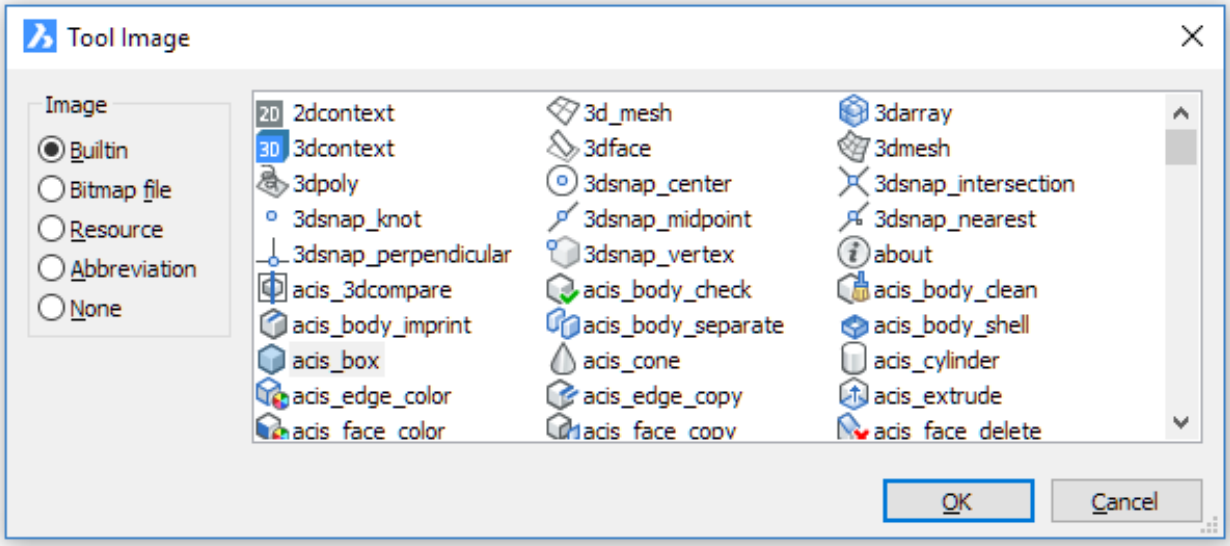

Figure 1.362

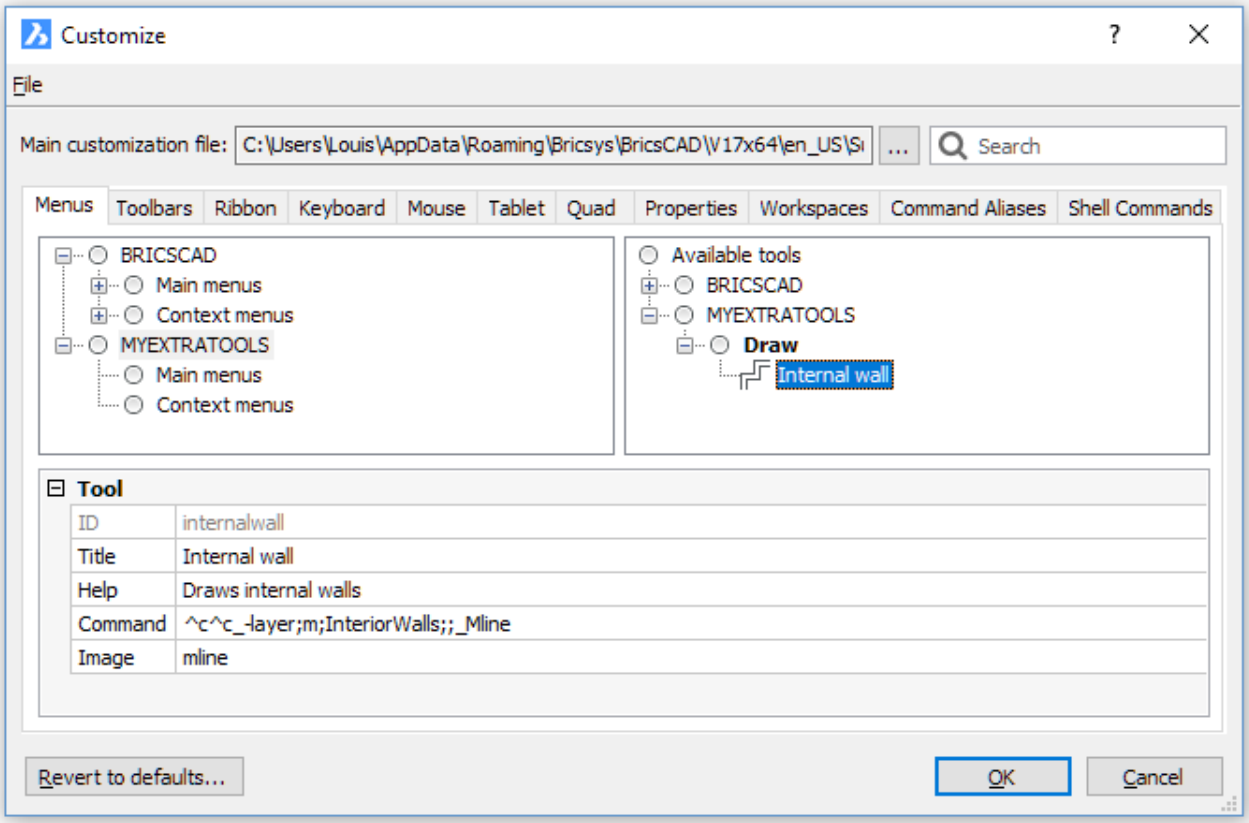


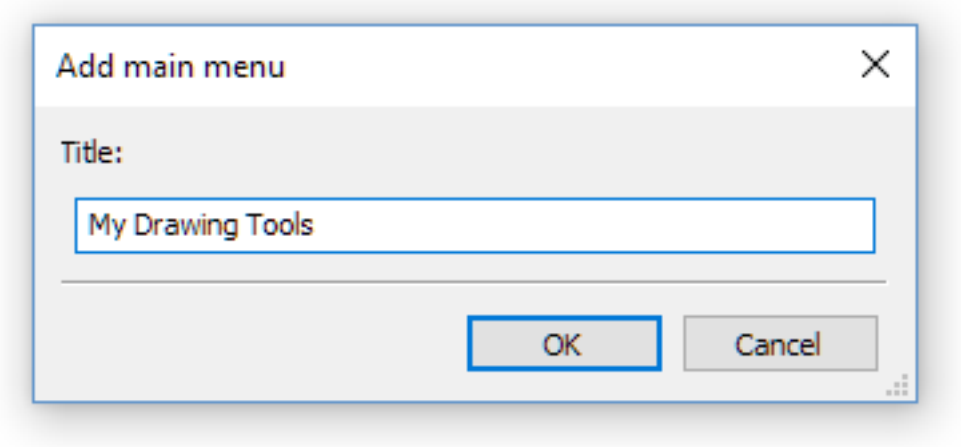
To add a main menu

New menus are added above the selected existing menu or as the first menu if you select the **Main Menus** subgroup.

1. In the Customize dialog (1.17.4) click the **Menus** tab.
2. Do one of the following:
   - Click the **Main Menus** subgroup of the menu group, then right click and choose **Append main menu** in the context menu.
   - Select an existing menu in the **Main Menus** subgroup, then right click and choose **Insert main menu** in the context menu.
3. Type a name in the **Title** field of the **Add main menu** dialog. (1.363 on the following page)
4. Click the **OK** button.
5. **Optional** Repeat steps 2 through 5 to add more menus.
6. Click the **Apply** button to save the definition(s).

NOTE	The new main menu is not added to the **Menu bar** until at least one menu items is added to it.

Figure 1.363



To add a submenu to a menu

New submenus are added above the selected existing item or as the first item if you select the menu.

1. In the Customize dialog (1.17.4) click the **Menus** tab.
2. If collapsed, expand the menu group (e.g. BRICSCAD).
3. If collapsed, expand the **Main menus** group of the menu group.
4. Do one of the following:
   - Select the menu, then right click and choose **Append submenu** in the context menu.
   - Select an existing item in the menu, then right click and choose **Insert submenu** in the context menu.
5. Type a name in the **Title** field of the **Add submenu** dialog.
6. Click the **OK** button.

To add a context menu

New context menus are added above the selected existing context menu or as the first context menu if you select the **Context Menus** subgroup.

1. In the Customize dialog (1.17.4) click the **Menus** tab.
2. Do one of the following:
   - Select the **Context Menus** subgroup of the menu group, then right click and choose **Append context menu** in the context menu.
   - Select an existing context menu, then right click and choose **Insert context** menu in the context menu.
3. Select a menu in the **menu** list of the **Add context menu** dialog. (1.364 on the next page)
4. **Optional:** Select **As regular context menu**, then click the **Add Context...** button. The **Add context alias** dialog box displays: (1.365 on the facing page) Choose:
   - CMCOMMAND: to replace the default **Command** context menu.
   - CMDEFAULT: to replace the default **Default** context menu.
   - CMEDT: to replace the default **Edit** context menu.
   - GRIPS: to replace the default **Grips** context menu.
   - SNAP: to replace the default **Entity Snap** context menu.
5. Click the **OK** button to confirm.
6. **Optional** repeat the previous step to add another alias. Select an alias, then click the **Remove** button to remove the alias. (1.366 on page 382)
7. **Optional** Select **As context menu on specific entities:** , then click the **Add Entity Type(s)...** button. The **Add Entity Alias** dialog box displays: (1.367 on page 384)

To add a toolbar

New toolbars are added above the selected existing toolbar or as the first toolbar if you select the menu group.

1. In the Customize dialog (1.17.4) click the **Toolbars** tab.
2. Do one of the following:
   - Select a menu group, then right click and choose **Append toolbar** in the context menu.
   - Select an existing toolbar in a menu group, then right click and choose **Insert toolbar** in the context menu.
3. Type a name in the **Title** field of the **Add toolbar** dialog. (1.368)
4. Click the **OK** button.
5. **Optional:** Adjust the Toolbar properties. (1.369 on the following page)
   - **Title**: The toolbar name must include alphanumeric characters with no punctuation other than a dash (–) or an underscore (_). The **Title** along with the **Alias** enables the toolbar to be referenced programmatically.
   - **Position**: Defines the display position of the toolbar when the CUI file is loaded. The options are: **Floating**, **Top**, **Left**, **Bottom** or **Right**. The latter four refer to the window edge where the toolbar will be docked.
   - **Display**: Defines whether the toolbar displays or not when the CUI file is loaded.
   - **Rows**: Specifies the number of rows when the toolbar position is floating. View bars with controls cannot have multiple rows.
   - **Xval**: When the position is Floating, specifies the X coordinate in pixels, measured from the left edge of the screen to the left side of the toolbar.
   - **Yval**: When the position is Floating, specifies the Y coordinate in pixels, measured from the top edge of the screen to the top of the toolbar.
6. Click the **Apply** button to save the definition(s).

NOTE	The new toolbar is loaded only if the **Display** property is set to **Show**. See Opening a Toolbar (1.15.3) for more information on opening toolbars.

Figure 1.368

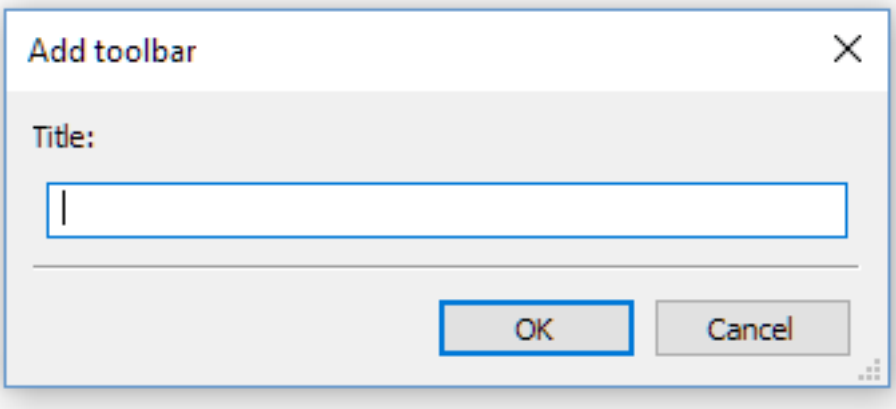

Figure 1.369

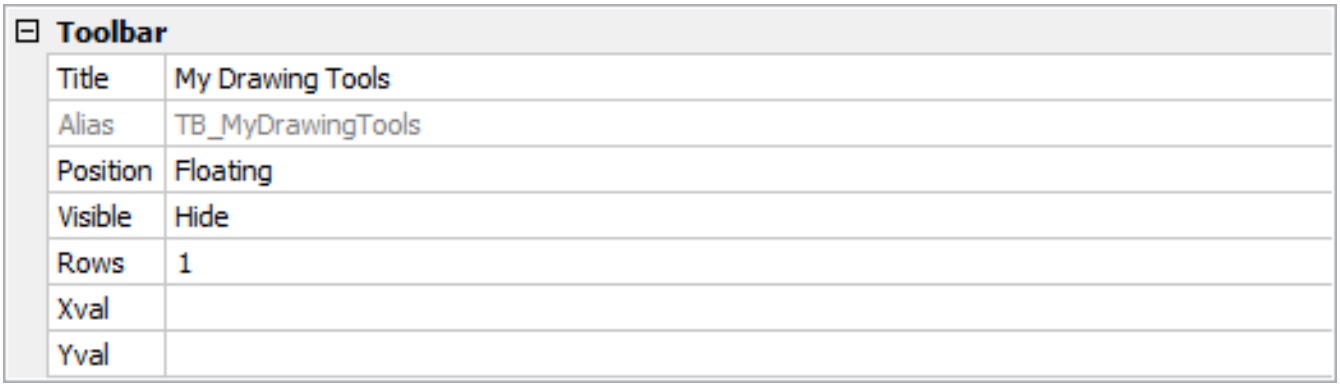

To add a flyout to a toolbar

1. In the Customize dialog (1.17.4) click the **Toolbars** tab.
2. If collapsed, expand the menu group (e.g. BRICSCAD).
3. Do one of the following
   - Select a toolbar, then right click and choose **Append Flyout** in the context menu, to add the flyout at the end of the toolbar.
   - Expand the toolbar, right click a tool then choose **Insert flyout** in the context menu, to add the flyout above the selected tool.
4. The **Add flyout** dialog box displays: (1.370 on the next page) Type a name in the **Title** field of the **Add flyout** dialog, then click the **OK** button. A new empty toolbar is created and inserted as a flyout in the selected toolbar: (1.371 on the facing page)
5. Do one of the following:
   - Click the **Target Alias** field, then click the settings field and select an existing toolbar in the drop-down list.
   - Add tools to the new toolbar.

Figure 1.370

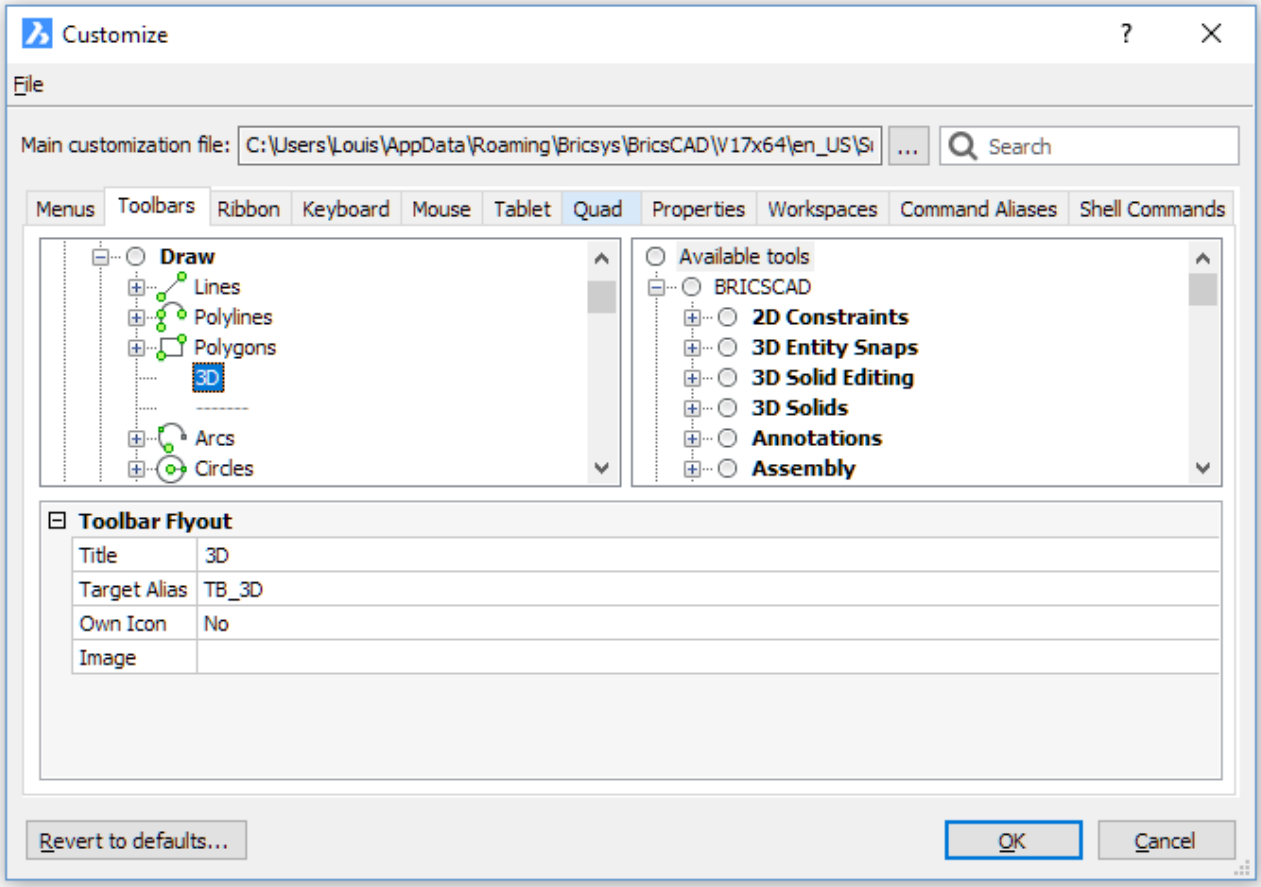

Figure 1.371

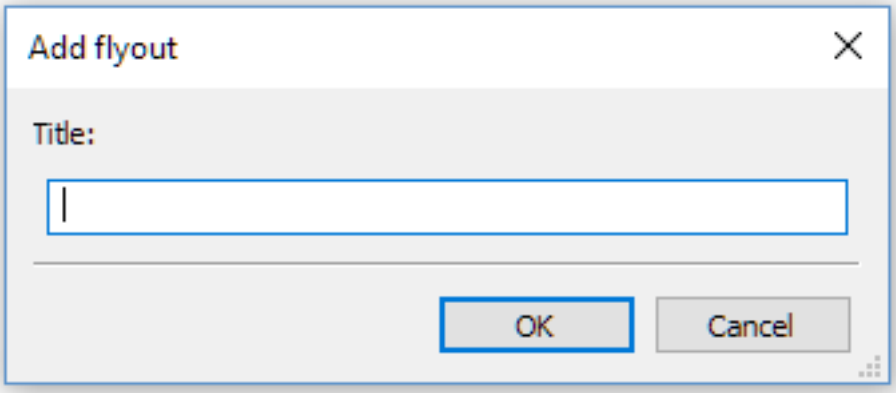

To add a control to a toolbar

1. In the Customize dialog (1.17.4) click the **Toolbars** tab.
2. If collapsed, expand the menu group (e.g. BRICSCAD).
3. Do one of the following:
   - Select the toolbar, then right click and choose **Append control** in the context menu. The new control will be added as the first item in the toolbar.
   - Select an existing item in the toolbar, then right click and choose **Insert control** in the context menu. The new control will be added above the selected existing item.
4. Select a control in the **Add control** dialog. (1.372 on the next page)
5. Click the **OK** button.
6. To specify the width of the control, do one of the following:
   - Accept the **Default** width.
   - Type the width in pixels in the **Width** field. (1.373 on the facing page)

NOTE	Type **Default** or **0** (zero) in the **Width** field to restore the default width of the control field.

Figure 1.372

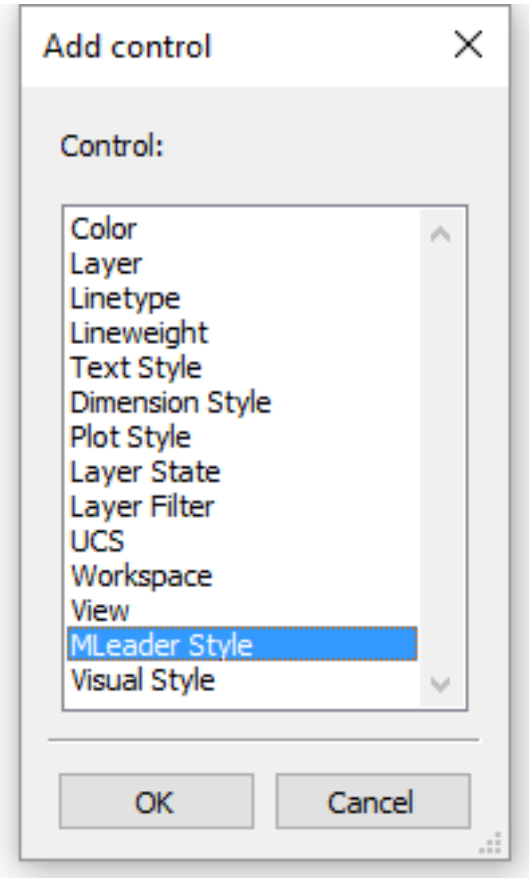

Figure 1.373

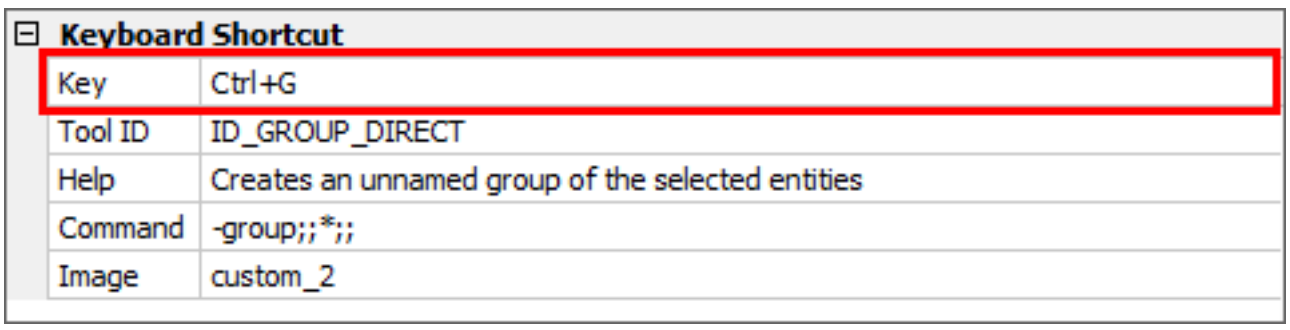
Toolbar Control	
Control	Dimension Style
Width	Default

To add a keyboard shortcut

1. In the Customize dialog (1.17.4) click the **Keyboard** tab.
2. If collapsed, expand the menu group (e.g. BRICSCAD).
3. Do one of the following:
   - Select the menu group, then right click and choose **Append shortcut** in the context menu. The new shortcut will be added at the end of the shortcut list.
   - Select an existing shortcut in the toolbar, then right click and choose **Insert shortcut** in the context menu. The new shortcut will be added above the selected existing shortcut.
4. Do one of the following:
   - Proceed with the **Add an existing tool** procedure.
   - Proceed with the **Add a new tool** procedure.
5. In the **Properties** grid of the new shortcut select the **Key** field, then press the key combination you want to assign to the shortcut. (1.374)

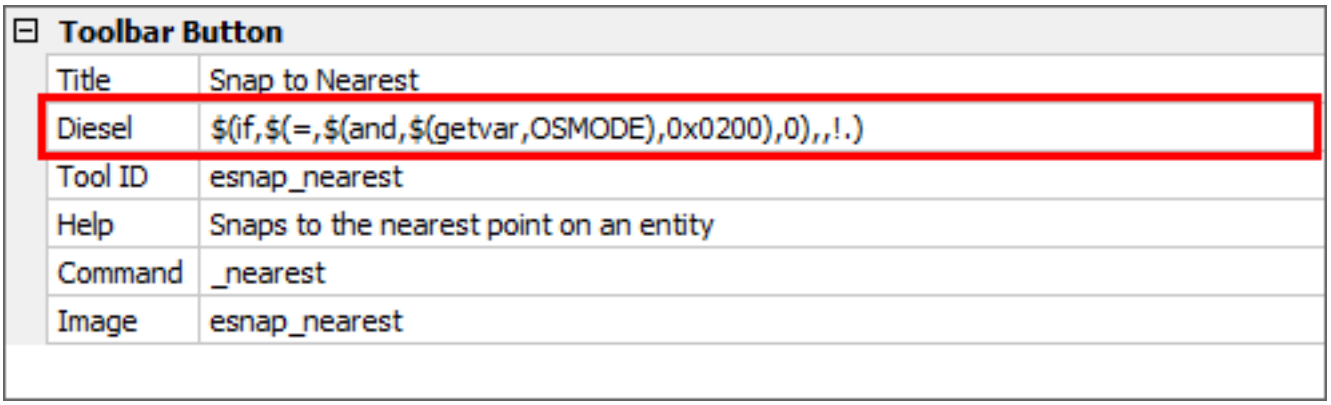
Figure 1.374



To add an existing tool to a menu, toolbar or shortcut

1. In the Customize dialog (1.17.4) select the item you want to add an existing tool to.
2. In the **Available Tools** pane, expand the toolbox that contains the tool you want to add.
3. Drag the tool to the target item:
   - Drop the tool on top of the item name to append the tool.
   - Drop the tool on top of another tool to insert the new tool above the existing tool.
4. **Optional:** Edit the tool in the settings grid, e.g. to add a diesel expression in the **Diesel** field. (1.375)

Figure 1.375



To create a new tool

1. In the **Add Tool** dialog choose **Create new tool.**
2. Select the **Toolbox** in which you want to create the new tool.
3. Type a name for the new tool in the **Title** field of the **Add tool** dialog.
4. **Optional:** Type a help string in the **Help** field of the properties grid.
5. Type a command or command macro in the **Command** field of the properties grid. (1.376 on the next page) In the screenshot above the **Command** field contains a macro that makes the **InteriorWalls** layer current, then launches the **Mline** command.If the layer does not exist yet, it is created first.
6. Click the **Browse** button (), then select an image for the new tool.
7. Do one of the following:
   - Select **Builtin**, then choose one of the built-in icons. (1.377 on page 394)

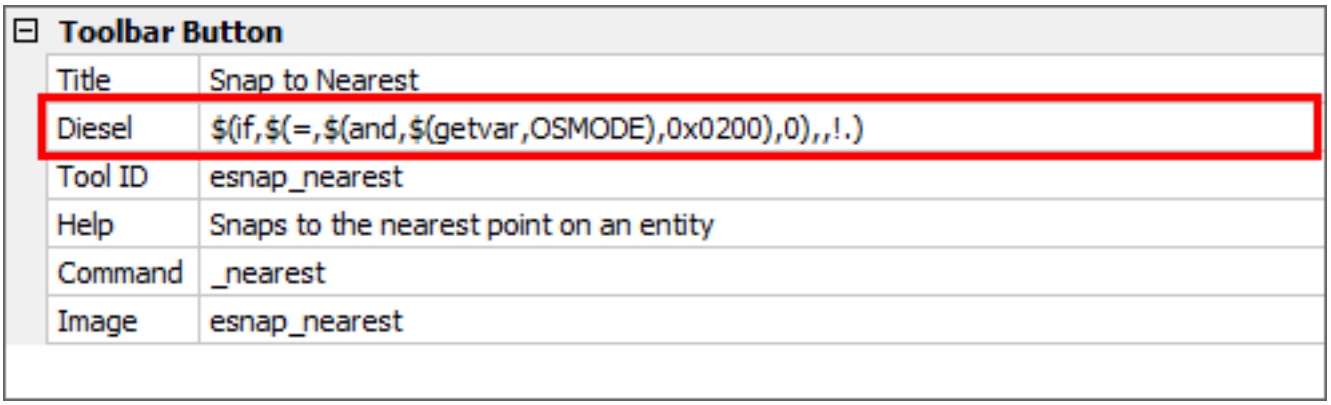
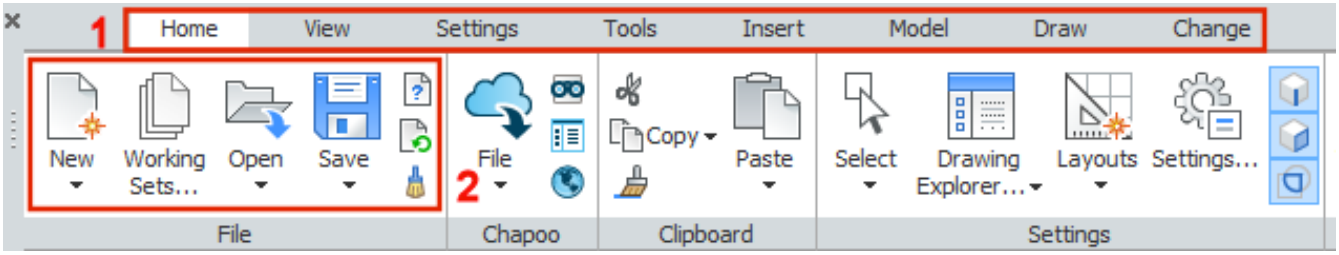
Figure 1.377



To change the order of the tools in a menu or toolbar

1. In the Customize dialog (1.17.4) select the menu or toolbar.
2. Drag the tool to its new position:
   - Drop the tool on top of the item name to move it to the last position.
   - Drop the tool on top of another tool to move the tool above this tool.

Figure 1.378



1.17.6 Ribbon

Commands: Ribbon (6.26.32) and RibbonClose (6.26.49) A ribbon organizes tools in a series of **Panels** (2) which are grouped in different **Tabs** (1). The number of tabs and their order depends on the current workspace and is defined in the **Ribbon** node of the workspace (see Editing a Workspace (1.17.11)). (1.378) The RibbonDockedHeight (1.17.10) system variable stores the preferred height of the Ribbon bar. Values between 0 and 500 are accepted. Set the value to 0 (zero) for automatic height calculation.

Ribbon Panels

A ribbon panel is composed of one or more rows. In a row you can add one or more command buttons or row panels, which in turn can hold one or more command buttons.

(1.387 on page 407)
Ribbon Panel
(1.388 on page 408)
Structure of the Ribbon Panel in the Customize dialog

The **Entity Snaps** ribbon panel above is composed of:

- a launcher (1)
- a single row, holding three command buttons (2), a row panel (3) with three rows of four command buttons each, two command buttons (4) and a row panel (5) with three rows of one command each.

Ribbon Buttons

The following button types are available:

- Command button (2): launches a command
- Split button (1): groups a series of command buttons, much like a flyout toolbar.
- Toggle button (3): toggles a setting; shows the current status of setting

(1.379)

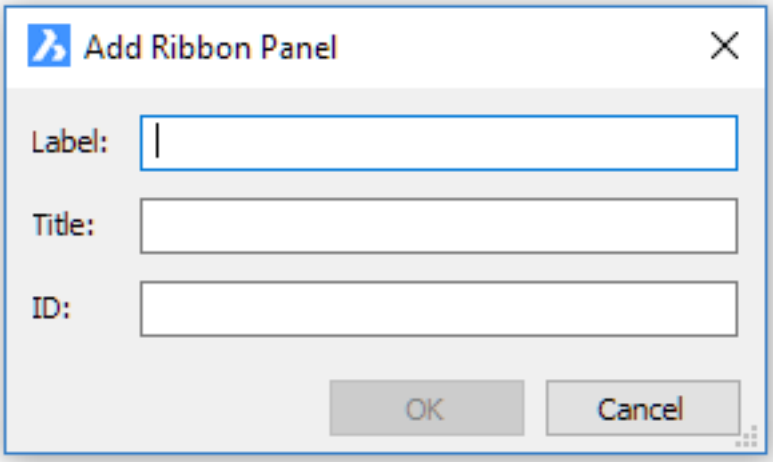
To remove a panel from a ribbon tab

1. Select the panel.
2. Do one of the following:
3. Press the **Delete** key.
4. Right click and choose **Remove** in the context menu.

Creating a ribbon panel

1. Open the Customize dialog (1.17.4).
2. Click the **Ribbon** tab on the **Customize** dialog.
3. Right click the **Ribbon Panels** group and choose **Append ribbon panel** in the context menu.
4. Fill out the fields in the Add Ribbon Panel dialog box: (1.382 on the next page) Label: Caption of the panel in the ribbon. Title: Used in the **Select Ribbon Panel** dialog when selecting the panels for a ribbon tab ID: A unique name to identify the ribbon panel.
5. Click the **OK** button.

Figure 1.382



Editing a ribbon panel

1. Open the Customize dialog (1.17.4).
2. Click the **Ribbon** tab on the **Customize** dialog.
3. Expand the **Ribbon Panels** group.
4. Expand the ribbon panel.

To add a row to a ribbon panel Do one of the following:

- Right click the ribbon panel and choose **Append Row** in the context menu. The row is added at the bottom of the ribbon panel tree.
- Right click an existing row and choose **Insert Ribbon Row** in the context menu. The row is added above the existing row.
- **Optional:** Drag the row to a different location in the ribbon panel tree.

To add a launcher to a ribbon panel

1. Right click the ribbon panel and choose **Add launcher** in the context menu.
2. Either select an available tool or Create a New Tool (1.17.5), then click the **OK** button. (1.383 on the following page)

Editing a panel row

1. Open the Customize dialog (1.17.4).
2. Click the **Ribbon** tab on the **Customize** dialog.
3. Expand the **Ribbon panels** group.
4. Expand the ribbon panel.
5. Expand the ribbon rows and ribbon row panels.

To add a row panel to a row Do one of the following:

- Right click the row and choose **Append Row Panel** in the context menu. The row panel is added at the bottom of the row tree.
- Right click an existing row panel and choose **Insert Row Panel** in the context menu. The row panel is inserted above the existing row panel.

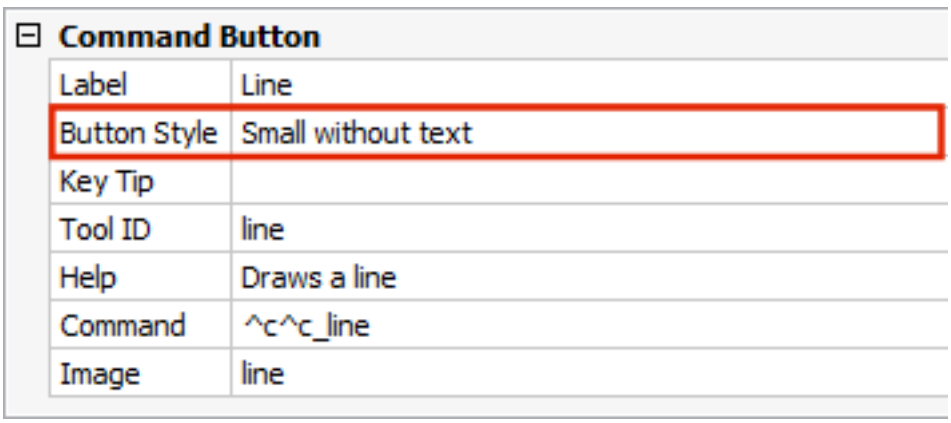
To add a command button to a row

1. Drag and drop a tool from the **Available Tools** list onto the row. Drop the tool on the row to add a command button at the bottom of the row tree. Drop the tool on an existing command button to add a command button above an existing command button.
2. Set the **Button Style** in the **Command Button** grid. (1.384) The options are:

Icon	Style
	Small
Polyline	Small with text
	Large
Spline	Large with text

3. **Optional:** Drag the command button to a different position in the same row or onto a different row.

Figure 1.384



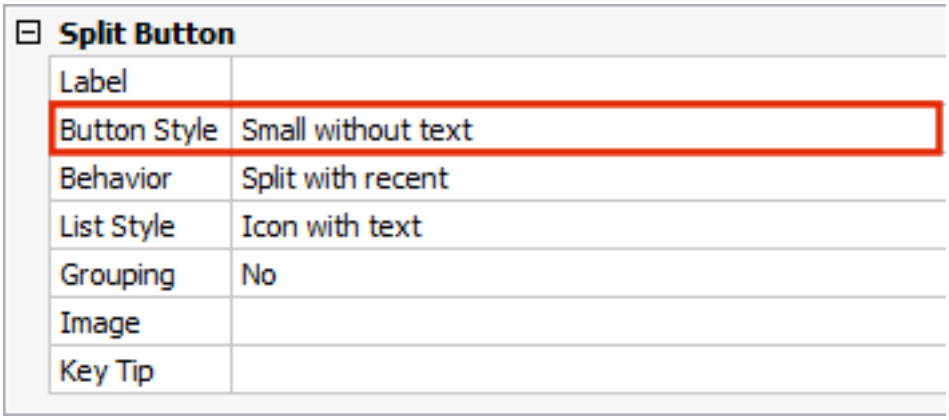
To add a split button to a row

1. Select the row, then right click and choose **Append split button** in the context menu. The split button is added at the bottom of the row tree.
2. Drag a series of related tools from the **Available Tools** list onto the split button.
3. Set the **Button Style** in the **Split Button** grid. (1.385) The options are:

Icon	Style
	Small
	Small with text
	Large
	Large with text

1. Type a label text in the **Label** field.
2. **Optional:** Set the **Behavior** to **Split with recent (static text)** : always display the split button label, instead of the label of the most recently used tool.
3. **Optional:** Drag the split button to a different position in the same row or onto a different row.
4. Drag and drop tools from the **Available Tools** list onto the split button.

Figure 1.385



To add a toggle button to a row

1. Select the row, then right click and choose **Append Toggle Button** in the context menu.
2. Either select an available tool or Create a New Tool (1.17.5), then click the **OK** button. (1.386 on the next page)
3. The toggle button is added at the bottom of the row tree.
4. **Optional:** Drag the toggle button to a different position in the same row or onto a different row.

1.17.7 Tool Palettes

Command: TOOLPALETTES (6.29.28), TOOLPALETTESCLOSE (6.29.30), TPNAVIGATE (6.29.31) The **ToolPalettes** command opens the Tool Palettes bar. The **ToolPalettesClose** command closes the Tool Palettes bar. The **TpNavigate** command displays a tool palette or a tool palette group. On a tool palette you can add blocks, hatches and commands in a tabbed window. Drag a tool from the palette to the graphic screen to launch the related tool.

To open the Tool Palettes Bar

Do one of the following:

- Hover over a toolbar (Windows) or an empty toolbar area (Windows and Linux), then right click and choose **Tool Palettes Bar** in the context menu.
- Type **toolpalettes** in the command bar, then press Enter.

(1.389 on the following page)

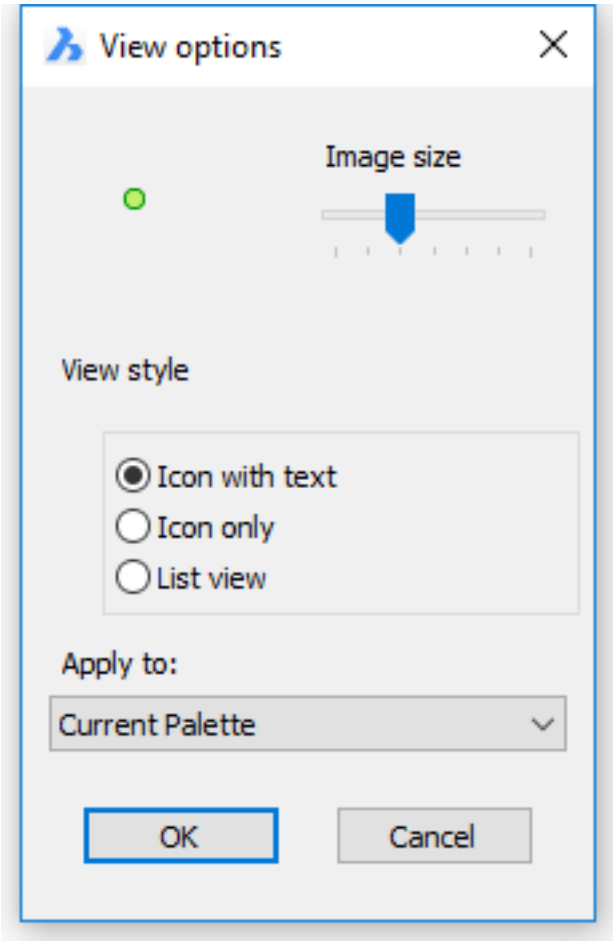
To set the view options

1. Right click in an empty space of the icon area on the **Toolpalettes Bar** and choose **View Options...** in the context menu. The **View Options** dialog displays. (1.390 on the next page)
2. Drag the **Image Size** slider to adjust the image size.
3. Select either **Icon with text**, **Icon only** or **List view.**
4. Choose either **Current Palette** or **All Palettes** from the **Apply to** list button.
5. Click the **OK** button to confirm.

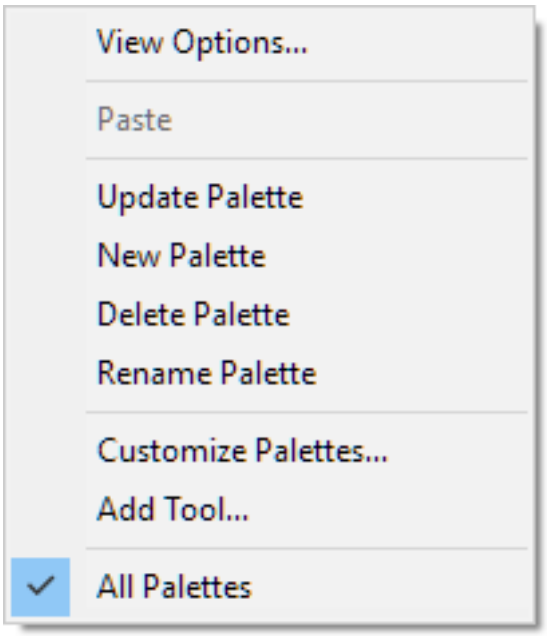
Figure 1.390



To add a new tool palette

1. Move the cursor to the icon area of the **Tool Palettes Bar**, then right click. A context menu displays: (1.392 on page 414)
2. Choose **New Palette** in the context menu. A new tab is added.
3. Type a name for the new palette in the **Name** field.

Figure 1.391



To open the customize dialog box

1. Move the cursor to the icon area of the **Tool Palettes Bar**, then right click. A context menu displays: (1.392 on the next page)
2. Choose **Customize Palettes** in the context menu. The **Customize** dialog box displays: (1.393 on the following page)

Figure 1.392

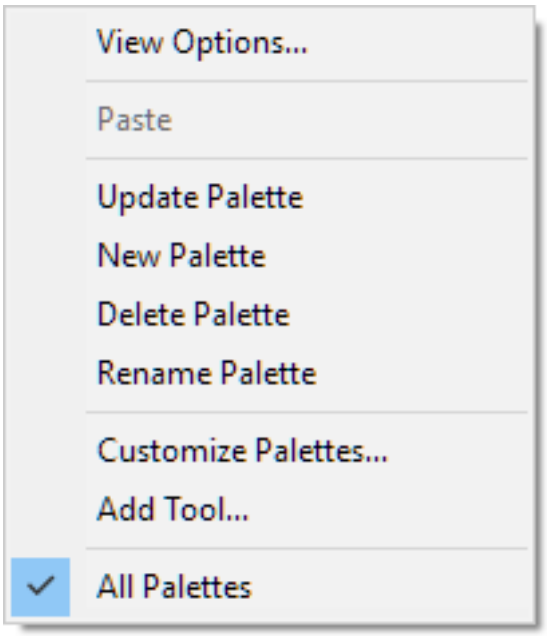


Figure 1.393

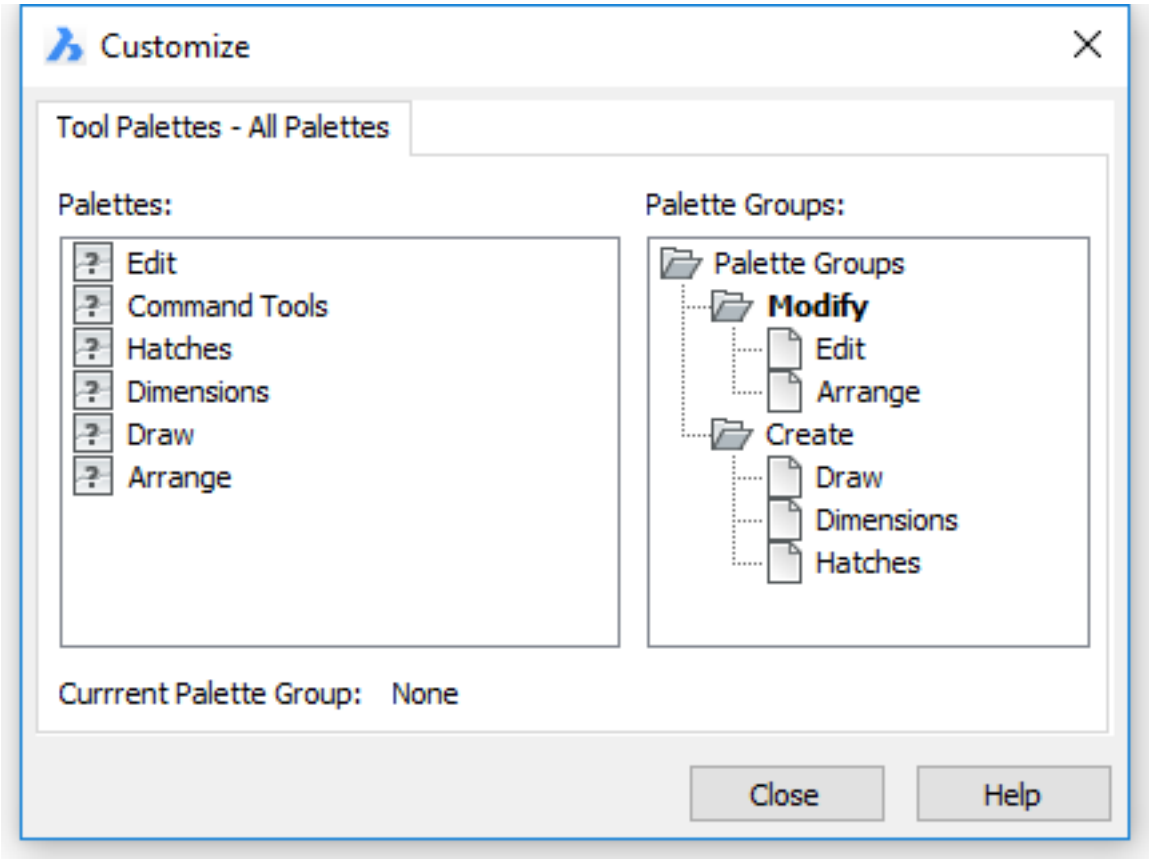


To import a tool palette

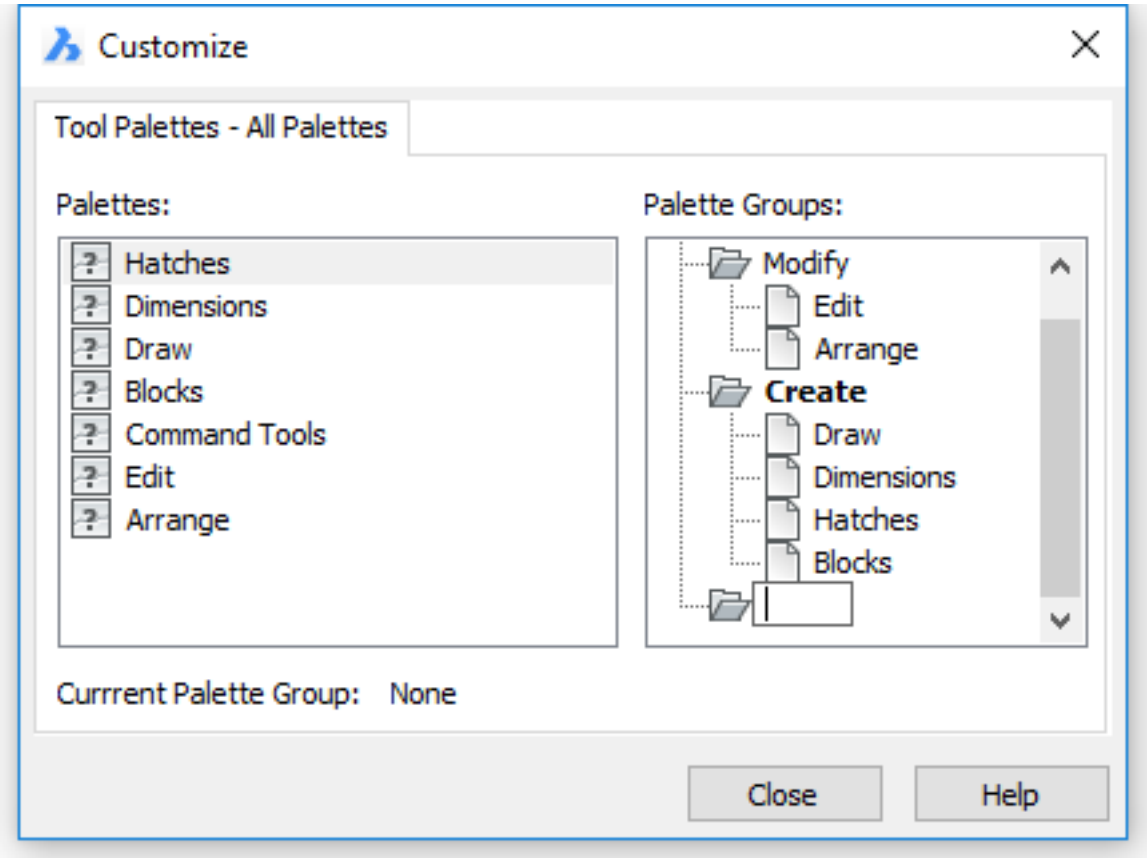
1. Open the Customize dialog box.
2. In the **Palettes** pane on the **Customize** dialog box, right click and choose **Import** in the context menu.
3. On the **Import Palette** dialog, select a folder, then select a palette file (*.btc or *.xtp).
4. Click the **Open** button or double click to import the palette. The palette is added in the **Palettes** list.
5. Click the **Close** button to close the **Customize** dialog box.

Working with palette groups

To create a palette group

1. Open the Customize dialog box.
2. Place the cursor on the **Palette Groups** root folder name.
3. Right click and choose **New Palette** in the context menu. A new group folder is added at the bottom of the palette groups tree. (1.394 on the next page)
4. Type a name for the new group.

Figure 1.394



To create a palette subgroup

1. Open the Customize dialog box.
2. Place the cursor on an existing group name.
3. Right click and choose **New Palette** in the context menu. A new group folder is added as a subgroup of the selected group.
4. Type a name for the new group.

To add a palette to a group

1. Open the Customize dialog box.
2. Place the cursor on a palette.
3. Press and hold the left mouse button, then drag the palette onto a palette group name.
4. Release the left mouse button to add the palette to the group.

To remove a palette from a group

1. Open the Customize dialog box.
2. Select the palette in the group.
3. Right click and choose **Remove** in the context menu.

To set a palette group current

1. Open the Customize dialog box.
2. Select the palette group in the palette groups tree.
3. Right click and choose **Set Current** in the context menu.

To delete a palette group

1. Open the Customize dialog box.
2. Select the palette group in the palette groups tree.
3. Right click and choose **Delete** in the context menu.

To rename a tool palette

1. Right click tool palette tab and choose **Rename Palette** in the context menu.
2. Type a new name for the palette in the **Name** field.
3. Press Enter to confirm.

To delete a tool palette

1. Right click tool palette tab and choose **Delete Palette** in the context menu.
2. Click the **OK** button on the **Confirm Palette Deletion** box.

Adding a hatch pattern

1. Select the palette you want to add a hatch pattern to.
2. Open the Hatch and Gradient (1.25.27) dialog box.
3. Select either **Predefined** or **Custom** from the **Type** list button.
4. Double click the **Swatch** field on the **Hatch and Gradient** dialog box. The **Hatch Pattern Palette** displays.
5. Select the hatch pattern you want to add, then right click and Choose **Add to Current Tool Palette**. The hatch pattern is added on the current tool palette. (1.395 on the following page)
6. (option) Repeat steps 5 and 6 to add more hatch patterns.
7. (option) Drag-and-drop patterns to change their order on the palette.

Adding blocks

Blocks can be added from the current drawing or from any drawing.

Adding blocks from the current drawing:

1. Choose **Drawing Explorer - Blocks** in the **Tools** menu.
2. On the **Drawing Explorer - Blocks** dialog box select the block or blocks you want to add.
3. Right click and choose **Add to Current Tool Palette** in the context menu.

Adding blocks from any drawing:

1. If not already available, add the containing folder to the Folders (6.13.15) list on the **Drawing Explorer - Drawings** dialog box.
2. Select the drawing in the containing folder on the **Drawing Explorer - Drawings** dialog box.
3. Click the **Expand** icon (+) of the containing drawing. The **Blocks** icon of the drawing displays.
4. Click the **Blocks** icon of the containing drawing. The blocks in the drawing display in the **Details** pane.
5. Select the block or blocks you want to add. Press and hold the Ctrl key to select multiple blocks.
6. Right click and choose **Add to Current Tool Palette** in the context menu.
7. (option) Drag-and-drop blocks to change their order on the palette.

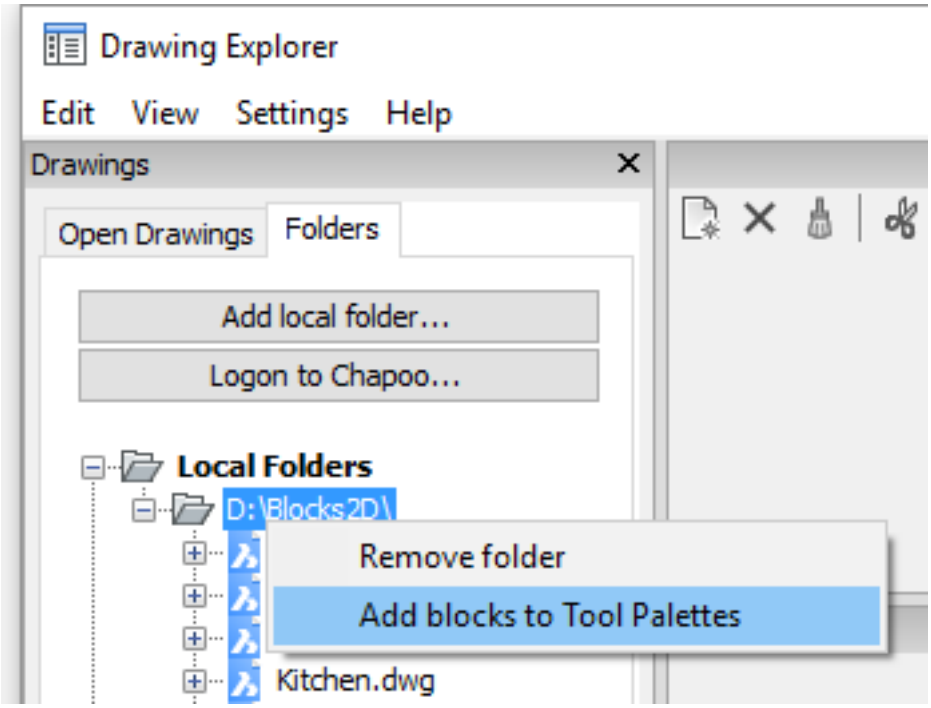
Adding all blocks from multiple drawings. This procedure collects all blocks in each of the drawings of the selected folder and add them to a palette of the drawing name. New palettes are created if necessary.

1. If not already available, add the containing folder to the Folders (6.13.15) list on the **Drawing Explorer - Drawings** dialog box.
2. Select the folder, then right click and choose **Add blocks to Tool Palettes** in the context menu. (1.398 on the next page)

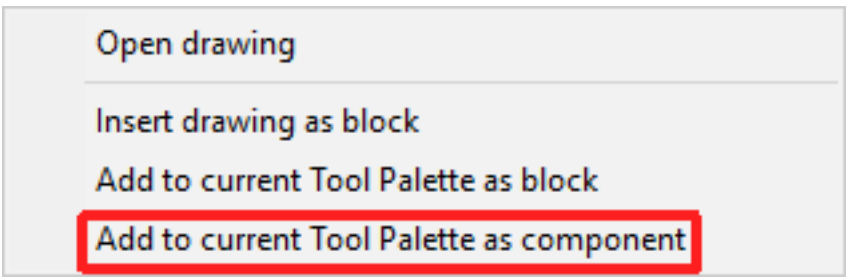
Figure 1.398



To add a drawing as a component.

1. If not already available, add the containing folder to the Folders (6.13.15) list on the **Drawing Explorer - Drawings** dialog box.
2. Select the drawing in the containing folder on the **Drawing Explorer - Drawings** dialog box.
3. Right click and choose **Add to Current Toolpalette as component** in the context menu. (1.399) When placing a component from the tool palette, the **-BmInsert (6.8.16)** command is launched.

Figure 1.399



Adding a command

1. Choose **Customize** in the **Tools** menu.
2. Under **Available Tools** on the **Customize** dialog, expand the containing toolbox, then select the command in the commands list.
3. Right click and choose **Add to Current Tool Palette** in the context menu.
4. (1.400 on the next page)
5. (option) Drag-and-drop commands to change their order on the palette.

NOTE	See the topic Creating Custom Tools (1.17.5) to create your own tools, which you can then add to a tool palette.

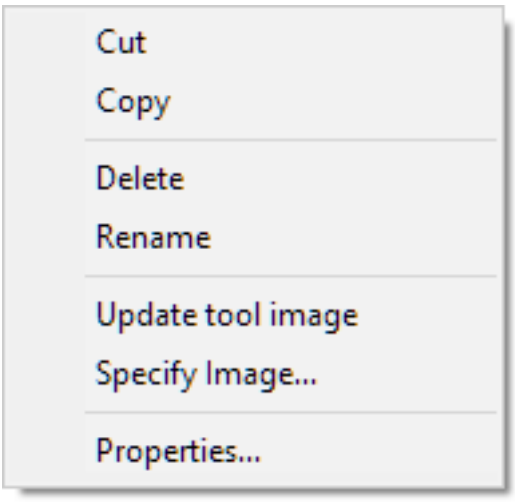
Managing tools

To manage the tools on a tool palette do the following:

1. Right click the tool. A context menu displays: (1.404)
2. Choose an option in the context menu.

Figure 1.404



To specify a tool image

1. Right click the tool and choose **Specify Image** in the context menu. A file dialog box displays.
2. Select the image file, then click the **Open** button.

NOTE	To restore the original tool image: Right click the tool and choose **Remove Image** in the context menu.

To move a tool Drag-and-drop tools to re-arrange tools on a palette: drag the tool to the desired location and drop the tool on top of the existing tool. To move a tool from one palette to another, do the following:

1. Right click the tool on the source palette and choose **Cut** in the context menu.
2. Select the target palette.
3. Right click and choose **Paste** in the context menu. The tool is added at the bottom of the palette.

To copy a tool To copy a tool from one palette to another, do the following:

1. Right click the tool on the source palette and choose **Copy** in the context menu.
2. Select the target palette.
3. Right click and choose **Paste** in the context menu. The tool is added at the bottom of the palette.

Tutorial: Customizing Commands in the Tool Palette Click here (1.12.14) to watch

1.17.8 User Profile Manager

Command: ProfileManager (6.24.52) In BricsCAD you can customize the settings that control your drawing environment, which can then be saved in a **user profile** . You can create multiple user profiles, e.g. a profile to run BricsCAD with a white background and a limited set of toolbars and another profile with no command bar and all toolbars and snap settings needed to draw comfortably in 3D. User profiles can also be used when multiple users share the same computer and each user likes to create his personal drawing environment. User profiles can be exported to a file, which can then be imported on a different computer. This allows you to copy your settings to a new computer or to install the same settings on multiple computers. If you use third party applications on top of BricsCAD, you might want to create a user profile to use with each of these applications. The **User Profile Manager** is a standalone tool that lists the existing profiles and provides all tools needed to Load, Create, Set Current, Copy, Rename, Delete, Export and Import user profiles.

Content of a user profile

User profiles save many settings that control the drawing environment. Once you start BricsCAD using a user profile, it automatically tracks and stores changes that you make to your drawing environment.

- Main Cui file.
- Current Workspace: BricsCAD has six standard workspaces: Drafting, Drafting (toolbars), Modeling, Modeling (toolbars), Mechanical and BIM.
- Configuration settings: all system variables which are saved in the Registry () and user preferences.
- Default plot settings.
- Settings in dialog windows, e.g. search options in the **Settings** dialog.
- Project (1.19.11) settings
- Recent paths
- Status bar (1.15.2) settings
- Properties Panel (1.15.4) settings
- Toolbar and menu configuration
- Worksets (6.33.15).

To Launch the User Profile Manager

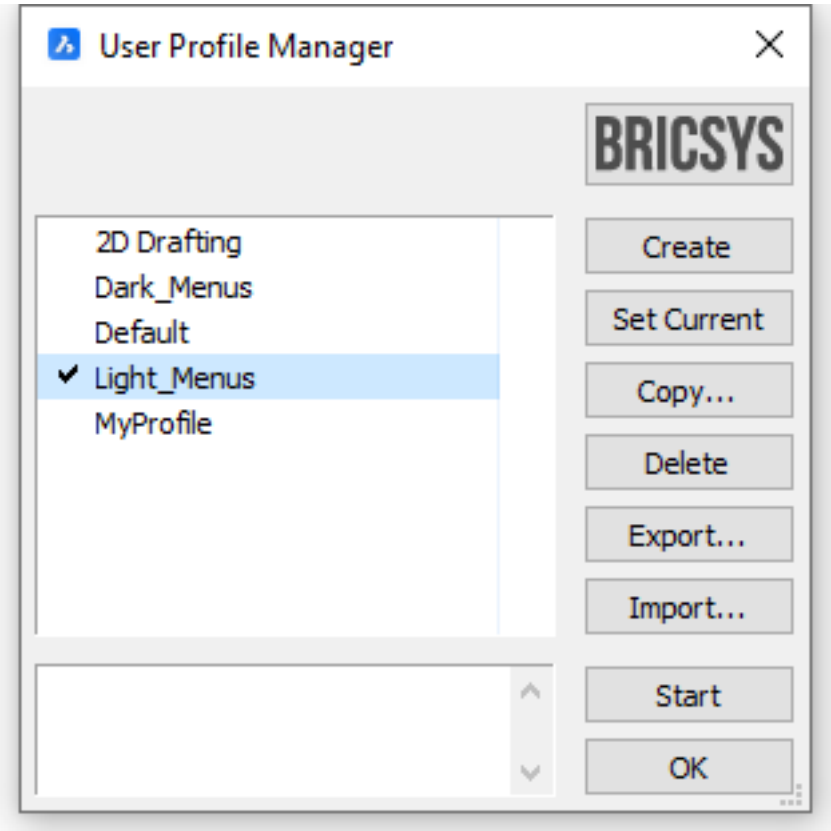
Do one of the following:

- When BricsCAD is running, launch the PROFILEMANAGER (6.24.52) command.
- Type **User Profile Manager** in Windows command line.
- Double click **profilemanager_app.exe** in the BricsCAD program folder (e.g. C:\Program Files\Bricsys\BricsCAD Vx). (6.1975 on page 5176)

In the **User Profile Manager** dialog:

- The **Current Profile** is marked.
- **Create:** Creates a new profile, using default settings.
- **Set Current:** Loads the selected profile.
- **Copy:** Click to make a copy of the selected profile.
- **Delete:** Click to delete the selected profile.
- **Export...:** Click to save the selected profile to a file on your computer, disk, or network. The file is saved with an **.arg** extension.
- **Import...:** Click to open a profile that has been saved to an **.arg** file).
- **Start:** Starts BricsCAD with the selected user profile.. This option is available only when the command is launched using **profilemanager_app.exe** in the BricsCAD installation folder.
- **OK:** Closes the **User Profile Manager** dialog
- Double click a profile in the list to load the profile.

Figure 1.405



Starting BricsCAD with a specific user profile

When you start BricsCAD, the user profile that was current when you closed the previous BricsCAD session is used. To create a desktop shortcut to launch BricsCAD using a specific user profile, do one of the following:

- Add the **/P option** to the **Target** settings of the BricsCAD shortcut. To open the shortcut settings dialog: right click the shortcut icon on the desktop and choose **Properties** in the context menu. A typical BricsCAD shortcut could be: **"C:\Program Files\Bricsys\BricsCAD Vx\bricscad.exe" /P UserProfileName** (1.406 on the next page)
- Launch the User Profile Manager, then either double click a user profile or select a user profile and click the **Start** button.

NOTES

- The **/P** option is case insensitive.
- A space is needed between the file location and /P option.
- When BricsCAD is already running a second instance of BricsCAD is launched, at least on condition that the **SINGLETON** variable is OFF. This variable controls whether multiple BricsCAD sessions can run simultaneously. See the Settings dialog (1.17.10) for more information about variables and settings.
- If the user profile in the argument of the **/P** option does not exist, the user profile is created automatically using default hard-coded values for all settings.
- If the user profile name contains spaces, use double quotes: e.g. /P "background white".

To import a user profile from another user

When you import a user profile of another user all user dependent search paths (e. g. the **local root** and **roamable root** folders - see BricsCAD User Files (1.17.2)) still refer to the other user, as a result the folders cannot be found and error messages such as "Unable to open program parameters file: default.pgp" might pop up when you start BricsCAD. To correct this problem do the following:

1. Open the exported user profile (*.arg) in a text editor such as Notepad.
2. Replace the user name dependent references with an environment variable. On a Windows XP computer replace **C:\\Documents and Settings\\username** with **%USERPROFILE%.** On a Windows Vista or Windows 7 computer replace **C:\\Users\\username** with **%USERPROFILE%.**
3. Use the **Find/Replace** procedure to quickly replace all references.
4. Save the user profile (*.arg)
5. Import the user profile.

Start BricsCAD using the imported profile. The environment variable **%USERPROFILE%** will be replaced with: **C:\\Users\\currentusername**.

NOTE	Environment variables in profiles, using the %<variable_name>% format, are supported in V10.3.11. and higher.

1.17.9 Command Aliases

Command aliases are alternative names for BricsCAD commands. You can launch the LINE command by entering L at the command prompt. There is no need to type the complete name. After typing the command alias at the command prompt the command is executed. Some commands have more than one alias: e.g. REC, RECT and RECTANGLE are all aliases for Rectang (6.26.6), whereas the last alias is even longer than the command name. In general, command aliases can increase your speed in entering the commands at keyboard. Command aliases are saved in a *.pgp file (P roG ram P arameters file). By default the **default.pgp** file in the **Support** folder of the Roamable Root folder (1.17.2) is used. If a command can be executed transparently (= while another command is being executed), the alias can also be used transparently. To execute a command or an alias transparently, precede the command name or alias with an apostrophe (').

NOTES

- Unlike commands, aliases are only local and cannot be used as global (preceded by a underscore (_).
- Command aliases cannot be used in scripts (*.scr).

To edit the alias file in a text editor

In order to modify existing aliases or to create new ones, the **default.pgp** file can be edited using an ASCII text editor (e.g. Notepad). The first section of the **default.pgp** file defines the **Shell** commands. The second section of the **default.pgp** file defines command aliases. The following syntax is used to define a command alias: **alias, *command** **alias** = the character string to be entered at the command prompt. The command alias must be followed by a comma (,). **command** = the BricsCAD command. The command name must be preceded by an asterisk (*). Comment lines must be preceded by a semicolon (;). Comment lines can be used to add additional information, e.g. when the file was last edited and by whom. Some commands, such as Hatch (6.16.3) or Boundary (6.6.15), can be preceded by a hyphen (-) to access the command line version of the command instead of the dialog box version. Command aliases can be created for these commands also, e.g.: **vi, *-view** Execute the REINIT (6.26.22) command to reload the alias file when it was externally edited.

Using the Customize dialog to edit the alias file

1. Open the Customize dialog (1.17.4).
2. Click the **Aliases** tab on the **Customize** dialog. (1.407 on the following page)
3. **Optional** To create a new alias:
   - Click the **Add** button. The **Add Alias** dialog box displays: (1.408 on the next page)
   - Click the down arrow at the right hand side of the **Command** field, then select a command. You can start typing the command name in the **Command** field to easily find the command in the list.
   - Type the command alias for the command in the **Alias** field.
   - Click the **OK** button.
4. **Optional** To edit an existing alias:
   - Select the alias in the list.
   - Click the **Edit** button. The **Edit Alias** dialog box displays: (1.409 on page 439)
   - Type a new alias in the Alias field. If the alias already exists you are prompted to overwrite the existing alias.
   - Click the **OK** button.
5. **Optional** To delete an alias:
   - Select the alias in the list.
   - Click the **Delete** button. A **Confirm** box displays.
   - Click the **OK** button on the Confirm box to delete the alias.
6. Click the **OK** button on the **Customize** dialog to stop.

Figure 1.407

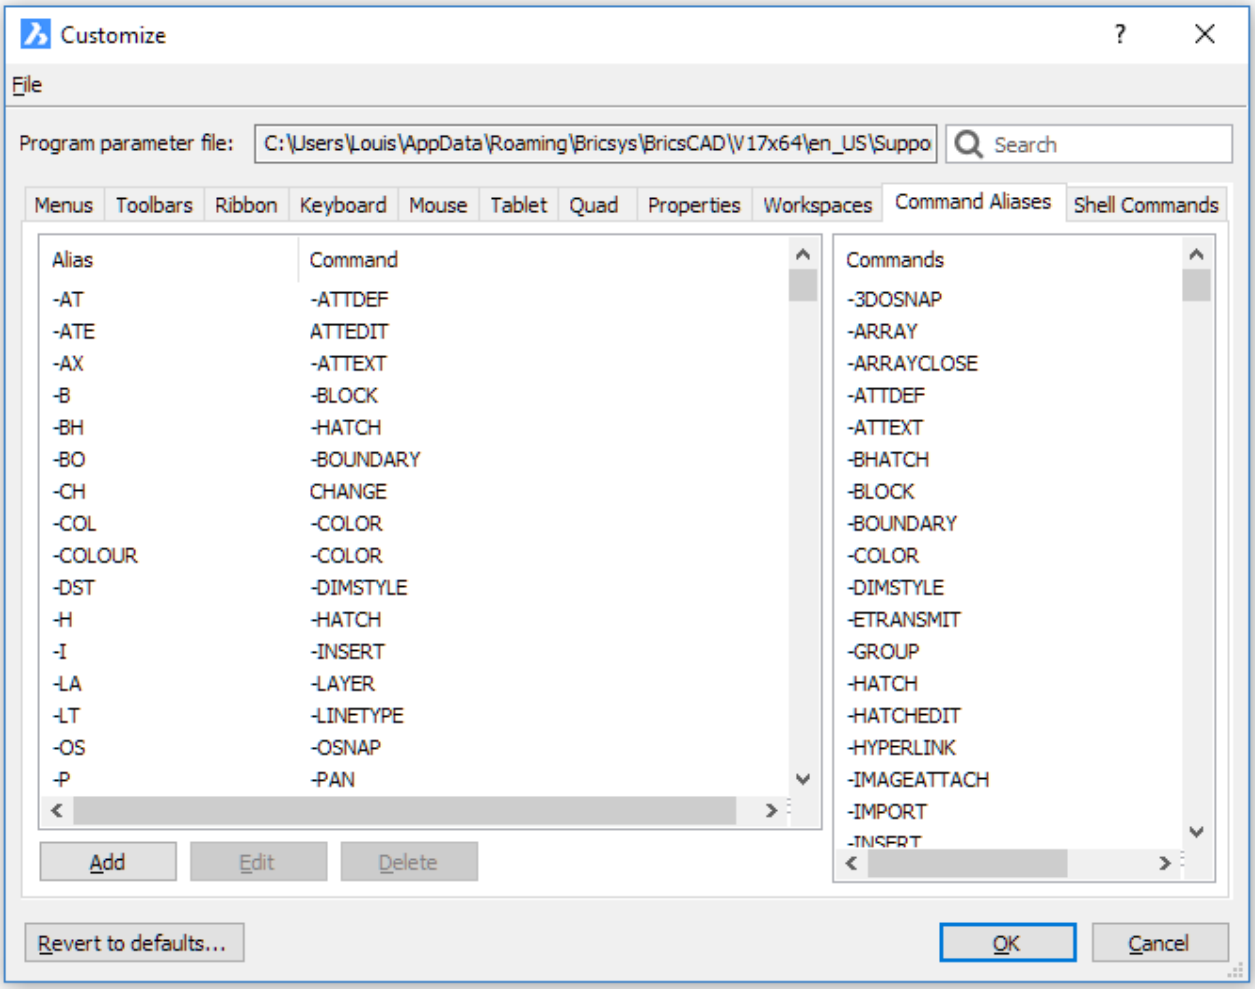

Figure 1.408

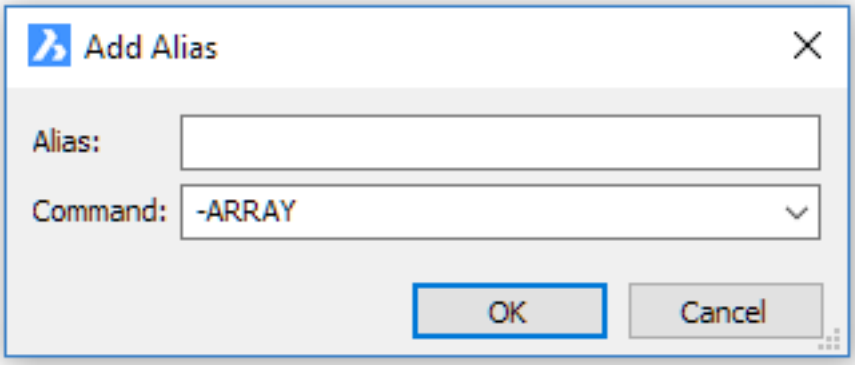

Figure 1.409

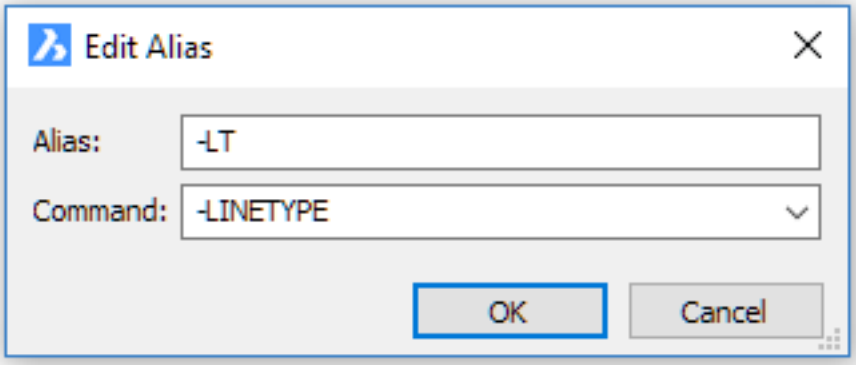

NOTE	If you use the **Customize** dialog to edit the alias file, it is not necessary to execute the ReInit (6.26.22) command.

Tutorial: Abbreviating Command Input with Aliases Click here (1.12.11) to watch

1.17.10 Settings dialog box

Command: Settings (6.27.25)

Tutorial: Settings is Better Than Options and Here's Why Click here (**??**) to watch

Access the Settings dialog box

BricsCAD centralizes all system variables and user preferences in a single dialog box called Settings. If you like to type, you can access the Settings dialog box with the Options (6.23.11) or DSettings (6.10.43) commands. If you prefer graphical access, you'll find the **Settings** tool in the **General** command group on the Quad. (1.410 on the next page) Tools in the Settings dialog box enable you to find and edit the 900+ system variables and user preferences in BricsCAD. You can even export all them and their values to a CSV file. (1.411 on page 442) The tools at the top of the Settings dialog box, allow you to view the settings in different ways:

- : Categorized
- : Alphabetical
- : Differences compared to the defaults

Below those tools is the list of settings. And, at the bottom, you'll find useful information about the selected setting. (1.412 on page 443)

1. Selected setting
2. Name
   - System variable names are fully capitalized: INSUNITS
   - User preference names are mixed case: TemplatePath
3. Title
4. Description
5. Type and save location
   - : Editable setting
   - : Not-editable setting
   - : Saved in the drawing = can be defined differently in each drawing
   - : Saved in the registry = applies to all drawings opened in the current user profile
   - : Setting cannot be saved
   - 
     : Most settings correspond to AutoCAD variables. There are, however, a few that are unique to BricsCAD. They are clearly indicated by an additional icon.

Categorized View

The Categorized tool displays a tree view that groups the variables into the various categories. You can expand each category to access relevant variables. And, in many cases, you can expand additional subcategories.

Alphabetical View

If you know the name of the setting you want to modify, you may prefer to display the settings instances rather than categorically. Doing so lists all the settings alphabetically based on their **Title**. The title is different from the actual variable name. For example, **Angle direction** controls the ANGDIR system variable. Configure Settings dialog box

Click the **Configure** icon () on the **Settings** toolbar. The **Configure Settings Dialog** allows you to control how BricsCAD searches for settings and how modified settings are listed when the **Differences** view mode is selected. (1.415 on the facing page)

Find settings

To find a setting do the following:

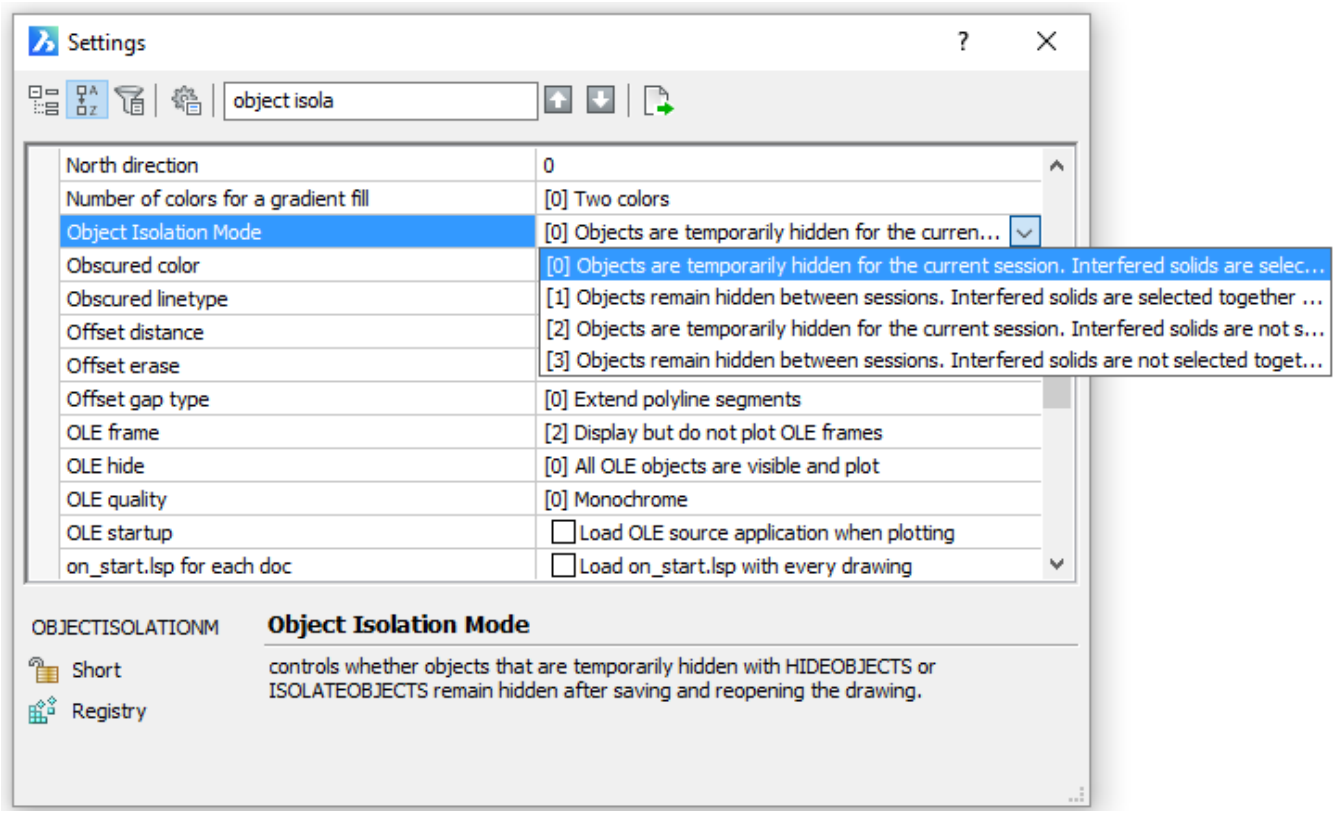
1. **Optional** Open the **Configure Settings Dialog** to set the Find where options.
2. Type a string in the Search field. As you type the first setting matching the content of the search field highlights.
3. Do one of the following:
   - Keep typing typing: the next matching setting highlights as you type.
   - Click the **Find Next** () or **Find Previous** () buttons to jump to the previous or next setting matching the content of the search field. The background color of the search field turns green when the final matching setting has been reached.

Edit settings

After you find the setting you want, select it to view its current value and properties. If the setting is editable, you can click in the value box to change it. The value options vary depending on the setting. For example, some may require you to enter a number, while others may include a check box or drop-down list. (1.416 on the next page)

Some settings are grey indicating they're read-only. In addition, a lock icon () in the lower left corner of the Settings dialog box clearly identifies them as read-only .

Figure 1.416



Edit system variables at the Command line

The Settings dialog box offers a graphical and intuitive method for you to view and edit system variables and user preferences. It can be particularly useful if you don't know the exact name of the variable or if you want to change several variables. However, if you prefer to view and edit variables via the Command line, you can do that too! Simply enter the variable name or launch the SETVAR (6.27.28) command. System variable names are recognized by the **Autocomplete** feature of the command bar if the **Exclude the display of system variables** option of the **AUTOCOMPLETEMODE** system variable is not checked. User preference names are recognized by the **Autocomplete** feature of the command bar if the **Display preference variables** option of the **AUTOCOMPLETEMODE** system variable is checked.

Export settings

Regardless of how you view or edit settings in BricsCAD, you can easily export them to a comma delimited (CSV) file. Click the **Export** icon ( ) then enter the file name and location on the **Export Settings** dialog box. With the CSV file created, you can open it in a spreadsheet app to easily view all the variable properties. This can be especially helpful for troubleshooting behavior differences between different systems or drawings.

1.17.11 Workspaces

Commands: Workspace (6.33.14), WsSave (6.33.19) The **Workspace** command sets the current workspace and lets you create, modify and save workspaces. The **WsSave** command saves the current workspace under a different name, thus creating a new workspace. Workspaces define settings and preferences regarding a specific working environment. The following workspaces are available:

- Drafting
- Drafting (toolbars)
- Modeling
- Modeling (toolbars)
- Mechanical
- BIM

See: Exploring each workspace (**??**) The name of the workspace is stored in the WSCURRENT system variable of the current User Profile (1.17.8). If the GETSTARTED (1.17.10) system variable is ON, the BricsCAD Launcher (**??**) dialog box (1.19.1) displays on startup. Here you can select workspace to use.

Managing workspaces

Workspaces are defined in the **Workspace** tab page on the **Customize** dialog. Do one of the following:

- Open the Customize dialog (1.17.4), then select the **Workspace** tab.
- Right click the **Current Workspace** field in the Status Bar (1.15.2), then choose **Customize...** in the context menu.

(1.417 on the facing page) A workspace definition is composed of:

- Menus : defines which menus are available.
- Toolbars : defines which toolbars display by default.
- Panels: controls the visibility of dockable panels (1.15.7). (1.418 on page 454) Right click a palette then choose an option in the context menu:
  - Show: 
  - Hide: 
  - Don't change: 
- Ribbon : defines the available ribbon tabs.
- Quad Tabs: defines the order and availability of the Quad tabs.
- On Switch : defines the system variables and user preferences to be set and the commands to be executed when switching to the workspace.

Setting the current workspace

Do one of the following:

- Right click the **Current Workspace** field in the Status Bar (1.15.2), then select a workspace in the context menu.

  1. (1.419)

- Choose a workspace in the **Workspaces** toolbar. (1.420 on the next page)
- Type **wscurrent** at the command prompt. You are prompted: **New value for WSCURRENT, or . for none/<"2d DRAFTING">:** Type the name of the new current workspace, then press enter.

NOTES

- If the WSAUTOSAVE (1.17.10) system variable is On, upon switching to another workspace, the toolbar positions of the current workspace are saved in the CUI file. The default value for WSAUTOSAVE is ON.
- It is not recommended to alter the workspace if the name of the user profile refers to a workspace.

Figure 1.419

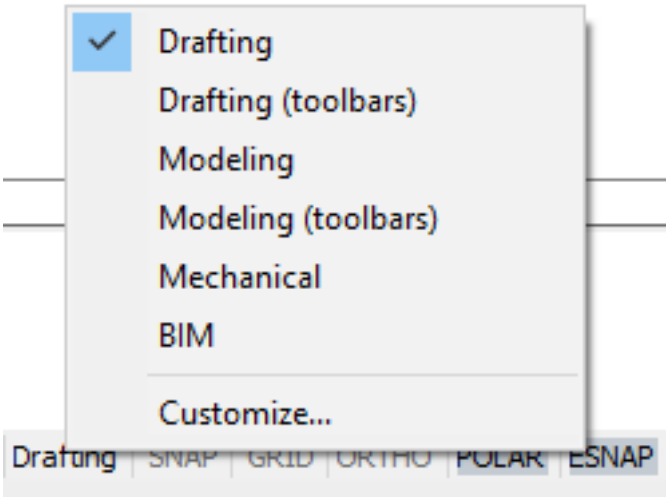

Figure 1.420

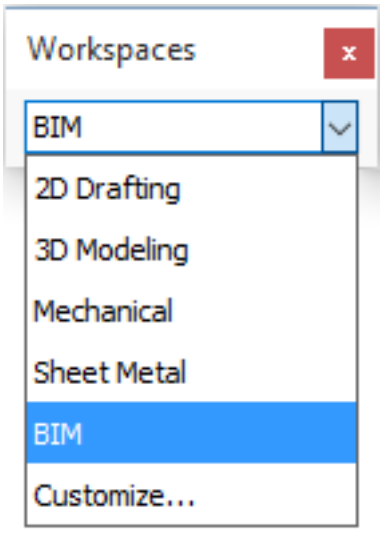

Creating a workspace

1. Right click the **Current Workspace** field in the Status Bar (1.15.2), then choose **Customize...** in the context menu.
2. Do one of the following:
   - Select **Workspaces** , then right click and choose **Append Workspace** in the context menu.
   - Select an existing workspace, then right click and choose **Insert Workspace** in the context menu.
3. Type a name for the new workspace, then click the **OK** button.(1.421)

When appending a workspace, the new workspace is created below the last existing workspace. When inserting a workspace, the new workspace is created above the selected workspace. (1.422 on the next page) A newly created workspace contains the following items:

- A standard menu set
- A standard toolbar set
- All palettes set to **Don't change**
- An empty ribbon
- A default set of Quad tabs
- An empty **On Switch** sequence

Editing a workspace

1. Right click the **Current Workspace** field in the Status Bar (1.15.2), then choose **Customize...** in the context menu.
2. Click the **Expand** button (+) of the workspace.
3. Edit the menu set:
   - Change the order: Drag a menu to another location.
   - Delete a menu: select the menu, then right click and choose **Remove** in the context menu.
   - Insert a menu:
     - Right click a menu in the list and choose **Insert menu** in the context menu. The **File** menu is inserted by default.
     - In the **Workspace Menu** grid, select the **ID** field and select the desired menu in the list.
4. Edit the toolbar set:
   - Change the order: Drag a toolbar to another location.
   - Delete a toolbar: select the toolbar, then right click and choose **Remove** in the context menu.
   - Insert a toolbar:
     - Right click a toolbar in the list, and choose **Insert toolbar** in the context menu. The **Standard** toolbar is inserted by default.
     - In the **Workspace Toolbar** grid, select the **ID** field and select the desired toolbar in the list.
5. Edit the visibility of the palettes:
   - Select the palette.
   - Click the **Display** property in the **Workspace Palette** grid, then set the desired 'on switch' behavior: **Show** , **Hide** or **Don't change** .
6. Edit the composition of the ribbon:
   - To add a tab: right click an existing tab, then choose **Insert tab** in the context menu and select the tab in the **Select Ribbon Tab** dialog.
   - To remove a tab: right click the tab and choose **Remove** in the context menu.
   - To change the position of a tab: press and hold the left mouse button, then drag the tab to the desired place.
7. Edit the Quad settings:
   - To change the order of the Quad command groups: press and hold the left mouse button, then drag a command group to its new position.
   - Right click a Quad command group, then choose **Switch off** in the context menu to remove the command group from the Quad cursor menu.
   - Right click a currently switched off Quad command group then choose **Switch on** in the context menu to add the command group to the Quad cursor menu.
8. Edit the **On Switch** procedure: To add a command to the **On Switch** sequence: select the command in the available commands pane and drag it to the **On Switch** node. (1.423 on the facing page)

NOTE	See To create a new tool (1.17.5) if you want to add a custom tool to the **On Switch** sequence.

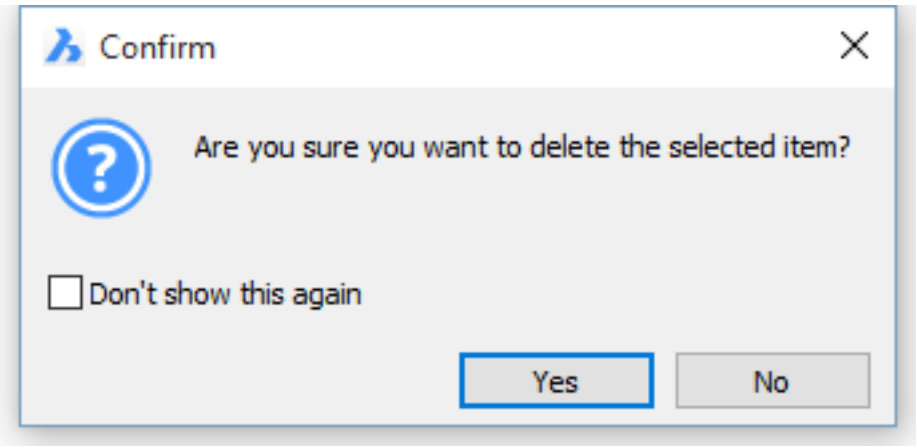
Deleting a workspace

1. Right click the **Current Workspace** field in the Status Bar (1.15.2), then choose **Customize Workspaces...** in the context menu.
2. Right click the workspace, then choose Delete in the context menu. A Confirm dialog box displays: (1.424)
3. Press the **Yes** button to delete the selected workspace.

Note: Do not delete default workspaces, as they are used in the BricsCAD Launcher (**??**). When one of the default workspaces is deleted, use the **Importing a Workspace** procedure below to restore the missing workspace from Default.cui in the .../UserDataCache\Support\en_US subfolder of the BricsCAD installation folder.

Figure 1.424



Importing a workspace

The option in the **File** menu on the **Customize** dialog box can import workspaces from another CUI file into the current main CUI.

1. Open the Customize (1.17.4) dialog.
2. In the **File** menu choose **Import Workspace(s)...** The **Choose a Customization File** dialog displays.
3. Browse to the folder where the CUI file, you want to import the workspace from, is saved. By default BricsCAD saves CUI files in the **Support** folder of the Roamable Root folder (1.17.2). e.g. **C:\Users\<user_name>\AppData\Roamin**
4. Select the CUI file. A dialog box, listing all workspaces in the selected CUI file, displays: (1.425 on the following page)
5. Select the workspace to import in the list, then click the **OK** button. Press and hold the Ctrl-button to select multiple workspaces.

Figure 1.425

1.18 3D Modeling

1.18.1 Making 3D surfaces

https://www.youtube-nocookie.com/embed/zmJd9V_HJ6M Just as BricsCAD makes 3D solid models from 2D entities, it also can make 3D surfaces from them. After completing this lesson, you will be able to:

- Understand how to create surface models using Extrude, Revolve, and Loft.
- Create your own 3D surfaces from 2D entities.
- Define the path of a loft by using guides.

1.18.2 Modify 3D surfaces

https://www.youtube-nocookie.com/embed/x5Pw8POSfn8 Once you've made 3D surfaces, BricsCAD lets you manipulate them with commands like XFaces (makes copies of individual faces), sweep profiles along paths, thicken surfaces into solids, twisting surfaces, and change the continuity of twisted surfaces. After completing this lesson, you will be able to:

- Understand the limitations in editing 3D surfaces
- Modify 3D surfaces with the Twist command
- Extract faces with the XFaces command
- Make new surfaces with the Sweep command

1.18.3 Slice, section and interfere

https://www.youtube-nocookie.com/embed/22CEWcG57TY Slicing Up 3D Models. Slicing, Sectioning and Finding Interferences. After completing this video, you will be able to:

- Understand how to use Slice, Section, and Interfere.
- Slice, section and find interferences between 3D models
- Know the difference between slices, sections and interferences.

1.18.4 Extrude and revolve

https://www.youtube-nocookie.com/embed/B4hTPwJAzCo Extruding and Revolving 2D Entities. A third way to create a 3D model in BricsCAD is to draw entities in 2D (called a "sketch") and then extrude or rotate them into 3D bodies. After completing this lesson, you will be able to:

- Understand how to use Extrude and Revolve.
- Create your own 3D models from 2D entities.
- Know the difference in extruding and revolving open and closed entities.

1.18.5 Slicing up 3D models

https://www.youtube-nocookie.com/embed/22CEWcG57TY **Slicing, Sectioning and Finding Interferences** After completing this video, you will be able to:

- Understand how to use Slice, Section, and Interfere.
- Slice, section and find interferences between 3D models
- Know the difference between slices, sections and interferences.

1.18.6 Snap to 3D geometry

https://www.youtube-nocookie.com/embed/VWQ6r5AK8fE

1.18.7 Loft 3D Surfaces

https://www.youtube-nocookie.com/embed/AV8wukyZ9LY The loft command creates surfaces along two or more cross-sections (open entities, such as splines) that determine the look across the length of the 3D loft entity. For additional control, you can optionally specify guidelines, which control how the surface looks along the length of the loft. After completing this lesson, you will be able to:

- Understand how to use Loft
- Create your own lofted 3D bodies from 2D and 3D entities
- Know the difference between cross-sections and guidelines

1.18.8 Thicken 3D and 3D entities

https://www.youtube-nocookie.com/embed/KjbRTkfvXj8 The Thicken command is useful for turning 2D entities into 3D bodies. As well, it copies 3D faces, thickening them into independent 3D bodies. After completing this lesson, you will be able to:

- Understand when to use Thicken
- Create new shapes by thickening existing ones
- Know the difference between thickening 2D entities and 3D faces

1.18.9 Twist 3D solids

https://www.youtube-nocookie.com/embed/DQgmdipAat0 The dmTwist command is one of the trickier ones to understand, and so this video explicitly shows you the purpose of its many options. It shows you how to do full twists, partial twists, on-axis, and off-axis twists of 3D solids. After completing this lesson, you will be able to:

- Use the dmTwist command
- Understand the meaning of its options
- Know the different results, depending on the axis

1.18.10 Sweep profiles along paths

https://www.youtube-nocookie.com/embed/qUuByFK0IU4 The Sweep command takes a 2D profile (a closed entity) and then extrudes it along a path (usually an open entity). The result is a 3D body that resembles a handrail or similar. After completing this lesson, you will be able to:

- Create your own 3D swept models
- Understand the difference between profiles and paths
- Know the shortcomings of the Sweep command

1.18.11 Use surface modeling and deformable modeling

Youtube This video shows how the deformable modeling and surface modeling tools can be used to edit imported geometry. The imported camera body is going to be edited with the Direct modeling tools. First of all remove the redundant hole. Then make a new hole to mount the new camera lens using the Extrude tool. To remove the camera flash, select the faces that need be removed and apply the Delete tool. BricsCAD intelligently removes the set of faces and restores the underlying shape. Secondly, use the Repair tool to check the model on geometric inconsistency. Switch to the Report tab in Mechanical Browser (3.3.2) to see all the issues that have been found. Fix all issues of the model. Then use the deform Point tool to edit the surface. This tool applies force to the specified base point in a specific direction. The base point, direction and target deformation position can be specified. Next, use the Extrude tool with the Subtract option. Then reduce the camera body using Move Point. With the Dynamic UCS switched off, Move Point will align deform direction with z axis of the current UCS. To create the mount for the camera flash, use the Extrude tool. Thirdly, use the Thicken tool to thicken the surface and insert the lens. Then you use the Simplify tool to replace the geometry of the faces and edges under the given entity by analytic surfaces and curves Finally, align the lens using a concentric constraint. Back to Tutorial Overview

1.18.12 Turning 2D Entities in Simple 3D

https://www.youtube-nocookie.com/embed/U8PxsCGA_fA Turning 2D Entities in Simple 3D. The most basic way to create 3D entities in BricsCAD is to add a thickness to entities and a Z coordinate to endpoints. After completing this, you will be able to:

- Use thickness to turn some 2D entities into 3D ones.
- Change the Z elevation of some entities.
- Know which entities work with Z and thickness.

1.18.13 3D Manipulator

Youtube BricsCAD provides an on-screen widget called the Manipulator for moving, copying, rotating, resizing (scale), and mirroring entities and bodies in 3D. After completing this video, you will be able to:

- Use manipulator widget in BricsCAD.
- Activate the manipulator several ways.
- Know the actions the manipulator can do.

1.18.14 Section planes

https://www.youtube-nocookie.com/embed/14SglJiQtbw To look inside 3D models, like houses or gearboxes, BricsCAD provides the SectionPlane command. Once in the drawing, you can manipulate the section plane to see other parts of the model. The effect of section planes can be saved (as blocks). After completing this lesson, you will be able to:

- Understand how to use section planes and change their look
- Create your own 3D and 2D sections, and save them as blocks
- Know the difference a section entity and a section plane

1.18.15 Flatten and extract faces and edges

https://www.youtube-nocookie.com/embed/opGotp0H3RY 3D models don't have to stay 3D; BricsCAD can flatten them with a variety of commands, each with their pros and cons. The Flatten command flattens the entire 3D model to a series of 2D lines and polylines that look "3D"; the FlatShot command does similarly, but makes a copy and then lets you specify the look of hidden lines (such as dashed, colored). By contrast, the XEdges command makes copies of individual edges on 3D models as 3D splines and circles; while XFaces command extracts faces as 3D surfaces. After completing this lesson, you will be able to:

- Understand how to flatten 3D models
- Extract edges and surfaces from 3D models
- Know how to use Flatten and FlatShot, and XEdges and XFaces

1.18.16 Deform faces

https://www.youtube-nocookie.com/embed/0xvrPDI1j8E Faces normally are flat or made of simple curves, but BricsCAD can deform them into complex shapes. The dmDeformPoint stretches a face between edges and a point in space. The dmDeformCurve command is similar, but deforms a face to stretch it between its edges and an entity in space, like a circle. After completing this lesson, you will be able to:

- Understand what it means to deform faces
- Use the dmDeformPoint and dmDeformCurve commands
- Create new kinds of 3D models as deformed ones

1.18.17 Naming 3D parts

https://www.youtube-nocookie.com/embed/g7KzMCwak_4 Naming the Parts of 3D Models Three-D modeling has its own jargon, which can be confusing to neophytes, and so this video illustrates the bit and parts of 3D models. After completing this lesson, you will be able to:

- Talk about the parts of 3D models accurately
- Identify features like the vertex, edge, and face
- Know the difference between solids, surfaces, and meshes

1.18.18 Draw 2D Entities in 3D Space

https://www.youtube-nocookie.com/embed/rwHA_-DCE2k Drawing in 3D is 6x harder than 2D, because models have six sides to them and some parts are inevitably hidden from view. This video shows tips and tricks in seeing more than one side at a time, and you learn the names of standard engineering views. You learn the importance of normals, and how to easily draw on the sides of 3D faces, as well as rotate entities in 3D space. After completing this lesson, you will be able to:

- Understand how to use x,y,z coordinates
- Draw 2D entities on 3D models
- Use normals and commands like 3DRotate to change the orientation of 2D entities in 3D space

1.18.19 Solids, surfaces and Meshes

https://www.youtube-nocookie.com/embed/jUEt6Mp7opw Pros and Cons of Using Solids, Surfaces, or Meshes. BricsCAD provides three different kinds of 3D models -- solids, surfaces, and meshes -- and lets you convert from one to another. After completing this lesson, you will be able to:

- Know the difference between solids, surfaces, and meshes
- Understand how well each can be edited
- Convert between solids, surfaces, and polyface meshes

1.18.20 Boolean operations

https://www.youtube-nocookie.com/embed/NXiCmOof0kY Joining, Separating, and Removing 3D Solids. Once you have several solid primitives in a BricsCAD drawing, you want to combine them, cut them, and drill into them. After completing this video, you will be able to:

- Understand how to use Boolean operations.
- Modify two or more 3D models.
- Know when and how to use Union, Intersect, and Subtract.

1.18.21 3D fillet and chamfer

https://www.youtube-nocookie.com/embed/9TOYoqlgr4o Making Edges Curved and Slanted. After completing this video, you will be able to:

- Understand how to use Fillet and Chamfer.
- Modify 3D models by curving and slanting edges.
- Know how to fillet and chamfer interactively.

1.18.22 Solid edit: part 1

https://www.youtube-nocookie.com/embed/zjoMlZJaqKo The many faces of Solid Edit. After completing this video, you will be able to:

- Understand how to use the SolidEdit command.
- Copy and color faces of 3D models.
- Shell a 3D model to make it hollow.

1.18.23 Solid edit: part 2

https://www.youtube-nocookie.com/embed/HXf4Px-fyKw Copy, Color Edges, Move, Extrude Faces. After completing this video, you will be able to:

- Understand how to copy and color edges.
- Use the SolidEdit options Move and Extrude on faces.
- Know the difference between extruding and moving faces.

1.18.24 Static UCS, Set 2D Drawing Planes in 3D

https://www.youtube-nocookie.com/embed/4hGRvMM9FYo While dynamic UCS is useful in BricsCAD for modeling in 3D on existing faces, sometimes a static UCS (user-defined x,y-plane) is more convenient. After completing this video, you will be able to:

- Understand how to use UCSs in BricsCAD.
- Orient your own coordinate systems.
- Know how to reset the UCS.

1.18.25 3D Primitives

https://www.youtube-nocookie.com/embed/pJZwzipiWK0 Modeling Basic 3D Bodies. Another way to create a 3D model is by assembling basic 3D entities that BricsCAD calls "primitives." After completing this video, you will be able to:

- Understand what 3D primitives are
- Create 3D primitives
- Know how to draw with Box, Pyramid, Wedge, Sphere, Cylinder, Cone, Torus. and PolySolid.

1.18.26 Viewing in 3D

https://www.youtube-nocookie.com/embed/l5-Y2a9XjFM Viewing 3D models is trickier than 2D plans, because of the sides and backs that you normally do not see in 3D, and so BricsCAD provides quick ways to change your view of the model. After completing this video, you will be able to:

- Zoom, pan, and orbit 3D models in BricsCAD.
- Use the LookFrom widget to change views.
- Create multiple views of a 3D model at the same time.
- Save specific viewpoints by name for reuse.

1.18.27 3D Direct Modeling Basic Commands

https://www.youtube-nocookie.com/embed/FI7Q4XweiSw

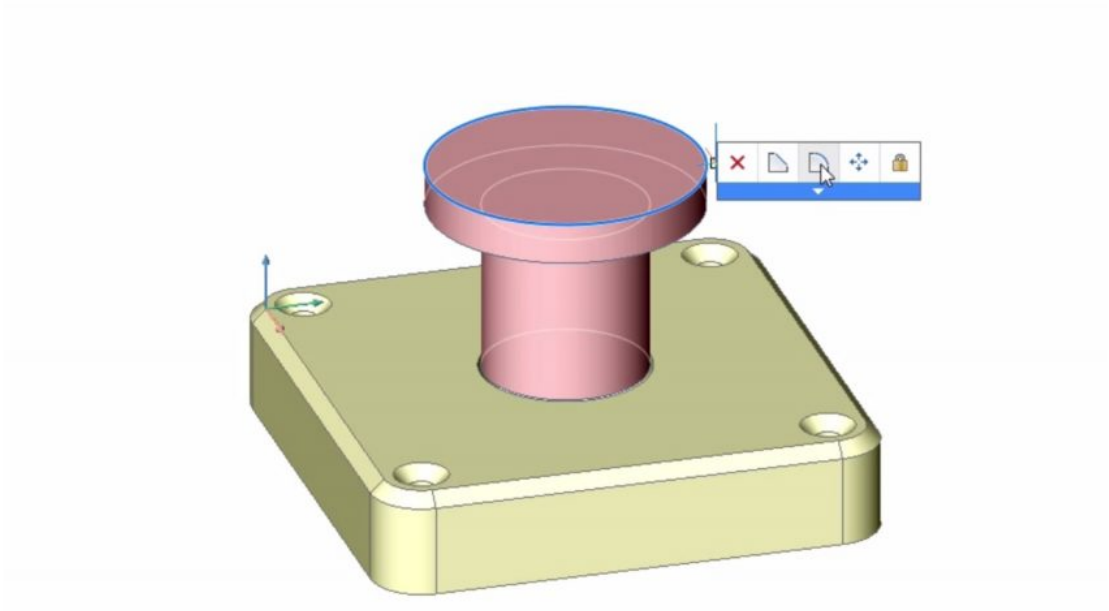
This tutorial shows how you can create complex models using powerful direct modeling technology that combines the best of two worlds: parametric and direct modeling.

Commands like chamfer, fillet, push/pull and extrude are all just one click away with the newly designed quad cursor. All designed bodies can be save as separate components. Bricscad also comes with a library which contains more than 30 thousands standard parts.

Using the context-sensitive quad cursor, your mouse movements are significantly reduced.

(1.426 on the next page) Back to Tutorial Overview

Figure 1.426



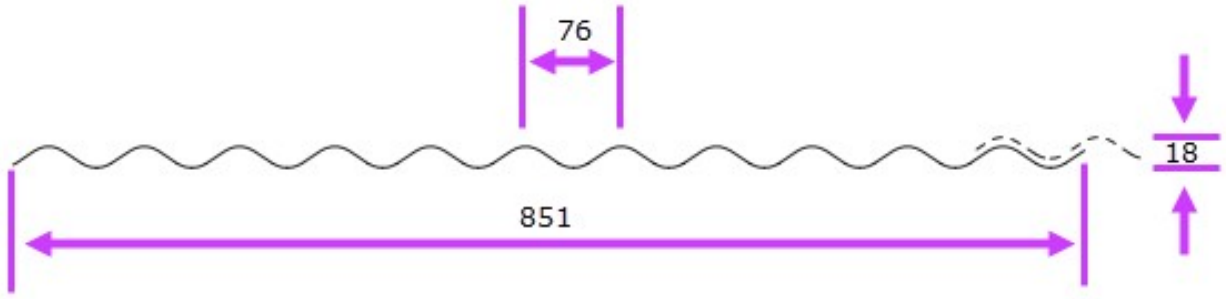
1.18.28 Extending onto the curve

https://www.youtube-nocookie.com/embed/kg9e3z7P5NY With BricsCAD V16.2, dynamic UCS (DUCS) has been enhanced to allow you to work with curved surfaces. In this example we use this extension to DUCS to quickly populate the connections on a pressure vessel. Back to Tutorial Overview

1.18.29 Making Beautiful Shapes from Lofts

https://www.youtube-nocookie.com/embed/EKGx7nzIPOY The Loft command is fascinating for the fantastical shapes it creates. It takes two or more 2D objects (like circles or ellipses at different elevations) or the faces of 3D solids, and then creates a solid that smoothly transitions between them. This video shows you how to use the Loft command between three ellipses, and then between two 3D solids. It shows the surprising effects you can achieve with lofts when you change the settings between ruled, smooth, normal, and draft-angle values. Back to Tutorial Overview

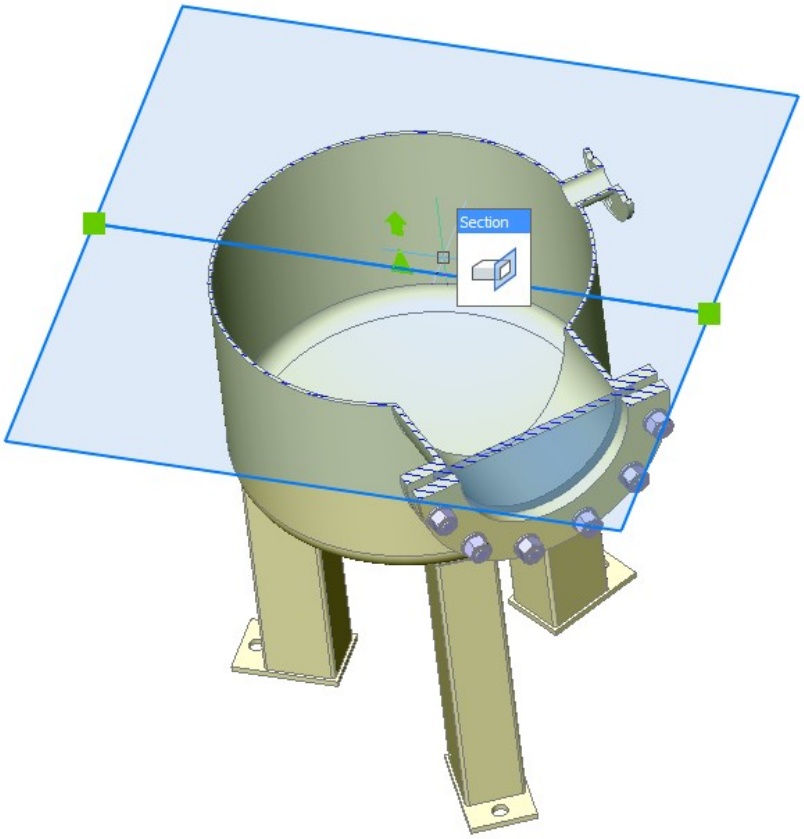
Figure 1.427



1.18.30 Project Geometry – Corrugate Iron

https://www.youtube-nocookie.com/embed/ujiS_02O9VU BricsCAD V16.2 introduces Project Geometry. This command projects 2D geometry onto a region, a surface or a 3D solid; creating linework that you can use in the development of your model. In this tutorial we are going to use PROJECTGEOMETRY to put a “twist” on an method given on the Bricsys Forum to create a Corrugated Iron profile from a HELIX. (1.427) Back to Tutorial Overview

Figure 1.428



1.18.31 3D Modeling at a Clip

https://www.youtube-nocookie.com/embed/BX5xVd4jFWE BricsCAD 16.2 includes an exciting new feature called Clip Display (CLIPDISPLAY (6.9.22)). Quite simply it's going to change how you work in 3D. If you're familiar with Live sections, then Clip display is similar, but there are some important differences. Firstly you can work with multiple SECTIONPLANE (6.27.18)s, or BIMSECTION (6.7.54)s at the same time. (1.428)

Continue to use all modeling and editing tools Clip display also only CLIPS the DISPLAY of the model, where a Live section temporarily replaces the model with cut solids. This means you are still working directly with your model, and can continue to use all modeling and editing tools, including object snaps. What's more Clip display will also allow you to snap to points created by the cutting plane itself, providing you with an additional set of options.

Clipped sections are updated in real time Finally Clipped sections are updated in real time as you move them, allowing you to quickly change focus around your model. Back to Tutorial Overview

1.18.32 Generate drawing views in BricsCAD

https://www.youtube-nocookie.com/embed/COkW63wpheM

Drawing views from any 3D model

In BricsCAD, you can generate drawing views from any 3D model. These views are updated automatically when the original model is changed.

Base View Use the "**base views**" command to generate 2D drawing views from your 3D model. Ever click is a new and different view placed on your sheet. You can change the properties of one or multiple views in the properties Bar. For example, disable hidden and tangent lines.

Drawing View The type of Section View can be changed in the drop-down menu in the "**drawing views**" section, which can be found in the Ribbon. Similarly, you can also create a half section from the bottom base view. You can see that the hatch angle is identical for different projections of the same solid. It changes according to the view section style of the solids. You can adjust the depth of the section by creating a section of the connecting flange of the valve and after placing the drawing view.

Detail view Through the "**detail view**" feature to zoom in on certain details of your drawing views. You can choose out of two option: create circular or rectangle detail views. If needed, you can also adjust the scale of your detail section.

Custom styles BricsCAD has a standard section style, but if that doesn't suit your needs, you can add new custom styles in the "**view section styles**" panel of the drawing explorer.

Customize your style Go the "**identifier**", where you can change the color of the identifier, its position and more. The preview images allows you to see all changes before they are applied. You can change color of the hatch, its scale, type and angles in the "**hatch**". Finally, in the "**cutting plane**", the linetype of the section lines, their color and lineweight can be changed. For the end and bend lines, you can change the position, color, lineweight and linetype. Similarly, you can create a custom View Detail Style and adjust all properties. To change the lineweight of the hatch, go to the drawing explorer and select "layers". You can adjust the current section view style to your own custom one in the **properties bar**. The detail section view styles can be changed in a similar way.

Finish your drawing To specify the necessary dimensions in your drawing, you can use the linear dimension tool. As finishing touch, you can add the Bill of Materials, which gathers data about all the materials used in your model. Back to Tutorial Overview

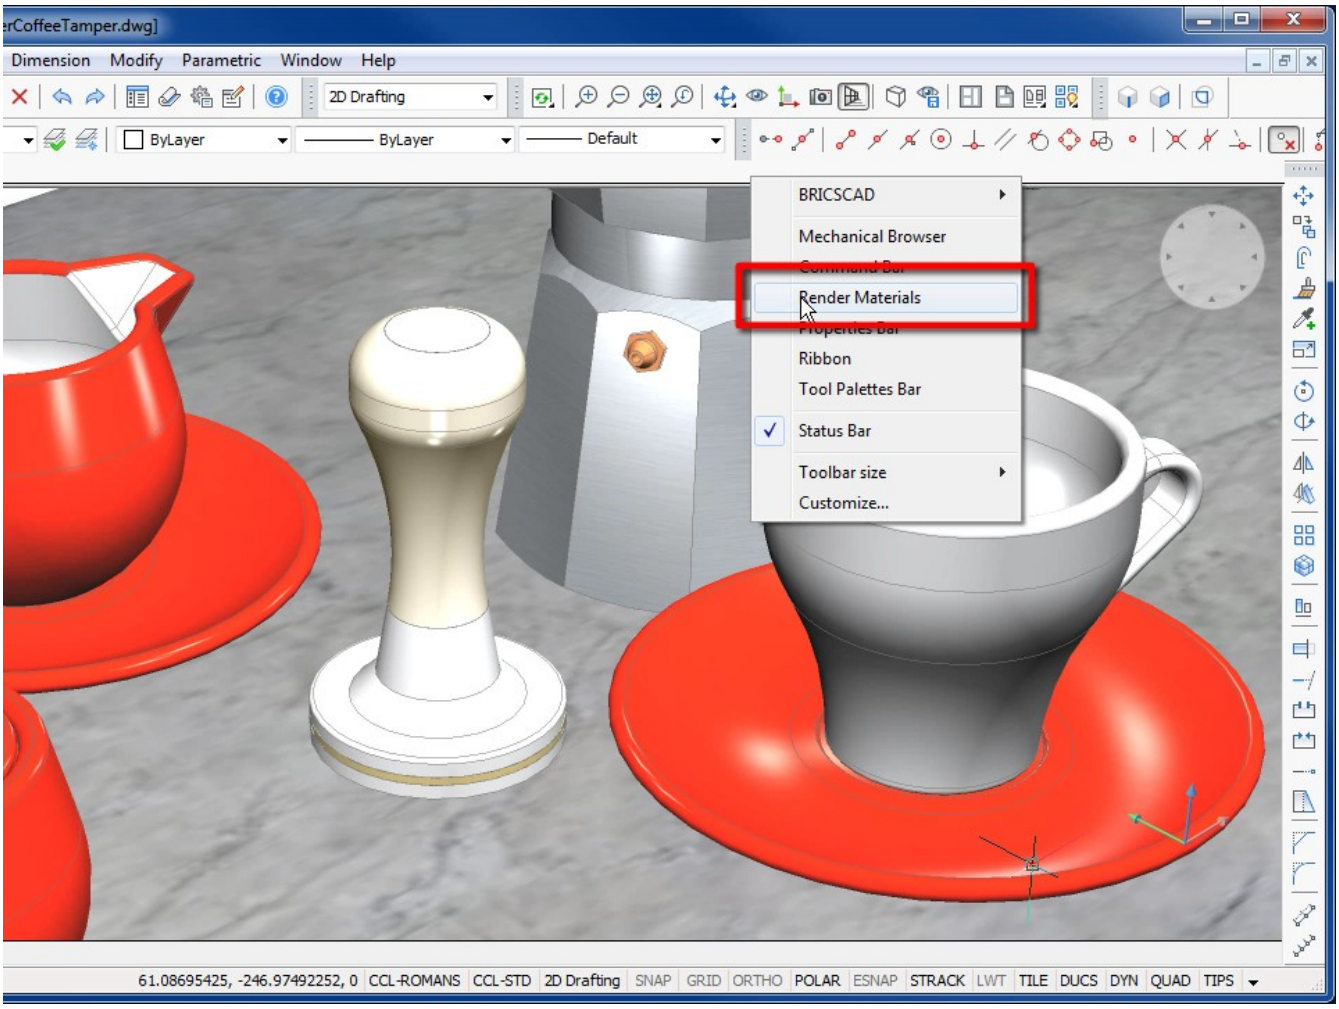
1.18.33 Project Geometry – Vessel

https://www.youtube-nocookie.com/embed/YHsk2B266kI

Use PROJECTGEOMETRY to markout your models

BricsCAD V16.2 introduces Project Geometry. This command projects 2D geometry onto a region, a surface or a 3D solid; creating linework that you can use in the development of your model. In this tutorial we are going to use PROJECTGEOMETRY to mark out potential nozzle positions on a pressure vessel. Back to Tutorial Overview

Figure 1.429



1.18.34 Bring life to your BricsCAD models with Render Materials

Youtube BricsCAD offers access to a huge render material library to bring your models to life. In fact the library has over 600 materials that you can choose from. In this video we'll work with render materials to demonstrate how you can add realism to your BricsCAD models. Opening render materials is simple. Just right click over any toolbar then select it from the menu. Alternatively you can type MATBROWSEROPEN (6.21.6) in at the command line. (1.429)

Simply drag and drop the material from the browser Applying materials is easy too. Simply drag and drop the material from the browser onto the object that you want to apply it to. This allows you to quickly try out a number of different materials. (1.430 on the next page) (1.431 on the following page) Back to Tutorial Overview

Figure 1.430

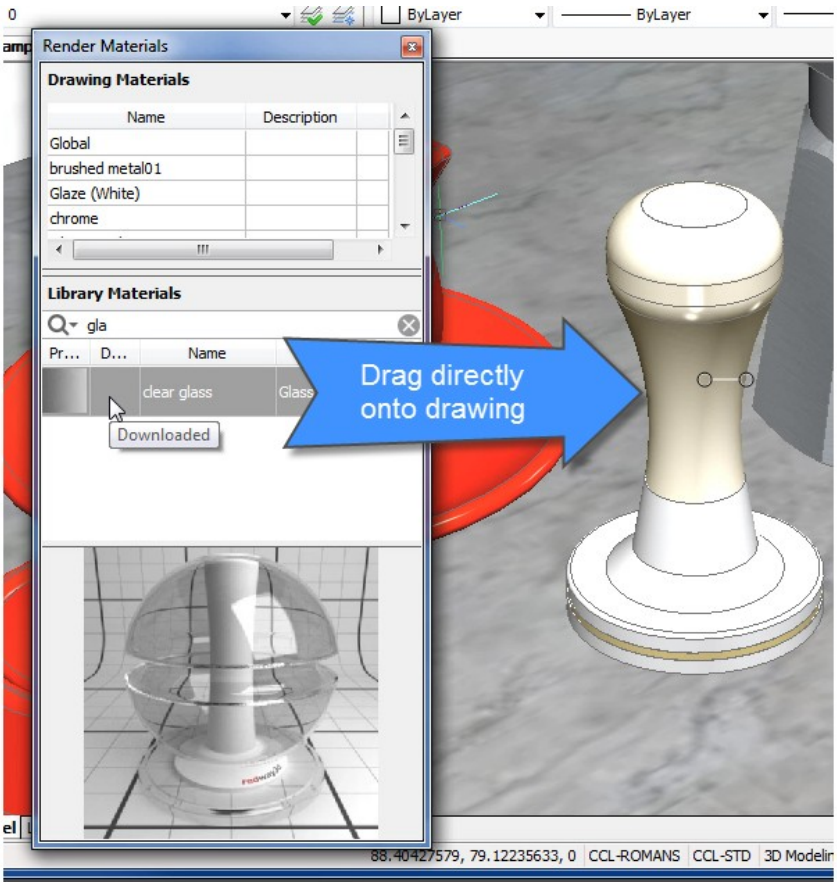


Figure 1.431

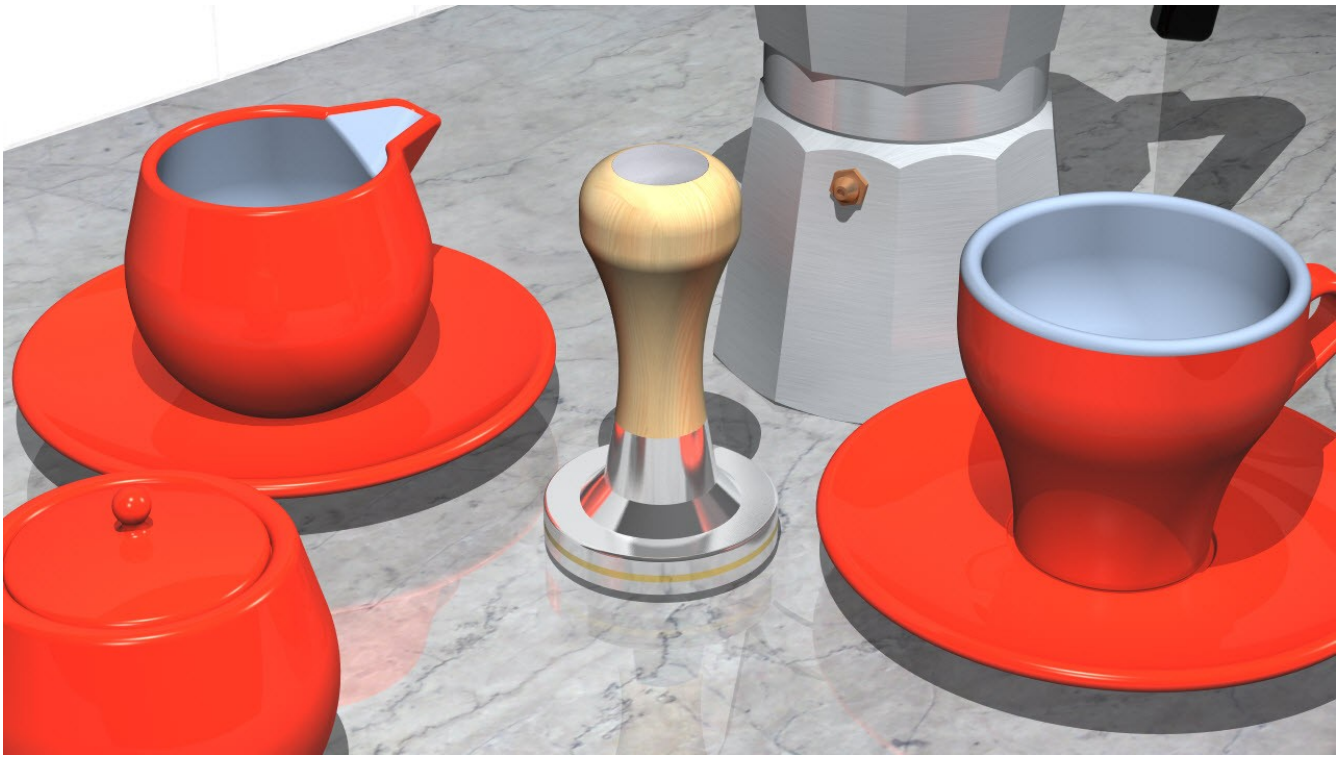


1.18.35 How to setup the 3DConnexion 3D mouse in BricsCAD

Youtube BricsCAD V14 now supports 3Dconnexion 3D mice. Users can simultaneously pan, zoom and rotate 2D/3D content while the standard mouse is free to select menu items of parts of the model. Back to Tutorial Overview

1.18.36 Dynamic UCS, Drawing on any 3D Face

https://www.youtube-nocookie.com/embed/WpnLG91wD94 Almost all drawing in 3D is done on a 2D plane (a.k.a. an x,y-plane), and so to make 3D modeling easier BricsCAD provides you with the dynamic UCS. After completing this video, you will be able to:

- Understand what dynamic UCS is
- Draw 2D and 3D entities on any 3D face
- Know how lock a face to draw away from it

1.19 Managing Drawings

1.19.1 Creating a drawing

Commands: NEW (6.22.5), NEWWIZ (6.22.6) and QNEW (6.25.1) In BricsCAD you can create new drawings:

- Using the Start tab.
- Using a default template drawing.
- Starting from scratch.
- Using a template drawing of your choice.
- Using a wizard.
- Double clicking a *.dwt file in a Windows Explorer window.

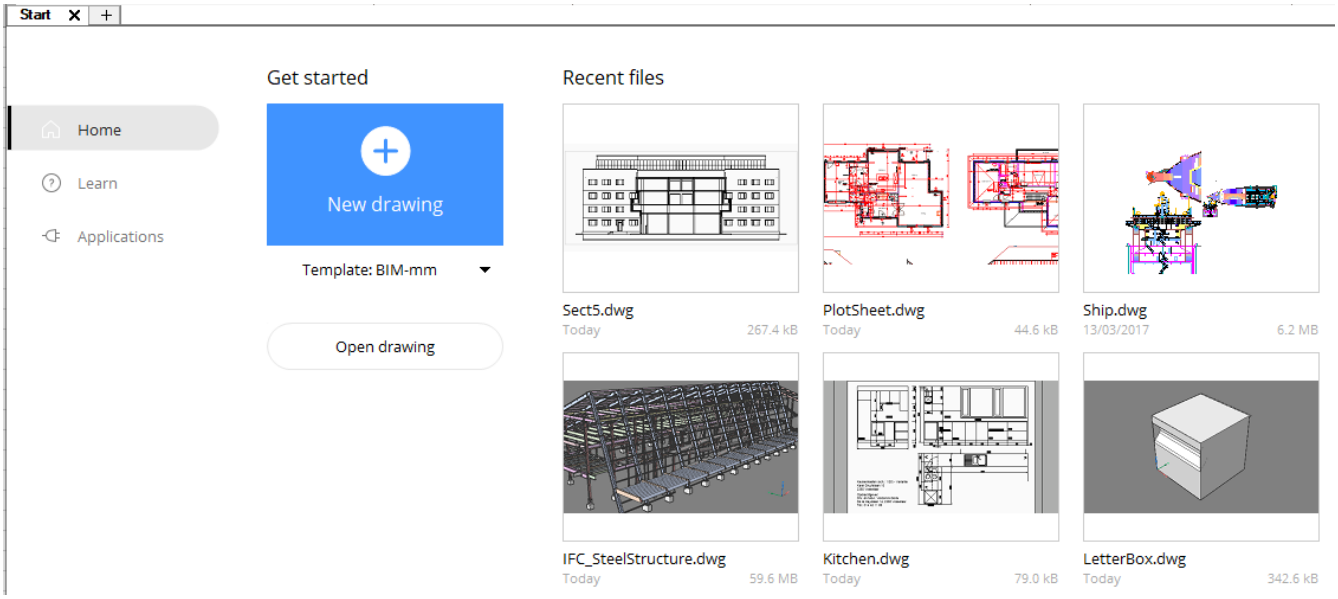
Using the Start tab

(6.1247 on page 4517) Launch the GOTOSTART (6.15.18) command to open the Start tab if necessary. The name of the current drawing template displays beneath the New Drawing button. Do the following:

1. (option) Click the template list button, to choose a different template drawing*.
2. Click the **New Drawing** button.

* All DWT drawings in the template folder are listed. Launch the TEMPLATEFOLDER (6.29.11) command to open the template folder.

Figure 1.432

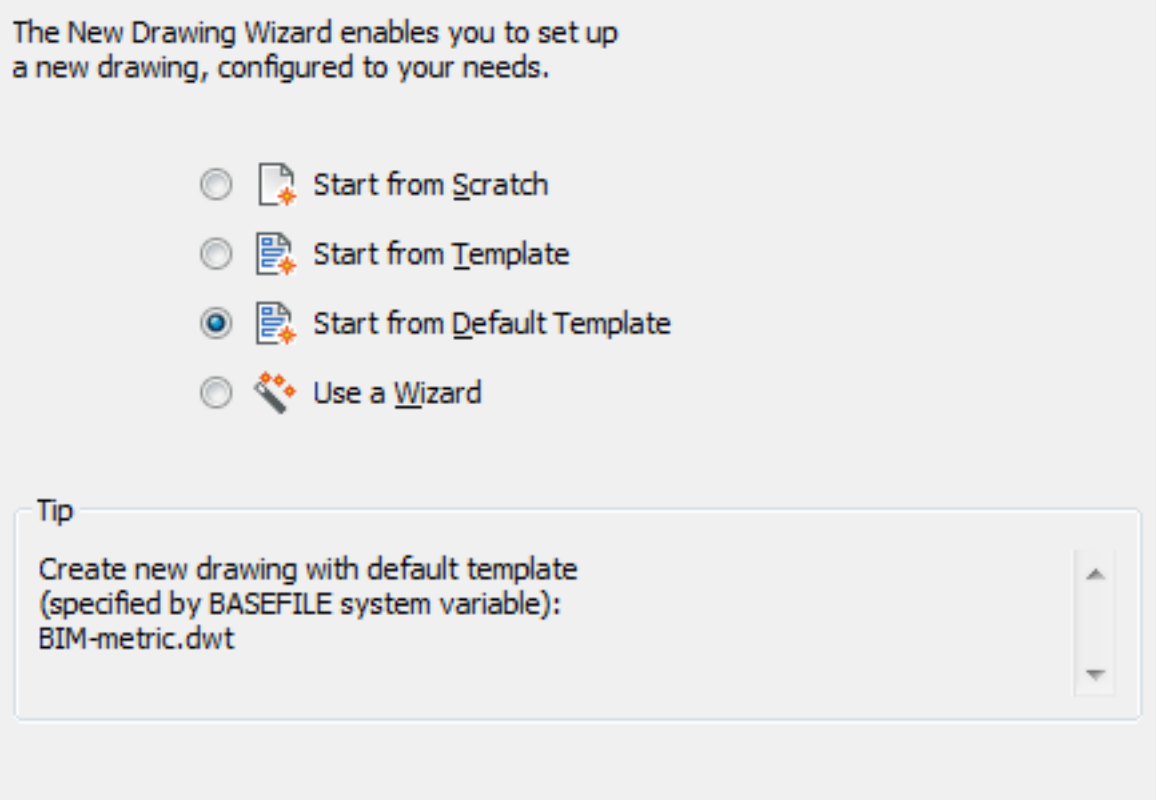


To create a drawing using a default template drawing

First method:

1. Do one of the following:
   - Choose **New wizard...** in the File menu.
   - Type **newwiz** in the command window, then press Enter.
2. On the Create New Drawing dialog choose **Start from Default template**, then click the **Next** button. The drawing is created as a copy of the default template. (1.433 on the facing page)

Figure 1.433



Second method: Do one of the following:

- Click the **QNew** tool button ( ) on the **Standard** toolbar.
- type **qnew** in the command bar, then press Enter.

The drawing is created as a copy of the default template defined by the BASEFILE system variable. If the default template drawing is not specified, the Create New Drawing wizard is launched if the STARTUP system variable is ON, otherwise the Select Template dialog displays.

To set the default template drawing

1. Open the Settings (1.17.10) dialog.
2. Under **Program Options / Files / Templates** select **Template (BASEFILE)**
3. Click the **Browse** button.
4. On the Choose a File dialog, select a drawing file (*.dwg) or drawing template (*.dwt), then click the **Open** button.

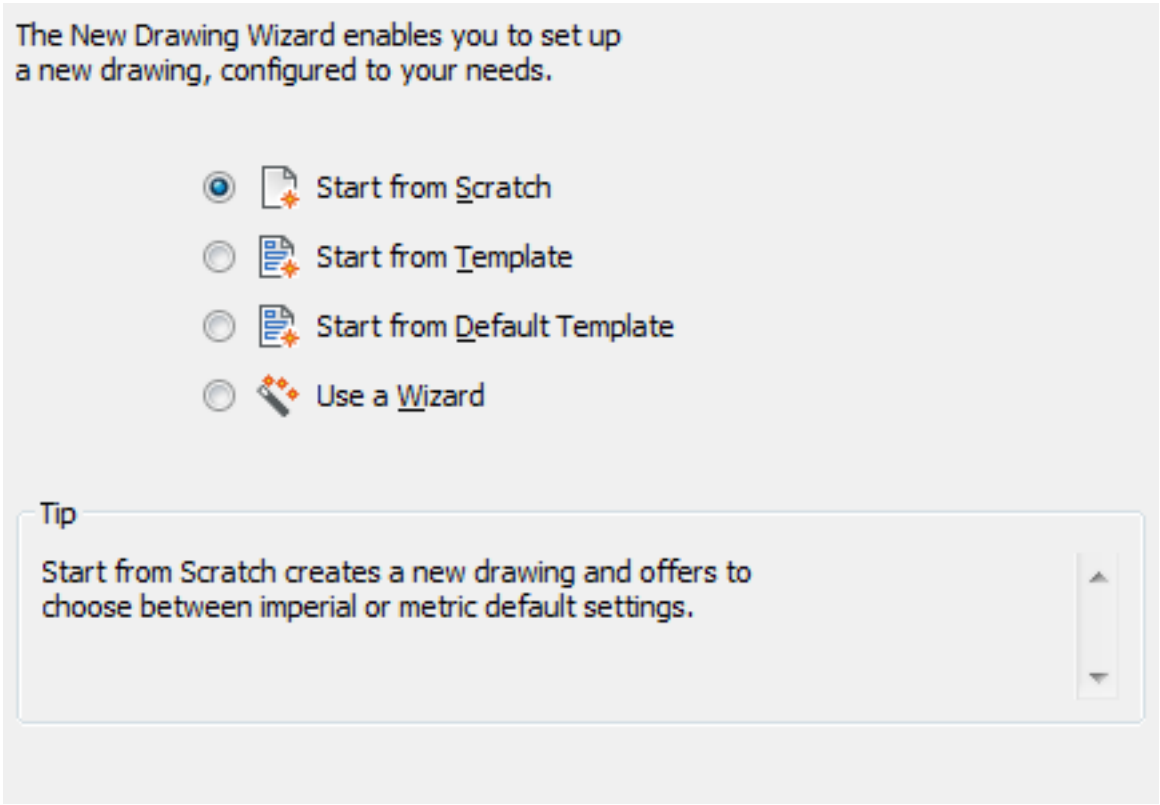
Tutorial: Creating Custom Template Drawings Click here (1.12.20) to watch

To create a drawing from scratch

1. Do one of the following:
   - Choose **New wizard...** in the File menu.
   - Type **newwiz** in the command window, then press Enter.
2. On the Create New Drawing dialog choose **Start from Scratch**, then click the **Next** button. (1.434 on the next page)
3. Choose between either **Imperial** or **Metric** default settings. Click the **Finish** button to create the drawing.

Note: Using the above procedure it depends on the status of the BASEFILE and PSTYLEPOLICY variables whether **CTB** (Color table) or **STB** (Named plot style table) will be used to set up plotter configurations in the newly created drawing.

Figure 1.434



BASEFILE	PSTYLEPOLICY	CTB or STB?
not specified	OFF	STB
not specified	ON	CTB
specified	ON or OFF	as defined in the template drawing

To set the Plot style policy

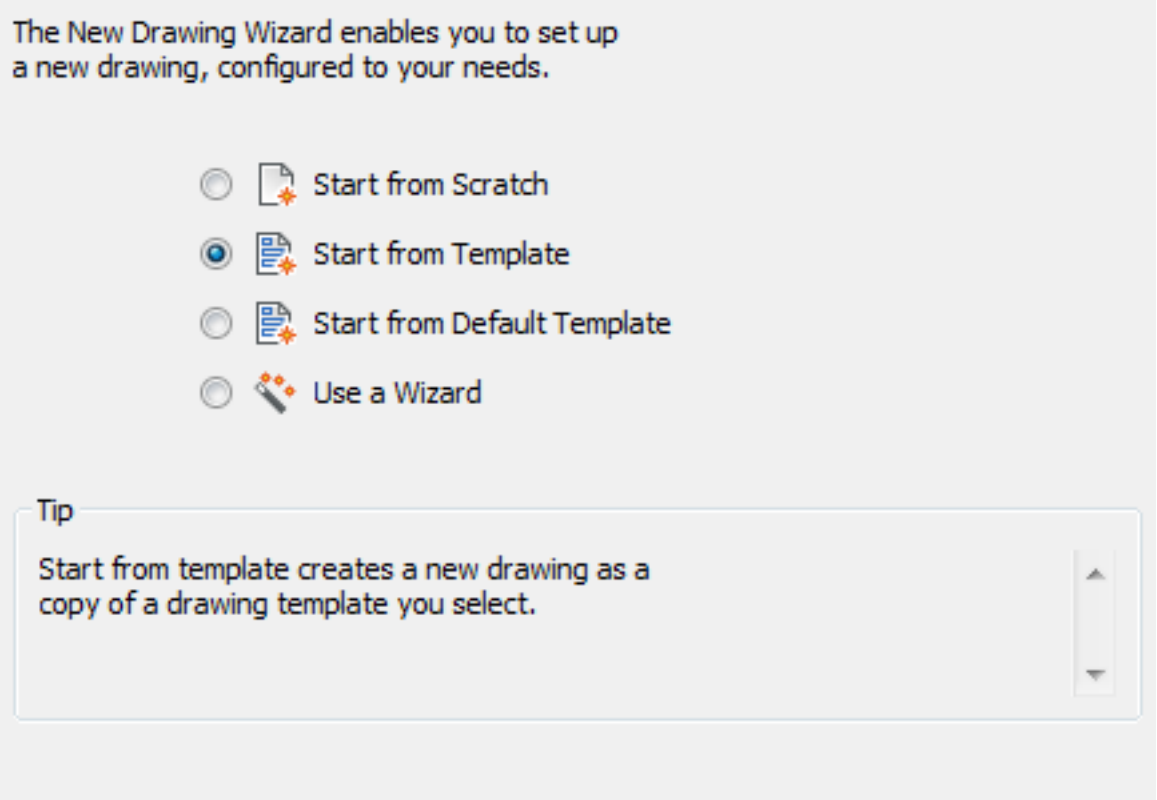
1. Open the Settings (1.17.10) dialog.
2. Under **Program Options / Plot and publish** select **Plot style policy (PSTYLEPOLICY)** .
3. Do one of the following:
   - Choose **Associate an entity's plot style with its color** for Color dependent plot styles.
   - Choose **No association between color and plot style** for Named plot styles.

To create a drawing using a template drawing

1. Do one of the following:
   - Choose **New wizard...** in the File menu.
   - Type **newwiz** in the command window, then press Enter.
2. On the Create New Drawing dialog choose **Start from template**, then click the **Next** button. (1.435 on the facing page)
3. Do one of the following:
   - Choose a template drawing in the **Select a template list**. By default this is the content of the **Template** folder in the **Local root** folder. Edit the **Template Path** variable to set your template folder differently.
   - Click the **Browse...** button to select a template drawing. You can choose between ***.dwg** and ***.dwt** file types.

The drawing is created as a copy of the selected template.

Figure 1.435



To create a drawing using the New command

1. Do one of the following:
   - Choose **New...** in the File menu.
   - Type **new** in the command bar, then press Enter.
2. The Select template dialog opens showing the content of the **Template** folder as defined in the **Template Path** variable.
3. Select the template drawing, then click the **Open** button. The drawing is created as a copy of the selected template.

To set the Template Path variable

1. Open the **Settings** dialog.
2. Under **Program Options / Files / Templates** select **Template Path (templatePath)**
3. Click the **Browse** button.
4. On the Browse for folder dialog, select a folder , then click the **OK** button.

To create a drawing using a wizard

1. Do one of the following:
   - Choose **New wizard...** in the File menu.
   - Type **newwiz** in the command window, then press Enter.
2. On the Create New Drawing dialog choose **Use a Wizard**, then click the **Next** button. (1.436 on the next page)
3. Choose between either **Imperial** or **Metric** default settings, then click the **Next** button. Select the **Unit of measurement** and the display **Precision**, then click the **Next** button. (1.437 on the following page)
4. Select the **Angle of measurement** and the display **Precision**, then click the **Next** button. (1.438 on page 507)
5. Choose between **Color Dependent** plot styles (CTB) or **Named** plot styles (STB), then click the **Next** button. (1.439 on page 507)

Figure 1.436

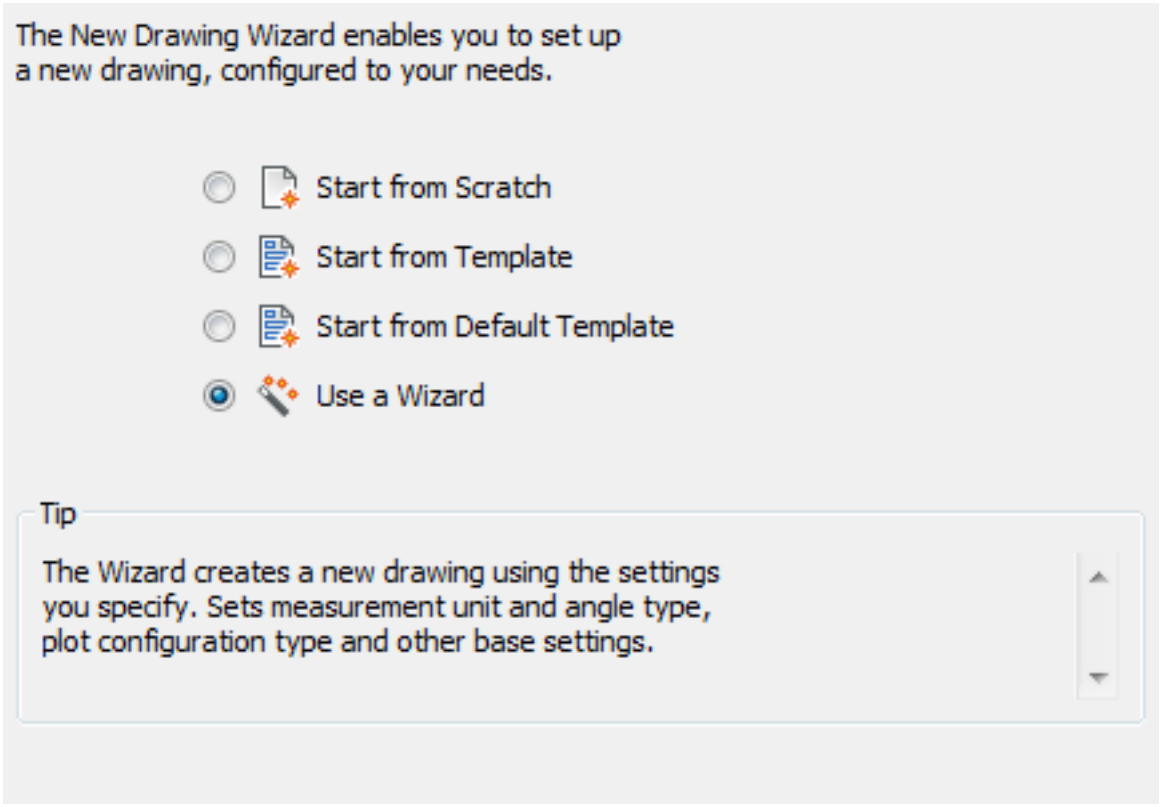


Figure 1.437

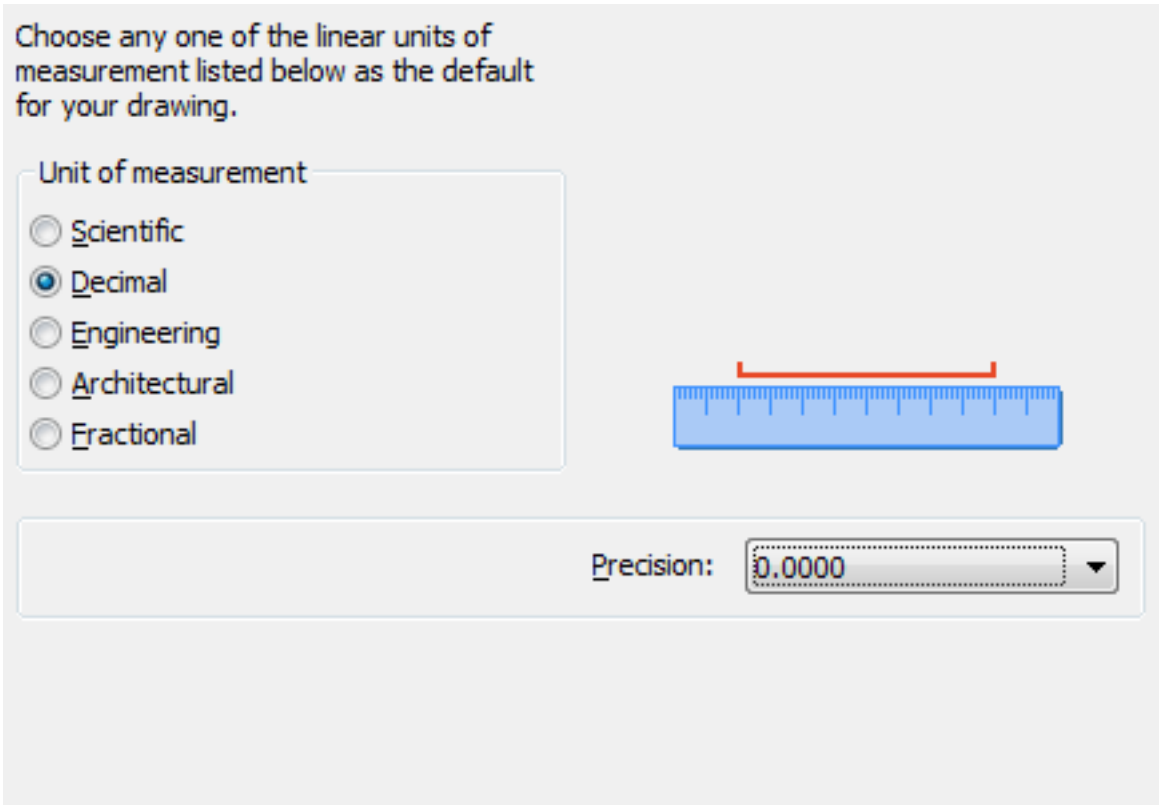

Figure 1.438

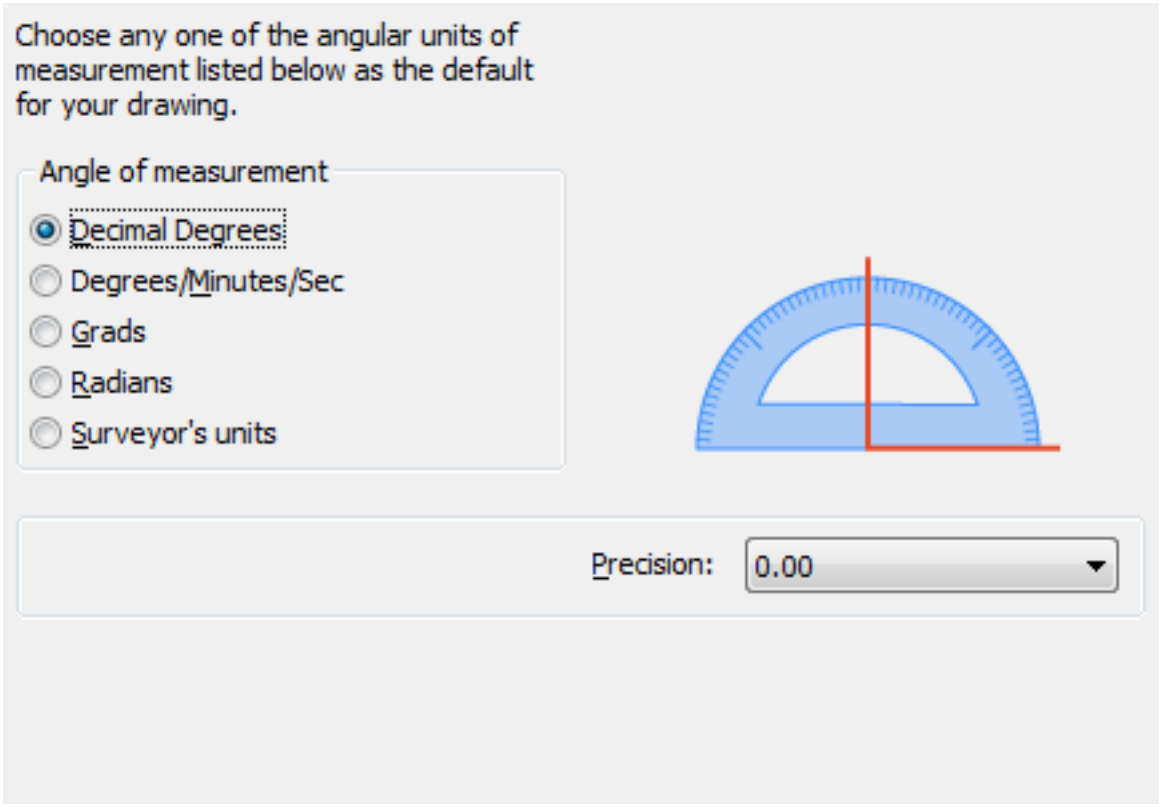

Figure 1.439

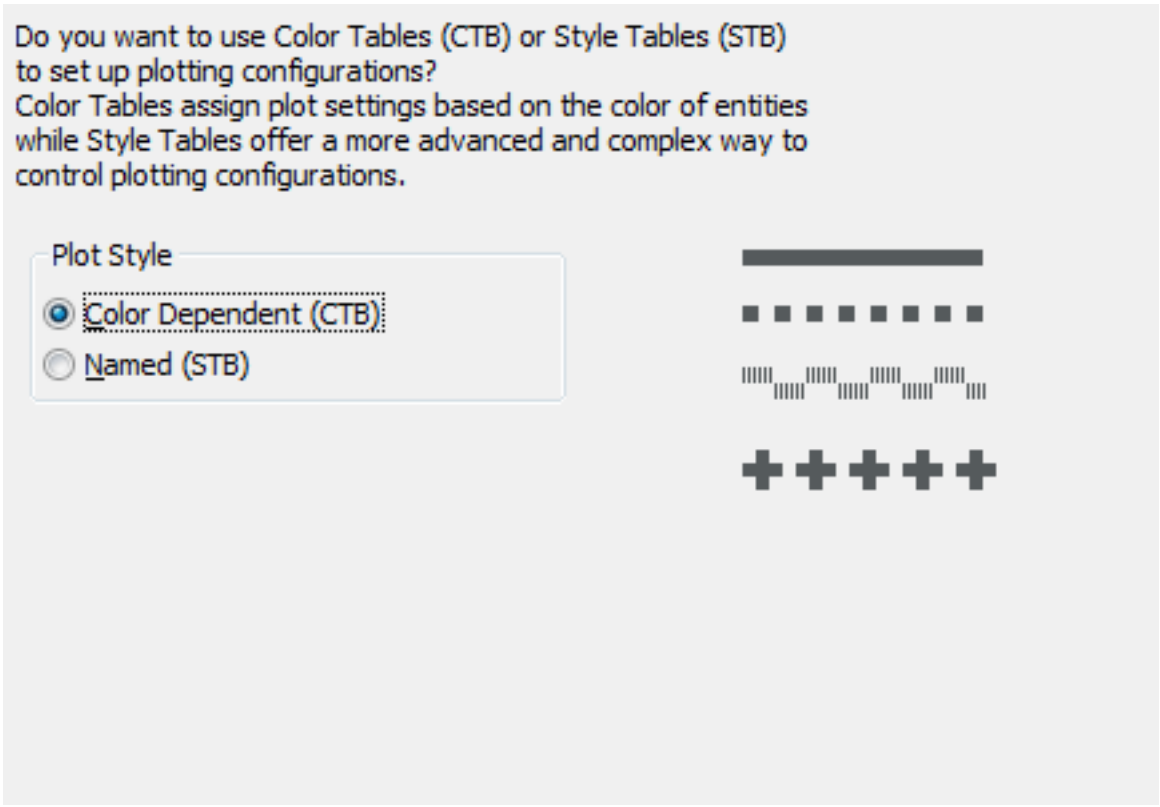

Figure 1.440

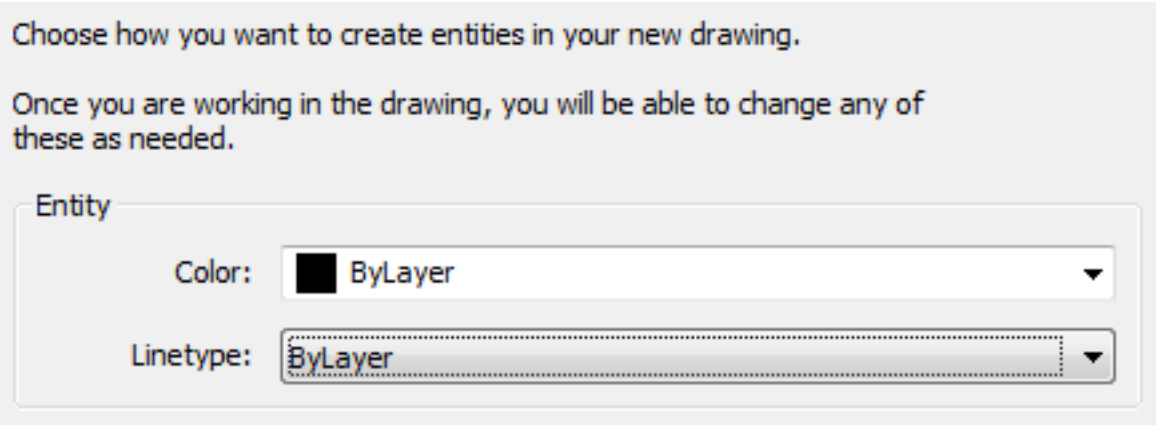
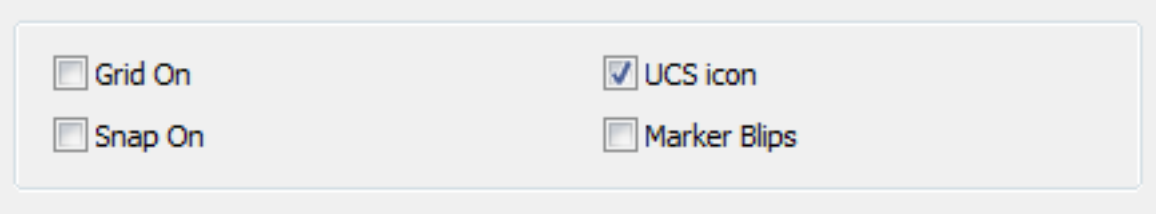


6. Select the default **Color** and **Linetype**. (1.440)
7. Define the **Grid**, **Snap**, **UCS icon** and **Marker Blips** settings. (1.441)
8. Click the **Finish** button to create the drawing. (option) Choose **Save As..** . in the File menu to save the drawing as a template in the **Templates** subfolder of the Local root (1.17.2) folder.

Figure 1.441



1.19.2 Drawing Explorer

Commands: Explorer (6.13.15), Layers (6.13.17), Layer States (6.20.9), Linetypes (6.20.32), Multiline Styles (6.21.26), Multileader Styles (6.21.24), Text Styles (6.27.55), Dimension Styles (6.11.19), Table Styles (6.29.6), Datalinks (6.10.1), Coordinate Systems (6.13.24), Views (6.31.2), Visual Styles (6.31.15), Lights (6.20.36), Materials (6.21.10), Render Presets (6.26.27), Blocks (6.13.11), External References (6.13.23), Images (6.13.13), PDF Underlays (6.13.14), Point Clouds (6.24.31), Dependencies (6.13.9), Page Setups (6.24.2), Section Planes (6.27.12), View Detail Styles (6.31.7), and View Section Styles (6.31.22). The **Drawing Explorer** window consists of a number of sub-windows or panes:

- **Drawings**:
  - **Open Drawings**: a list of all drawings that are currently open.
  - **Folders**: your favorite drawing folders
- **Details**: the details of the selected drawing or the details of the selected category in a drawing, e.g. layers, blocks, images, ...
- **Preview**: a preview of the selected drawing, layer, block, view, dimension style, table style, XRef, image or material. Use the arrow keys to browse through the items.
- **Editor**: to define or edit the properties of **Multiline Styles**, **Multileader Styles**, **Table Styles**, **Views**, **Visual Styles**, **Sunlight settings**, **Materials**, **Render Presets** and **Section Planes**.

You can select which panes you want to have open or closed in the View (6.31.2) menu. BricsCAD remembers the display settings for each category. (1.442 on the next page)

To open the Drawing Explorer

To open the Drawing Explorer window do one of the following:

- Click the **Drawing Explorer** tool button () on the Standard toolbar. The Drawing Explorer window opens showing the details of the most recently used category.
- Click the **Layer**, **Linetype**, **Text Style** or **Dimension Style** field in the Status Bar. The Drawing Explorer window opens showing the details of the clicked definitions category in the current drawing. (See Customizing the Status Bar (1.15.2) to enable/disable fields in the Status Bar.)
- Choose **Drawing Explorer** in the Tools menu, then select a category in the flyout. The Drawing Explorer window opens showing the details of the selected category. (1.443 on the following page)
- Type **explorer** in the command bar, then press Enter. The Drawing Explorer window opens showing the details of the most recently used category.

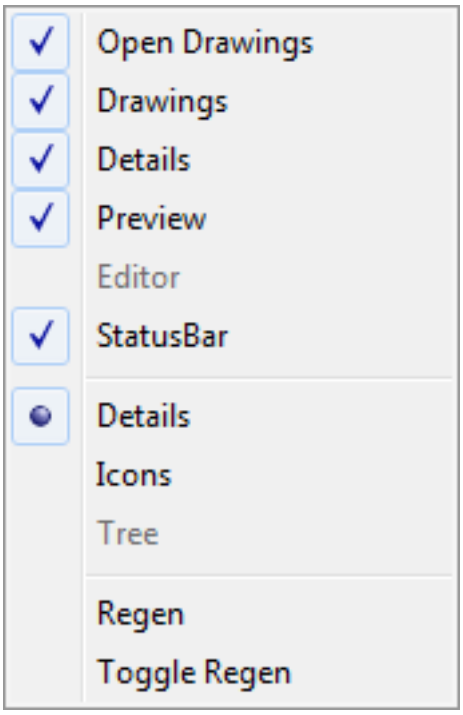
To control the Drawing Explorer layout

- In the View menu, check/uncheck the sub-window you want to open or close. (1.444 on the next page)
- If you click a settings category in the Drawings sub-window when the >Details sub-window is closed, the Details window is re-opened, showing the content of the selected settings category.
- To close a sub-window, click the close button () in its title bar.
- To restore the default layout choose **Restore Default Explorer Layout** in the Settings menu.

Figure 1.444



Opening a drawing

To open a drawing using the Drawing Explorer do the following:

1. Launch the Drawing Explorer.
2. In the **Drawings > Folders** sub-window browse to the folder of the drawing. (1.445 on the facing page)
3. Double click the drawing. The drawing opens, while the Drawing Explorer window stays open.
4. (optional) Repeat steps 2 and 3 to open more drawings.
5. Close the Drawing Explorer.

Note: When you select a drawing, a preview displays in the Preview sub-window.

Adding a drawing folder

1. In the **Drawings > Folders** sub-window of the Drawing Explorer main window click the **Add local folder...** button. The Browse For Folder window opens.
2. In the Browse For Folder window do one of the following:
   - To add an existing folder: select the folder you want to add.
   - To create a new folder: click the **Make New folder** button.
3. Click the **OK** button. The folder is added.

Notes

- Drawings in the subfolders of the selected folder can be opened too.
- The parent folder(s) of the selected folder is (are) greyed out in the drawing folder tree. Drawings in such folders cannot be opened.

To insert a block from an unopened drawing

The Block Manager (6.13.15) feature of the Drawing Explorer allows to insert blocks in the current drawing from unopened drawings.

To copy definitions between drawings

1. Open both the source and the target drawing.
2. Launch the Drawing Explorer (1.19.2).
3. In the source drawing select the category you want to copy items from, e.g. **Blocks**.
4. (option) In the Details toolbar, click the **Icon View** button ()
5. Select the item(s) you want to copy, e.g. a series of blocks. Press and hold the Ctrl key to select multiple items.
6. Press and hold the left mouse button to drag the selection set to the **Open Drawings** section of the Drawing Explorer.
7. Release the left mouse button when on the target drawing name. The selected items are copied to the target drawing. You will be prompted to overwrite items of the same name.

To merge the content of two layers

1. Open the Drawing Explorer > (1.19.2) Layers dialog window.
2. Select the layer you want to merge into another layer.
3. Choose **Merge to...** in the Edit menu. The Merge Layers dialog box displays.
4. Select the layer you want to merge to. (1.446 on the next page)
5. Click the **Merge** button. The content of the first layer is merged to the second layer. The first layer is purged from the drawing.

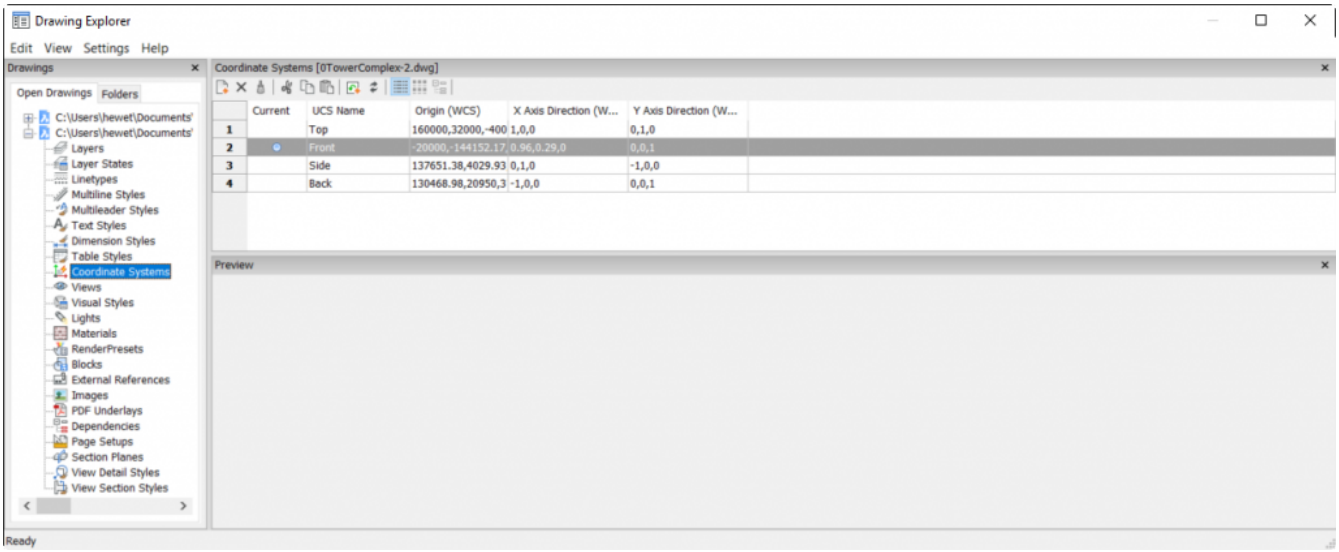
1.19.3 Exploring the Drawing Explorer

Tutorial: Tips and Tricks for Drawing Explorer Click here (1.9.4) to watch (1.447)

Coordinate systems

The Coordinate Systems panel displays all the named User Coordinate Systems (UCS) in the current drawing. If you choose the option to add a new coordinate system, the UCS command is launched enabling you to choose from options such as picking points or selecting an entity. (1.448 on the next page)

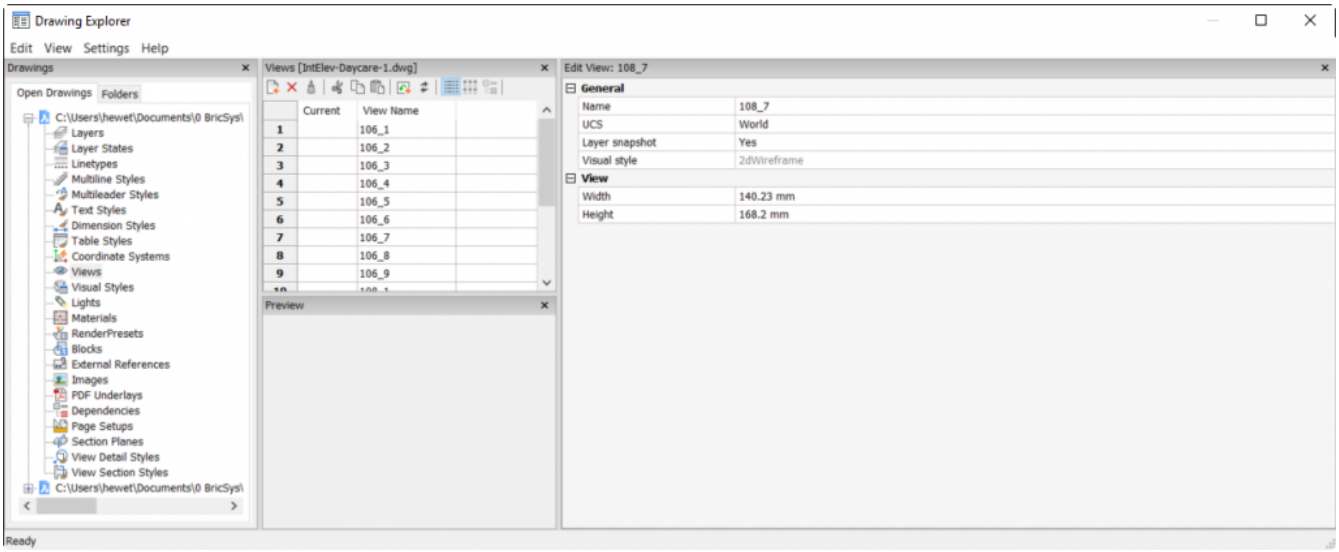
Figure 1.448



Views

The Views panel displays all the named views in the drawing. If you choose the option to add a new view, the VIEW command is launched. It allows you to save the current view or pick a window to define the view. You can view and edit properties for a selected view in the Edit View panel. (1.449 on the following page)

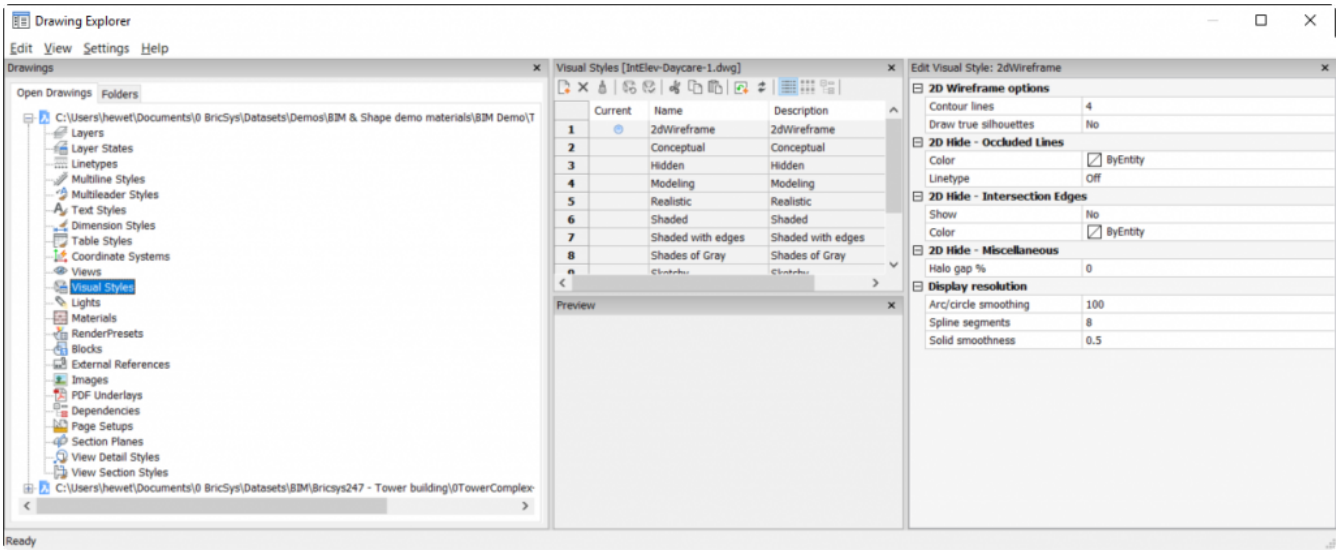
Figure 1.449



Visual Styles

The Visual Styles panel displays all the visual styles in the drawing. It includes 11 predefined visual styles and you can easily add your own. You can view and edit visual style properties in the Edit Visual Style panel. While most visual styles are intended for 3D visualization, some of them, such as Sketchy, can be useful for 2D design. Therefore, visual styles are fully supported in all editions of BricsCAD, including Classic. (1.450 on the next page)

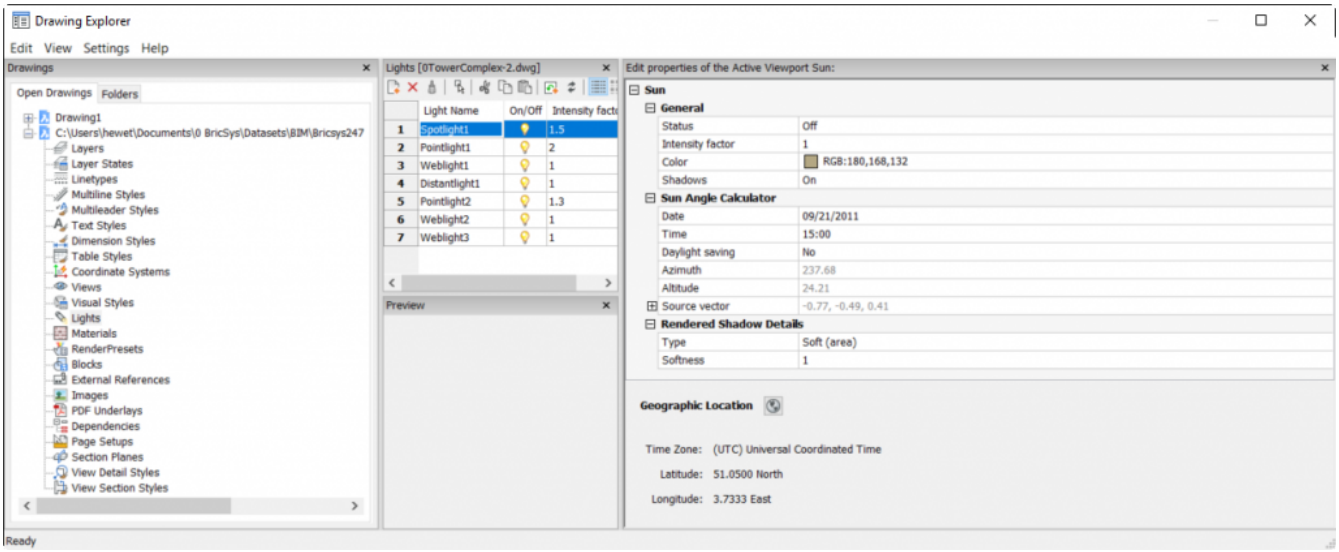
Figure 1.450



Lights

The Lights panel displays all the lights in the drawing. If you choose the option to add a new light, it launches the LIGHT command where you can select from Point, Spot, Web, or Distant lights. You can view and edit sun properties in the Edit Properties of the Active Viewport Sun panel. That panel also provides access to the geographic location dialog box. While you can create and modify lights in BricsCAD Classic, it doesn't support rendering. Therefore, the usefulness of lights in BricsCAD Classic is somewhat limited. (1.451 on the following page)

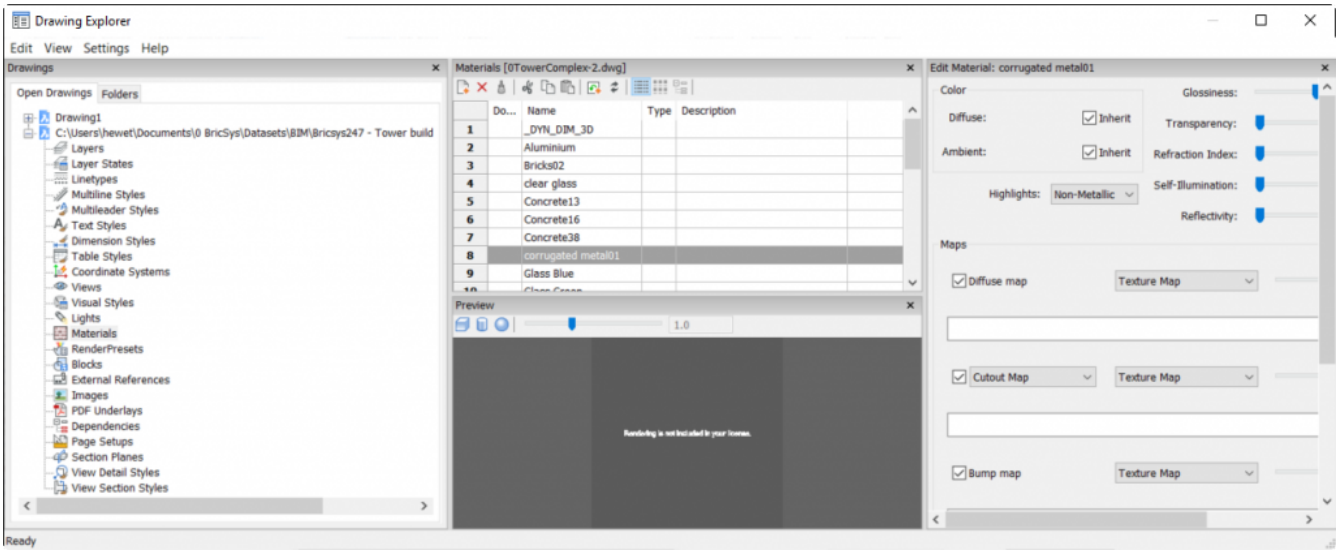
Figure 1.451



Materials

The Materials panel displays all the materials in the drawing. You can view and edit Material properties in the Edit Material panel. Like lights, however, material functionality is limited in the BricsCAD Classic edition because it doesn't support rendering. (1.452 on the next page)

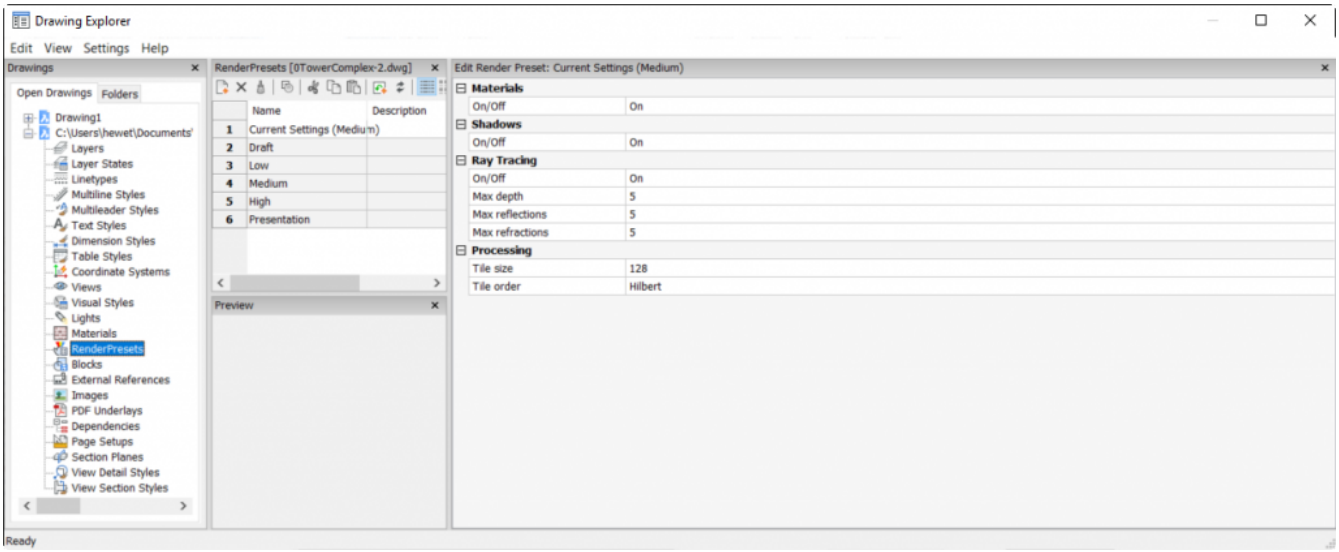
Figure 1.452



Render Presets

The Render Presets panel displays all the Render Presets in the drawing. It includes five pre-defined settings and you can easily add your own. While you can create and modify render presets in BricsCAD Classic, it doesn't support rendering. As a result, its usefulness in the Classic edition is limited. (1.453 on the following page)

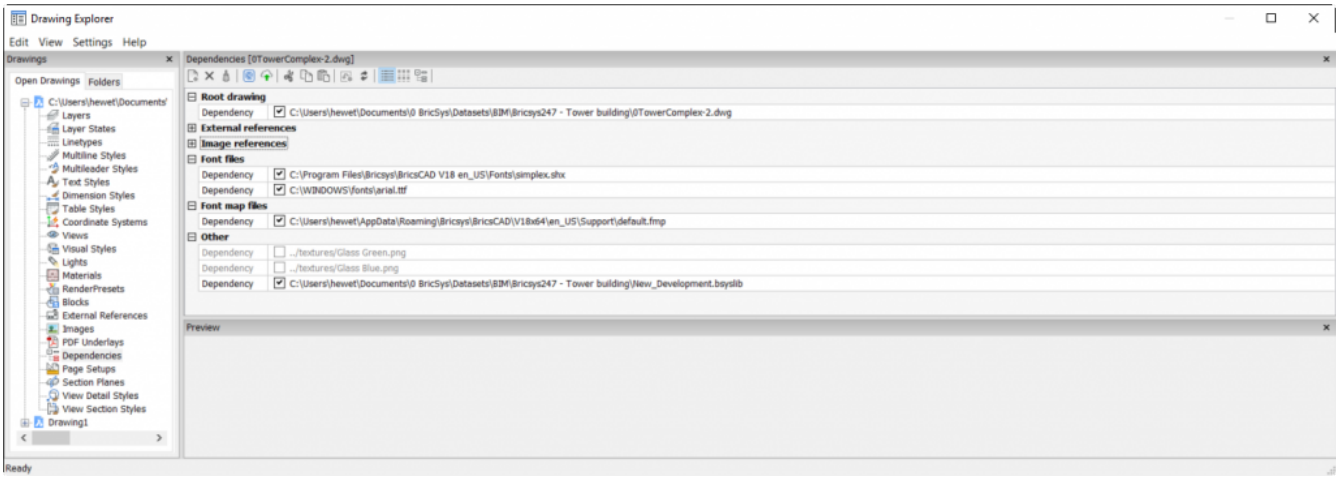
Figure 1.453



Dependencies

Dependencies in BricsCAD can best be compared to transmittal sets in AutoCAD®. In fact, if you launch the ETRANSMIT command, BricsCAD opens Drawing Explorer with the Dependencies panel displayed. There you can view all the dependent files including xrefs, images, fonts and more. Select which files to include in the transmittal set and then save them to a zip file or folder. You can also upload them to Bricsys 24/7 cloud storage. (1.454)

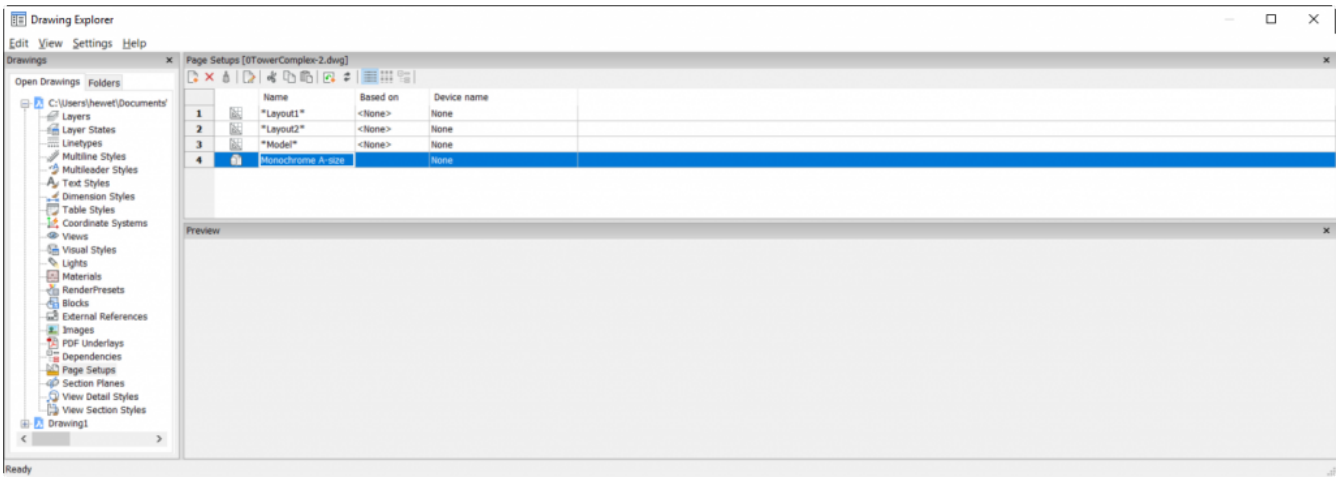
Figure 1.454



Page Setups

The Page Setups panel displays all the page setups in the drawing. If you choose the option to add a new page setup, it displays the Page Setup dialog box with its familiar controls. You can also select and edit any existing page setups. (1.455)

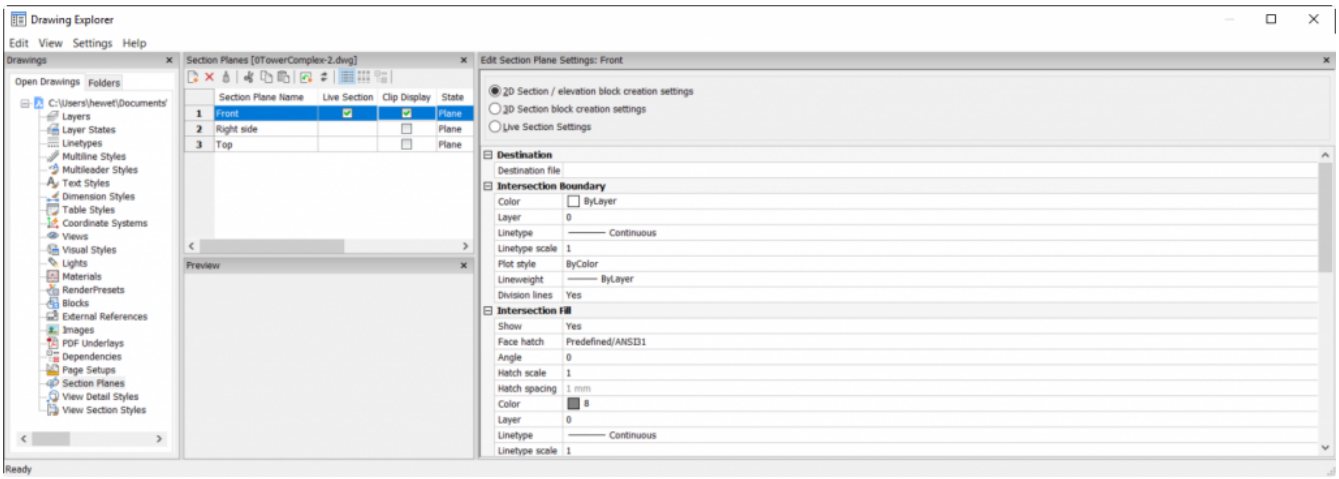
Figure 1.455



Section Planes

The Section Planes panel displays all the section planes in the drawing. If you choose the option to add a new section plane, it launches the SECTIONPLANE command where you can select a method, such as Orthographic, to define the new section plane. Easily view and modify properties of a section plane in the Edit Section Plane Settings panel. (1.456)

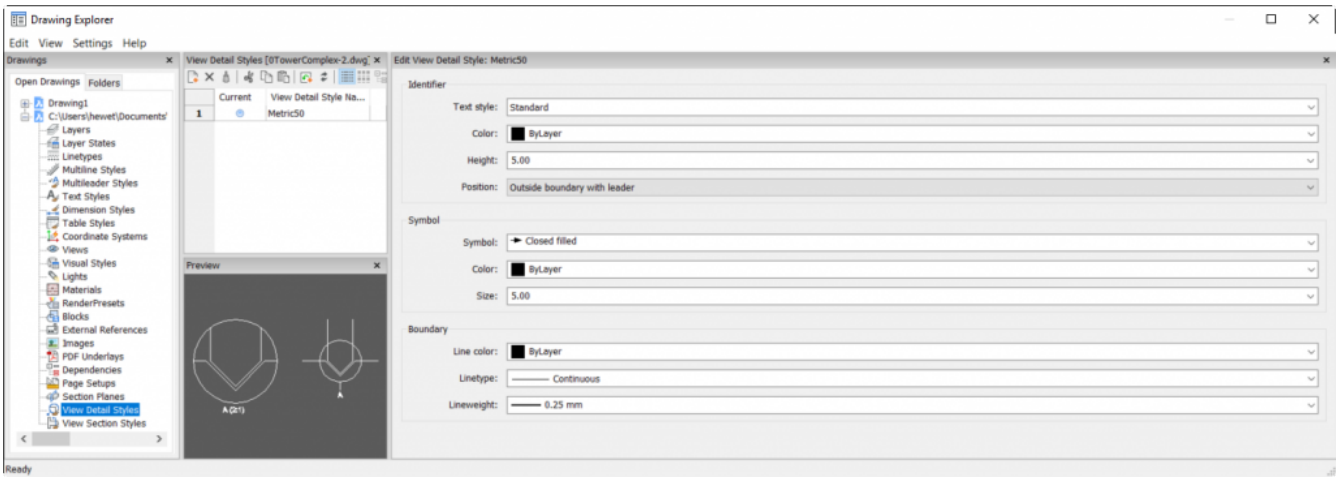
Figure 1.456



View Detail Styles

The View Detail Styles panel displays all the view detail styles in the drawing. Easily view and modify properties of a selected view detail style in the Edit View Detail Style panel. (1.457)

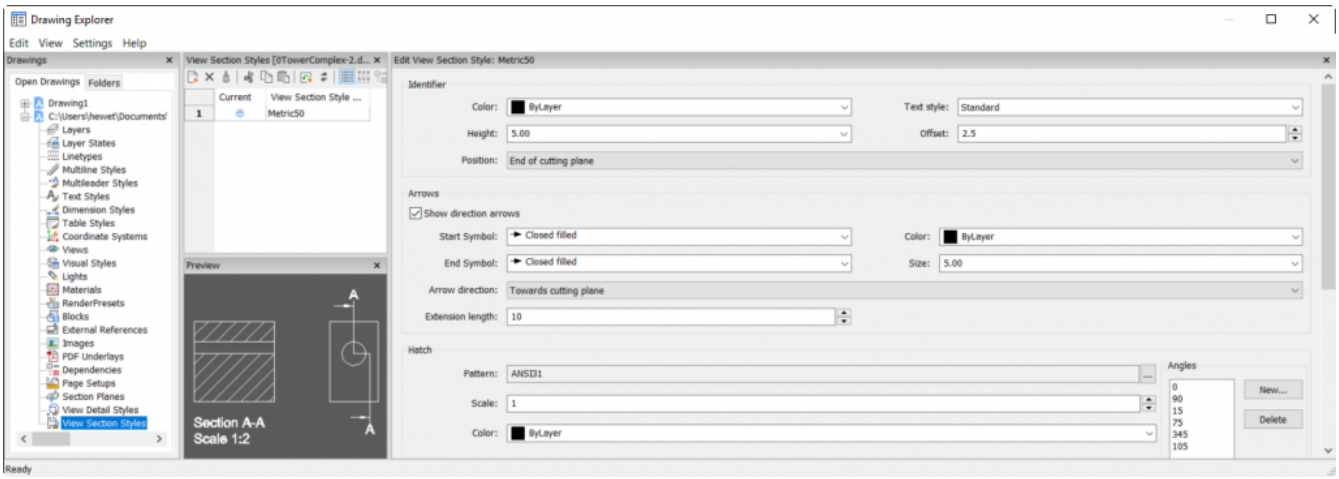
Figure 1.457



View Section Styles

The View Section Styles panel displays all the view section styles in the drawing. Easily view and modify properties of a selected view section style in the Edit View Section Style panel. (1.458)

Figure 1.458



Drawing Content

In addition to being able to select and modify each of the content types in Drawing Explorer, you can select the drawing itself. Doing so displays the number of occurrences of each type of content in the drawing. If you double-click on one of the items in the Details panel, that drawing content is displayed. (1.459 on the following page)

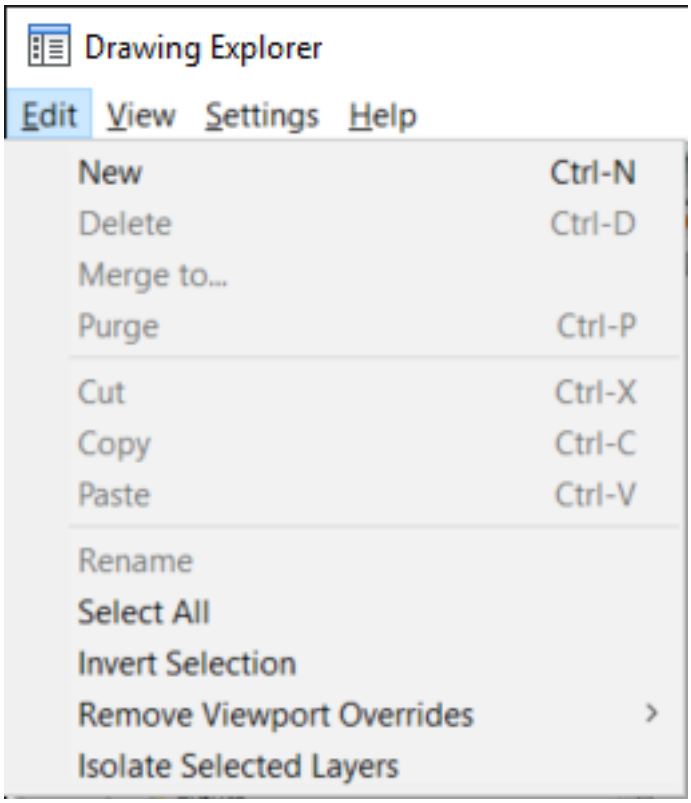
Menus

Drawing Explorer includes four menus: Edit, View, Settings and Help. Many of the options in these menus are also available from the tools and right-click menus in the panels. Others are only available from these menus.

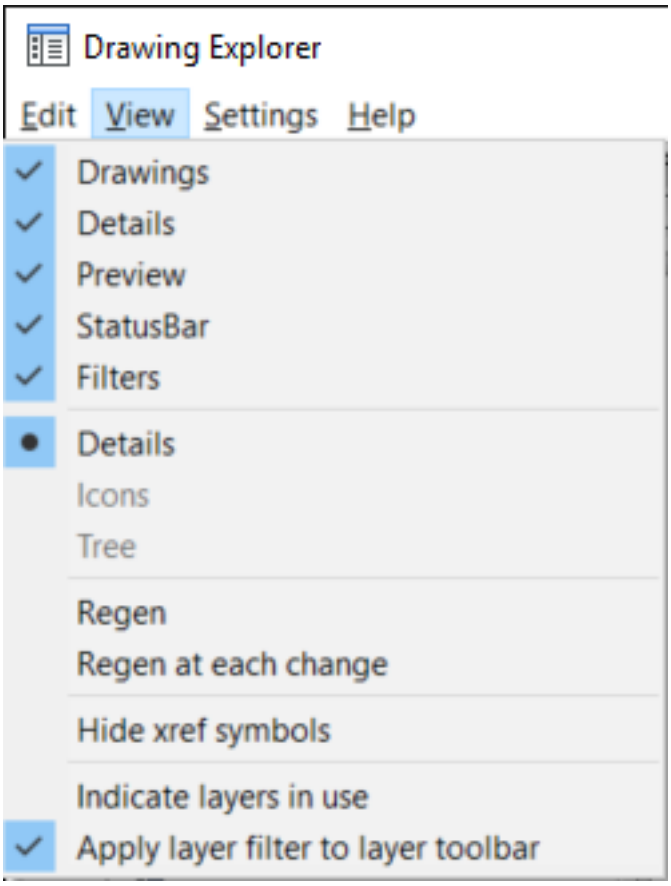
Edit The tools in the Edit menu can vary depending which type of content you select. These tools are also available in the various panels. (1.460 on the next page)

Figure 1.460



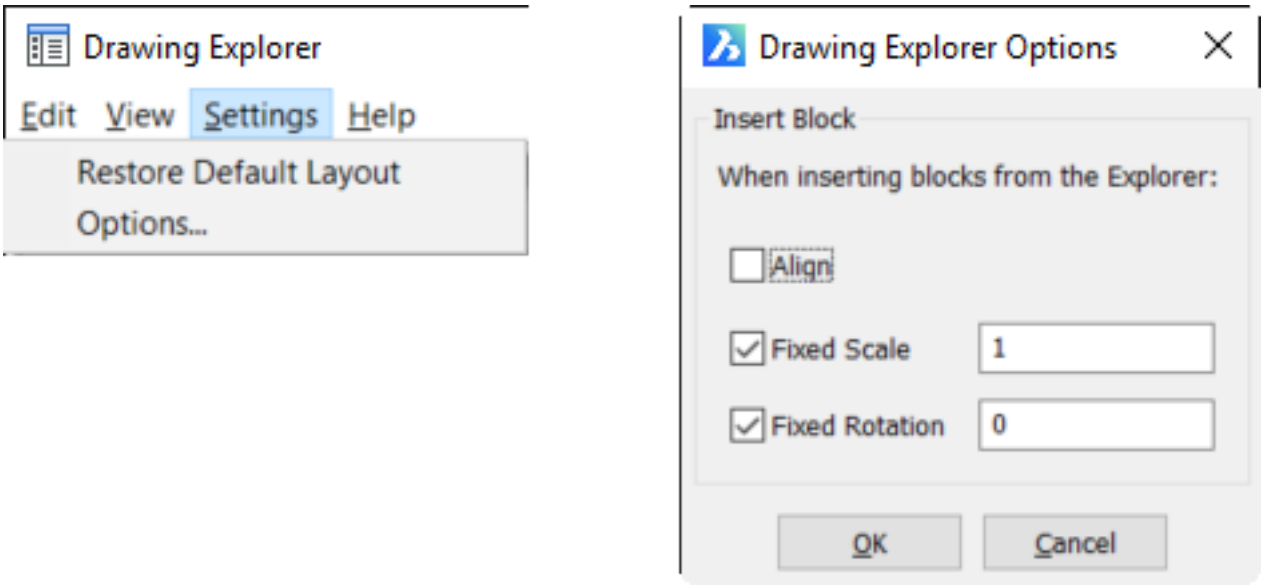
View The View menu enables you to control which panels display for each type of content. You can also specify if you want to display the content details, icons, or tree view. The Regen tools allow you to specify, for each type of content, whether you want the drawing area to regen each time you make a change to that content or if you want to manually regenerate. Hide xref symbols is relevant for content, such as layers or text styles, that may be listed as part of an xref. If you choose to hide xref symbols, the reference content does not display in the list. Most of the tools in the View menu are available for all the content types. However, a few tools are added for specific content. For example, the last two options in the following View menu are only available for Layers. (1.461 on the facing page)

Figure 1.461



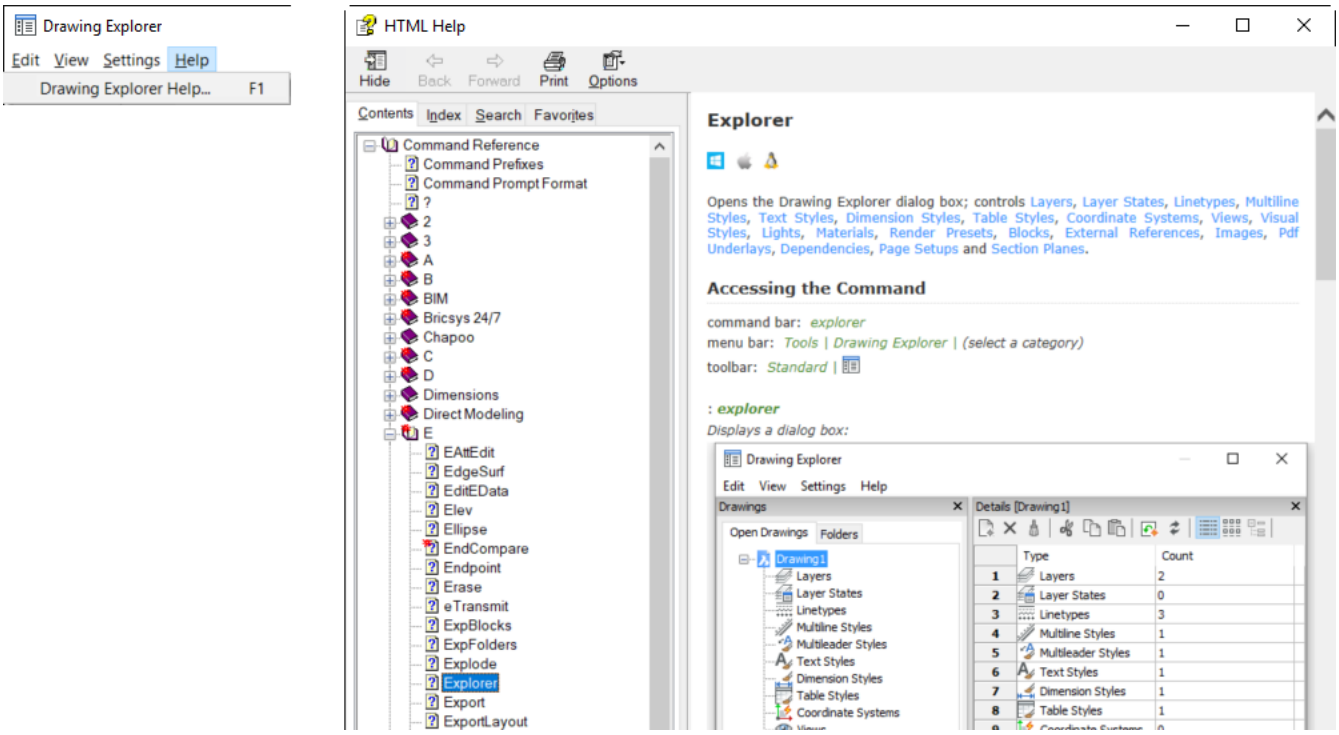
Settings The Settings menu has only two tools. The first one enables you to restore the layout of the selected content type back to the default settings. The reset will not affect other content types. The Options tool displays a dialog box that controls how blocks are inserted using Drawing Explorer. (1.462 on the next page)

Figure 1.462



Help The Help tool opens the BricsCAD Help window with the Explorer help content displayed. BricsCAD Help is also available online! (1.463 on the facing page)

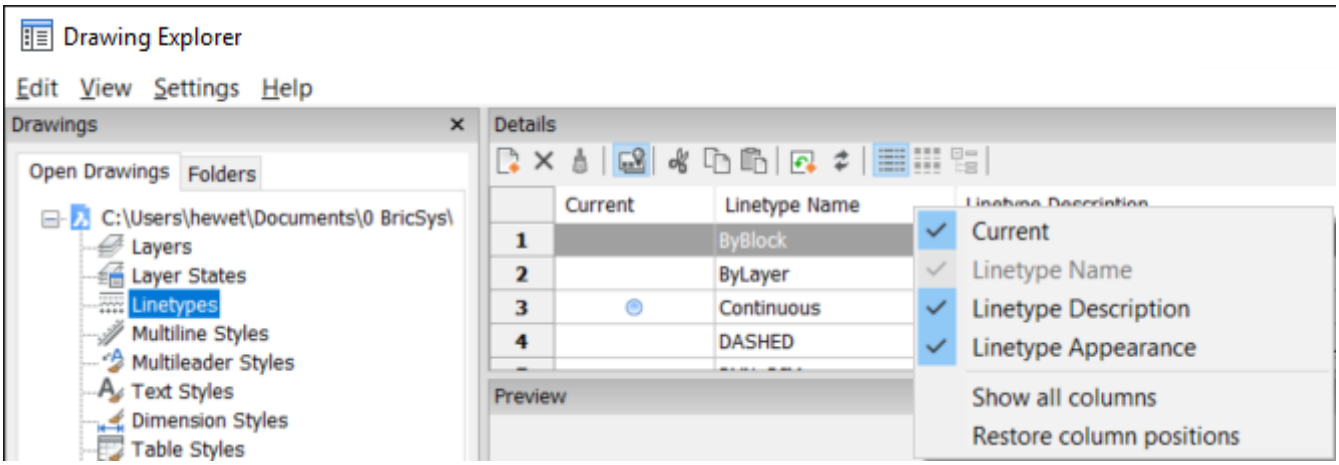
Figure 1.463



Column Controls

You can control the display of the columns for any named content by right-clicking on a column header or row number. Turn columns on or off individually or choose the option to Show all columns. You can drag and drop columns to rearrange them and easily restore them to their default positions. (1.464)

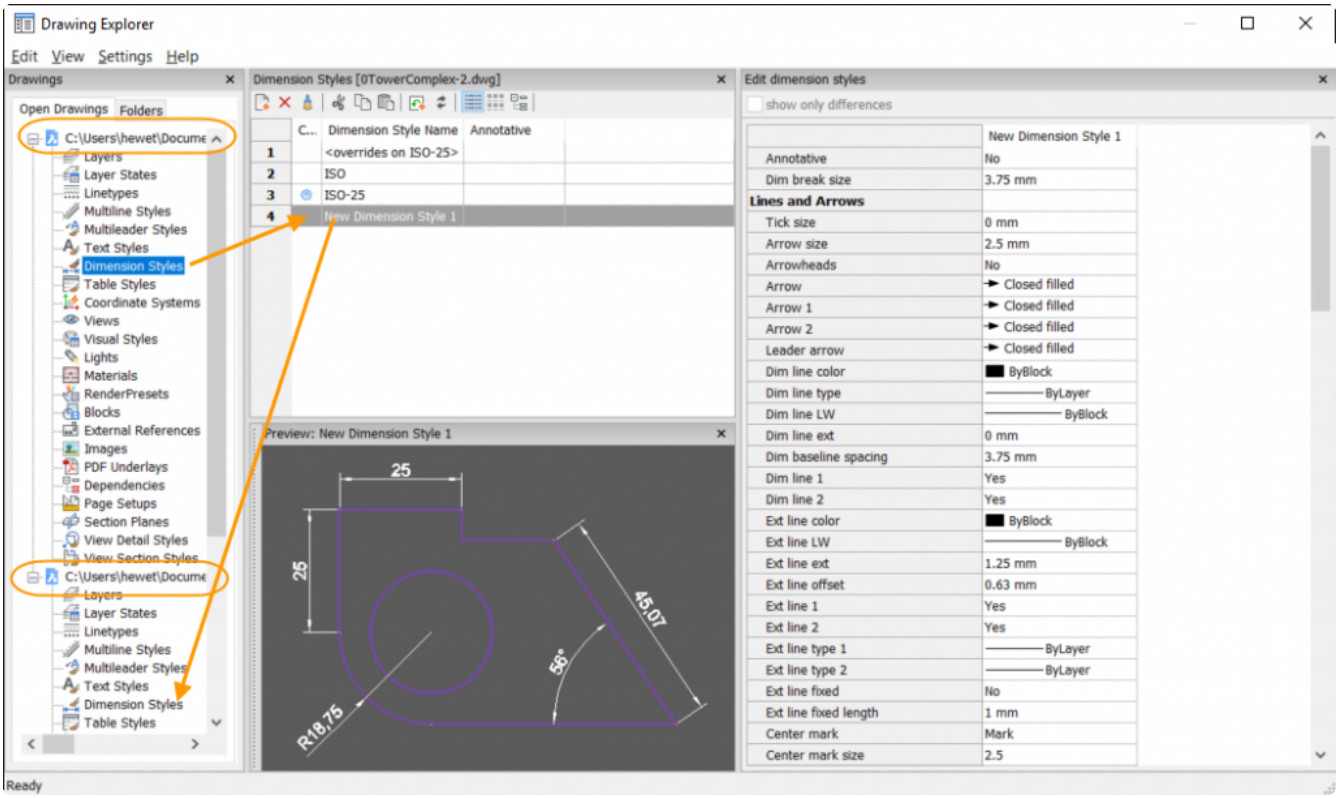
Figure 1.464



Open Drawings

Until now, we've focused on the named content of a single drawing. However, the Open Drawings tab in Drawing Explorer, lists all the open drawings enabling you to access named content from any of them. You can easily drag and drop or copy and paste named content from one open drawing to another! While drag and drop works for most of the content, it doesn't work for all. If drag and drop doesn't work for you, try copy and paste from the Edit or right-click menus. (1.465 on the facing page)

Figure 1.465

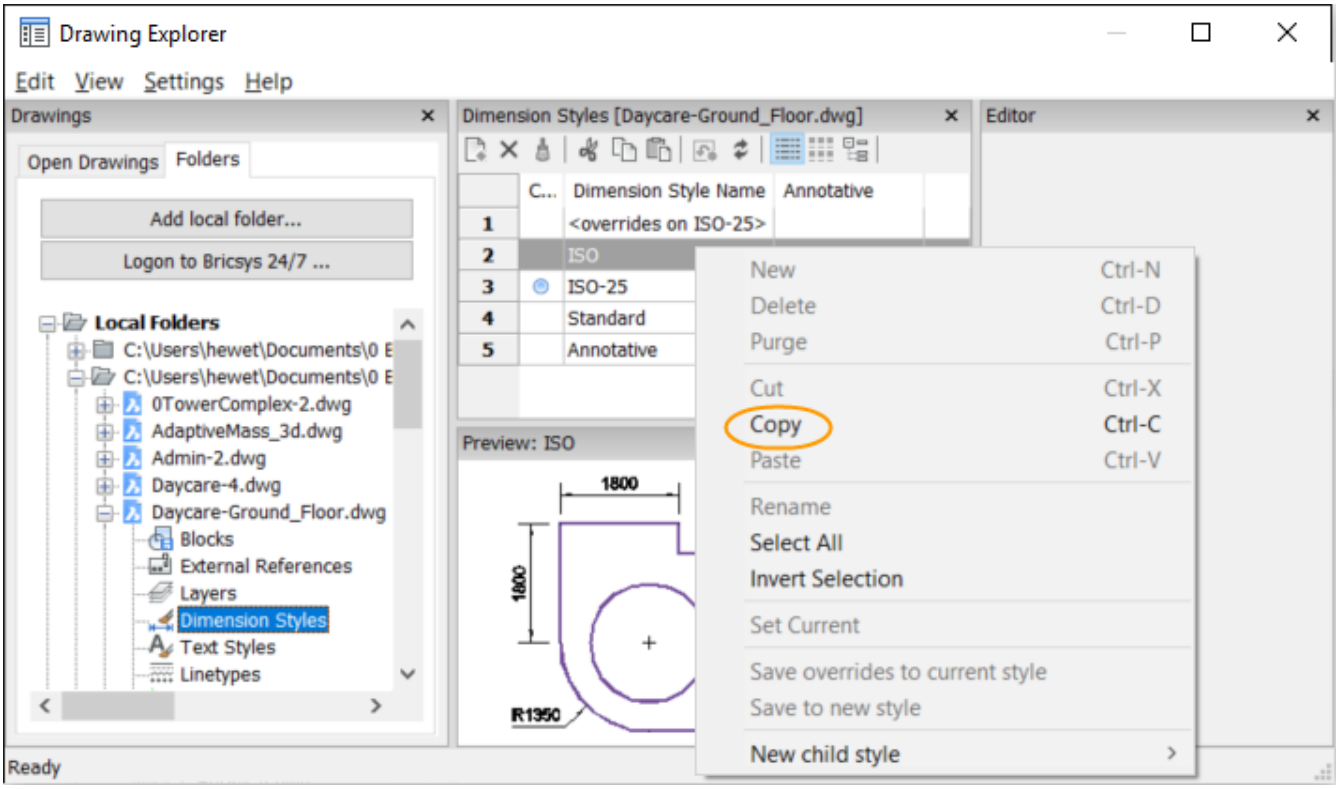


Folders

The Folders tab, to the right of the Open Drawings tab, enables you to access drawings from local folders and even from Bricsys 24/7.

Local Folders Add local folders to Drawing Explorer for easy access to named drawing content even if the drawings aren't open! Simply expand the drawing and select the content. Then copy it from that drawing and paste it into an open drawing. Voila! It's that easy! (1.466 on the next page)

Figure 1.466



Bricsys 24/7 Bricsys 24/7 offers secure and simple document management. You can Access your documents from anywhere and on any device. Share them with your global teams for secure project collaboration. And, the best part is that you access the drawings you store on Bricsys 24/7 directly from BricsCAD! From the Folders tab in Drawing Explorer, choose the option to Logon to Bricsys 24/7. If you don't yet have an account, choose Sign up to start your free trial. (1.467 on the facing page)

1.19.4 Drawing Properties

Command: DWGPROPS (6.10.46) The **Dwgprops** command opens the **Drawing Properties** dialog box, showing the general information and user defined properties stored with a drawing. Drawing properties include: general information, summary, statistics and user defined custom properties. Drawing properties can be referenced in a field (1.29.23) in multiline text entities or tables.

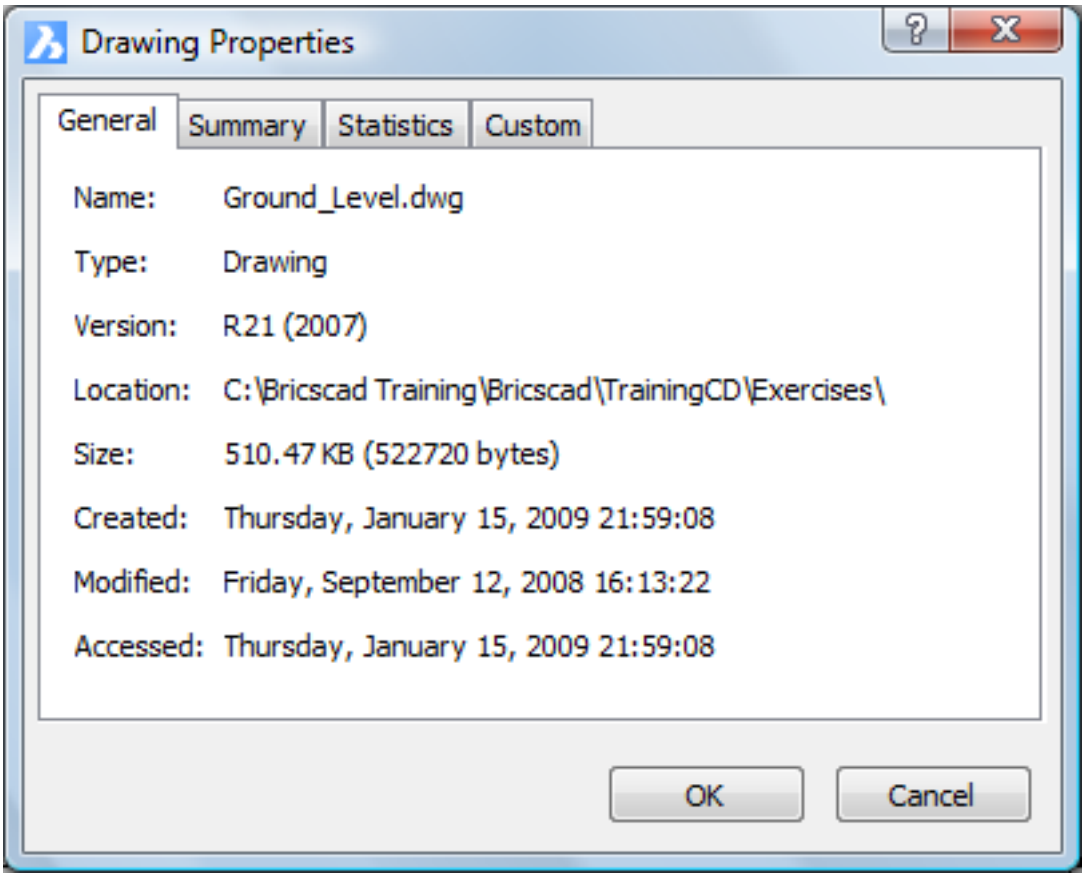
To open the Drawing Properties dialog

Do one of the following:

- Choose **Drawing Properties...** in the **File** menu.
- Type **dwgprops** in the command bar and press Enter.

(1.468 on the next page)

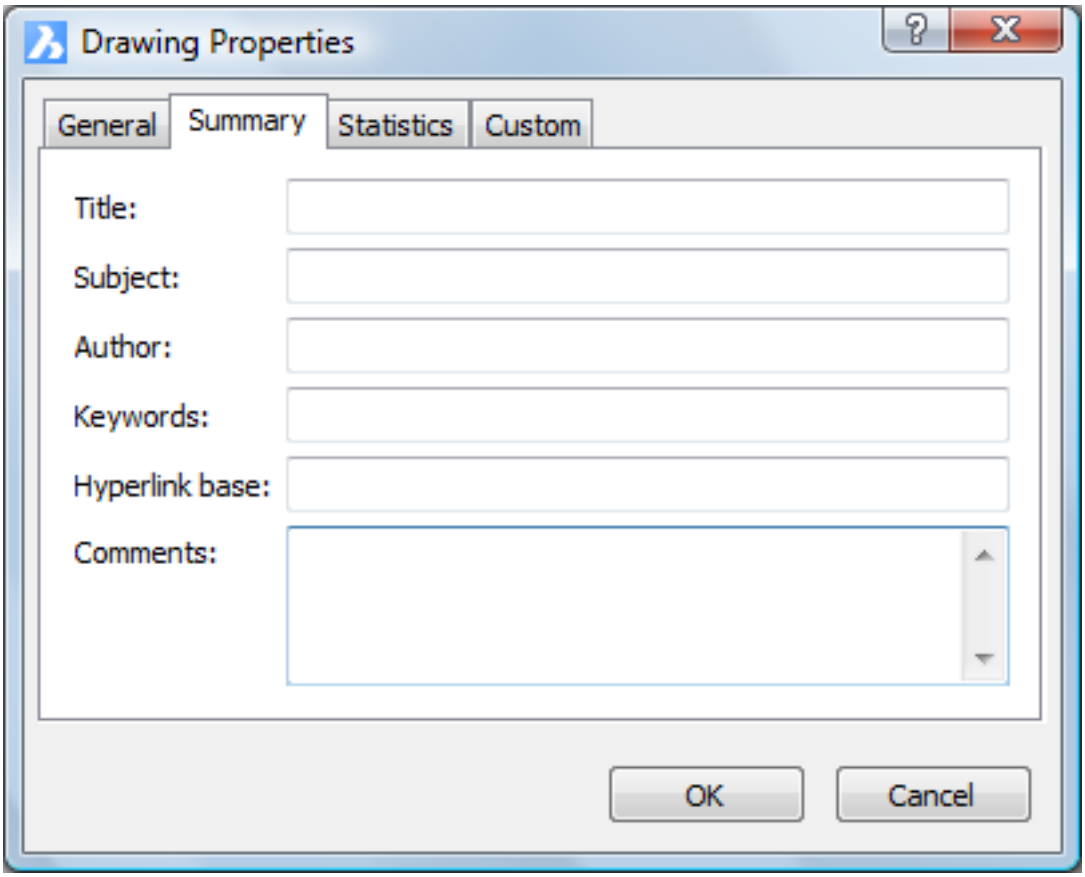
Figure 1.468



Defining default properties

1. Open the Drawing Properties (1.19.4) dialog.
2. Open the **Summary** tab page. (1.469 on the following page)
3. Fill out the property fields
4. Click the **OK** button.

Figure 1.469



Adding custom properties

1. Open the Drawing Properties (1.19.4) dialog.
2. Open the **Custom** tab page. (1.470 on the next page)
3. Click the **Add** button. The **Custom Property** dialog displays. (1.471 on the facing page)
4. Type a name in the **Name** field. The custom property name is listed under **Document** in the Field dialog.
5. Type a value in the **Value** field. The value displays in multiline texts (1.29.20) where the custom property is inserted as a field.

Figure 1.470

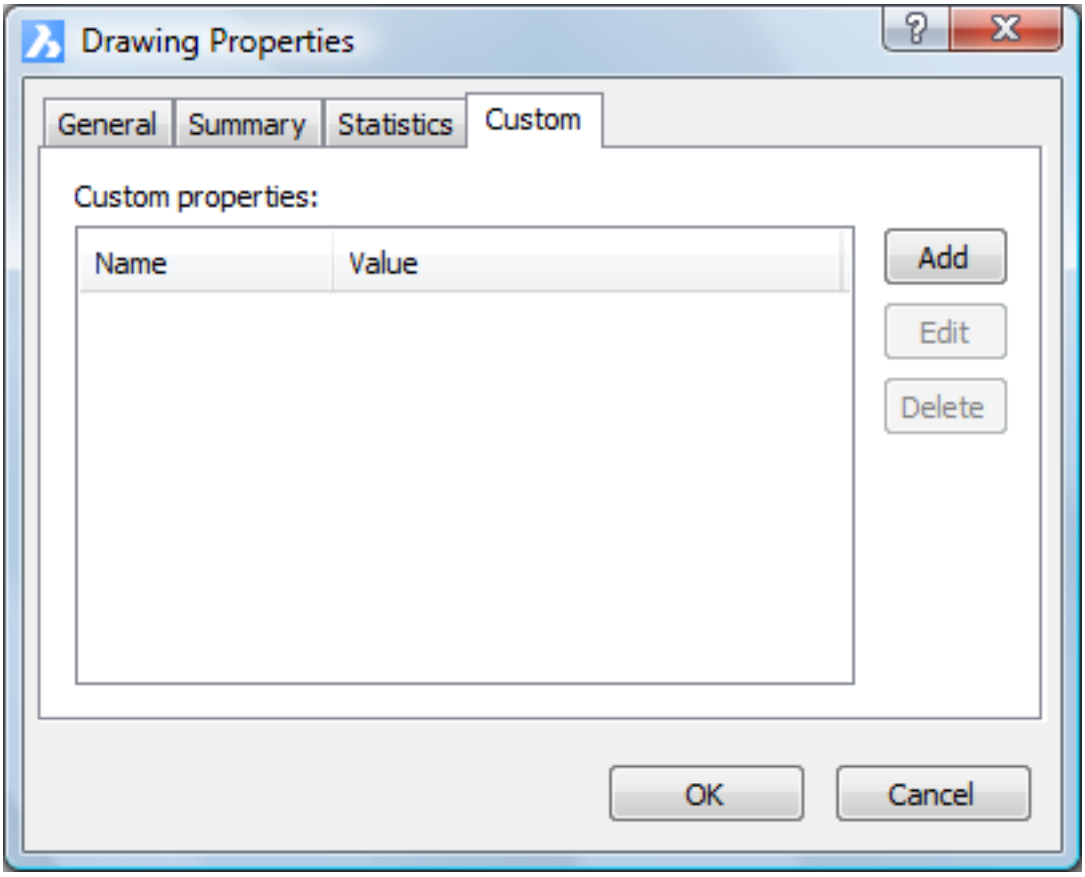


Figure 1.471

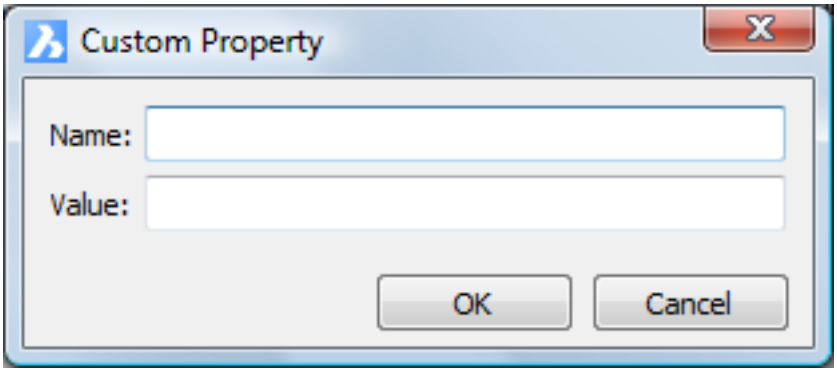

1.19.5 Drawing Security Options

Command : SECURITYOPTIONS (6.27.15) The **Securityoptions** command allows to protect your drawings with a password. Password protected drawings cannot be opened without entering the password first.

To set the password

Do one of the following:

- Choose **Security Options...** in the **File | Drawing Utilities** menu.
- Type **securityoptions** in the command bar, then press Enter.

1. The **Security options** dialog opens:
   (1.472)
2. Type the password in the **Enter Password** field.
3. Choose a crypt provider from the **Crypt Provider** list.
   (1.473 on the facing page)
4. Set the **Key Length** to **40**, **48** or **56**.
5. Click the **OK** button or press Enter. The **Security options** dialog closes. The Password dialog opens.
6. Type the password in the **Confirm Password** field.
7. Click the **OK** button or press Enter. The password is defined.

Figure 1.472

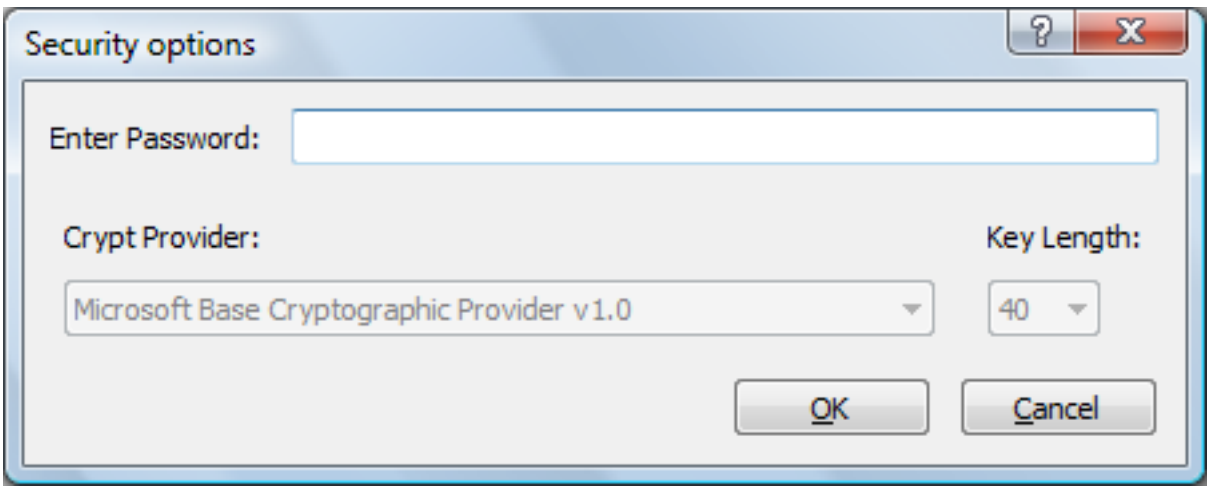

Figure 1.473

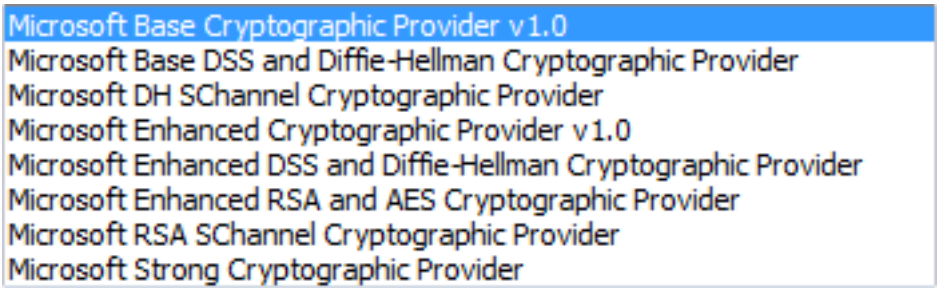
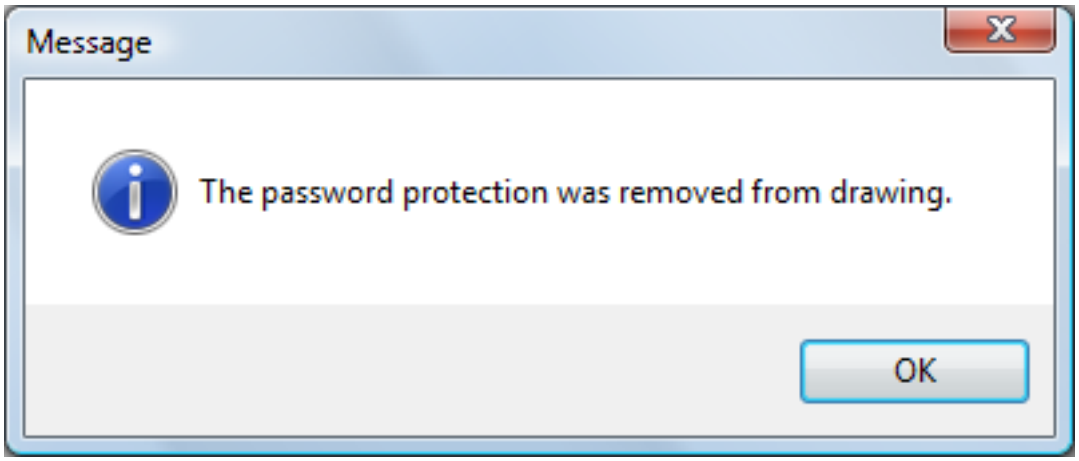


To remove the password

1. Type **securityoptions** in the command bar, then press Enter. The **Security options** dialog opens.
2. Empty the **Enter Password** field.
3. Click the **OK** button or press Enter. A message box displays to confirm that the password is removed. (1.474)

4. Click the **OK** button or press Enter to close the message box.

Figure 1.474



1.19.6 Opening and saving drawings

Commands: OPEN (6.23.8), SAVE (6.27.1), SAVEAS (6.27.3), SAVEALL (6.27.2), SAVEFILEFOLDER (6.27.4) The way BricsCAD opens and saves drawings is controlled through a series of system variables and user preferences. In the table below the SYSTEM VARIABLES are fully capitalized.

Name	Title	Description
ShowFullPathInTitle	Display full path in title	Controls whether the full path of a drawing displays in the title bar, or the file name only.
DrawingPath	Drawings path	Specifies an additional folder in the file dialog for the Open (6.23.8) and SaveAs (6.27.3) commands. On the Windows platform: the fifth folder in the **Open File** dialog's **Places** bar.
PlacesBarFolder1 - 4	First, Second, Third and Fourth folder	Sets the folders 1 through 4 in the **Places** bar of the non-standard **Open File** dialog (Windows platform only). Values between 0 and 5 are accepted: 0=Desktop, 1=My Computer, 2= My Documents, 3= Favorites, 4=Network, 5=My Recent Documents. Tip: Place shortcuts to your favorite drawing folders on your desktop or in your Favorites folder. (1.477 on page 550)
THUMBSIZE	Thumbnail preview image size	Range is 0 - 8; Default = 1 0 (64 x 64) 1 (128 x 128) 2 (256 x 256) 3 (512 x 512) 4 (1024 x 1024) 5 (1440 x 1440) 6 (1600 x 1600) 7 (1920 x 1920) 8 (2560 x 2560)
INDEXCTL	Index Control	Determines whether layer and/or spatial indexes are created and saved. The layer index lists all entities in the drawing and what layer they are on. The spatial index stores the location of all the entities in 3D space. The indexes are used to load Xrefs if demand loading is enabled. If a layer index exists, entities on layers which are Off or Frozen are not loaded. If a spatial index exists, entities in clipped Xrefs which are outside the clipping boundary are not loaded. The demand loading of Xrefs is controlled through the XLOADCTL system variable). Creating indexes slows down the saving of a drawing, but increases the speed of Xrefs. Therefore create indexes only for drawings that will be used as an external reference. 0 = No indexes 1 = Layer index only 2 = Spatial index only 3 = Layer index and spatial index.

XLOADCTL	Xref load control	Controls demand loading of entities in external references. If demand loading is turned on you will experience a performance increase: • When clipping external references which are saved with a spatial index (INDEXCTL = 2 or 3), entities in the external reference within the clipped area are loaded only. If the clipping area is modified, more or less entities are loaded from the reference drawing. • When freezing layers in external references which are saved with a layer index (INDEXCTL = 1 or 3), entities in the external reference on thawed layers are loaded only. If xref-dependent layers are thawed more entities are loaded. 0: Demand loading is OFF - The entire external reference is loaded. 1: Demand loading is ON - Referenced drawings are kept open and locked. Other users can open such drawings only as read-only. 2: Demand loading is ON - Temporary copies of referenced drawings are kept open and locked. Other users can open and modify the referenced drawings.
MTFLAG	Multi-Threading flags	Bitcode 1024: Delayed XREF loading. Delays the loading of Xrefs to idle time.
ISAVEBAK	Incremental save backup	Controls the creation of a backup file (BAK). Improves the speed of incremental saves if switched off, especially for large drawings. Please notice that in some cases (i.e. a power failure during a save), it might be possible drawing data are lost.
ISAVEPERCENT	Save percent	This system variable controls how often BricsCAD performs a full save. A full save reorganizes all the data in the drawing database and creates a compact file. A partial save stores all changes a the end of the drawing data base. A full save takes longer to be executed than a partial save. If ISAVEPERCENT = 0, each save is a full save. The higher the value of ISAVEPERCENT, the longer the time between two full saves.

NFILELIST	Recent File List	Specifies the number of files shown in the **Recent Files** flyout of the **File** menu. Values between 0 and 20 are accepted. Default =10.
PROXYGRAPHICS	Proxy graphics	Determines whether images of proxy entities(1) are saved in the drawing. If switched off, a bounding box displays instead.
PROXYNOTICE	Proxy notice	Displays a notice when you open a drawing containing proxy entities(1) created by an application that is not present.
PROXYSHOW	Proxy show	Controls how proxy entities(1) display in a drawing. 0 = Not displayed 1 = Graphic images 2 = Bounding box.
PROXYWEBSEARCH	Proxy web search	Determines whether BricsCAD checks for object enablers: 0 = Never 1 = If a live Internet connection is present.
SaveFormat	Save format	Sets the default dwg version to save a drawing.
SAVEFILEPATH	Save file path	Specifies the path and folder where automatic saves and temporary files are stored. The SaveFileFolder (6.27.4) command opens the SAVEFILEPATH location in the system file browser.
SAVETIME	Save time interval	Sets the interval in minutes for automatic saves. If set to zero, automatic saves are turned off. Automatic saves are created with a **.SV$** extension in the folder defined by the SAVEFILEPATH system variable.
VbaMacros	Enable macros	Defines whether macros are enabled when loading a VBA-project.
AutosaveChecksOnlyFirstbitDBMOD	Ignore all but first bit of DBMOD(2) for autosave	If this user preference is switched on, no autosave file will be created for files that are viewed only.
CloseChecksOnlyFirstBitDBMOD	Ignore all but first bit of DBMOD(2) for close	If this user preference is switched on, you can view a file, then close it without getting a request to save the file.

(1) Proxy entities are custom entities which are created by an add-on application. If the add-on is currently not loaded or not installed, such entities cannot be displayed properly. (2) DBMOD: Stores the status of the drawing modification as a bit-code as the sum of the following values: 1 = Object database modified, 4 = Database variable modified, 8 = Window modified, 16 = View modified, 32 = Field modified.

Using the Drag-and-Drop option menu

Select a file in a **Windows Explorer** dialog, then hold down the right mouse button and drag the file onto the drawing area of the BricsCAD application window. A context menu displays When a drawing file is selected: (1.475 on the next page) When another file type is selected: (1.476 on the facing page) Do one of the following: Choose **Default by File Extension** to

- open a drawing file (*.DWG, *.DXF or *.DWT)
- attach a PDF
- attach a raster image file
- insert a file as an OLE object (e.g. an Excel spreadsheet)

Choose **Insert Here** to:

Figure 1.475

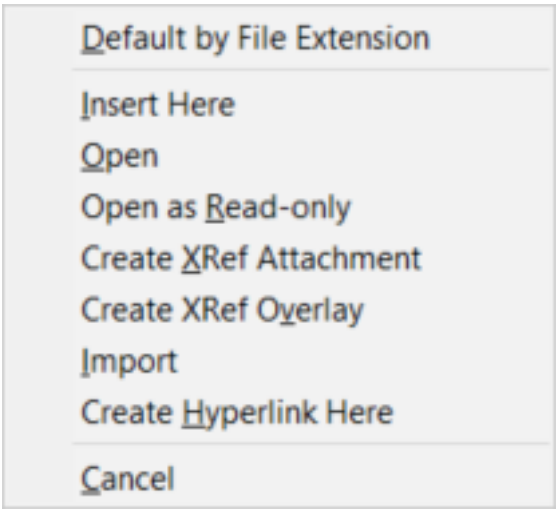


Figure 1.476

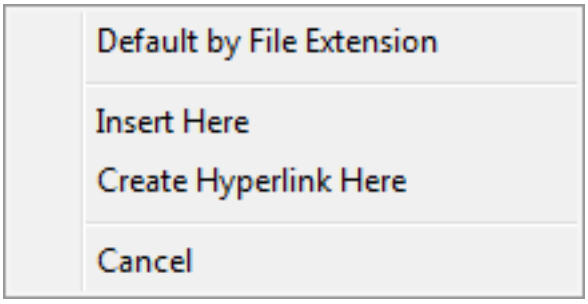

- insert a drawing file (*.DWG, *.DXF or *.DWT) as a block in the current drawing.
- attach a PDF
- attach a raster image file
- insert the file as an OLE object

Choose **Open** to open a drawing file (*.DWG, *.DXF or *.DWT). Choose **Create Xref** to attach a drawing file (*.DWG, *.DXF or *.DWT) as an external reference to the current drawing. Choose **Create Hyperlink Here** to create an hyperlink to the selected file.

NOTE	When multiple files are selected, the files are processed one after the other.

1.19.7 Getting drawing information

You can retrieve two types of information from a drawing:

- General information about the drawing.
- Information about the entities in the drawing

General drawing information

Commands : DWGPROPS (6.10.46), SETVAR (6.27.28), STATUS (6.27.60), TIME (6.29.17) The **Dwgprops** command opens the Drawing Properties (1.19.4) dialog box, showing the general information and user defined properties stored with a drawing. The **Setvar** command displays or changes the values of system variables (short for "set variables"). The **Status** command reports the status of the drawing: drawing name, the status of the most important system variables and the total number of entities in the drawing. The **Time** command reports on time in the drawing: current time, creation time, last update, total editing time and user elapsed time.

Information about entities

Commands : STATUS (6.27.60), AREA (6.4.18), MASSPROP (6.21.2), ID (6.17.4), LIST (6.20.34) The **Status** command reports the total number of entities in the drawing. Using Quick Select (1.32.6) you can see the number of entities for each category. The **Area** command finds the area and perimeter (or length) of 2D entities. The **Massprop** command reports the area, perimeter, and other mathematical properties of 3D solids and 2D regions (short for "mass properties"). The **ID** command reports the x,y,z coordinates of picked points. The **List** command lists the properties of selected entities.

1.19.8 Repairing a drawing

Commands: AUDIT (6.4.42) and RECOVER (6.26.3) The **Audit** command analyzes the integrity of the current drawing and optionally tries to fix errors. The **Recover** command repairs a damaged drawing, then opens the drawing.

To analyze the integrity of the current drawing

1. Do one of the following:

   - Choose **Audit** in the **File | Drawing Utilities** menu.
   - Type **audit** in the command bar, then press Enter.

   You are prompted: Fix any errors detected? Yes/<No>

2. Do one of the following:

   - Choose **Yes** in the context menu or type **Y** , then press Enter to analyze the integrity of the current drawing and fix the errors detected.
   - Choose **No** in the context menu or type **N** , then press Enter to analyze the integrity of the current drawing.

   The drawing is analyzed.

3. (option) Press F2 to open the **Prompt History** window in order to read the audit report: # objects audited Total errors found during audit #, fixed #.

NOTE

- Set the **AUDITCTL** settings variable to 1, to let **Audit** create an ASCII file describing problems and the action taken. This report, with the file extension .adt, is placed in the same directory as the current drawing .
- Use the **Recover** command to repair the errors that **Audit** cannot fix.

To repair a drawing

1. Do one of the following:

   - Choose **Recover** in the **File | Drawing Utilities** menu.
   - Type **recover** in the command bar, then press Enter.

   The **Open Drawing** dialog window displays.

2. Select the drawing, then press the **Open** button on the **Open Drawing** dialog window. The drawing is repaired and - if the repair succeeded - opened.

3. (option) Press F2 to open the **Prompt History** window in order to read the recover report.

1.19.9 Export to PDF

Command: EXPORT (6.13.18) Drawing files can be saved as a PDF file, optionally including layers.

Export to PDF settings

Choose **Export Options...** in the **File** menu to display the **PDF Export** settings in the Settings dialog (1.17.10). (1.478 on the next page)

- **Pdf embedded fonts** : Controls whether True Type Fonts are embedded in the PDF export.
- **Pdf TTF text as geometry** : If selected, TTF text is exploded to geometry.
- **Pdf SHX text as geometry** : If selected, SHX text is exploded to geometry.
- **Pdf simple geometry optimization** : Enable simple geometry optimization: e.g. separate segments to one polyline, use of Bezier curve control points.
- **Pdf zoom to extents mode** : If exporting model space, zoom to extents first, if the current model space view is zoomed in.
- **Pdf merge control** : Controls the appearance of crossing lines. The options are:
  Lines Overwrite : The topmost line obscures the line(s) under it.
  Lines Merge : The colors of crossing lines are merged.
- **Pdf layer support** : Controls whether layers are included in the PDF export. The options are: do not export layers, export layers which are on only, export all layers.
- **Pdf layouts to export** : Controls which layouts are exported. The options are:
  Active : only the active layout or model space is exported as a single-page pdf.
  All : All layouts, including model space are exported as a multi-page pdf.
- **Pdf papersize override** : If on, the papersize as defined in the BricsCAD Print settings is overridden. The papersize width and height defined by **PdfPaperWidth** and **PdfPaperHeight** is used instead.
- **Pdf overridden paper width** : Width (in mm) of the PDF paper, if **PdfPaperSizeOverride** is on.
- **Pdf overridden paper height** : Height (in mm) of the PDF paper, if **PdfPaperSizeOverride** is on. .
- **Pdf use plotstyles** : If on, the plotstyle of the layout controls the color and lineweight in the PDF export.
- **Image anti-aliasing** : Enables anti-aliasing for images that require upscaling when exporting.
- **Image compression** : Defines the compression for exported images: **None** or **JPEG** .
- **Vector Resolution DPI** : Controls the resolution of vector graphics when exporting to PDF. Default is 600 DPI.
- **Image DPI**: When a raster image is exported, this value controls the minimal resolution for the image.

Figure 1.478

PDF export

Pdf embedded fonts	☑ Enable embedded TTF fonts
Pdf TTF text as geometry	☐ Convert TTF text to geometry
Pdf SHX text as geometry	☐ Convert SHX text to geometry
Pdf simple geometry optimization	☑ Enable simple geometry optimization
Pdf zoom to extents mode	☑ Zoom to extents
Pdf Merge Control	[0] Lines Overwrite
Pdf layer support	[1] Use all layers with visible entities
Pdf layouts to export	[0] Active
Pdf papersize override	☐ Enable papersize override
Pdf overridden paper width	210
Pdf overridden paper height	297
Pdf use plotstyles	☑ Enables usage of plotstyles
Image anti-aliasing	☑ Enables anti-aliasing for images
Image compression	[1] JPEG
Vector Resolution DPI	2400
Image DPI	300

Exporting a drawing to PDF

1. (option) Adjust the Export to PDF (1.19.9) **settings**.
2. Choose **Export...** in the **File** menu. The **Export Drawing As** dialog opens.
3. In the **Save as type** : list select **Adobe PDF (*.pdf)** .
4. Select a folder to save the PDF file.
5. (option) Type a name in the File name field to replace the default <DRAWING_NAME>.pdf name.
6. Click the **Save** button to create the PDF.

Tutorial: Output As Pdf Click here (1.22.1) to watch

1.19.10 Comparing Drawings

Commands: DWGCOMPARE (6.10.51), ENDCOMPARE (6.13.6), KEEPME (6.19.1) The **DwgCompare** command compares a selected drawing with the current drawing during a comparison session. The **EndCompare** command concludes a comparison session. The **KeepMe** command allows to merge the compared drawings visually.

Comparison system variables

Name	Title	Description
CMPCLRMISS	Compare missing entities display color	Sets the color for displaying entities which are missing in the other drawing. The default color is Red .
CMPCLRMOD1	Compare modified entites display color 1	Sets the color for displaying modified entities in the current drawing. The default color is index color 253.
CMPCLRMOD2	Compare modified entities display color 2	Sets the color for displaying modified entities in the other drawing. The default color is Yellow.
CMPCLRNEW	Compare new entities display color	Sets the color for displaying entities which are new in the other drawing. The default color is Green.
CMPDIFFLIMIT	Maximal number of output entities	Sets the limit for entities comparison. The comparison will be aborted after reaching the difference limit. Values between 1 and 10 000 000 are accepted.

Executing a comparison session

1. Launch the DWGCOMPARE (6.10.51) command. You are prompted: CMPDIFFLIMIT = 10000000. Select the file to compare with or [Limit]:
2. (option) Choose the Limit option to set a new value for entities comparison.
3. Press Enter to display **File** dialog box. (1.479 on the following page)
4. Select the drawing to be compared with the current drawing, then click the **Open** button or double click the drawing name. The differences between the two drawings display using the Compare Display Colors (**??**). The Compare toolbar displays: (1.480 on the next page)
5. To check the **Diff Type** of an entity, do one of the following:
   - If Rollover Tips (1.15.2) are active, hover over the entity: (1.481 on the following page)
   - Select the entity and check the **Diff type** field in the Properties (6.24.54) panel. (1.482 on page 557)
6. Analyze the comparison in the Structure panel.
7. Merge the compared drawings (1.19.10).
8. Click the **Endcompare** tool button ( ) on the **Compare** toolbar to conclude the comparison session.

Figure 1.479

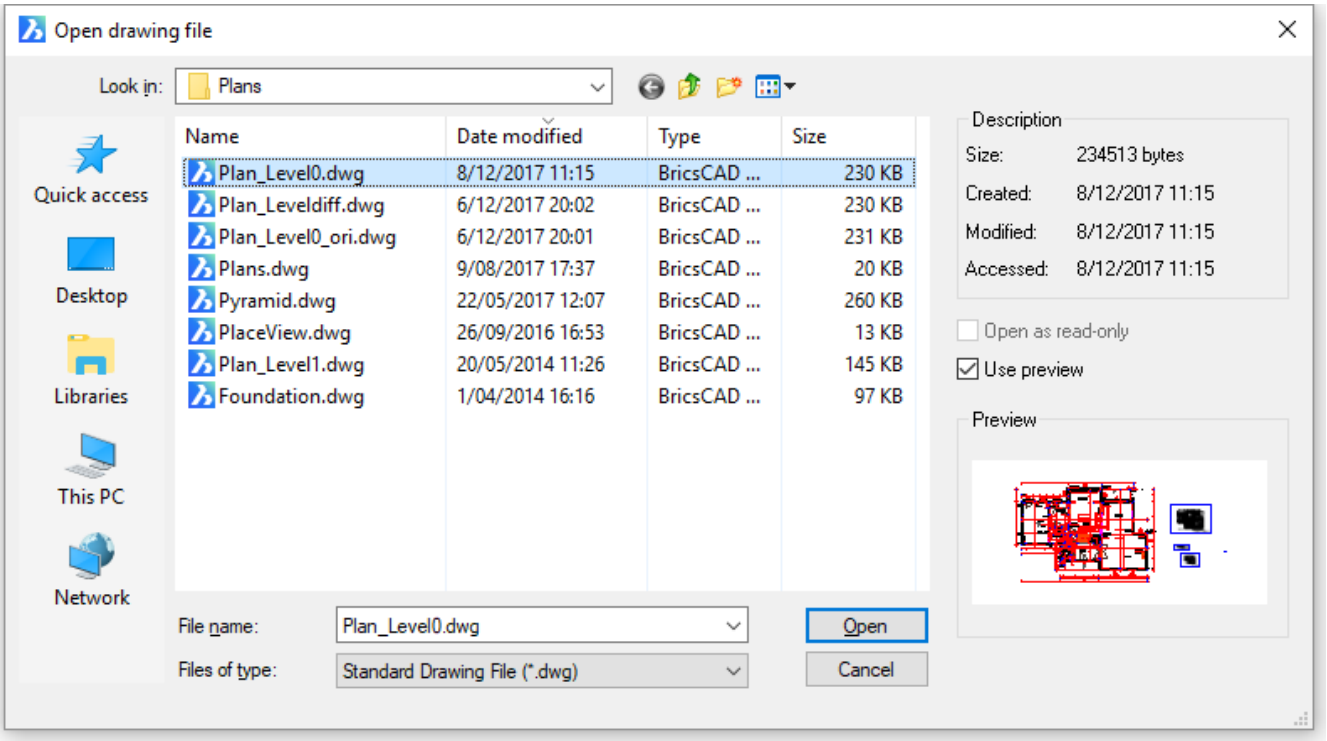

Figure 1.480

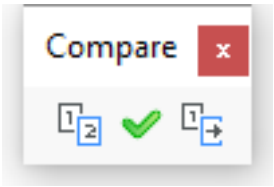

Figure 1.481

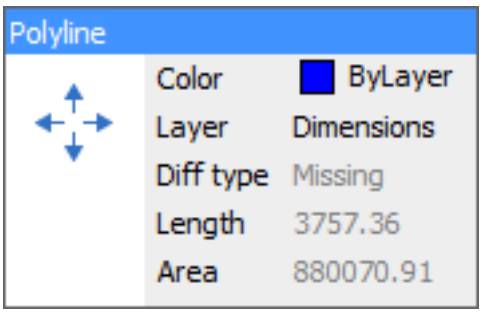

Figure 1.482

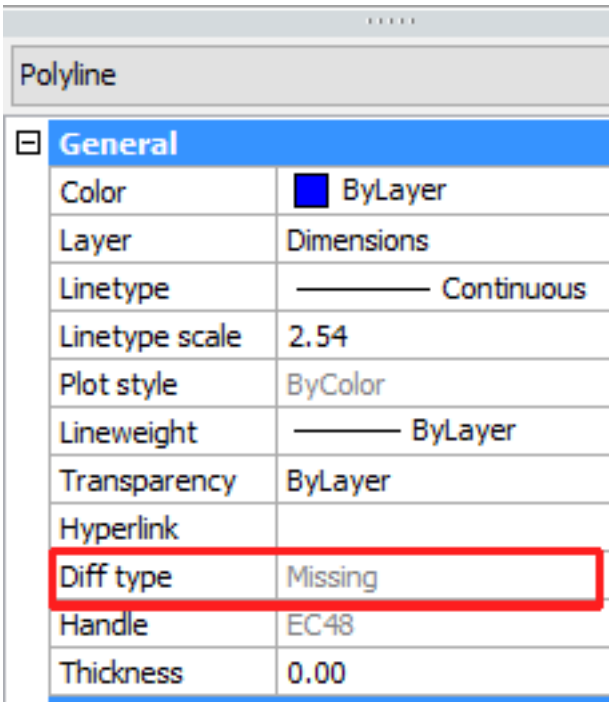

Analyzing the comparison in the Structure panel

1. Open the Structure panel (1.32.15).
2. Load the **Default.cst** configuration. See Load a Structure configuration file (1.32.15).
3. Expand the **Comparison** node. Four subnodes display: **Missing** , **Modified (Original**), **New** and **Modified (Compared)** . The number of entities in each subnode is indicated between brackets. (1.483)
4. Click a subnode to select the corresponding entities in the drawing (see also the note below).
5. Expand a subnode, then click an entity to highlight the corresponding entity in the drawing. Press and hold the Ctrl-key to select multiple entities.
6. Right click, then choose **Zoom** in the context menu to zoom onto the selected entity or entities.

NOTE	When selecting entities in the Structure panel, entities are either selected or highlighted in the drawing, or tree selection is ignored. See setting the options in the Structure panel (1.32.15).

Figure 1.483

Merging the compared drawings

1. Missing entities only exist in the current drawing; do one of the following:
   - Select the entities you want to keep, then click the **Keep Me** tool button (✔) on the **Compare** toolbar.
   - Select the entities you don't want to keep, then click the **Delete** tool button (✖).
2. Modified entities exist in both drawings; do the following:
   - In the **Modified (Original)** node: select the entities you want to keep, then click the **Keep Me** tool button (✔) on the **Compare** toolbar. The corresponding entities in the **Modified (Compared)** node are removed.
   - In the **Modified (Compared)** node: select the entities you want to keep, then click the **Keep Me** tool button (✔) on the **Compare** toolbar. The corresponding entities in the **Modified (Original)** node are removed.
3. New entities exist in the compared drawing only. Do the following:
   - Select the entities you want to keep, then click the **Keep Me** tool button (✔) on the **Compare** toolbar.
   - Select the entities you don't want to keep, then click the **Delete** tool button (✖).

The merge is complete when the **Comparison** node in the **Structure** panel disappears. A message displays in the Command bar: No more differences to show. Session is closed

1.19.11 Projects

Projects are especially useful to manage xrefs and images when exchanging drawings. If external references (xrefs) and images are not found in the saved path, the project search paths are used to find the external references and images. Projects are saved in the registry and contain one or more search paths.

Opening the Project settings

1. Click the **Settings** tool button ( ) on the **Standard** toolbar. **Or** Choose **Settings...** in the **Settings** menu. The **Settings** dialog opens.
2. Go to **Program Options > Files > Projects > Project search paths** .

Creating projects

To create a project:

1. Open the Project settings.
2. Click the **Browse** button at the right hand side of the **Project search paths** settings field. (1.484) The **Project Settings** dialog opens. (1.485 on the following page)
3. To create the first project:
   - Click the **New** button ( ) on the **Project Settings** dialog. (1.486 on the next page)
   - Type a name to replace the **NewProject1** default name.
4. To create additional projects.
5. Click **Projects** (on top of the projects tree) then click the **New** button ( ) .
6. Type a name to replace the **NewProject1** default name.

Figure 1.484

Figure 1.485

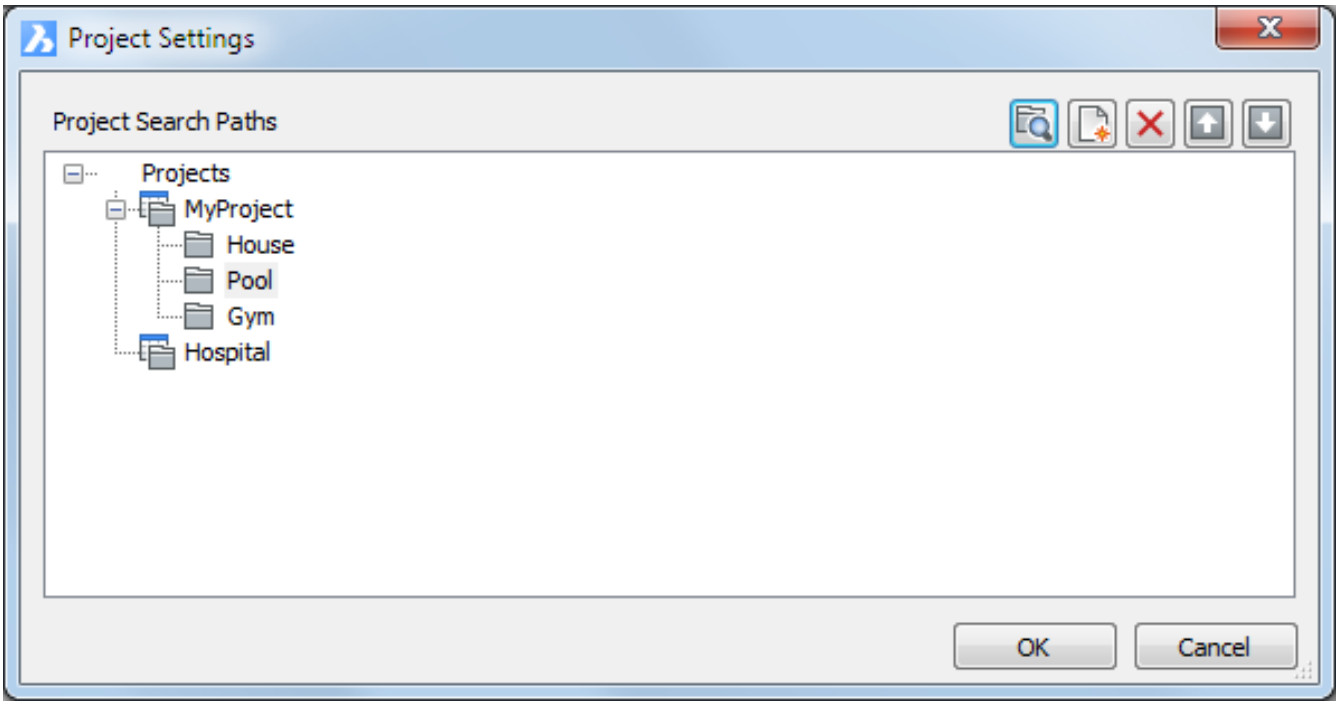

Figure 1.486

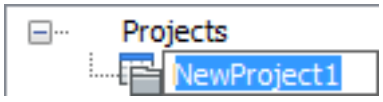
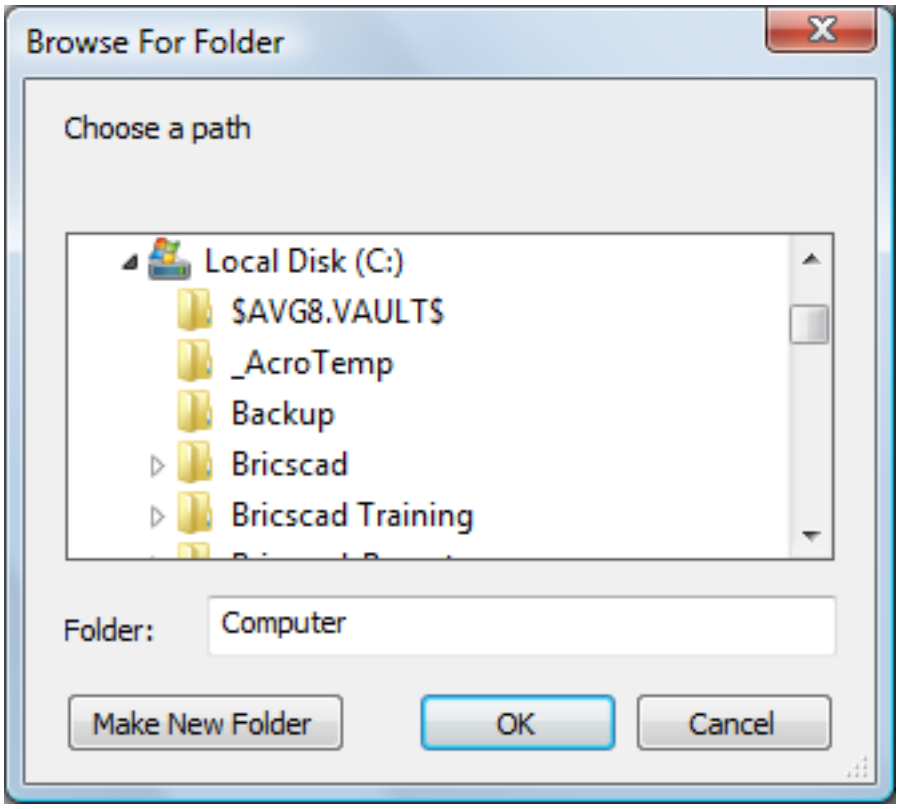


Adding search paths to a project

To add a search path to a project:

1. Open the Project settings.
2. Select the project in the **Projects** tree.
3. Click the **Browse** button ( ). The **Browse for folder** dialog opens. (1.487 on the facing page)
4. Do one of the following:
   - Select a folder.
   - Select a parent folder, then click the **Make New Folder** button to create a new folder.
5. Click the **OK** button to add the selected folder to the project search paths.

Figure 1.487



Changing the order of the search paths

1. Open the Project settings.
2. Click the **expand** button (+) of the project you want to edit.
3. Select a search path, then click the up ( ) or down ( ) buttons to change the order of the search paths.

Assigning a project to the current drawing

1. Open the Project settings.
2. Type the name of an existing project in the **Project name** settings field (**PROJECTNAME** system variable).

1.20 Images

1.20.1 Backgrounds for visualizing your 3D models

https://www.youtube-nocookie.com/embed/kDv8uWQbA6U

Backgrounds make your 3D visualizations better

A huge benefit of modeling in 3D is using your model for sharing and visualization. You can use backgrounds to enhance the visual quality of your 3D models in BricsCAD. This video by Ralph Grabowski shows you how to use the Background command to specify colors, gradients, and image parameters. First, set your Visual Style to "Model". The Background command needs a visual style set to something other than "2D wireframe" mode. Next, simply start the BACKGROUND command. Go to the top of the dialog, and you'll see your type choices – solid colors, gradients or images. Solids are pretty self-explanatory. Gradients transition from one color to another – for example, from blue sky to green grass. You have the ability to use a two-color or three-color gradient in BricsCAD. Using images as backgrounds gives you the ability to "place" your model in a scene. Select your image file, and you can move and scale it to fit your graphics window. Then, you can zoom, pan and adjust the viewing angle to better fit the model into the image. You have additional options that are available when you use an image as a background: stretch, center or tile the image to fit on the screen. Next, you can lock the aspect ratio of the image to keep it from distorting. Finally, the sliders in the Background dialog give you the choice of adjusting the background image's scale or offset.

Want more info?

If you want to learn more about 3D modeling, rendering and using backgrounds for visualization, just click on the links below. They'll take you to the related page in the BricsCAD on-line help system:

- The BACKGROUND command (6.6.3)
- MatchPerspective (6.21.7) – match the current MSPACE perspective view with a background image
- VisualStyles (6.31.15) – create and control visual style definitions in Drawing Explorer
- Materials (6.21.10) – create materials and edit their properties through the Drawing Explorer
- MaterialMap (6.21.9) – control texture mapping in BricsCAD Pro and Platinum

Back to Tutorial Overview

1.20.2 Image Geolocator

https://www.youtube-nocookie.com/embed/HlrQCXgNGUE

Placing Geocoded Images accurately is easy with BricsCAD

Utilizing aerial imagery with your drawings has a numerous benefits, and has become a common expectation in the production of good project documentation. But how do you go about aligning these types of images with your vector data? The good news is that BricsCAD has long been able to attach geocoded images in the correct location on your drawing. This tutorial shows you how painless this is to do with BricsCAD. Back to Tutorial Overview

1.21 Drawing Accurately

1.21.1 Drawing Accurately Overview

In BricsCAD the following drawing aids are available:

- Entity Snaps (1.21.15)
- 3D Entity Snaps (1.21.16)
- Dynamic dimensions (1.21.9)
- Polar Tracking (1.21.18)
- Entity Snap Tracking (1.21.17)
- Coordinate Input (1.21.11)
- Snap and Grid (1.21.12)
- Drawing Limits (1.21.12)
- Ortho Mode (1.21.2)
- User Coordinate Systems (1.21.21)
- Direct Distance Entry (1.21.4)
- Nearest Distance (1.21.10)

Tutorial: Drawing Accurately: Snap and Grid Click here (1.14.1) to watch

Tutorial: Drawing Accurately: Polar and Snap Tracking Click here (1.14.2) to watch

Tutorial: Drawing Accurately: Dynamic dimensions Click here (**??**) to watch

1.21.2 Orthogonal Mode

Command: Ortho (6.23.12) **Overview:** Orthogonal Mode restricts the movement of the cursor to be parallel to the X-axis or the Y-axis of the current coordinate system (1.21.21). For example, with the default 0-degree orientation (angle 0 at the "three o'clock" or "east" position), when the Orthogonal Mode setting is enabled, lines are restricted to 0 degrees, 90 degrees, 180 degrees, or 270 degrees. As you draw lines, the rubber-banding line follows either the horizontal or vertical axis, depending on which axis is nearest to the cursor: type the length of the line in the command bar, then press Enter.

NOTES

- When you enable the Isometric snap style (1.21.12), cursor movement is restricted to orthogonal equivalents within the current isometric plane.
- You can rotate the **Orthogonal Mode** axes using the Snap Angle (1.21.12) setting.
- Press and hold the Shift key to reverse the **Orthogonal Mode** setting.
- **Orthogonal Mode** is overruled by entity snaps.
- Turning on **Ortho Mode** automatically disables Polar Tracking (1.21.18) and vice versa.

To toggle Orthogonal Mode

Do one of the following:

- Click the **ORTHO** field in the Status Bar (1.15.2).
- Press the **F8** function key.
- Press and hold the Shift key.
- Type **ortho** in the command bar, then choose the appropriate setting.
- Set the **Orthogonal Mode** in the **Settings** dialog.

1.21.3 Unit Settings

Commands: UNITS (6.30.8) and -UNITS (6.30.9) **Overview:** The **Units** command sets units of linear and angular measurements through the Settings (1.17.10) dialog box. The **-Units** command sets units of linear and angular measurements in the command bar. The INSUNITS (1.30.5) (Insertion Units) system variable defines a drawing units value for automatic scaling when inserting blocks (1.30.5) or attaching Xrefs (1.30.19). Any length, area or volume property can be displayed using the unit(s) preferred by the user. The unit defined by INSUNITS is used as the base unit for any requested unit conversions. If INSUNITS = 0 (undefined) the PROPUNITS mechanism is disabled because the base drawing unit is undefined.

NOTES

- When LUNITS = 3 (Engineering) or 4 (Architectural), property values will be formatted in imperial notation.
- Automatic unit conversion during length input can be used when bitcode 1 of PROPUNITS (Format length properties) is set. E.g. when INSUNITS is set to "mm", entering "2m" in a length property field will result in entering [2000.0000 mm]. Entering "1ft" will give [304.8000 mm].

Name	Title	Description
INSUNITS	Insertion Units	Defines the value of 1 Drawing Unit (DU), which is used for automatic scaling when inserting or attaching blocks, images or Xrefs. When both INSUNITS and PROPUNITS are ON, Length, Area, Volume and/or Inertia properties will be formatted with a dedicated unit.
MEASUREMENT	Measurement	Sets drawing units as Imperial or Metric. The MEASUREMENT system variable controls whether ANSI or ISO hatch pattern and linetype files are used.
PROPUNITS	Property Units	Defines which property values are automatically formatted with a dedicated unit when INSUNITS is not zero. The value is stored as a bitcode, using the sum of the values of all selected options.
LUPREC	Linear Unit Precision	Sets the number of decimal places displayed for linear units.
AREAPREC	Area Precision	Sets the number of decimal places displayed for areas when the Area bit of PROPUNITS is ON. If set negative, the value of LUPREC is used.
VOLUMEPREC	Volume Precision	Sets the number of decimal places displayed for volumes when the Volume bit of PROPUNITS is ON. If set negative, the value of LUPREC is used.
LENGTHUNITS	Length Units	Defines a list of units used for displaying lengths when the Length bit of PROPUNITS is ON. If empty, all lengths display in the current drawing unit, as defined by INSUNITS. If multiple units are selected, the unit that fits best is used.

AREAUNITS	Area Units	Defines a list of units used for displaying areas when the Area bit of PROPUNITS is ON. If empty, all lengths display in the current drawing unit, as defined by INSUNITS. If multiple units are selected, the unit that fits best is used.
VOLMEUNITS	Volume Units	Defines a list of units used for displaying volumes when the Volume bit of PROPUNITS is ON. If empty, all lengths display in the current drawing unit, as defined by INSUNITS. If multiple units are selected, the unit that fits best is used.
UNITMODE	Unit Mode	Specifies how Imperial units display.

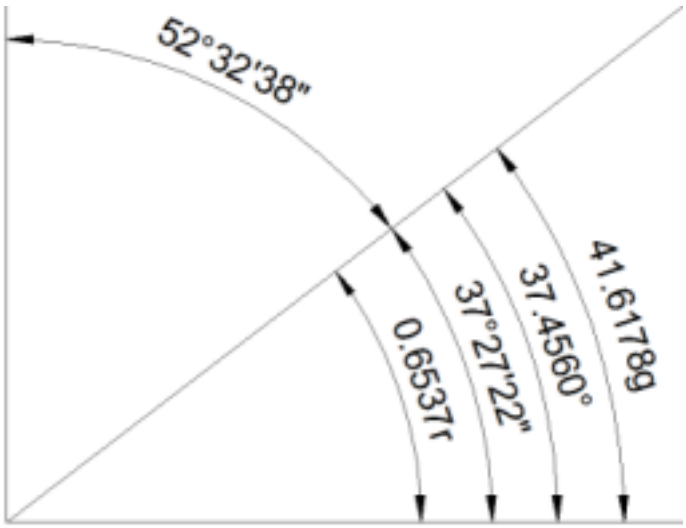
Entering angles

The **AUNITS** system variable defines the angular unit type. You can enter angles in any of 5 formats:

- Decimal degrees : 37.456 (AUNITS = 0)
- Degrees / Minutes / Seconds : 37°27'22" or 37d27'22" (AUNITS = 1)
- Gradians : 41.6178g (AUNITS = 2)
- Radians : 0.6537r (AUNITS = 3)
- Surveyor's Units : N52°32'38"E or N52d32'38"E (AUNITS = 4) Surveyor's units are measured from the North (N) or the South (S) to the East (E) or to the West (W).

(1.488 on the next page)

Figure 1.488



1.21.4 Direct Distance Entry

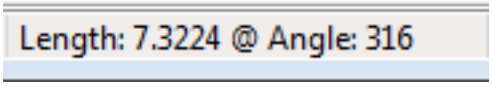
Direct Distance Entry (DDE) means that you can type the length of lines, polyline segments, circle radii and diameters, movement vectors in commands such as Move , Copy and Stretch , etc. in the command bar. When combined with either Orthogonal Mode (1.21.2) or Polar Tracking (1.21.18), **Direct Distance Entry** is a particularly efficient method to draw lines of a specified length and direction, and to move or copy objects over a specified distance. To help you keep track of the position of the cursor it is recommended to set the readout of the coordinate field in the Status Bar (1.15.2) to **Relative** .

To define the Coordinates setting

Do one of the following:

- Right click the then choose **Relative** in the context menu.
- Click the **Coordinates** field in the status bar (1.15.2) to cycle the **Coordinate** setting. The sequence is **Off** , **Relative** , **Absolute.**
- Press the **F6** function key or use the **Ctrl + I** keyboard shortcut to cycle the **Coordinate** setting. The sequence is **Off**, **Relative**, **Absolute.**
- Type **coords** in the command bar, then press Enter. Type 2 and press Enter.
- Open the Settings dialog (1.17.10) and expand the **Display/Viewing** settings sub-category under **Drafting** in the **Drawing** settings class. Set the **Coordinates** setting to **Coordinates in polar form for point, distance and angle selection** . (1.489)

Figure 1.489



1.21.5 Coordinate Reference System

Command: GeographicLocation (6.15.15) **Overview:** A Coordinate System is a set of mathematical rules for specifying how coordinates are to be assigned to points. The coordinate system is unrelated to the Earth. A Coordinate Reference System (CRS) is a coordinate system related to the Earth through a "Datum". A Geodetic Datum is a model of the Earth that specifies a reference surface (Ellipsoid or Spheroid). A projected coordinate reference system is the result of the application of a map projection to a geographic coordinate reference system. A map projection is a type of coordinate conversion. It uses an identified method with specific formulas and a set of parameters specific to that coordinate conversion method. Coordinates may be changed from one CRS to another through the coordinate operation. Two types of coordinate operation may be distinguished:

- **coordinate conversion**, where no change of datum is involved and the parameters are chosen and thus error free.
- **coordinate transformation**, where the target CRS is based on a different datum to the source CRS. Transformation parameters are empirically determined and thus subject to measurement errors. (Geodetic, Seven paramets, Molodenksy & etc.)

Geographic datasets are defined in **geodatabase.xml** that is placed in <User folder>\AppData\Roaming\Bricsys\BricsCAD\<R for Windows. The content of this file is composed of the 5 sections:

- CoordinateReferenceSystems
- Datums
- Ellipsoids
- Transformations
- ProjectionCode and Methods

1. CoordinateReferenceSystems

This section is the main xml node where all Coordinate Reference Systems are defined. It has many sub-nodes called **CRS**, each xml node must define a unique projected coordinate reference system and the necessary projected parameters. The supported CRS projection types are described in the **ProjectionCode** and **Methods** sections. **CRS** node attributes: Follow Table 1 of OGP Geomatics Guidance Note No 7, part 2

Attribute name	Description	Units
epsg	Unique EPSG database id.	Integer
name	Human-readable name of CRS, Example: "WGS 84 -- WGS84 - World Geodetic System 1984, used in GPS"	String
codeSpace	Owner of CRS. It is option.	String
x, **y**	Orientation of projected direction. Possible values: "Westing", "Easting", "Southing" and "Northing". Directions MUST be defined.	String
xAxis, yAxis	Orientation of geographic direction. Possible values: "Latitude" and "Longitude".	String
Greenwich	Greenwich Meridian relation.	Degree
proj	Projection method of CRS. Possible values: "LL", "LatLon", "LonLat" is a Geodetic Latitude-Longitude. "MercA", "Mercator_1SP" is a Mercator (variant A). "MercB", "Mercator_2SP" is a Mercator (variant B). "MercC" is Mercator (variant C). "MercSp" is a Mercator (Spherical). "MercPv" is a Popular Visualisation Pseudo Mercator. "TMerc" is a Transverse Mercator. "TMercSO" is a Transverse Mercator South Orientated. "LCC_1SP" is a Lambert Conic Conformal 1SP. "LCC_2SP" is a Lambert Conic Conformal 2SP. "LCC_2SP_BE" is a Lambert Conic Conformal 2SP Belgium.	String

AngleSG	Angle from Rectified to Skew Grid	Degree
Azimuth	Azimuth of initial line	String
FE	Easting at false origin, False easting	Float-Point value in CRS units
EC	Easting at projection center	Float-Point value in CRS units
FN	Northing at false origin, False northing	Float-Point value in CRS units
FC	Northing at projection center	Float-Point value in CRS units
LonI	The longitude of the western limit of the first zone of a Transverse Mercator zoned grid system	Degree
Lat	Latitude of natural origin, Latitude of standard parallel. It depends on Projection method.	Degree
Lat1	Latitude of 1st standard parallel	Degree
Lat2	Latitude of 2nd standard parallel	Degree
LatF	Latitude of false origin	Degree
LatC	Latitude of projection center	Degree
Lon	Longitude of natural origin, Longitude of origin	Degree
LonF	Longitude of false origin	Degree
LonC	Longitude of projection center	Degree
SF	Scale factor at natural origin	Float-Point value, unity
SFIL	Scale factor on initial line	Float-Point value, unity
SFPSP	Scale factor on pseudo standard parallel	Float-Point value, unity
W	Zone width in longitude	Degree
zone	Zoned Grid System	Degree
units	Units of conversion result from geographic coordinates to projected. Example: "Meter", unit "Degree" means no conversion, Geographic Coordinate System	String

Example: common attributes for all map projections based on EPSG:31468.

```
<CRS epsg="31468" codeSpace="OGP" name="DHDN / 3-degree Gauss-Kruger zone 4" y="Easting" x="Northing" C
```

For each node **CRS** there should be at least one sub-node **Datum** that refers via **epsg** or **alias** attributes to sub-node **Datum** in the **Datums** section. The sub-node **Datum** MUST have the **id** attribute of a unique CRS name. At least one of the epsg code and the alias of Datum must be valid.

Attribute name	**Description**	**Units**
epsg	Unique EPSG database id. Example: "4326"	Integer
alias	Unique Datum name. Example: "WGS 84"	String
id	Unique CRS name: combination of Projected method and Datum. Example: "WORLD-MERCATOR". It related to CS-MAP, AutoCAD names.	String
pjcode	Indicate code for the coordinate reference system projection method types. Corresponded to AutoCAD projection codes. For instanse, 3 - Transverse Mercator, 44 - UTM, 45 - Transverse Mercator of Snyder formulation and etc.	Integer

Example: there are unique CRS definitions according to Datums inside **CRS** node:

```
<Datum epsg="6314" alias="DHDN/3" id="DHDN/3.Gauss3d-4" pjcode="3" /> <Datum epsg="6314" alias="DHDN/2"
```

2. Datums

This section is a main node where all Datums are stored. Datum is a combination of the Earth model (Ellipsoid or Spheroid) and the transformation method to model WGS84. A **Datum** node specifies common parameters and contains at leat one inner sub-nodes **Datum** exactly one sub-node **Ellipsoid**. Each inner sub-node **Datum** should define a unique name within the **id** attribute and may specify transformation parameters to WGS84 model via sub-node **Transformation** that refers via **epsg** or **alias** attributes to a sub-node **Transformation** in the **Transformations** section.

Attribute name	Description	Units
alias	Unique id. Example: "DHDN/3". It related to CS-MAP, AutoCAD names.	String
epsg	Unique EPSG database id. Example: "6314"	Integer
name	Human-readable name of Datum, Example: "Deutsches Haupt-dreiecksnetz"	String
codeSpace	Owner of CRS. It is option.	String

Example:

```
<Datums> <Datum epsg="6314" codeSpace="OGP" name="Deutsches Hauptdreiecksnetz "> <Datum id="DHDN/3"> <Tr
```

3. Ellipsoids

The Ellipsoids section is the main section where models of the Earth are defined. Each **Ellipsoid** node should define an identification by a unique name (**alias**) and a semi-major axis (**a**) and one of the following attributes at least: flattering (**f**), semi-minor axis (**b**) or eccentricity (**e**).

Attribute name	Description	Units
alias	Unique id. Example: "WGS84". It related to CS-MAP, AutoCAD names.	String
epsg	Unique EPSG database id. Example: "7030"	Integer
name	Human-readable name of Datum, Example: "WGS 84"	String
codeSpace	Owner of CRS. It is option.	String
a	Length of the semi-major axis of the ellipsoid, the radius of the equator	Float-Point value, strongly in Meter
b	Length of the semi-minor axis of the ellipsoid, the distance along the ellipsoid axis between equator and pole	Float-Point value, strongly in Meter
f	Flattening	Float-Point value, unity
e	Eccentricity	Float-Point value, unity

Example:

```
<Ellipsoid epsg="7008" alias="CLRK66" name="Clarke 1866, Benoit Ratio" a="6378206.4000000004" b="6356583
```

4. Transformations

This section is a main node where all transformation methods are defined. Supported Transformation methods are described in the **ProjectionCode** and **Methods** sections.

Attribute name	Description	Units
alias	Unique id. Example: "DHDN_to_WGS84". It related to CS-MAP, AutoCAD names.	String
epsg	Unique EPSG database id. Example: "1673"	Integer
codeSpace	Owner of Transformation. It is option.	String
source	Source Datum	String

target	Target Datum	String
use	Transformation method. Supported transformations using geocentric methods: Geocentric translations, Four/Six/Seven Parameter Transformation, Similarity Transformation, Position Vector transformation and Coordinate Frame rotation.	String
method	Methods of building of rotation matrix, if applicable, "PVT" is Position Vector Transformation, "CFR" is Coordinate Frame Rotation	String
tX	X-axis translation	Meter
tY	Y-axis translation	Meter
tZ	Z-axis translation	Meter
rX	X-axis rotation	Degree
rY	Y-axis rotation	Degree
rZ	Z-axis rotation	Degree
dS	Scale difference	Unity
xp	Coordinate 1 of evaluation point	Meter
yp	Coordinate 2 of evaluation point	Meter
zp	Coordinate 3 of evaluation point	Meter
dtX	Rate of change of X-axis translation	Unity
dtY	Rate of change of Y-axis translation	Unity
dtZ	Rate of change of Z-axis translation	Unity
drX	Rate of change of X-axis rotation	Unity
drY	Rate of change of Y-axis rotation	Unity
drZ	Rate of change of Z-axis rotation	Unity
ddS	Rate of change of scale difference	Unity
t0	The reference epoch for time-dependent parameters.	Float point value
fallback	Alias of transformation from target datum to WGS84 datum.	String

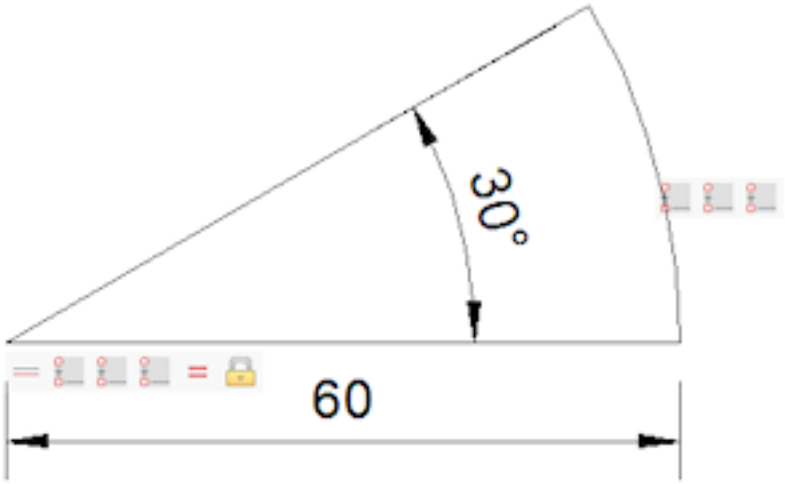
Example:

```
<Transformation epsg="1679" alias="Pulkovo42/2_to_WGS84" src="Pulkovo42/2" trd="WGS84" use="Param7" meth
```

5 . ProjectionCode and Methods

These sections describe the **ProjectionCode** and **Methods** that are mapped to AutoCAD definitions of projections and transformations types. They are used to store the definitions in an XML file of coordinate reference system definition inside the **AcDbGeoData** object that represents a geographic location.

Figure 1.490



1.21.6 2D Constraints Overview

Tutorial: 2D Dimensional Constraints Click here to watch Parametric constraints are used to maintain relationships and control dimensions of 2D geometry. There are two types of constraints:

- **Geometrical** constraints control relationships between entities.
- **Dimensional** constraints are used to control the dimensions of an entity, such as length, angle, radius or diameter.

In the example below:

- The width and opening angle are controlled by dimensional constraints.
- Coincident geometrical constraints ( ) are applied to the endpoints of the arc and the polyline and to the center point of the arc and the polyline vertex.
- The polyline segments have an equal ( ) geometrical constraint.
- One segment of the polyline has a horizontal ( ) geometrical constraint.
- The polyline vertex has a fix ( ) geometrical constraint.

(1.490) Parametric constraints allow to:

- Maintain geometric design intent.
- Make multiple versions of a design by applying different values to dimensional constrains.

(1.494 on page 576) (1.495 on page 577) Two versions of the same fully constrained drawing representing a roundabout

NOTE	It is recommended to first apply geometric constraints, then dimensional constraints.

When using constraints a drawing can be in one of three states:

- **Unconstrained**: no entities are constrained. The drawing can be modified using modification commands and procedures.
- **Underconstrained**: some entities are constrained. It might be impossible to apply some changes using modification commands and procedures.
- **Fully constrained**: all possible and relevant geometric and dimensional constraints are applied to the design geometry. The drawing can be modified only by changing the values of the dimensional constraints.

Figure 1.491

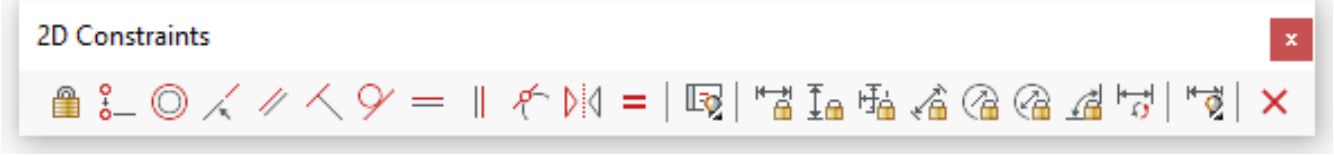


Figure 1.492

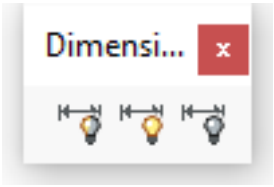

Figure 1.493

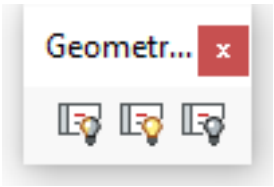
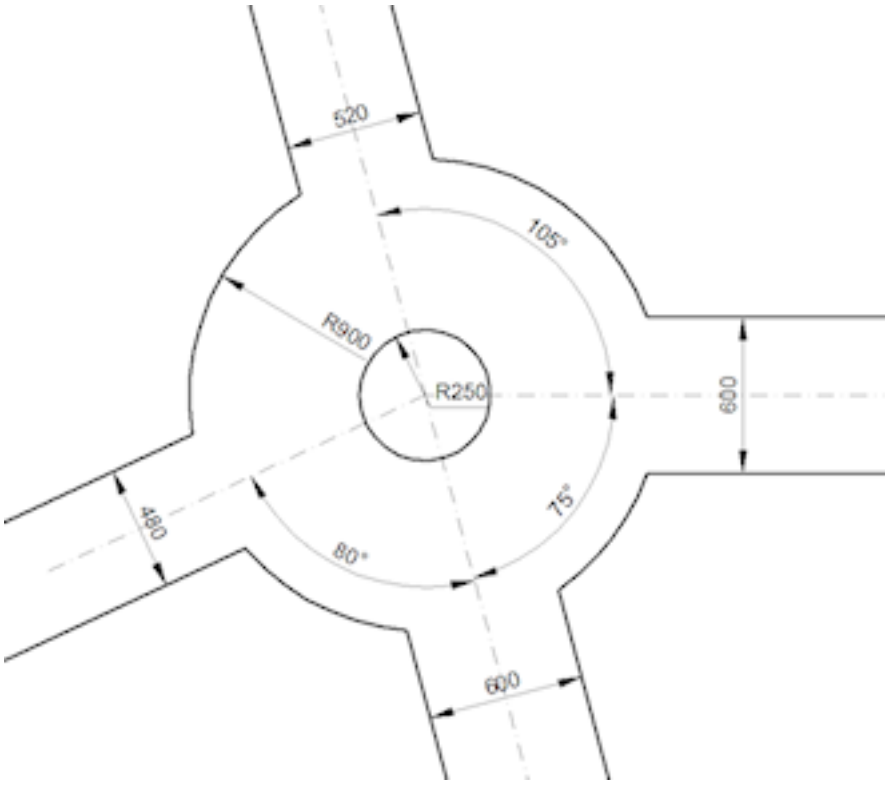


Commands and toolbars

2D parametric constraints tools sit on the **2D Constraints** toolbar: (1.491 on the facing page) Tools to control the display of constraintbars and geometrical constraints sit on two flyout toolbars: **Dimensional Constraint** : (1.492) and **Geometric Constraint:** (1.493) **Command Icon Description** Geometric Constraints DcDisplay (6.10.9) Allows to set dimensional constraints to be displayed or hidden. Shows all dimensional constraints. Hides all dimensional constraints. GeomConstraint (6.15.17) Applies geometric relationships between entities and/or valid constraint points on entities. GcFix (6.15.7) Constrains points and entities at a fixed position. GcCoincident (6.15.3) Applies a coincident geometrical constraint to two points or constraints a point to an entity. GcConcentric (6.15.4) ===NO VALID URL FOR IMAGE=== Constrains the center points of circles, arcs, ellipses or elliptical arcs to coincide. GcCollinear (6.15.2) Forces lines or polyline segments to be collinear. Parallelel (6.15.9) Forces two lines or linear polyline segments to be parallel to each other. GcPerpendicular (6.15.10) Constrains two lines or polyline segments to lie perpendicularly to each other. GcTangent (6.15.13) Constrains two entities to maintain a point of tangency to each other or their extensions. The following entities are accepted: lines, polyline segments, circles, arcs, ellipses or elliptical arcs. GcHorizontal (6.15.8) Constrains lines, linear polyline segments or pairs of points to lie parallel to the X-axis of the current coordinate system. GcVertical (6.15.16) Constrains lines, linear polyline segments or pairs of points to lie parallel to the Y-axis of the current coordinate system. GcSmooth (6.15.11) Forces a spline to maintain fluid geometric continuity with another spline, line, arc or polyline. GcSymmetric (6.15.12) Constrains two entities or points to lie symmetrically with respect to a selected line. GcEqual (6.15.6) Constrains arcs and circles to the same radius, or lines and polyline segments to the same length. Dimensional Constraints ConstraintBar (6.9.27) Controls the display of the constraint bar of entities. Constraint bars are always hidden when opening a drawing. Shows all constraintbars. Hides all constraintbars. Dimconstraint (6.10.30) Applies a dimensional constraint to an entity or between constraint points on entities. Converts associative dimensions to dynamic dimensions. DcHorizontal (6.10.10) Constrains the horizontal distance (X-distance) between two points with respect to the current coordinate system. DcVertical (6.10.15) Constrains the ver-

Figure 1.494



NOTE	The PARAMETERCOPYMODE (1.17.10) system variable controls copying of constraints and related parameters when entities are copied. 0: Do not copy 2D constraints. 1: Replace all expressions with constants. 2: Use existing parameters; if a parameter is missing, replace it with a constant. 3: Use existing parameters; create a new parameter if a parameter is missing. 4: Use existing parameters; create a new parameter if a parameter is missing, or has a different value.

Figure 1.495

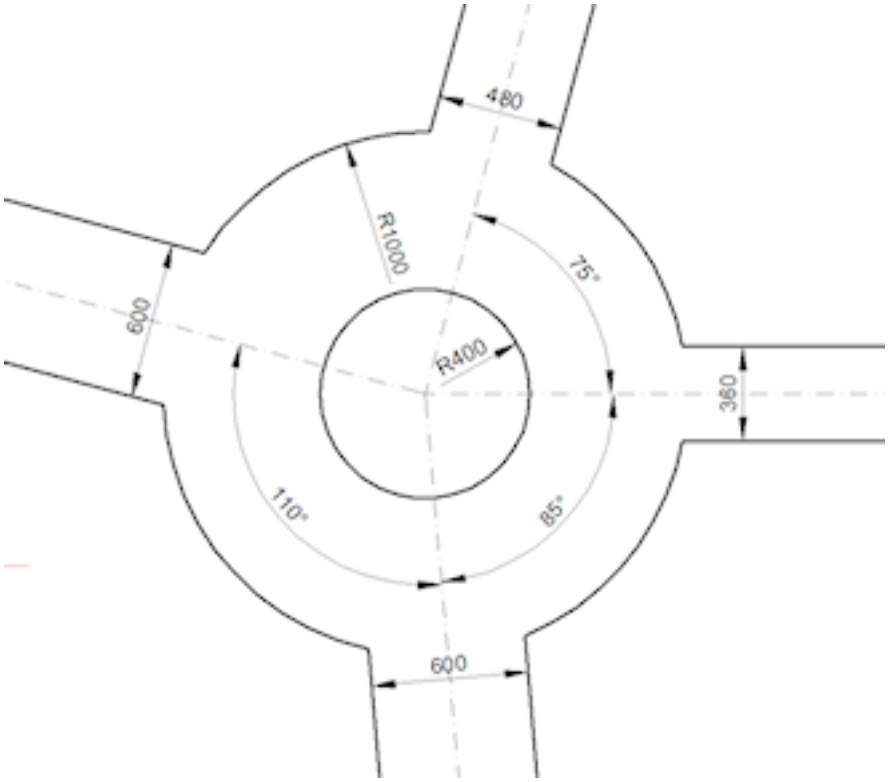


Figure 1.496

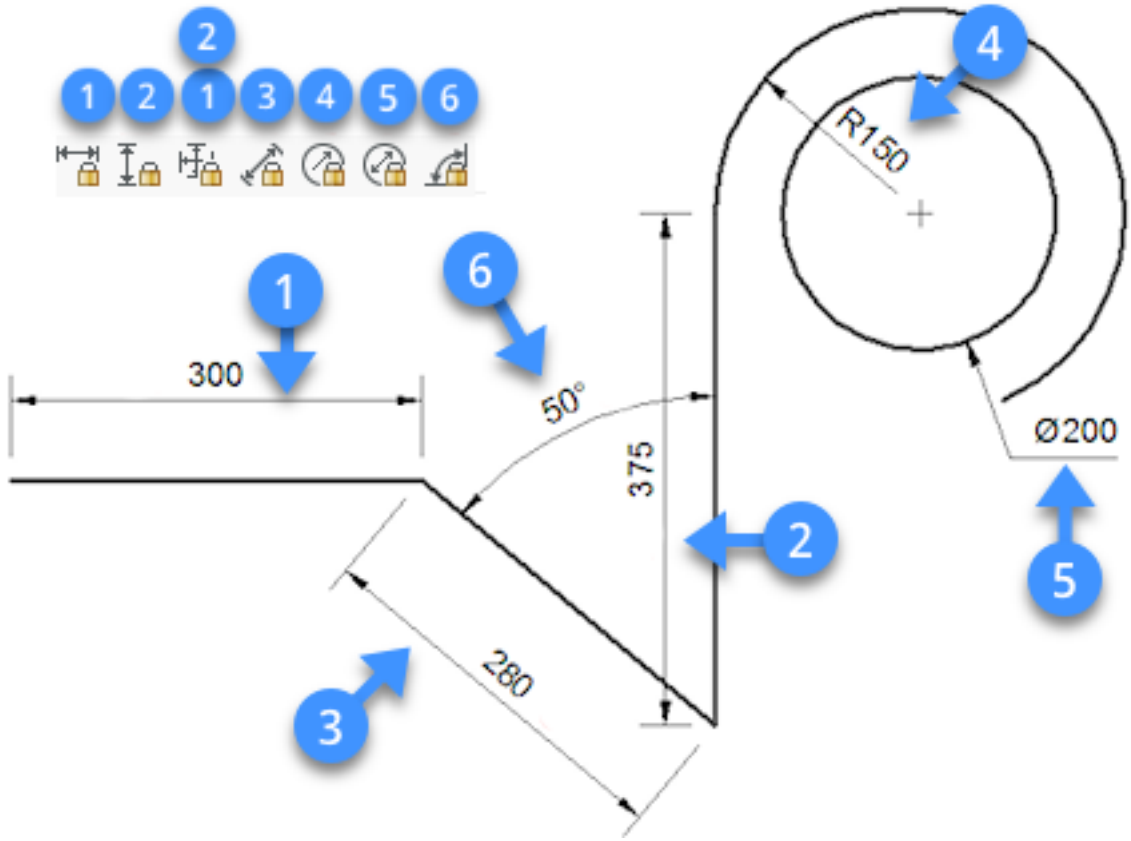


1.21.7 Using Dimensional Constraints

Commands: DIMCONSTRAINT (6.10.30), DCALIGNED (6.10.6), DCANGULAR (6.10.7), DCCONVERT (6.10.18), DCDIAMETER (6.10.8), DCDISPLAY (6.10.9), DCHORIZONTAL (6.10.10), DCLINEAR (6.10.12), DCRADIUS (6.10.11), DCVERTICAL (6.10.15), DELCONSTRAINT (6.10.26) **Overview:** The dimensions of the geometry can be controlled by dimensional constraints:

- Horizontal distance between points (1).
- Vertical distance between points (2).
- Distance between points or the length of lines and polyline segments (3).
- Radius of arcs, circles and arc polyline segments (4).
- Diameter of arcs, circles and arc polyline segments (5).
- Angle between entities or between points and entities (6).

(1.496) **Note:** Dimensional constraints are created using thencurrent dimension style.

To edit dimensional constraints

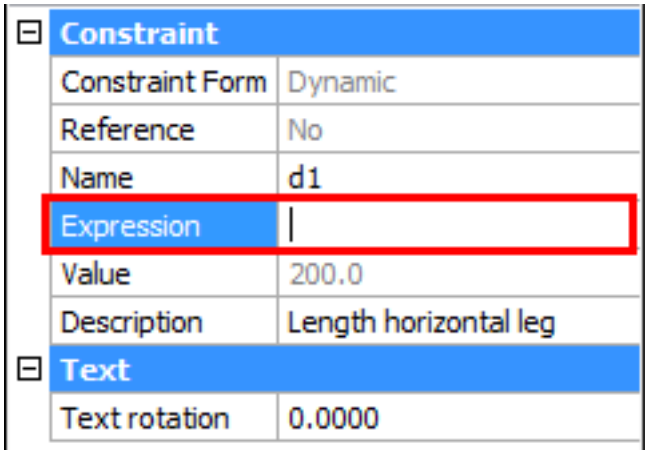
Dimensional constraints can be edited:

- using the DDEDIT (6.10.13) command
- in the Properties (6.24.54) bar
- in the Mechanical Browser (3.3.2)

To edit dimensional constraints in the Properties bar.

1. Select the dimensional constraint. The properties of the entity display in the Properties bar.
2. Type a new value or expression (1.21.7) in the **Expression** field, then press Enter. The readout of the **Value** field changes accordingly. (1.497 on the facing page)

Figure 1.497



3. (option) Edit the **Name** field.
4. (option) Edit the **Description** field.
5. (option) Edit the **Text rotation** field.
6. Press the Esc key to unselect.

Note: Select multiple dimensional constraints simultaneously to set their value equally.

To edit dimensional constraints in the Mechanical Browser:

1. If not already open, open the Mechanical Browser (3.3.2). (1.498 on the next page)
2. Select a parameter. The properties the selected parameter display in bottom part of the Mechanical Browser (3.3.2).
3. (option) Select the **Name** field, then type a new name.
4. (option) Select the **Expression** field, then type a new value or expression.
5. (option) Select the **Description** field, then type a new description.
6. (option) Set the **Exposed** field, which specifies whether the parameter is exposed when the drawing is inserted in another drawing using **BmInsert**. The options are:
   - Auto : the parameter is exposed only if it does not depend on other parameters.
   - ON = the parameter is always exposed.
   - OFF = the parameter is never exposed.
7. (option) Set the **Units** property: Undefined, 1-dimensional (linear), 2-dimensional (planar) or 3-dimensiona (volume)l. Select the field, then click the down-arrow button and choose an option.

To edit a single dimensional constraint:

1. Double click the dimensional constraint. You are prompted: _ddedit The Edit Text dialog box displays. (1.500 on page 581)
2. Type a new value in the **Text** field, then press Enter or click the **OK** button. The new value is applied and the geometry is rebuild accordingly.

Figure 1.498

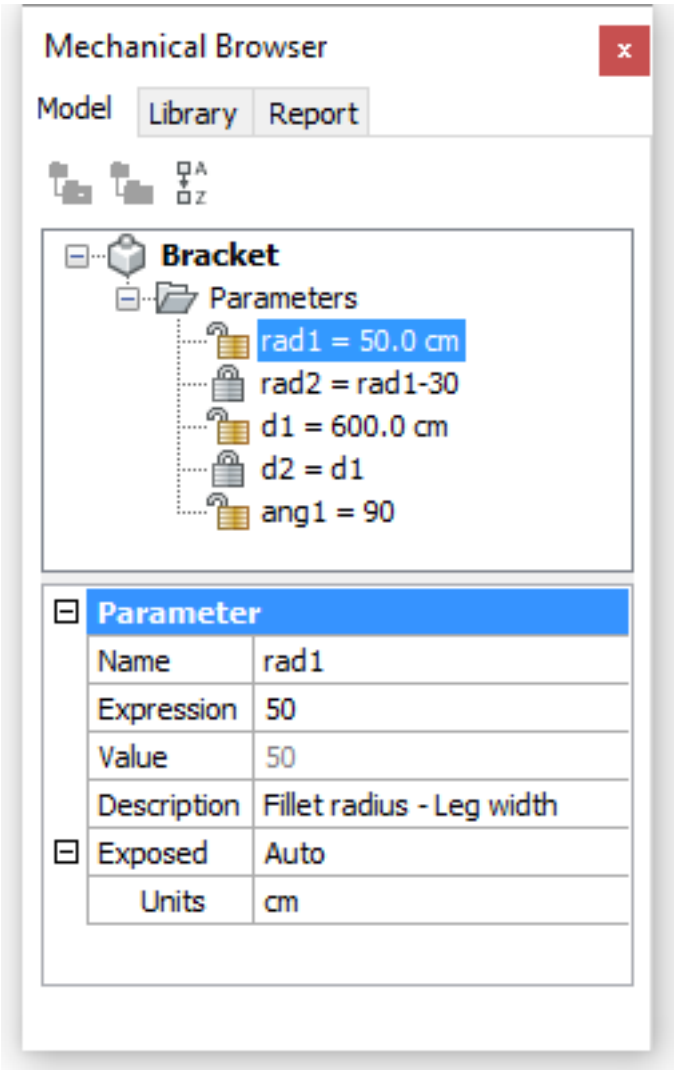


Figure 1.499

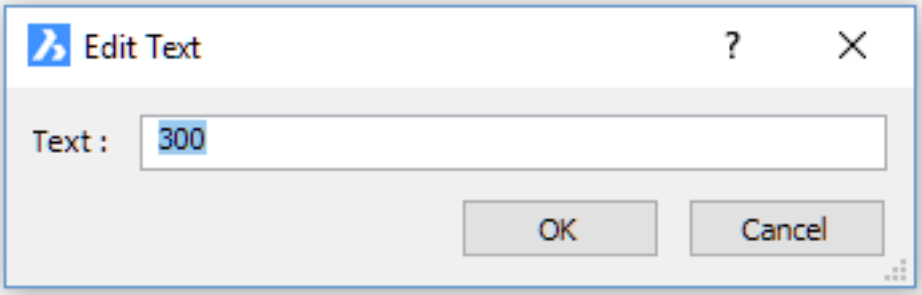
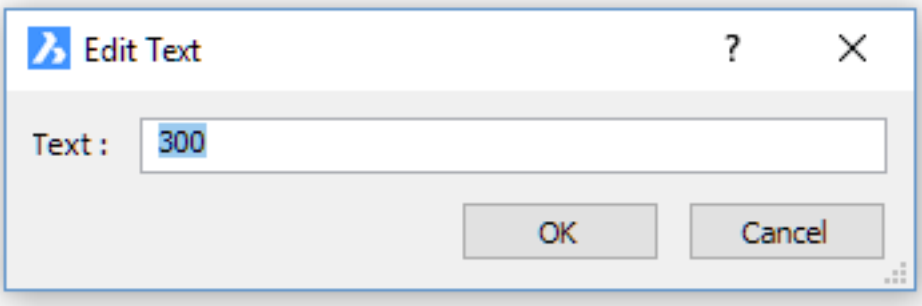


To edit multiple dimensional constraints:

1. Type **ddedit** or **ed** in the command bar, then press Enter. You are prompted: Select entity to modify:
2. Click the a dimensional constraint. The Edit Text dialog box displays. (1.500)
3. Type a new value in the **Text** field, then press Enter or click the **OK** button.
4. (option) Repeat steps 2 and 3 to edit more dimensional constraints.
5. Press Enter or right click to stop editing dimensional constraints. All edited dimensional constraints are updated simultaneously. The geometry is rebuild accordingly.

Figure 1.500



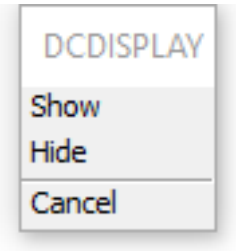
To set the visibility of dimensional constraints

Tools to control the display of dimensional constraints sit on the Dimensional Constraint toolbar. Dimensional constraints are hidden when a drawing is closed and reopened.

To set the display of dimensional constraints of a selection of entities

1. Do one of the following:
   - Click the **Show/Hide Dimensional Constraint** tool button ( ) on the 2D Constraints or Dimensional Constraint toolbar.
   - Choose **Show/Hide Dimensional Constraint** in the Parametric menu.
   - Type **dcdisplay** in the command bar.

   You are prompted: Select Entities.
2. Select the entities, then right click or press Enter. BricsCAD reports the number of selected entities. You are prompted: Enter an option [Show/Hide] <Show>: A prompt menu displays:



3. Do one of the following:
   - Press Enter to display the dimensional constraints of the selected entities.
   - Choose **Hide** or **Show** in the context menu.
   - Type **H** or **S** in the command bar, then press Enter.

To set the visibility of the dimensional constraints of all entities Do one of the following:

- Click the **Show All** tool button ( ) on the Dimensional Constraint toolbar to display the dimensional constraints of all entities.
- Click the **Hide All** tool button ( ) on the Dimensional Constraint toolbar to hide the dimensional constraints of all entities.

NOTES

The DYNCONSTRAINTMODE (1.17.10) system variable controls the visibility of hidden dimensional constraints when selecting entities:

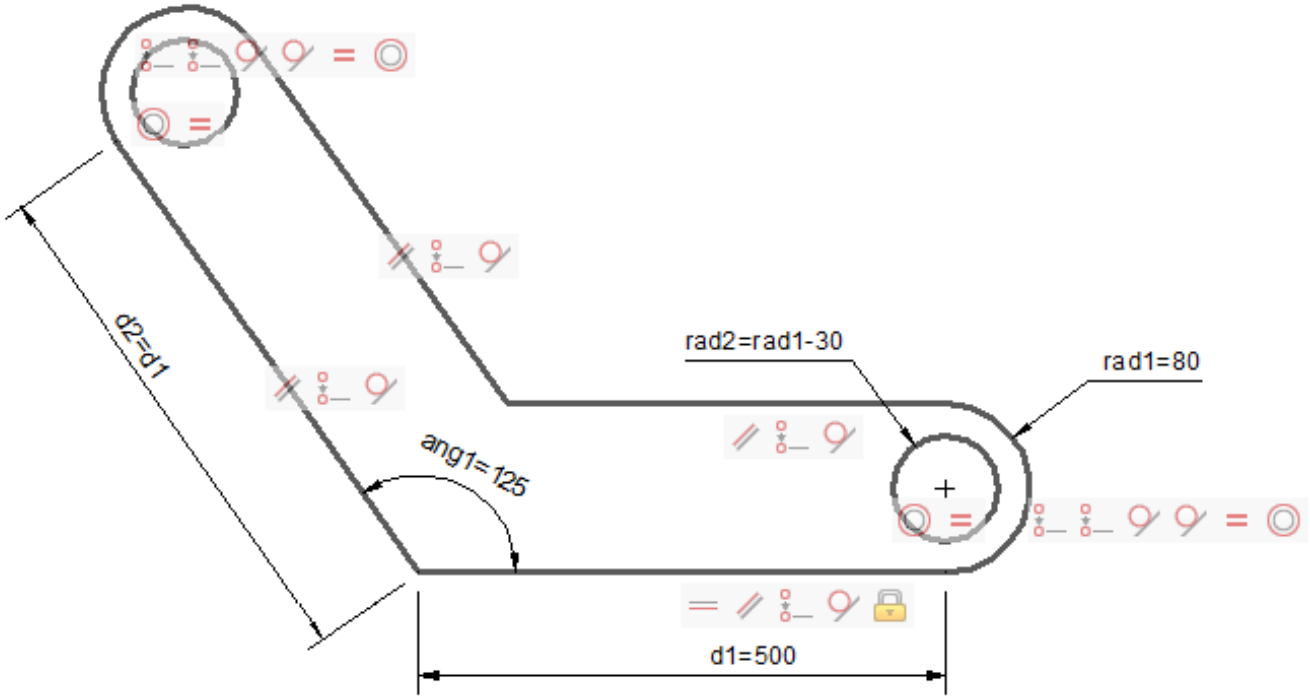
- ON: Display dimensional constraints when entities are selected.
- OFF: Dimensional constraints remain hidden when entities are selected.

The DYNCONSTRAINTMODE (1.17.10) system variable controls the visibility of hidden dimensional constraints when the constrained entity is selected. When hovering over an entity with a dimensional constraint, the blue constraint glyph ( ) displays if the SELECTIONPREVIEW (1.32.4) system variable is set to 1 or 3

Using expressions to define dimensional constraints

Each dimensional constraint is named automatically upon its creation. The naming is as follows: distance: d1, d2, d3, ... radius: rad1, rad2, rad3, ... diameter: dia1, dia2, dia3, .. angular: ang1, ang2, ang3, .. The name of a constraint can be used as a parameter in a mathematical expression to define another dimensional constraint. The dimensions of the bracket below are controlled through the **rad1** radius, **d1** distance and **ang1** angular dimensional constraints. The radius of the hole (**rad2**) and the length of the second leg (**d2**) are defined by expressions. Geometrical constraints force the width of the second leg and the hole in it to be equal to the first leg. (1.501)

Figure 1.501



Creating a new parameter

1. Select either the part name or **Parameters** in the Mechanical Browser (3.3.2), then right click. A context menu displays.
2. Select **Add new parameter** in the context menu. A new parameter is created.
3. Edit the properties of the new parameter. (1.502)

NOTES

- The constants **Pi=3.14...** and **e=2.72...** can be used in expressions. The constants names are not allowed to be used as parameter name and name of 3D constraint.
- The CLEANUNUSEDVARIABLES (6.9.15) command purges parameters that are not used in constraint expressions or linked to dimensions.

Tutorial: 2D Dimensional Constraints Click here (1.16.5) to watch

Figure 1.502

Parameter	
Name	v6
Expression	1
Value	1
Description	
Exposed	Auto
Units	

Using operators in expressions The following operators can be used in expressions:

Operator	Description
+	Addition
-	Subtraction or Negative
	Multiplication
/	Division
^	Exponentiation
%	Modulo or Remainder operator The expression "5 % 2" would evaluate to 1, because 5 divided by 2 leaves a quotient of 2 and a remainder of 1 .

Expressions are evaluated according to the standard mathematical rules of precedence:

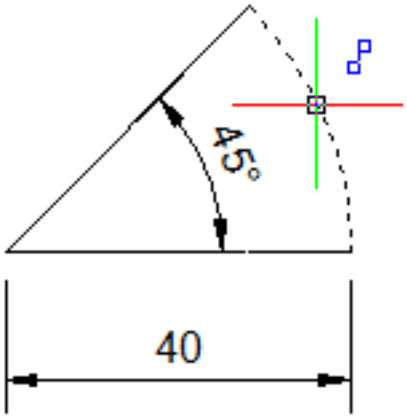
1. Expressions within brackets; innermost sets first.
2. Standard operations order:
   (a) exponent
   (b) multiplication and division
   (c) addition and subtraction
3. Operators of equal precedence from left to right.

Using functions in expressions The following functions can be used in expressions:

Function	Syntax
Cosine	cos(expression)
Sine	sin(expression)
Tangent	tan(expression)
Arc cosine	acos(expression)
Arc sine	asin(expression)
Arc tangent	atan(expression)
Hyperbolic cosine	cosh(expression)
Hyperbolic sine	sinh(expression)
Hyperbolic tangent	tanh(expression)
Arc hyperbolic cosine	acosh(expression)
Arc hyperbolic sine	asinh(expression)
Arc hyperbolic tangent	atanh(expression)
Square root	sqrt(expression)
Signum function (-1,0,1)	sign(expression)
Round to nearest integer	round(expression)
Truncate decimal	trunc(expression)
Round down	floor(expression)
Round up	ceil(expression)
Absolute value	abs(expression)
Largest element in array	max(expression1;expression2) 1
Smallest element in array	min(expression1;expression2) 1
Degrees to radians	d2r(expression)
Radians to degrees	r2d(expression)
Logarithm, base e	ln(expression)
Logarithm, base	10 log(expression)
Exponent, base e	exp(expression)
Exponent, base 10	exp10(expression)
Power function	pow(expression1;expression2) 1
Random decimal, 0-1	Random

(1) Use the list separator character as defined on your system: , (comma) or ; (semicolon).

Figure 1.503



1.21.8 Using Geometric Constraints

Commands : GEOMCONSTRAINT (6.15.17), GCCOINCIDENT (6.15.3), GCCOLLINEAR (6.15.2), GCCONCENTRIC (6.15.4), GCCENTER (6.15.5), GCEQUAL (6.15.6), GCFIX (6.15.7), GCHORIZONTAL (6.15.8), GCPARALLEL (6.15.9), GCPERPENDICULAR (6.15.10), GCSMOOTH (6.15.11), GCSYMMETRIC (6.15.12), GCTANGENT (6.15.13), GCVERTICAL (6.15.16) A geometric constraint is a non-numerical relationship between the parts of a geometric figure. Geometric constraints:

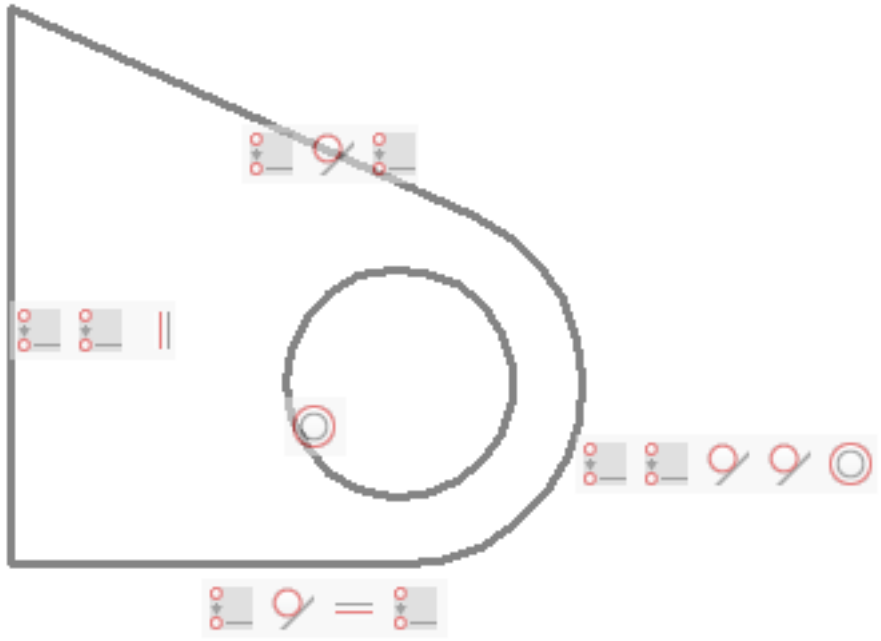
- Associate geometric entities together two by two (coincident, concentric, collinear, parallel, perpendicular, tangent, smooth, symmetric, equal).
- Specify a fixed angle (horizontal, vertical).
- Specify a fixed location (fix).

When a geometric constrained is applied to an entity:

- The position of the entity is adjusted according to the applied constraint.
- An icon displays next to the entity, to indicate the applied constraint. If multiple geometric constraints are applied, the icons are joined to a constraint bar.
- If the SELECTIONPREVIEW (1.32.4) system variable is set to 1 or 3, a blue constraint glyph ( ) displays next to the cursor when you move the cursor over entities that have constraints applied to them.

(1.503) In the image below the endpoints of the three lines and the arc are joined by coincident constraints. The midpoint of the circle and the arc are made concentric. Two lines are forced to be tangent to the arc. One line has a vertical constraint (= parallel to the Y-axis of the current coordinate system), one line has a horizontal constraint (= parallel to the X-axis of the current coordinate system) (1.504 on the next page)

Figure 1.504



To set the display of constraint bars

Tools to control the display of constraintbars sit on the Geometric Constraint toolbar. Constraint bars are hidden when a drawing is closed and reopened.

To set the display of constraint bars of a selection of entities

1. Do one of the following:

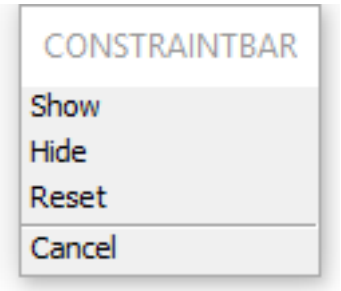
   - Click the **Show/Hide Geometric Constraint** tool button ( ) on the 2D Constraints or Geometric Constraint toolbar.
   - Choose **Show/Hide Geometric Constraint** in the Parametric menu.
   - Type **constraintbar** in the command bar.

   You are prompted: Select Entities.

2. Select the entities, then right click or press Enter. BricsCAD reports the number of selected entities. You are prompted: Select option for constraints [Show/Hide/Reset] <Show>: A prompt menu displays: (1.506 on the following page)

3. Do one of the following:
   - Press Enter to display the constraint bar of the selected entities.
   - Choose **Hide** or **Show** in the context menu.
   - Type **H** or **S** in the command bar, then press Enter.

Figure 1.505



To set the display of constraint bars of all entities Do one of the following:

- Click the **Show All** tool button ( ) on the Geometric Constraint toolbar to display all constraint bars.
- Click the **Hide All** tool button ( ) on the toolbar Geometric Constraint to hide all constraint bars.

NOTE

The value of the CONSTRAINTBARDISPLAY (1.17.10) system variable controls the visibility of geometric constraints:

- 1: Display constraint bars when geometrical constraints are added.
- 2: Display hidden dimensional constraints when the constrained entities are selected.

To control the position of a constraint bar

By default constraint glyph bars are created close to the midpoint of the entity and are kept at that relative position when the entity position changes. You can drag the constraint bar to a different location. This new relative position is then maintained until the **Reset** option of the CONSTRAINTBAR (6.9.27) command restores the default position of the constraint bar.

To relocate a constraint bar:

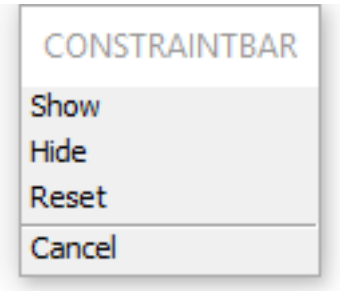
1. Place the cursor on the constraint bar.
2. Press and hold the left mouse button to move the constraint bar.
3. Release the left mouse button at the desired location.

To restore the default position of the constraint bars:

1. Do one of the following:
   - Click the **Show/Hide Geometric Constraint** tool button ( ) on the 2D Constraints or Geometric Constraint toolbar.
   - Choose **Show/Hide Geometric Constraint** in the Parametric menu.
   - Type **constraintbar** in the command bar.

   You are prompted: Select Entities.
2. Select the entities, then right click or press Enter. BricsCAD reports the number of selected entities. You are prompted: Select option for constraints [Show/Hide/Reset] <Show>: A prompt menu displays: (1.506)
3. Do one of the following:
   - Choose **Reset** in the context menu.
   - Type **R** in the command bar, then press Enter.

Figure 1.506



Working with the constraint bar

Using the constraint bar you can:

- Control a constraint. Move the cursor over a constraint icon. A tooltip displays, indicating the constraint type (1) The associated entity highlights (2) The corresponding icon on the constraint bar of the associated entity highlights (3) (1.507)
- Delete a constraint. Move the cursor over the constraint icon, then right click. Click **Delete** . The constraint is deleted and the icon is removed from this constraint bar and from the constraint bar of the corresponding entity. (1.508 on the next page)
- Hide the constraint bar of an entity. Move the cursor of the constraint bar, then click the **Close** button. (1.509 on the following page)

Figure 1.507

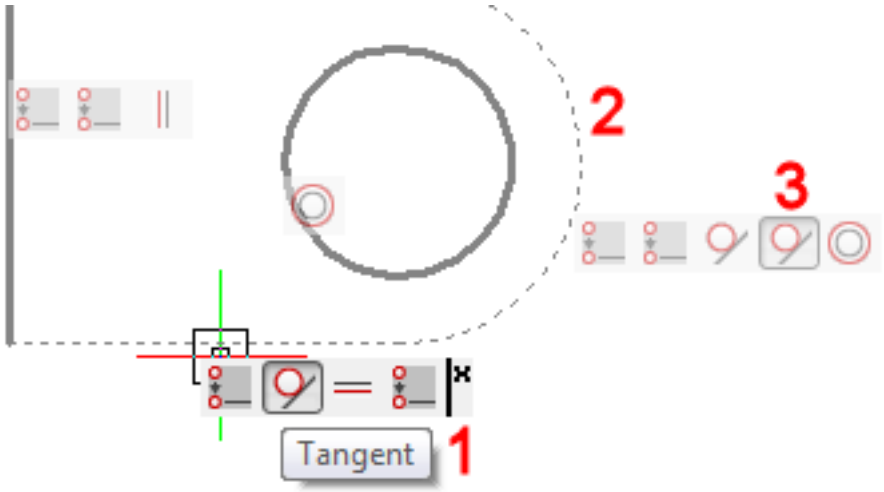


Figure 1.508

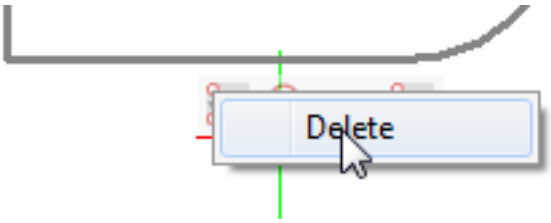

Figure 1.509

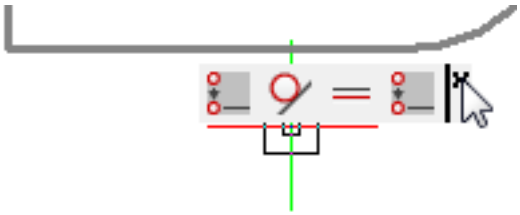


Deleting constraints

To delete a single constraint: right click the constraint icon, then click the **Delete** button. To delete all constraints from a selection set:

1. Click the **Delete 2D Constraints** icon ( ) on the 2D Constraints toolbar. You are prompted: Select entities to delete all constraints:
2. Select (1.32.7) the entities you want to delete the constraints from.
3. Right click to stop selecting entities and delete all constraints from the selection set.

Using fix constraints

A fix geometric constraint ( ) forces a point or an entity to a fixed location.

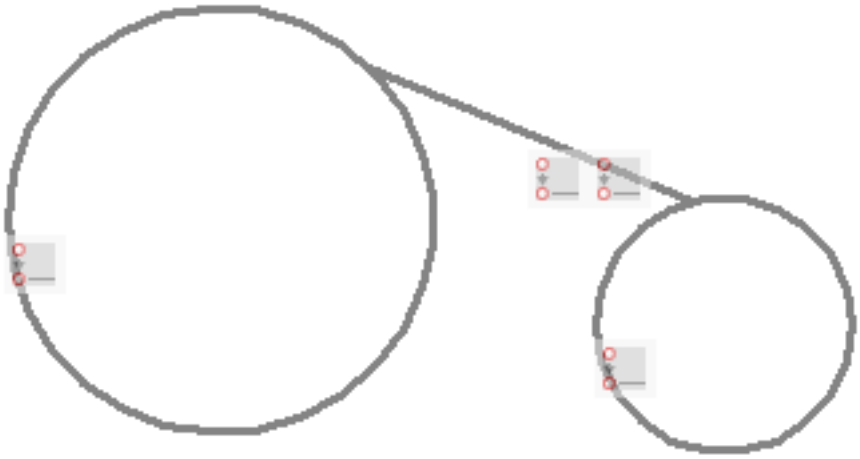
- If a fix geometric constraint is applied to a line or a polyline segment, the angle of the line or polyline segment is fixed. The endpoints can still be moved.
- If you fix an arc or a circle, the center point is fixed too.

Note: It is recommended to apply a fix constraint to important geometric features in your design. This prevents the geometry from moving unexpectedly when you edit the design.

Using coincident constraints

A coincident geometric constraint can be applied to two points or to a point and an entity. The endpoints of lines, polylines, splines, rays and arcs (circular and elliptical) and the center point of circles, ellipses and arcs (circular and elliptical) are accepted. These points can be made coincident (= to lie on the entity or on the extension of the entity) with a line, a polyline segment, a circle or an arc (circular and elliptical). (1.510 on the next page) Figure: Coincident constraints between the endpoint of a line and two circles. If the endpoints or center points of entities already coincide, the **Autoconstraint** option of the **GcCoincident** command automatically applies coincident constraints to such points.

Figure 1.510



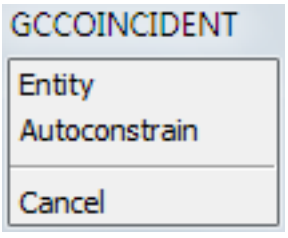
To apply a coincident constraint between a point and an entity:

1. Click the **Coincident** tool button (⊙—) on the 2D Constraints toolbar. You are prompted: Select first point or [Entity/Autoconstrain] <Entity>: A prompt menu displays: (1.511)
2. Do one of the following:
   - Press Enter.
   - Choose **Entity** in the prompt menu.

   You are prompted: Select an entity:
3. Select the entity. The entity highlights. You are prompted: Select point or [Multiple]:
4. Snap to the endpoint of an entity or the center point of a circle or an arc. The selected point is forced to lie on the selected entity (or its extension).

Note: If you choose **Multiple** in step 3, you can select multiple points.

Figure 1.511



Usage of a coincident constraint between a point and an entity (1.512 on the next page)

By applying coincident constraints between the pentagon vertices and the circle, and equal constraints between one side and the four other sides, the circle radius defines the size of the pentagon. (1.513 on the facing page) Coincident constraints between the endpoints of the tangent lines and the circles prevent the tangent lines to extend beyond the tangent points. (1.514 on page 594) Coincident constraints are used to:

- force the endpoints of the red line to lie on the bold lines;
- force the midpoint of the red line to lie on the dash-dot line.

The bold lines and the dash-dot line have a perpendicular constraint with the red line. As a result the dash dot line will always lie in the middle of the two bold lines.

Figure 1.512

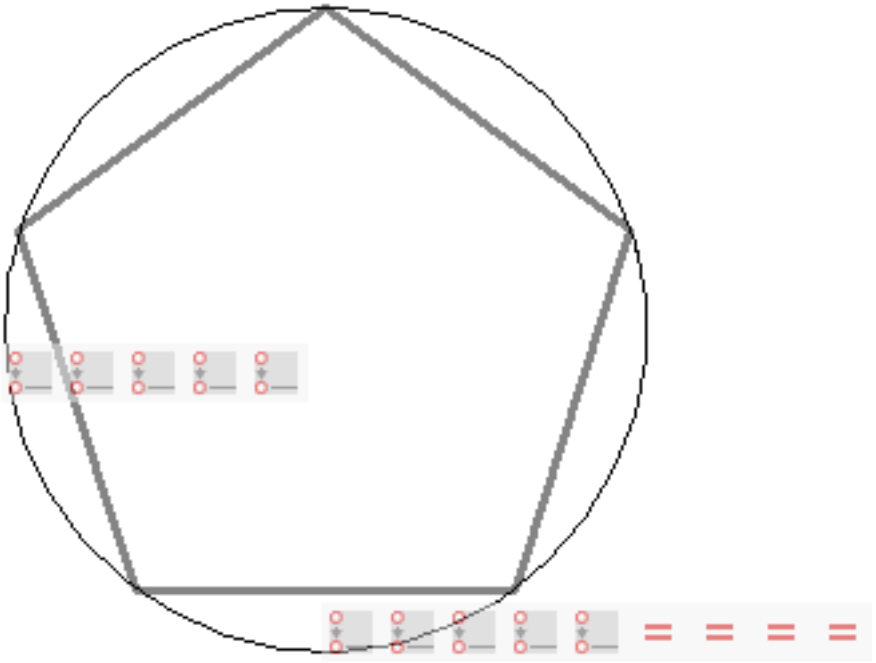


Figure 1.513

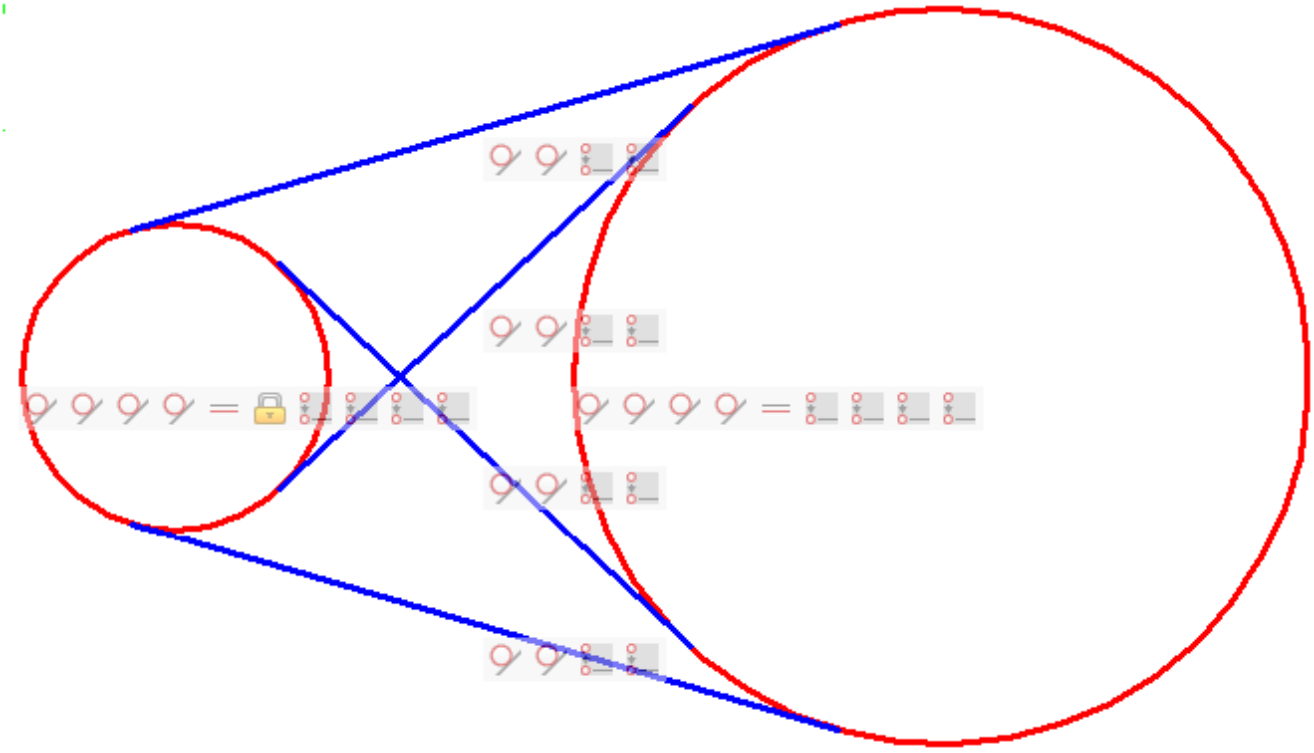

Figure 1.514

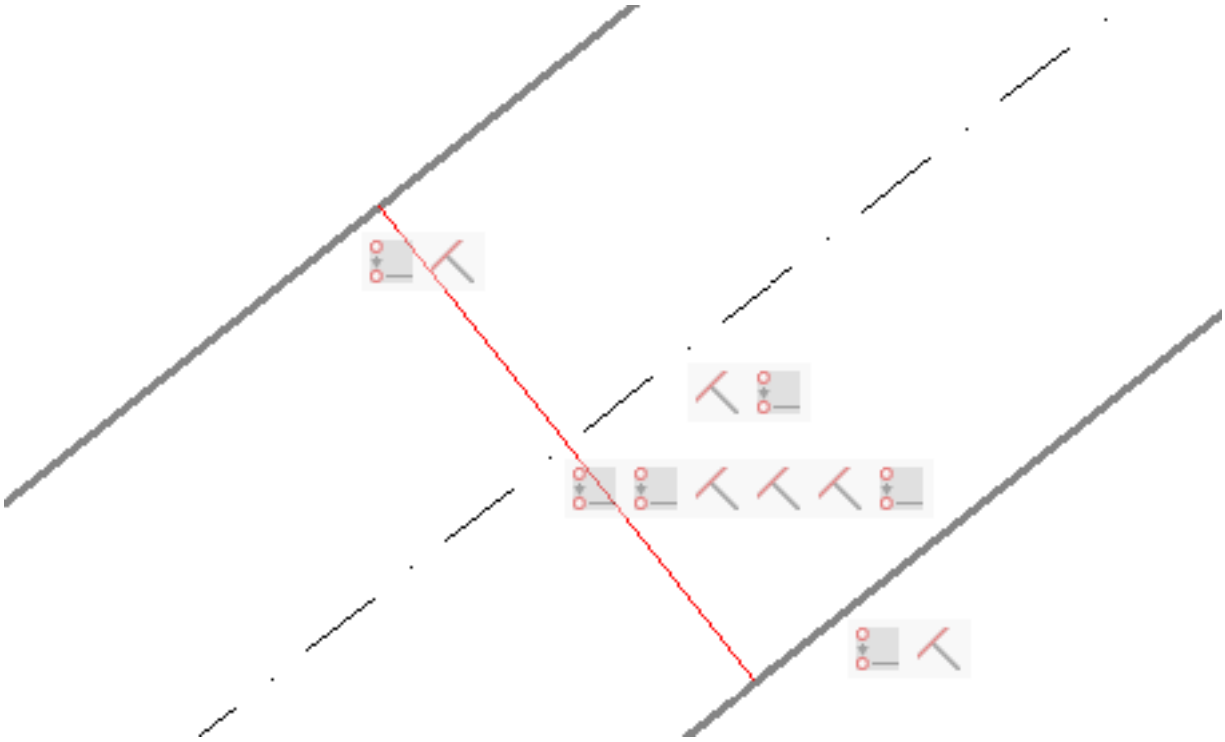

Using horizontal and vertical constraints

Horizontal and vertical geometric constraints force two points, a line or a polyline segment to be parallel to the X-axis (horizontal) or the Y-axis (vertical) of the current coordinate system. Therefore these constraints can be used to keep lines at a fixed angle, rather than only horizontal or vertical.

To constrain a line to a fixed angle

1. Align the X-axis of the coordinate system to the desired angle.
   - Type **UCS** in the command bar, then press Enter.
   - Choose **Z** in the prompt menu or type **Z** , then press Enter.
   - Type the angle, then press Enter.

2. Click the **Horizontal** tool button ( ) on the 2D Constraints toolbar. You are prompted: Select an entity or [2Points] <2Points>:

3. Click the line or polyline segment. The selected entity is constrained to be parallel to the X-axis of the current UCS.

4. (option) Restore the WCS: Type **UCS** in the command bar, then press Enter twice.

Note: Use the **Vertical** tool in the above procedure to constrain entities to be parallel to the Y-axis of the current UCS.

1.21.9 Dynamic Dimensions

Dynamic dimensions provide an interface at the cursor position to specify the length and angle of the linear entity being created or grip-edited. As such dynamic dimensions help you to focus on the drawing area. The behavior and appearance of dynamic dimensions is controlled through a series of system variables and user preferences.

Defining the Dynamic Dimensions Settings

1. Right click the **DYNMODE** field in the Status Bar (1.15.2), then choose **Settings** in the context menu. The **Dynamic input** settings in the Settings (1.17.10) dialog display: (1.515 on the following page)
2. Define the **DYNMODE** system variable, to switch the display of dynamic dimensions and/or dynamic input on/off. Please notice that dynamic input at the pointer is not implemented yet.
3. Define the **DYNDIGRIP** system variable, to select the dynamic dimension types to be displayed. Distance fields have a blue background; angle fields have a green background.
   - Resulting length: total length of the line or polyline segment (1.516 on the next page)
   - Extended length: incremental length of the line (1.517 on page 597)
   - Absolute angle: angle relative to the X-axis of the current UCS (1.518 on page 597)
   - Relative angle: angle relative to the original angle of the linear entity (1.519 on page 598)
   - Arc radius: radius of arcs and circles (1.520 on page 598)
4. Define the **DYNDIVIS** system variable to choose the number of dynamic dimensions that display simultaneously.
   - Only the first dynamic dimension (**DYNDIVIS** =0): hit the TAB key to display and edit the next dynamic dimension, as defined by the **DYNDIGRIP** system variable.
   - Only the first two dynamic dimension (**DYNDIVIS** =1): hit the TAB key to edit the next dynamic dimension, as defined by the **DYNDIGRIP** system variable and display the next plus one.
   - All dynamic dimensions as defined by **DYNDIGRIP** (**DYNDIVIS** =2): hit the TAB key to edit the next dynamic dimension
5. Set the dynamic dimensions user preferences to define the appearance (color, linetype and position) of dynamic dimensions.

NOTE	If bitcode 16 (= format dynamic dimensions) of the PROPUNITS (1.21.3) system variable is set, dynamic dimensions are formatted using a dedicated unit. (1.523 on page 601) Automatic unit conversion during length input can be used when bitcode 1 of PROPUNITS (**??**) (Format length properties) is set. E.g. when INSUNITS (**??**) is set to "mm", entering "2m" in a length property field will result in entering [2000.0000 mm]. Entering "1ft" will give [304.8000 mm]. If no unit is specified in the entry field, the unit as specified by INSUNITS (**??**) is used.

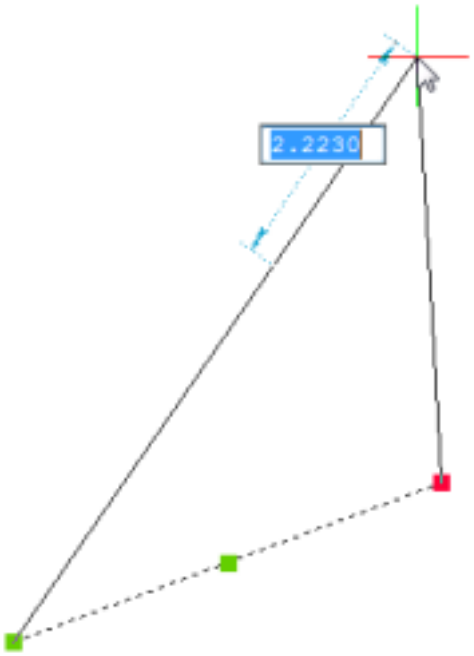

Figure 1.518

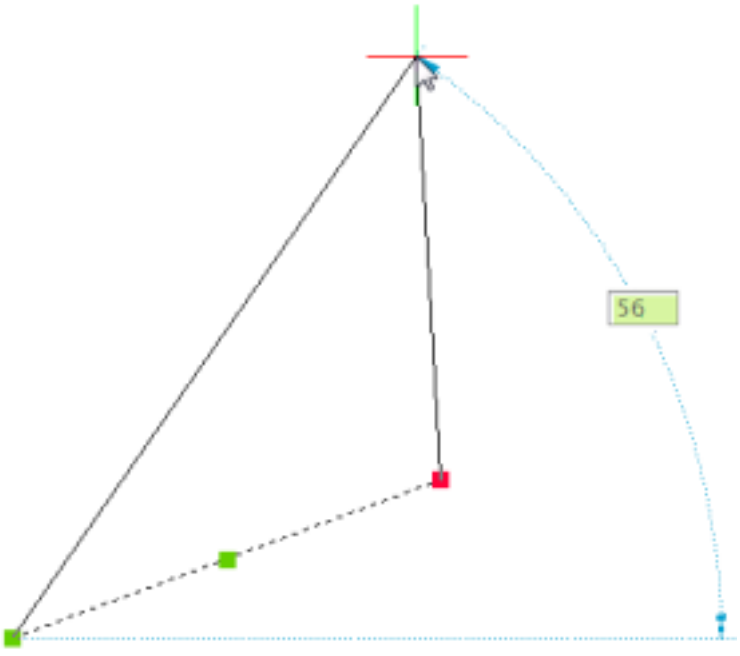

Figure 1.519

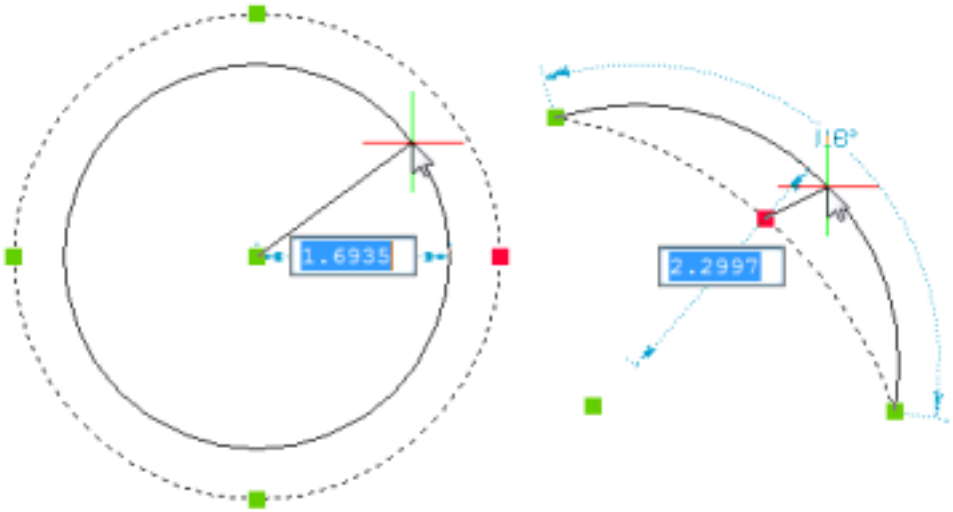
Figure 1.520



Using dynamic dimensions when creating entities

1. Launch the command to create a 2D entity (e.g. Line and **DYNDIVIS** = 1 or 2).
2. Specify the first point, then move the cursor to display the dynamic dimensions. The **Length** dynamic dimension highlights.
2. Do one of the following:
   - Type the desired length of the line, then hit the TAB key to jump to the **Angle** dynamic dimension. The **Length** dynamic dimension is locked and displays in red and the **Angle** dynamic dimension is selected.
   - Type the desired length of the line, then click to create the line at the angle defined by the cursor position.
   - Hit he TAB key to jump to the **Angle** dynamic dimension.
4. Do one of the following:
   - Type the desired angle, then hit the Enter key to create the line.
   - Type the desired angle, then hit the TAB key to return to the **Length** dynamic dimension.
   - Hit the Enter key to create the line at the angle defined by the cursor position.
   - Hit the TAB key to return to the **Length** dynamic dimension.

NOTES

- If **DYNDIVIS** = 0, only one dynamic dimension displays. Hit the TAB key to display the next field.
- If you type a value in the **Length** field, and add a comma (,) the content of the **Length** field is copied to the command line and the @-character is placed in front automatically, which allows you to specify the next point using relative coordinates (1.21.11) with respect to the previous point.

Using dynamic dimensions to grip-edit entities

1. Select the entity or entities. All grips on the selected entities display.
2. Click the grip you want to edit, then move the cursor. Depending on the value of the DYNDIVIS (1.17.10) system variable one, two or all dynamic dimensions display simultaneously . The first dynamic dimension highlights.
3. Do one of the following:
   - Type the desired value for the currently highlighted dynamic dimension, then hit the TAB key to jump to the next dynamic dimension. The dynamic dimension is locked and displays in red.
   - Type the desired value for the currently highlighted dynamic dimension, then press Enter to stop.
   - Hit the TAB key to jump to the next dynamic dimension.
4. Repeat step 3 or press Enter to stop.

Tutorial: Dynamic Grips and Tips Click here (1.14.4) to watch

Using dynamic dimensions to measure entities

2. Select the entity or entities. All grips on the selected entities display.
3. Hover the cursor over a grip. The grip highlights and all dimensions related to the selected grip display. (1.521 on the next page) (1.522 on the following page) Dynamic dimensions used to measure a rectangle (left) and a line (right).

   (c) (option) Click to start editing the selected grip.

   Note: Dynamic dimensions when hovering over a non-selected grip display in 2DWireframe visual style only.

Figure 1.521

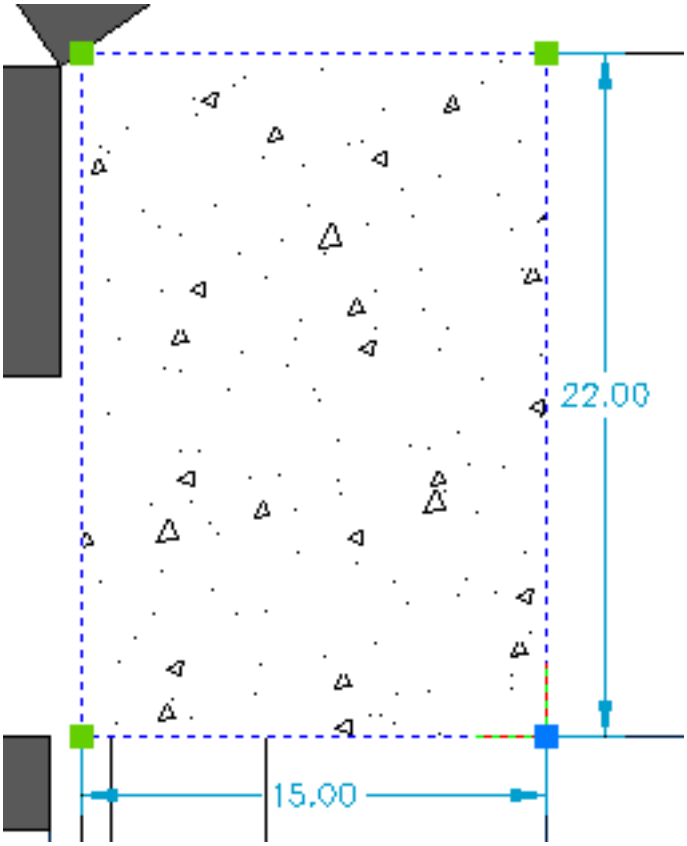


Figure 1.522

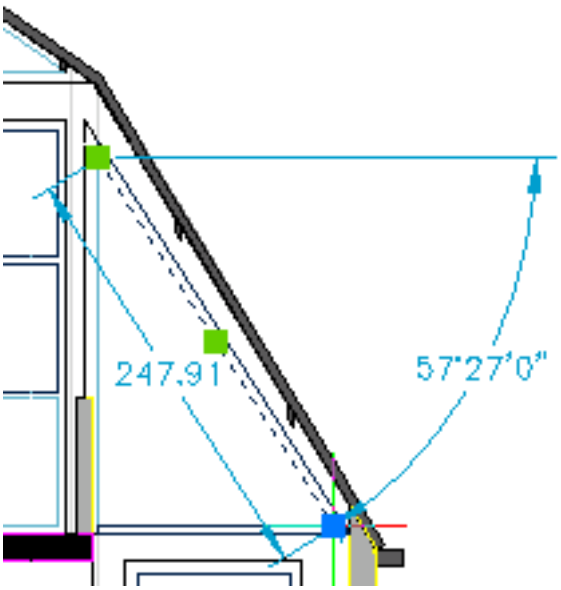

Using dynamic dimensions with tracking points

If the **Tracking dynamic dimensions** option of the DYNMODE (1.17.10) system variable is set, dynamic dimensions display when entity snap tracking points (1.21.17) or temporary tracking points (1.21.15) are acquired.

Figure 1.523

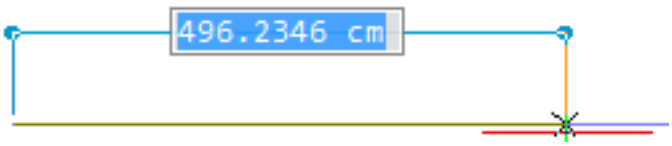

Figure 1.524

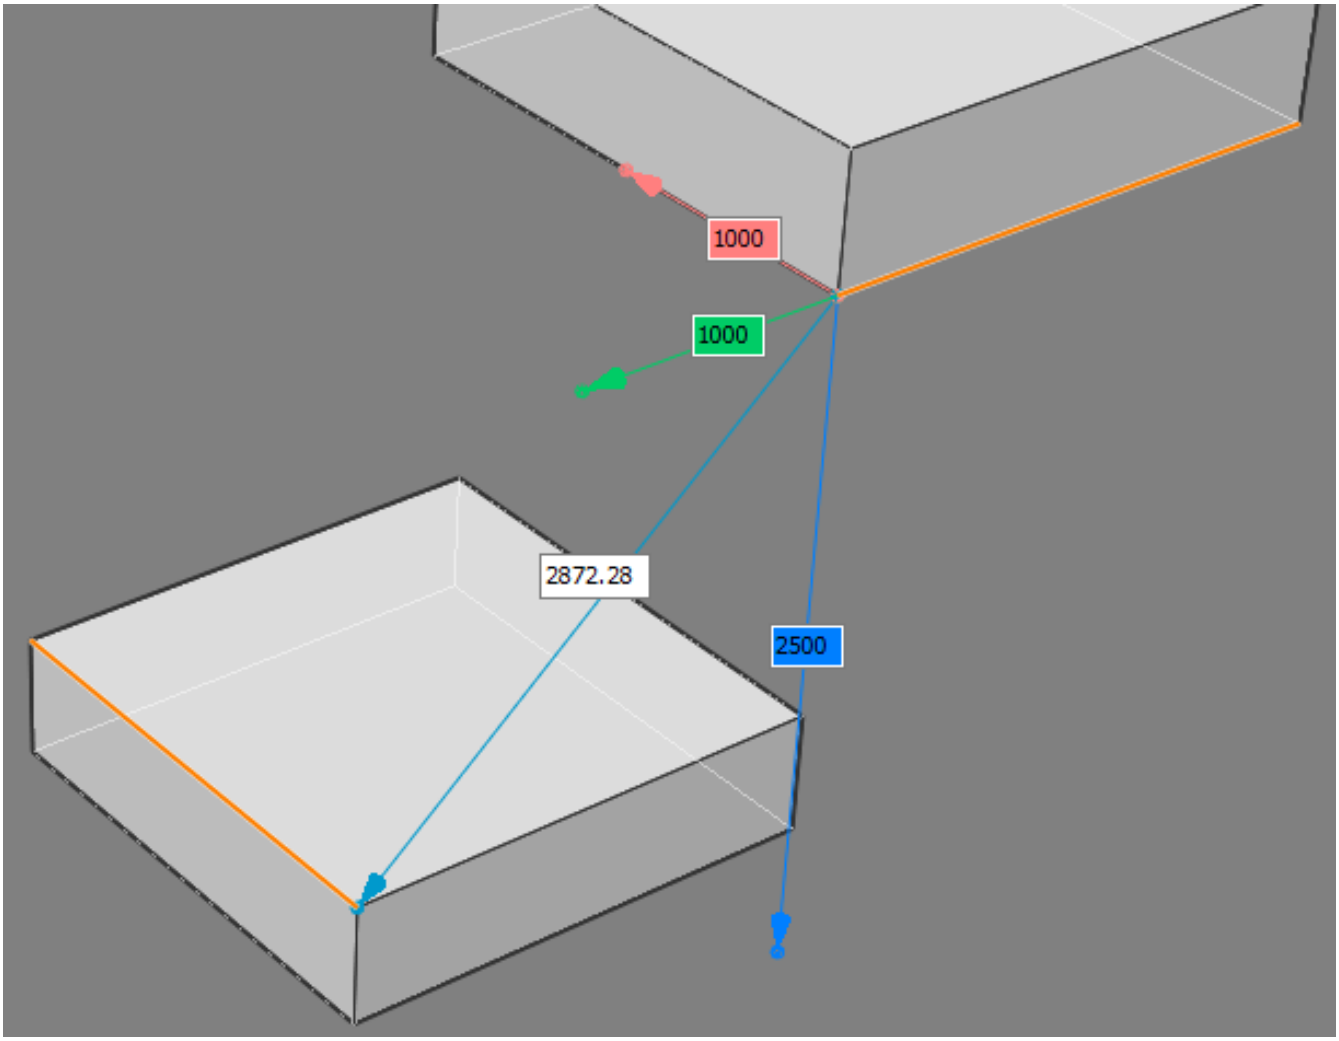

1.21.10 Nearest distance

The Nearest Distance feature allows to dynamically view and modify the distance between two selected entities or subentities. In addition the aligned nearest distances along the X-, Y- and Z-axes of the WCS display. Double clicking a Nearest Distance field:

- toggles the display of the X-, Y- and Z-axis aligned distance fields.
- zooms out to fully display the selected entities if necessary.

(1.524) The NEARESTDISTANCE (1.17.10) system variable controls the display of the Nearest Distance feature. (1.525)

Figure 1.525

Nearest Distance	0x0001 (1)
1	☑ Show nearest distance dimension
2	☐ Show OX aligned nearest distance dimension
4	☐ Show OY aligned nearest distance dimension
8	☐ Show OZ aligned nearest distance dimension

Using Nearest Distance

Do the following:

1. Select the first entity or subentity*.
2. Select the second entity or subentity*. The nearest distance displays. The arrowhead points to the second entity.
3. (option) Double click a distance field to zoom out in order to fully display the selected (sub)entities.
4. (option) Click a distance field and type a value. The second entity is moved.

* Press and hold the Ctrl-key to select a subentity. The Nearest Distance feature can be used to:

- Measure the distance between two entities or subentities.
- Adjust the distance between a (sub)entity and a block. (1.526)
- Modify the dimensions of a rectangle. (1.527 on the following page)
- Adjust the distance between 3D solids. (1.528 on the next page)
- Edit the width of a 3D solid. (1.529 on page 605)
- Measure and edit the height of 3D solid. (1.530 on page 606)
- ...

Figure 1.526

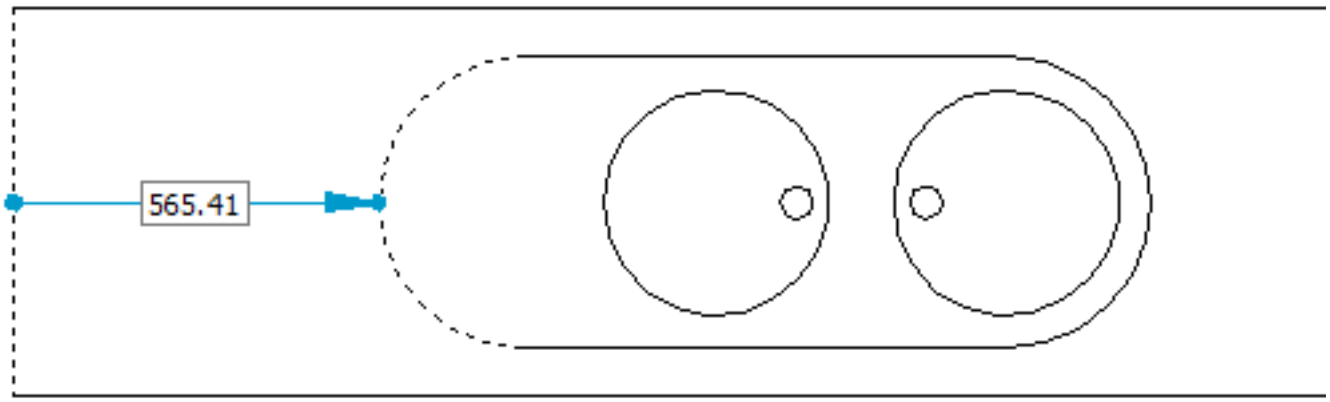

Figure 1.527

Figure 1.528

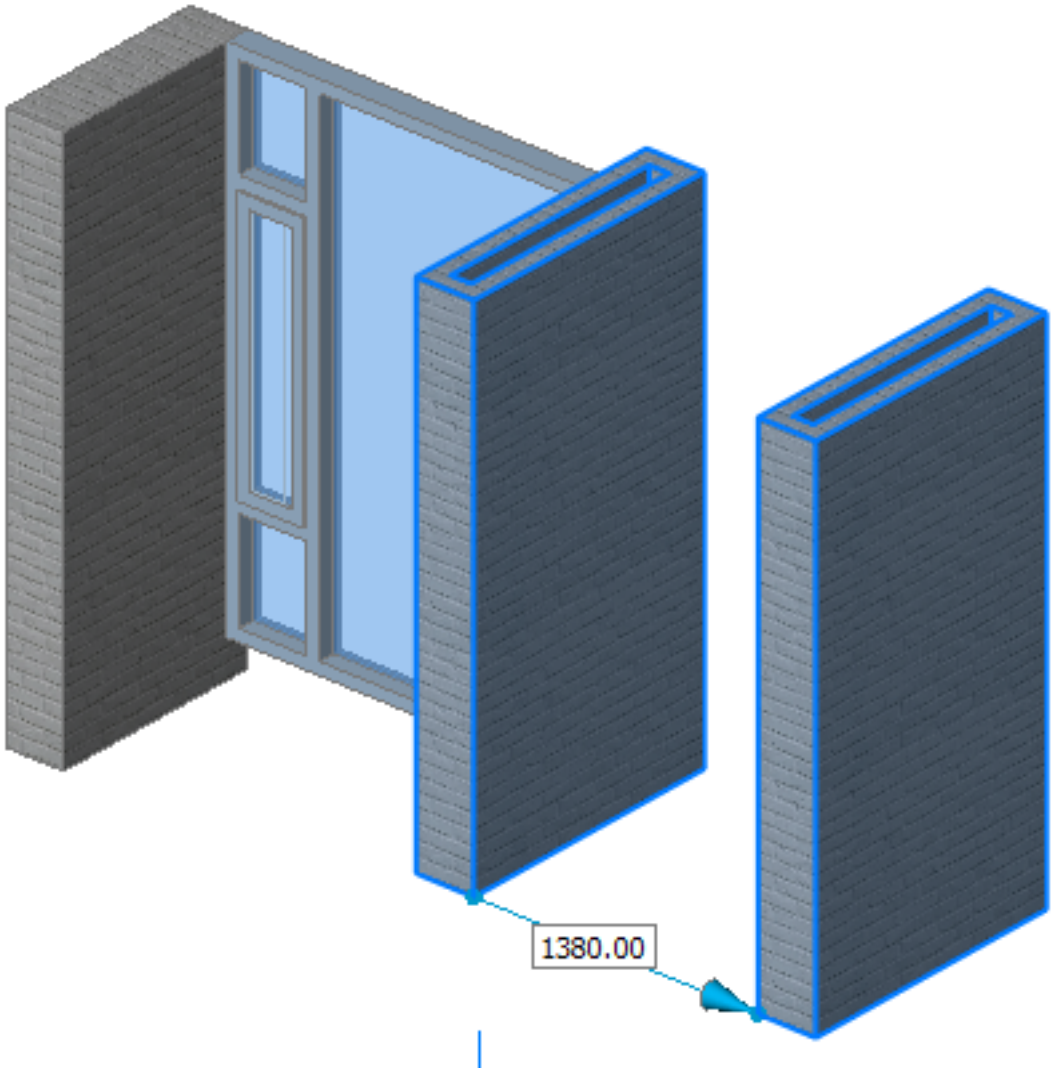

Figure 1.529

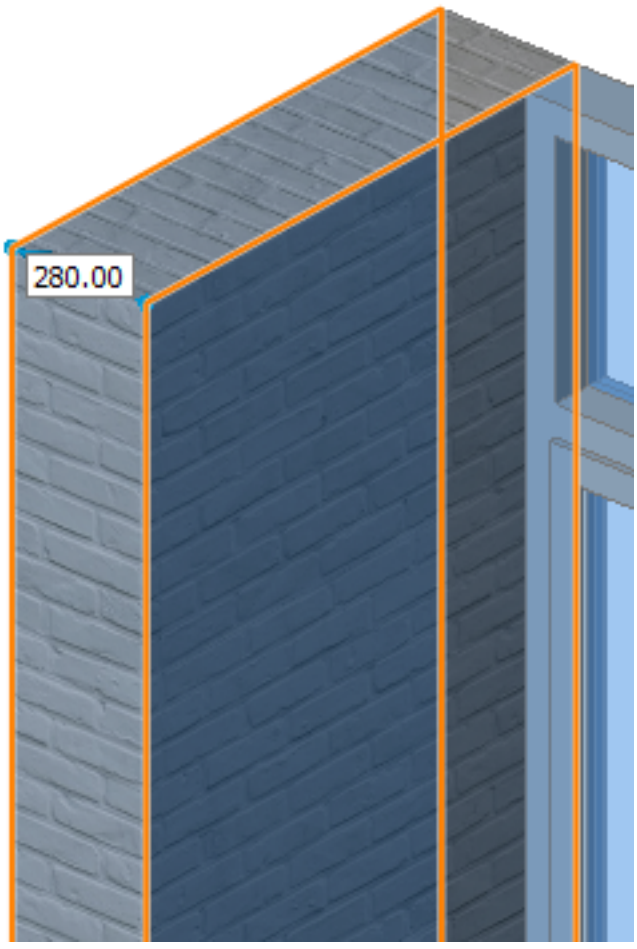

Figure 1.530

1.21.11 Coordinate Input

When you create entities in a drawing, they are located in relation to the drawing's underlying Cartesian coordinate system. Every drawing has a fixed coordinate system called the **World Coordinate System** (WCS). You can also define arbitrary coordinate systems located anywhere in three-dimensional space. These are called user coordinate systems (1.21.21) (UCS) and can be located anywhere in the WCS and oriented in any direction. To specify points and distances using the keyboard you can use the following formats:

- Cartesian coordinates: x,y,z
- Cylindrical coordinates: R<alpha,z
- Spherical coordinates: R<alpha<beta

Relative coordinates

If you place the @-character in front of the entry, the coordinates are calculated with respect to the previous point. This technique is called **Relative Coordinates** . When Dynamic Dimensions (1.21.9) are active and you type a value in the **Length** field and add a comma (,) the content of the **Length** field is copied to the command line and the @-character is placed in front automatically, which allows you to specify the next point using relative coordinates with respect to the previous point.

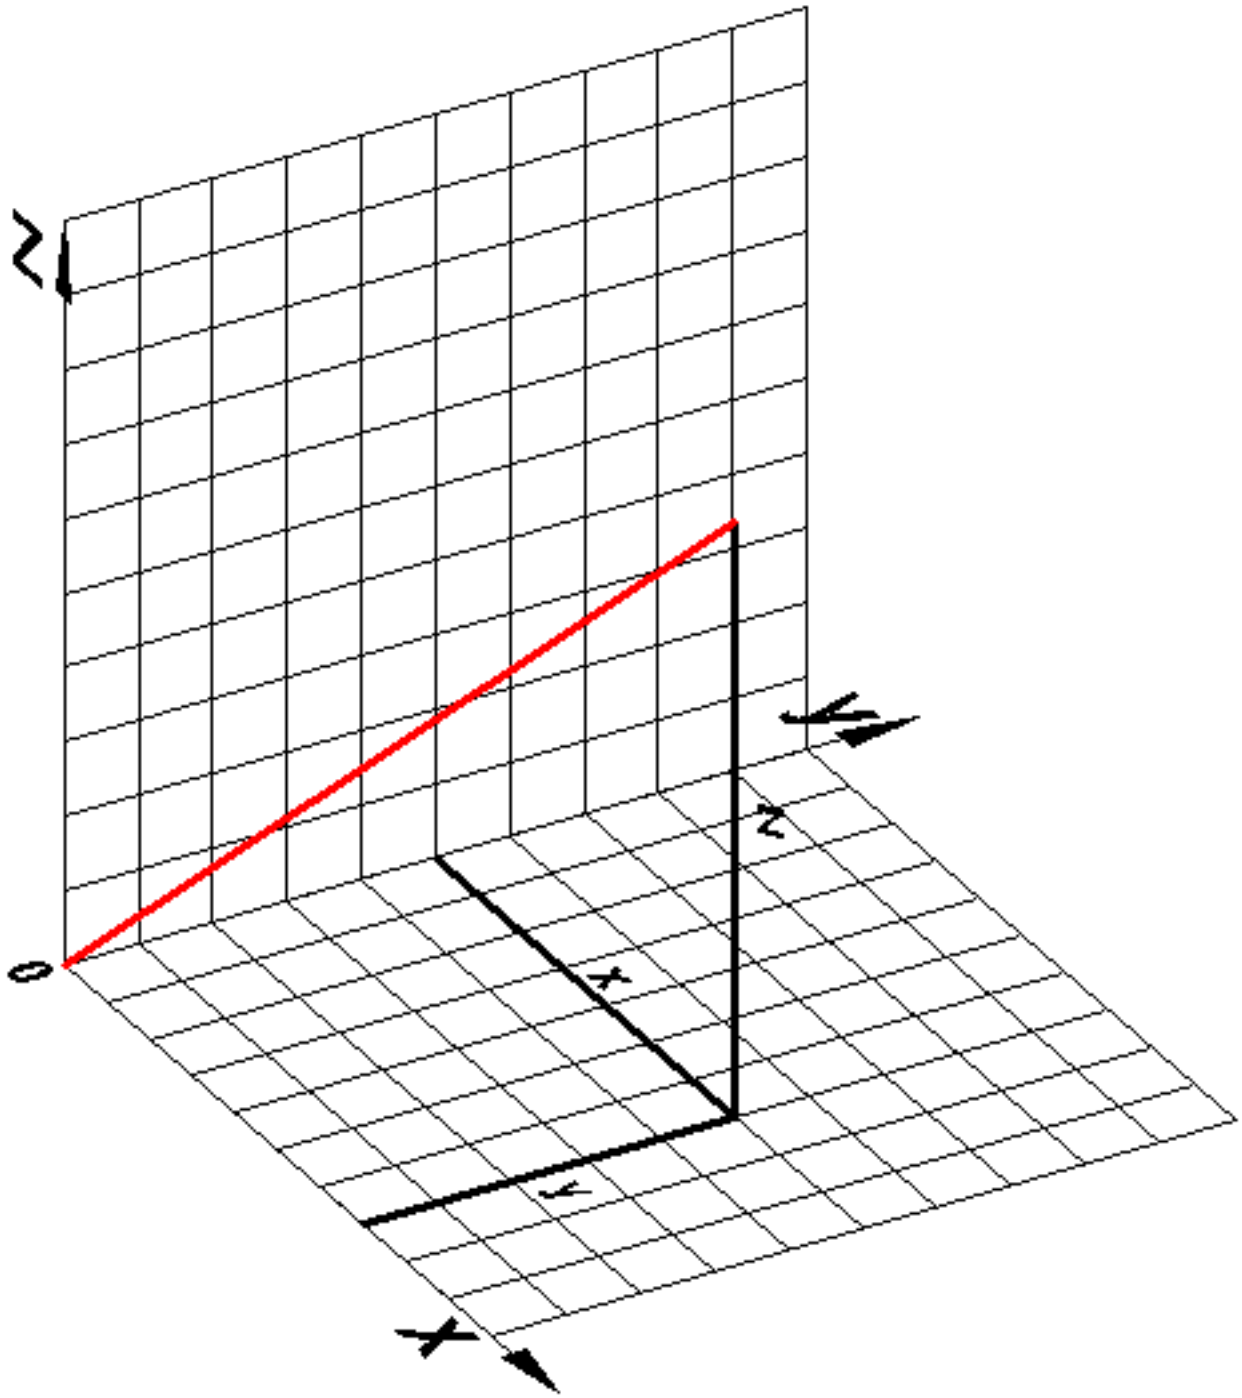
Absolute coordinates

When a user defined coordinate system is active you can enter absolute coordinates (World coordinates) if you place an asterisk (*) in front. E.g. *0,0 refers to the origin of the WCS (World Coordinate System).

Working with Cartesian coordinates

In the Cartesian coordinate system we use three perpendicular axes: the x-axis, the y-axis and the z-axis. All axes originate in the origin point of the coordinate system. The x-axis and the y-axis define a horizontal plane, while the x-axis and the z-axis and the y-axis and the z-axis define vertical planes. A point is defined by its distances to the yz-, xz- and xy- planes. These distances are called the xyz-coordinates of a point. (1.531 on the following page) If you want to enter the absolute Cartesian coordinates of a point, type the x-, y- and z- coordinates separated by commas: 45.5,57.3,60 If you omit the z-coordinate, the point is placed in the xy-plane (Z = 0). If you place the @-character in front of the entry (@x,y), the coordinates are calculated with respect to the previous point. This technique is called **Relative Cartesian coordinates** .

Figure 1.531



Using relative Cartesian coordinates to draw a rectangle

1. Launch the RECTANGLE (1.25.18) command.
2. Specify the first corner of the rectangle.
3. In the command bar type: @<width>,<height>
4. <width> = the width of the rectangle in drawing units, measured along the x-axis
5. <height> = the height of the rectangle in drawing units, measured along the y-axis

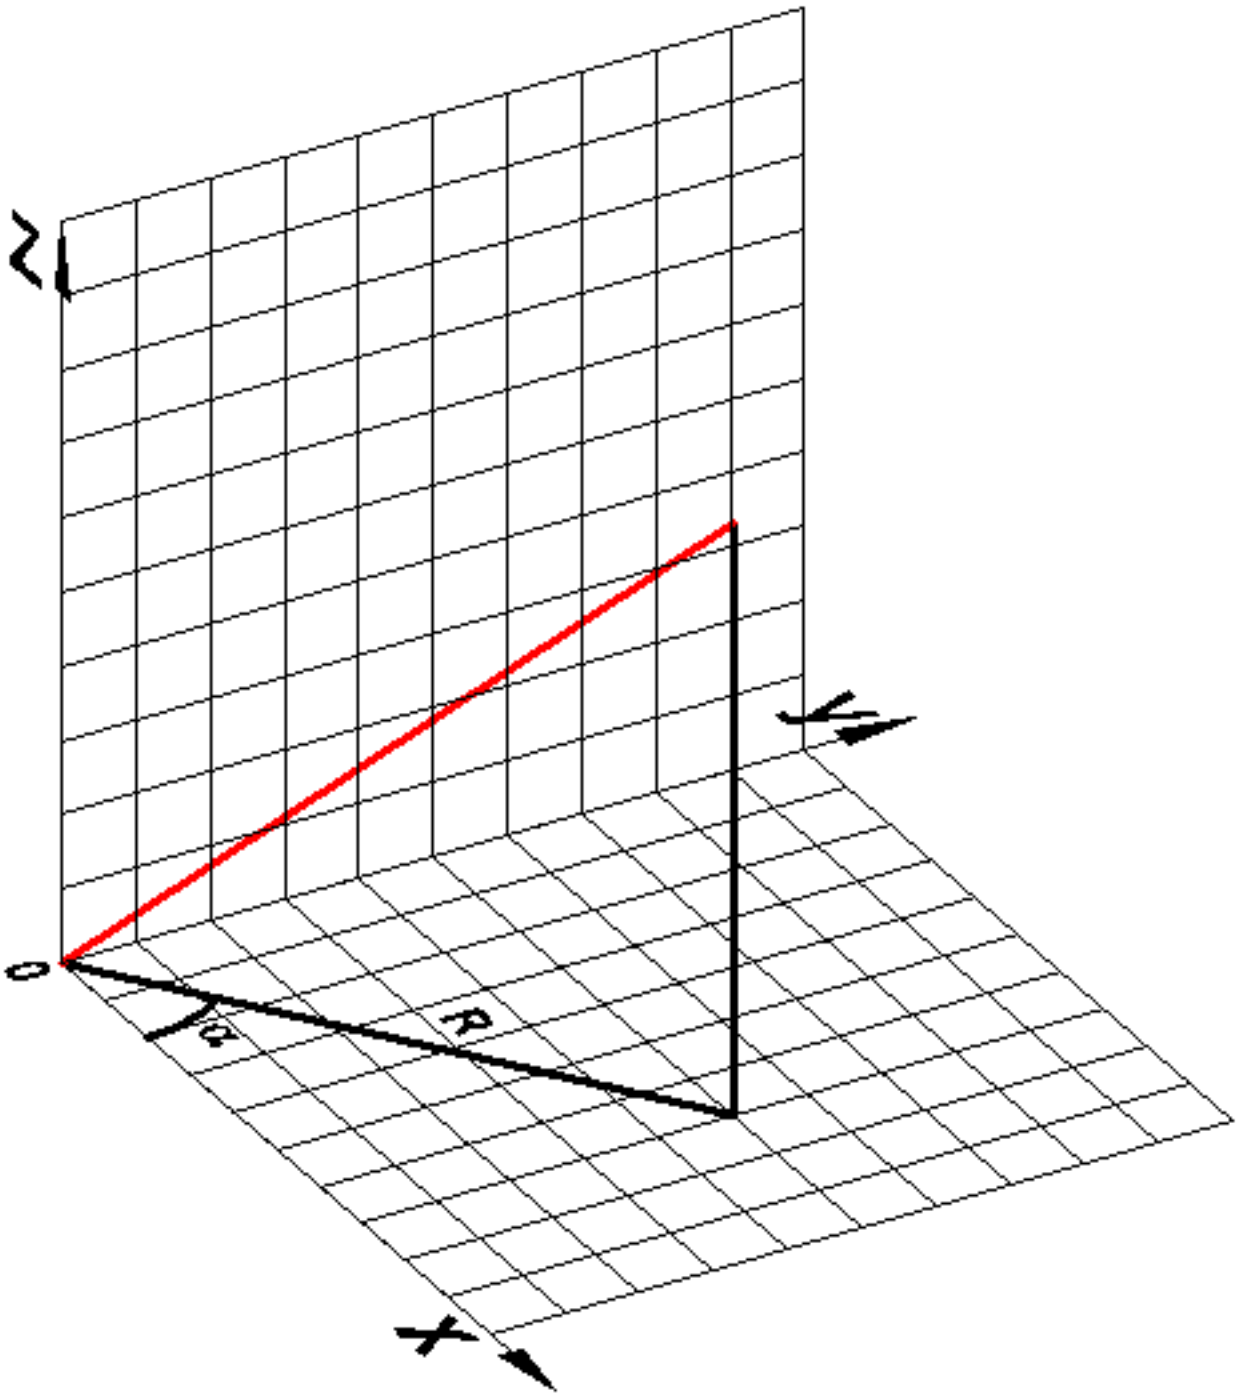
Working with cylindrical coordinates

In a cylindrical coordinate system we use three perpendicular axes: the x-axis, the y-axis and the z-axis. All axes originate in the origin point of the coordinate system. The x-axis and the y-axis define a horizontal plane, while the x-axis and the z-axis and the y-axis and the z-axis define vertical planes. A point is defined using the following format: R<alpha, z.

- R = distance to the origin in the xy-plane
- <alpha = the angle between R and the x-axis (positive angles are measured counter clockwise)
- z = the height above the xy-plane.

If the z-coordinate is omitted, cylindrical coordinates are referred to as polar coordinates. If you place the @-character in front of the entry, the coordinates are calculated with respect to the previous point. This technique is called **Relative Cylindrical coordinates** . (1.532 on the next page)

Figure 1.532



Working with spherical coordinates

In a cylindrical coordinate system we use three perpendicular axes: the x-axis, the y-axis and the z-axis. All axes originate in the origin point of the coordinate system. The x-axis and the y-axis define a horizontal plane, while the x-axis and the z-axis and the y-axis and the z-axis define vertical planes. A point is defined using the following format: R<alpha<beta

- R = distance from the origin
- <alpha = angle in the xy-plane (positive angles are measured counter clockwise)
- <beta = angle measured from the xy-plane (positive angles are measured counter clockwise, above the xy-plane)

(1.533 on the following page)

Figure 1.533

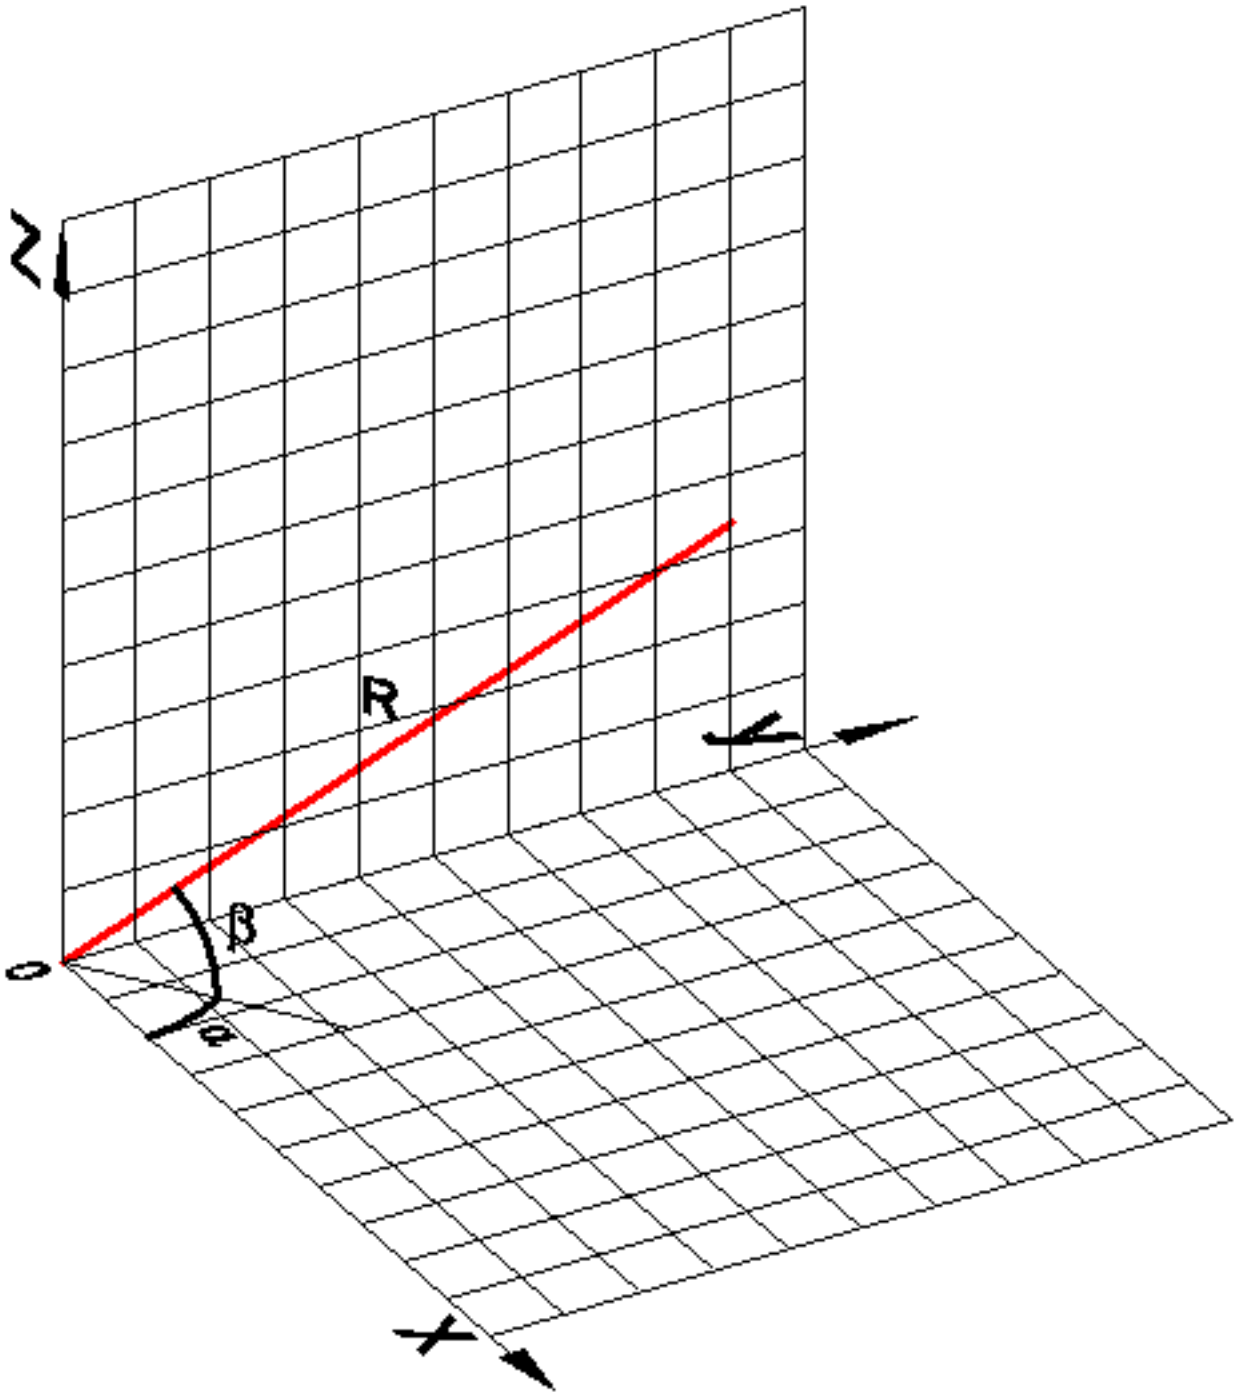


Figure 1.534

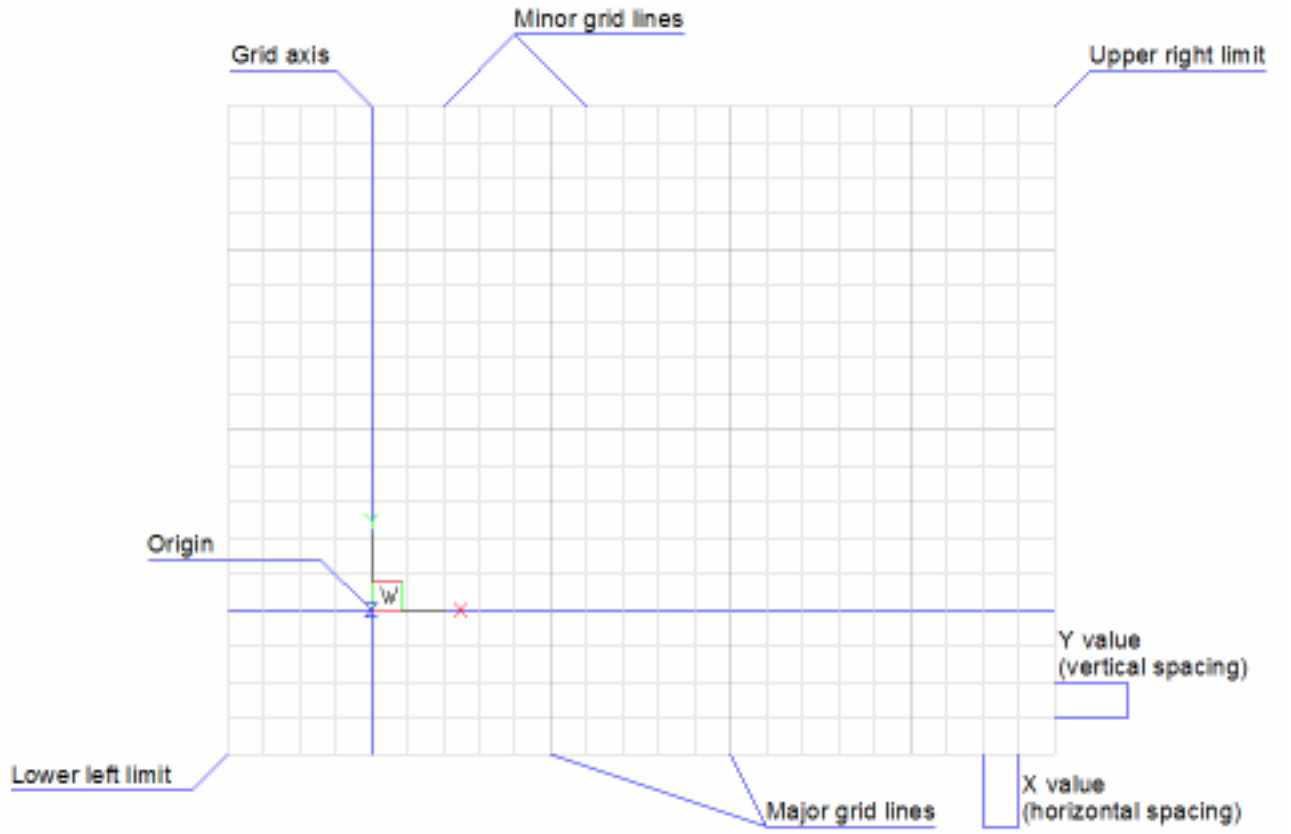


1.21.12 Using Snap and Grid

Commands : SNAP (6.27.41), GRID (6.15.23) and LIMITS (6.20.38) Grid and snap help you to draw fast and accurately. A grid is a set of evenly spaced lines or dots that serve as a visual distance reference. The GRIDSTYLE (1.17.10) system variable controls whether grid lines or dots (6.15.23) display. The GRIDDISPLAY (1.17.10) system variable controls the display of the grid (6.15.23). The grid can also indicate how far the drawing limits extend. (1.534) The snap feature creates a set of evenly spaced, invisible magnetic points**,** which make the crosshairs move in even increments. Both grid and snap are like the intersection points of the lines on a piece of grid paper. Grid points are for visual reference only and they do not print. Snap constrains the points that you can pick with the mouse.

- Click the **Grid** tool ( ) on the Settings toolbar or the **Grid** field in the Status Bar (1.15.2), or press **Ctrl+G** to toggle grid display on/off.
- Click the **Snap** tool ( ) on the Settings toolbar or the **Snap** field in the Status Bar (1.15.2), or press **Ctrl+B** to toggle snap on/off. The setting is saved through the SNAPMODE system variable. If SNAPTYPE = 2, adaptive grid snap (1.21.13) is used and SNAPMODE is denied.
- Both **snap** and **grid** can be set differently in each viewport (1.23.11).
- The **Snap** option of the **Grid** command equals the grid spacing to the current snap spacing.
- Grid lines or dots do not print.

Tutorial: Drawing Accurately: Snap and Grid Click here (1.14.1) to watch

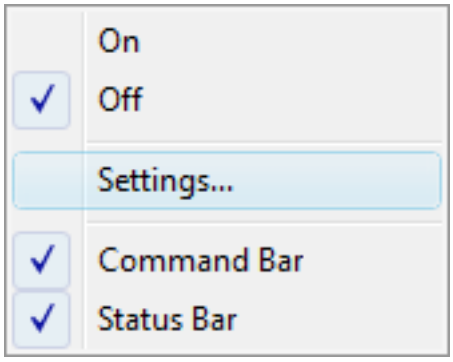
Using the adaptive grid

When SNAPTYPE = 2, the movement of the cursor is controlled by an adaptive grid of which the spacing depends on the current zoom factor of the view and the value of AdaptiveGridStepSize user preference. The value of this preference is expressed in pixels. As a result the step size of the adaptive grid increases when you zoom out, and decreases when you zoom in. The step size of the ruler in the Manipulator (1.32.10) also depends on the AdaptiveGridStepSize user preference.

Display the Snap and Grid settings

Do one of the following:

Figure 1.535



- In the Status Bar (1.15.2), right click on the **Snap** field, then choose **Settings** in the context menu. (1.535)
- Open the Settings (1.17.10) dialog, then click the **Drawings** button. Under **Drafting** , expand **Coordinate Input** and **Snap/Grid** .

To synchronize snap and grid spacing

1. Type **Grid** in the command bar, then press Enter. You are prompted: Grid is on: OFF/Aspect/<Grid spacing (synced with snap)>:
2. Type **s** , then press Enter.
3. Type **Snap** in the command bar, then press Enter. You are prompted: Snap is on, x and y = 0.2000: OFF/Rotate/Style/Aspe spacing>:
4. Type a new value for the snap spacing, then press Enter. The value is applied to both snap and grid.

Note: The grid spacing remains in sync with the snap spacing until you set the grid spacing differently using the **Grid** command or in the **Settings** dialog.

To set the Drawing Limits

See the LIMITS (6.20.38) command.

To toggle the Drawing Limits

Click the **Drawing Limits** tool button ( ) on the Settings toolbar to toggle the LIMCHECK (1.17.10) system variable on/off. If LIMCHECK = ON, it is not possible to draw outside the drawing limits. The appearance (pressed or unpressed) of the **Drawing Limits** tool button reflects the current status of the **Drawing Limits.** The **Display beyond LIMITS area** option of the GRIDDISPLAY (1.17.10) system variable defines wether or not the grid display indicates the drawing limits.

Using Isometric Snap

You can use the Isometric snap and grid option to create two-dimensional isometric drawings. With the isometric option, you can draw a simulated three-dimensional view on a two-dimensional plane, much the same as you might draw on a piece of paper. Do not confuse isometric drawings with three-dimensional drawings. The isometric option always uses one of three preset planes, which are denoted as **Left**, **Right** and **Top**. You cannot alter the arrangement of these planes. If the Snap Angle is 0, the three isometric axes are 30 degrees, 90 degrees, and 150 degrees. When you set the **Snap Style** setting to **Isometric Snap** and then set the **Snap Isometric Pair** setting to **Left**, **Top** or **Right**, the snap intervals, grid, and crosshairs align with the selected plane. The grid is always shown as isometric and uses y-coordinates to calculate the grid spacing. If the Orthogonal Mode (1.21.2) is active, the movement of the crosshairs is constrained to the current isometric plane. Press the **F5** function key to toggle the **Snap Isometric Pair** setting.

1. Display the **Snap/Grid** settings in the Settings (1.17.10) dialog: (1.536 on the next page)
2. Turn on the **Orthogonal Mode** .
3. Use the SNAP command to set the **Snap Style** setting to **Isometric Snap** .
4. Press the **F5** function key to set the appropriate drawing plane: **Top**, **Left** or **Right**. (1.537 on the facing page)

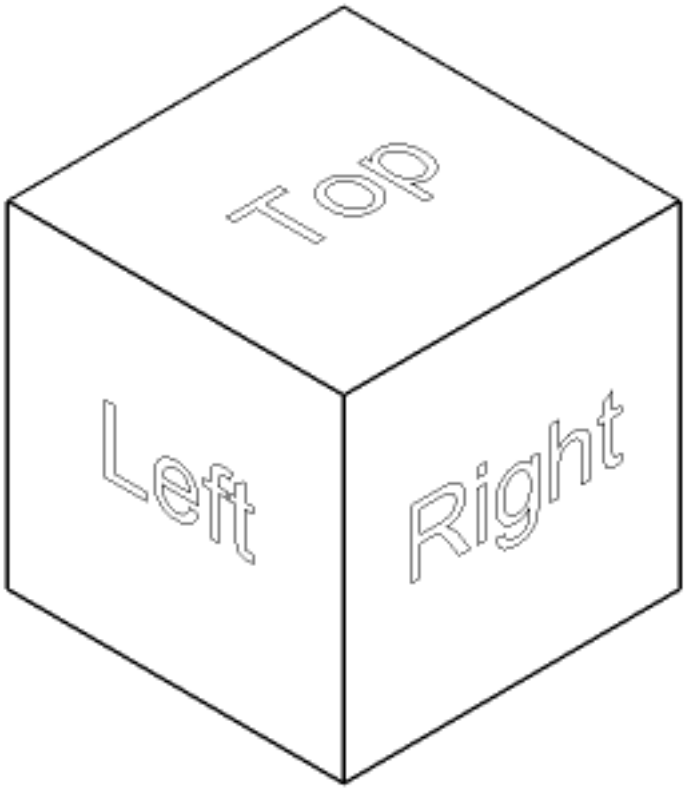
Figure 1.537



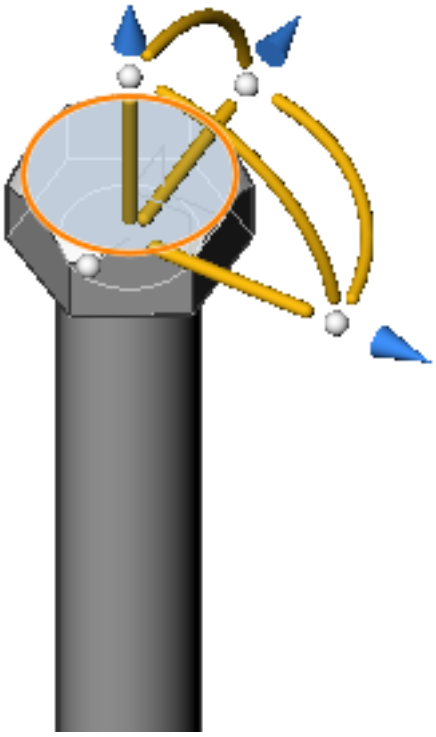
Setting the Snap Angle

You can rotate a dotted grid using the Snap Angle setting (if **Snap Angle** is different from zero, grid lines do not display).

1. Display the **Snap/Grid** settings in the Settings (1.17.10) dialog:
2. Select the **Snap Angle** setting.
3. Type a new value in the Snap Angle setting field.
4. Close the Settings dialog.

Note: You can also set the **Snap Angle** by typing **snapang** in the command bar. When in a command, type **'snapang** (with an apostrophe in front), to set the **Snap Angle** variable transparently (= without interrupting the running command).

Figure 1.538



1.21.13 Adaptive grid snap

The adaptive grid snap feature lets you create, edit, nudge (1.21.14) and manipulate (6.21.3) entities using concise values without keyboard entry. The snap step size is adapted according to the current screen zoom factor. The adaptive grid snap is active if **SNAPTYPE = 2**. This system variable overrides **SNAPMODE**. The AdaptiveGridStepSize user preference controls the smallest available step size; default = 4 pixels. Do the following:

1. Move the cursor over an entity or subentity, then shortly hold down the left mouse button (= long left click). The Manipulator widget displays: (1.538)

2. Move the cursor over the axis in the direction you want to move the entity. The selected axis highlights; the other parts of the Manipulator are faded. (1.539 on the following page)

3. Move the cursor. The Ruler displays. The current displacement distance displays in a dynamic field. The grid snap resolution automatically adapts according to the zoom factor.

(1.540 on the next page) Ruler divisions at 2 mm	(1.541 on page 619) Ruler divisions at 5 mm

4. (option) Zoom in or out to adjust the dynamic grid.

5. Do one of the following:
   - Click to conclude.
   - Type a value in the dynamic field, then press Enter.

Figure 1.539

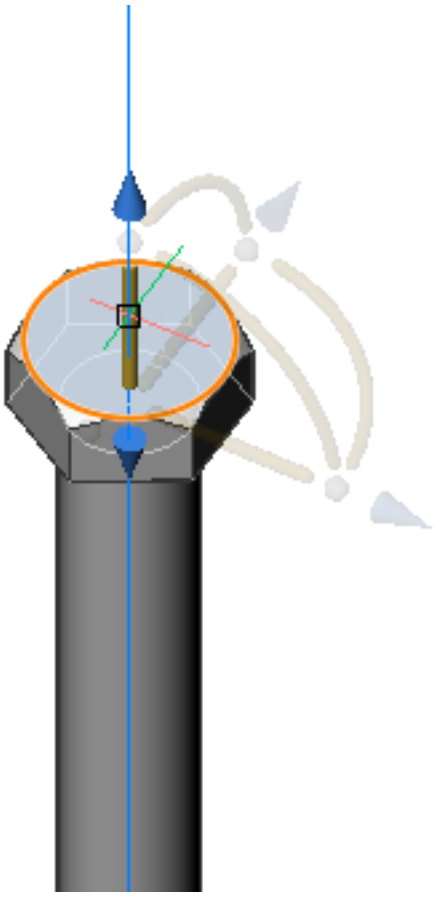


Figure 1.540

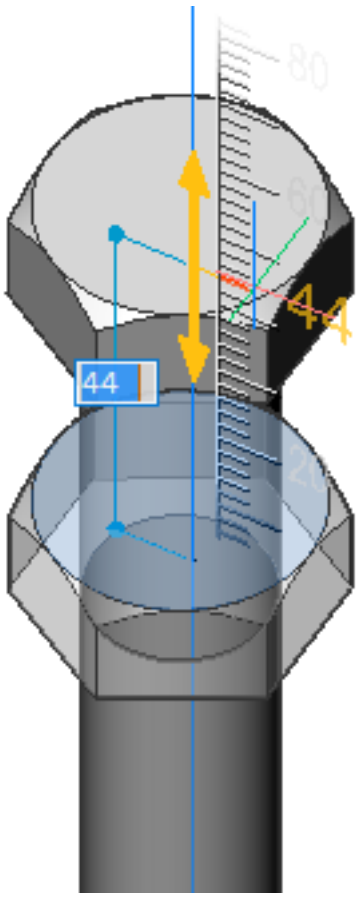

Figure 1.541

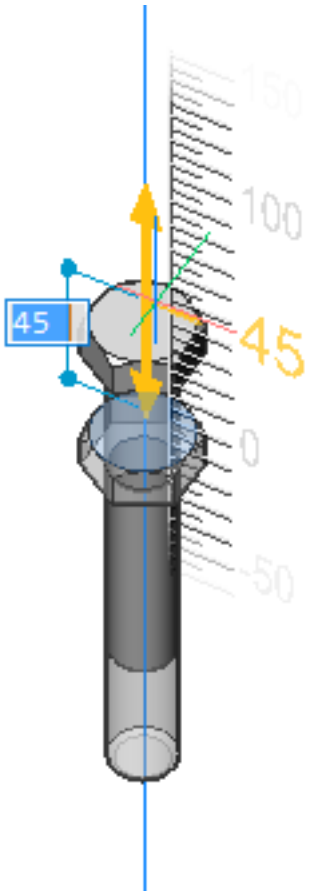

1.21.14 Nudge

The Nudge drawing aid lets you move selected entities or subentities in small increments along the X, Y, or Z axis using the keyboard.

Using Nudge

1. Select one or more entities or subentities.
2. (option) Hold the Ctrl key down, then use the left/right arrow keys to move the selection along the X axis of the current coordinate system. The command line reads: NUDGE: offset along the X axis of the UCS: 10*
3. (option) Hold the Ctrl key down, then use the up/down arrow keys to move the selection along the Y axis of the current coordinate system. The command line reads: NUDGE: offset along the Y axis of the UCS: 10*
4. (option) Hold the Shift key down, then use the up/down arrow keys to move the selection along the Z axis of the current coordinate system. The command line reads: NUDGE: offset along the Z axis of the UCS: 10*

* The step size used by the NUDGE functionality is based on the adaptive grid snap (1.21.13) resolution. Zoom in/out to decrease/increase the step size.

1.21.15 2D Entity Snaps

Commands: 2DINTERSECTION (6.2.1), 3DINTERSECTION (6.3.7), NEAREST (6.22.2), CENTER (6.9.3), ENDPOINT (6.13.7), EXTENSION (6.13.22), FROM (6.14.13), GCENTER (6.15.5), INSERTION (6.17.18), INTERSECTION (6.17.19), MIDPOINT (6.21.16), MTP (6.21.35), NONE (6.22.8), PARALLEL (6.24.5), PERPENDICULAR (6.24.25), NODE (6.22.7), QUADRANT (6.25.7), TANGENT (6.29.10) Entity snaps enable you to quickly select exact geometric points on existing entities without having to know the exact coordinates of those points. With entity snaps, you can select the end point of a line or arc, the center point of a circle, the intersection of any two entities, or any other geometrically significant position. You can also use entity snaps to draw entities that are tangent or perpendicular to an existing entity. You can use entity snaps any time you need to specify a point. You can work with entity snaps in one of two ways:

- Enable a running entity snap that remains in effect until you turn it off by choosing an entity snap when no other command is active.
- Enable a one-time entity snap for a single selection by choosing an entity snap when another command is active. You can also use a one-time entity snap to override a running entity snap.

When using entity snaps, the program recognizes only visible entities or visible portions of entities. You cannot snap to entities on layers that have been turned off or to the blank portions of dashed lines. If the **APBOX** system variable is on, the entity Snap Aperture Box is added to the crosshairs when one or more entity snaps are active. When you move the cross hairs, the program snaps to the snap point closest to the center of the Snap Aperture Box. The **Snap Marker** indicates the current snap point. The DRAGSNAP (1.17.10) system variable controls the snap behavior while 'dragging', providing an increased WYSIWIG experience. DRAGSNAP controls whether rubberband dynamics are displayed at the current cursor location or at the current entity snap location. DRAGSNAP applies to all modify commands that display dynamics, such as COPY, PASTECLIP, PASTEBLOCK, MOVE, ROTATE, MIRROR, SCALE and STRETCH.

- **DRAGSNAP = 0** (Default): dragged entities display at the cursor location.
- **DRAGSNAP = 1**: dragged entities display at the current entity snap location.

The OSOPTIONS (1.17.10) system variable suppresses entity snaps on certain entity types. The value is stored as a bitcode using the sum of the values of the selected options.

- 1: Entity snapping is disabled for hatch entities.
- 2: Entity snapping is disabled for geometry with negative Z values when using a dynamic UCS.
- 4: Entity snapping is disabled for endpoints of dimension extension lines.

Note: Press the **TAB** key, without moving the mouse, to cycle through all possible entity snaps. If the **DYNMODE** variable has a positive value (Dynamic Dimensions (1.21.9) switched ON) entity snap cycling is not possible. Click the **DYNMODE** field in the Status Bar (1.15.2) to toggle the display of dynamic dimensions.

To define the Entity Snap settings

1. Open the Settings dialog (1.17.10).
2. In the Settings dialog, expand the **Program Options** settings class.
3. Under **Program Options** expand the **Display** settings group, then scroll down to the **Entity Snap** settings. (1.542 on page 623)

User Preference	Title	Description
SnapMarkerSize	Snap marker size	Sets the size of the snap marker. (default size is 6)
SnapMarkerThickness	Snap marker thickness	Sets the thickness of the snap marker. (default thickness is 2)
SnapMarkerColor	Snap marker color	Sets the color of the snap marker. (default color = 20)

3dSnapMarkerColor	3d snap marker color	Sets the color of the 3d snap marker (default color = 5 (Blue). See 3D Entity Snaps (1.21.16). If OSNAPZ = 1 (Ignore entity snap elevation) the 3d snap marker displays also at the the identified 3D point, which is then projected onto the XY plane of the current UCS at the current Elevation. (1.550 on page 636) The 3d snap marker (1) displays the identified 3d point, the snap marker (2) displays at the current Elevation height.
DisplaySnapMarkerInAllViews	Snap marker in all views	If multiple viewports are open, enables the display of the snap marker in all viewports.
DisplayTooltips	Snap tooltips	Enables the display of the Entity Snap tooltips.

4. Under **Drawing** expand the **Drafting** settings group then go to **Coordinate Input** > **Entity Snaps**. (1.543 on the next page)

System Variable	Title	Description
OSMODE	Entity snap mode	Sets the entity snap modes and toggles entity snap on/off.
3DOSMODE	3D entity snap mode	Sets the entity snap modes for 3D entity features such as the midpoint of an edge or the center of a face.
OSNAPCOORD	Entity snap coordinates	Determines whether entity snaps override keyboard coordinate entry.
OSNAPZ	Ignore entity snap elevation	Replaces the Z-coordinate of the snapping point with the current value of the ELEVATION system variable.
OSOPTIONS	Entity snap options	Suppresses entity snaps on hatches and/or dimension extension lines or negative z-values in dynamic UCS mode.
APBOX	Entity snap aperture box	Toggles the display of the aperture box (2).
APERTURE	Entity snap aperture	Sets the size of the Autosnap aperture box. (default size is 10).
DGNOSNAP	DGN entity snap	Enables entity snapping to entities in DGN underlay files.
DWFOSNAP	DWF entity snap	Enables entity snapping to entities in DWF underlay files.
PDFOSNAP	PDF entity snap	Enables snapping to the geometry in PDF underlay files.

To set the Entity Snaps

Do one of the following:

- Click the buttons on the Entity Snaps toolbar. The buttons of the currently active entity snap modes are pressed. (1.544)
- Press and hold the Shift key, then right click and select the Entity Snap mode in the context menu. The icons of the currently active Entity Snap modes are outlined. (1.545 on the next page)

When no command is active, the above procedures toggle the Entity Snap modes on/off. When a command is active, the above procedures set a 'one shot' override of the current Entity Snap modes. Alternatively you can type a single letter shortcut as indicated in the table below.

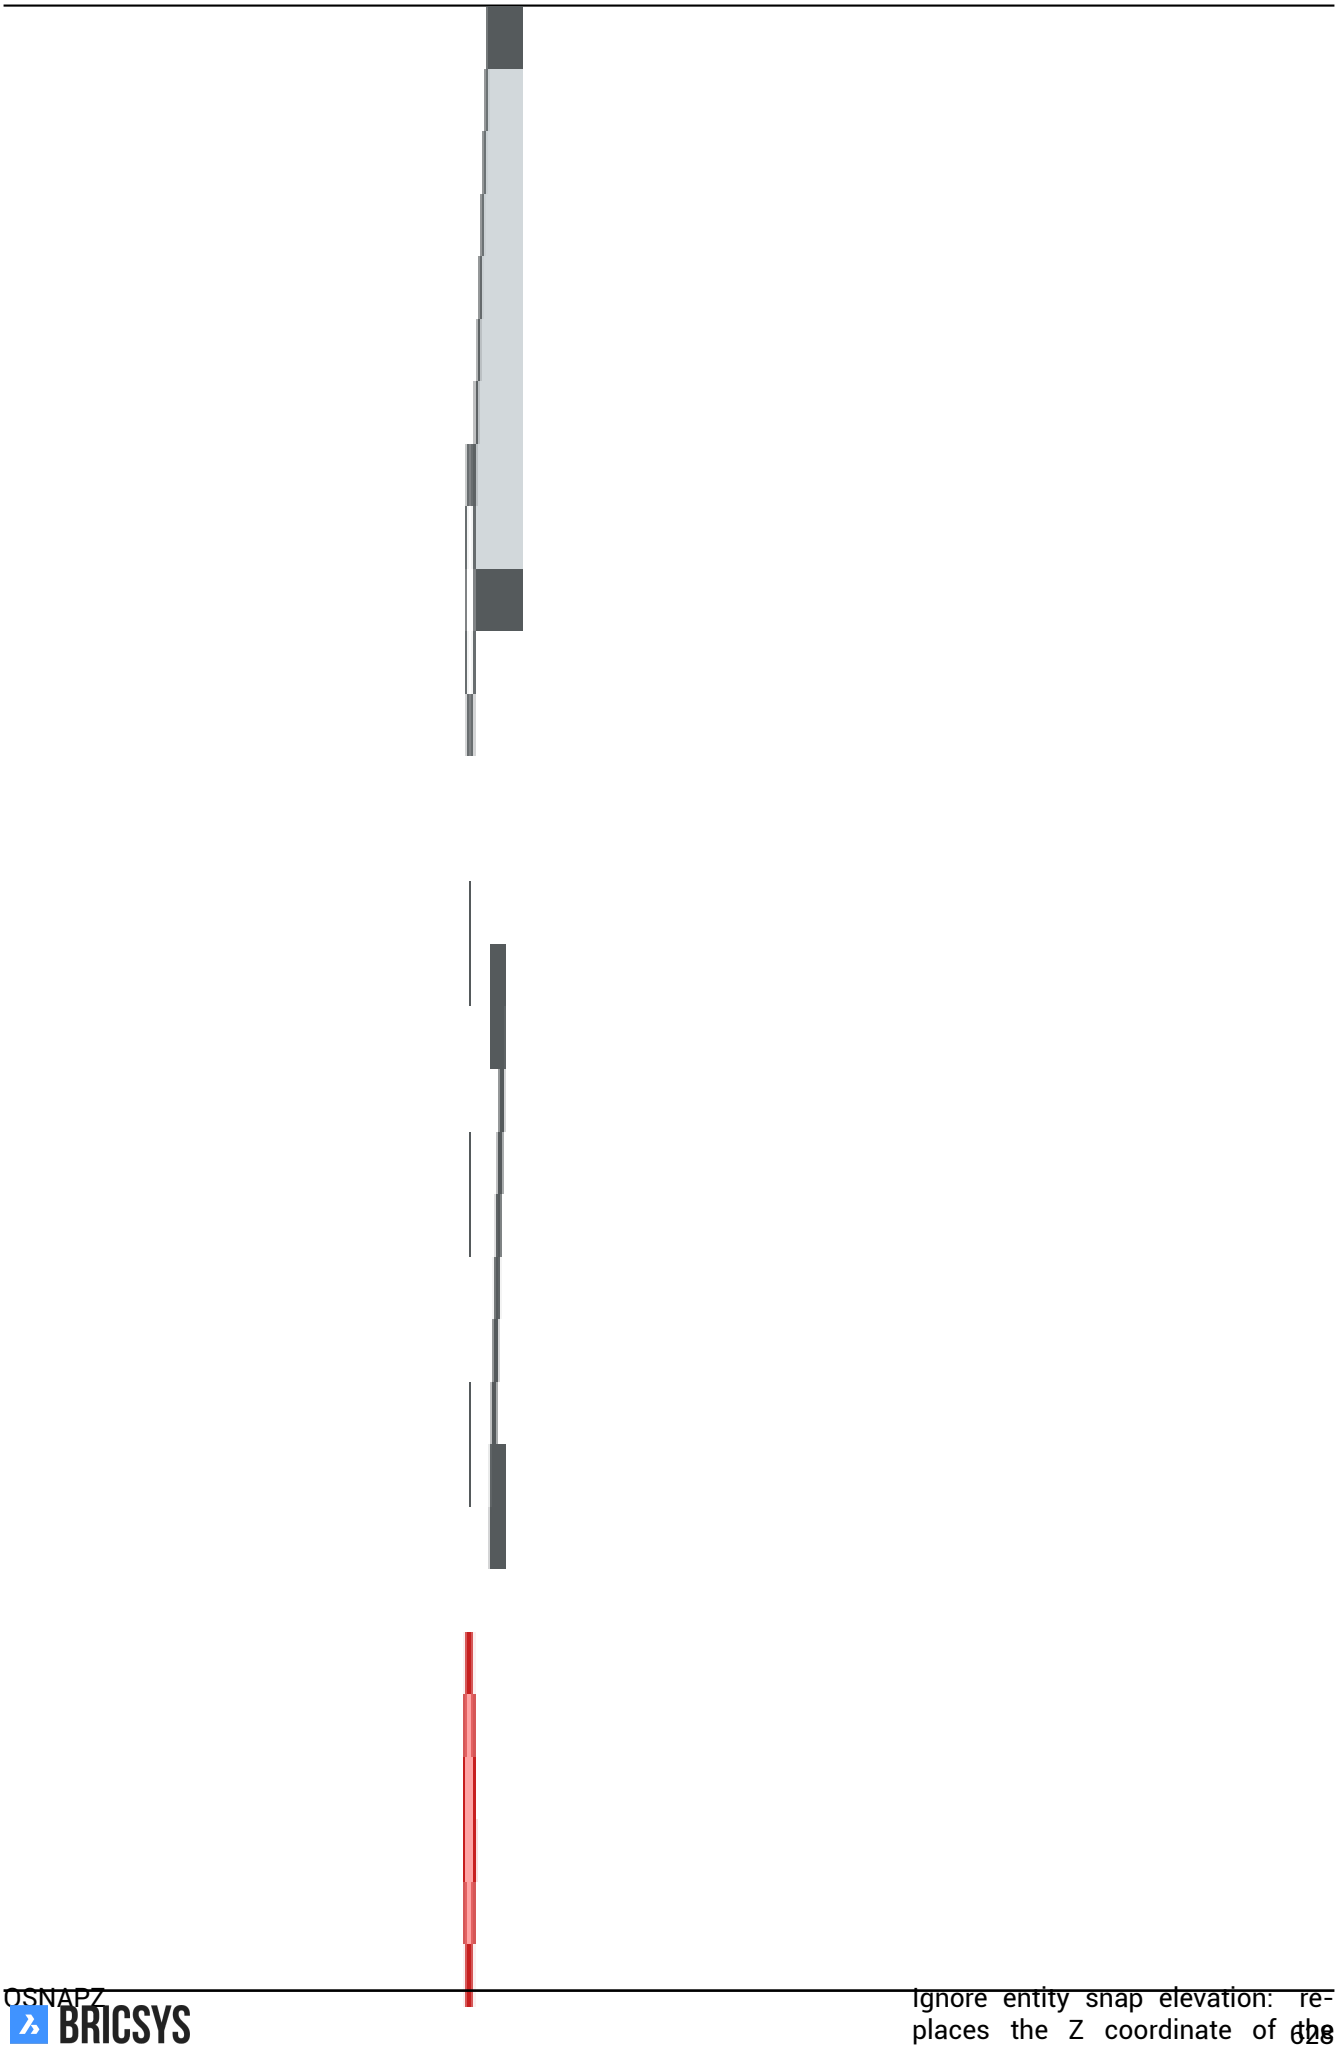
Name	Icon	Marker	Context menu shortcut*	Transparent shortcut**	Description
TK				tk	Use temporary tracking points. Prompts you to identify temporary points; press Enter to accept the last temporary point.
MTP			2	mtp	Snaps to a point in the middle between two points. Prompts you to identify two points.
ENDPOINT			E	end	Snaps to the nearest endpoint of an entity or polyline segment.
MIDPOINT			M	mid	Snaps to the midpoint of an entity or polyline segment.
NEAREST			N	nea	Snaps to the nearest point on an entity.
CENTER			C	cen	Snaps to the center point of an arc, circle, polygon, ellipse or elliptical arc.
GEOMETRIC CENTER			G	gce	Snaps to the centroid of any closed polylines and splines, planar 3d polylines, regions and planar faces of 3D solids.

PERPENDICULAR		P	per	Snaps to the perpendicular point of another entity. You can snap to an arc, circle, ellipse, line, polyline, infinite line, ray, spline or edge of a plane to form a perpendicular alignment with that entity or with an extension of that entity.
PARALLEL		L	par	Displays a tracking line parallel to the selected entity.
TANGENT		T	tan	Snaps to the point on an arc, ellipse, spline or circle that, when connected to the previous point, forms a line tangent to that entity.
QUADRANT		Q	qua	Snaps to the closest quadrant of an arc, circle, ellipse, or elliptical arc.
INSERTION		I	ins	Snaps to the insertion point of an attribute, block or text entity.
NODE		O	poi nod	Snaps to a point entity.
INTERSECTION		R	int	Snaps to the intersection of any combination of entities.

APPARENT INTERSECTION			A	app	Snaps to the apparent intersection in the current view of two entities that do not intersect in three-dimensional space. Snaps also to the intersection of any combination of entities.
EXTENSION			X	ext	Snaps to the extension of an entity or to the intersection of the extension of two entities.
NONE			Y	non	Turns off all entity snap modes.

Entity Snap Modes * Type this letter to quickly select the entity snap mode in the right click context menu. ** Type the transparent shortcut in the command bar when a command prompts for a point. Other running entity snaps are temporarily disabled.

System Variable	Icon	Description



OSNAPZ

Ignore entity snap elevation: replaces the Z coordinate of the snapped point with the current

OSOPTIONS		Entity snap to hatches: allows to snap to hatches.
OSOPTIONS		Entity snap to negative-z: allows entity snaps with a negative z-value when a **Dynamic UCS** is active,

NOTE

You can toggle the **Entity Snaps** on/off:

- by clicking the **ESNAP** field in the Status Bar (1.15.2).
- by hitting the **F3** function key.

Working with multiple Entity Snap modes

1. Move the cursor to the entity you want to snap. One of the active Entity Snap modes markers display.
2. Do not move the mouse; press the TAB key. The entity the snap point is on highlights.
3. Do one of the following:
   - Click to accept the snap point.
   - Press the TAB key. The next possible Entity Snap mode marker displays. The entity the snap point is on highlights.
4. (option) Repeat step 3 until the right snap point is found.

NOTES

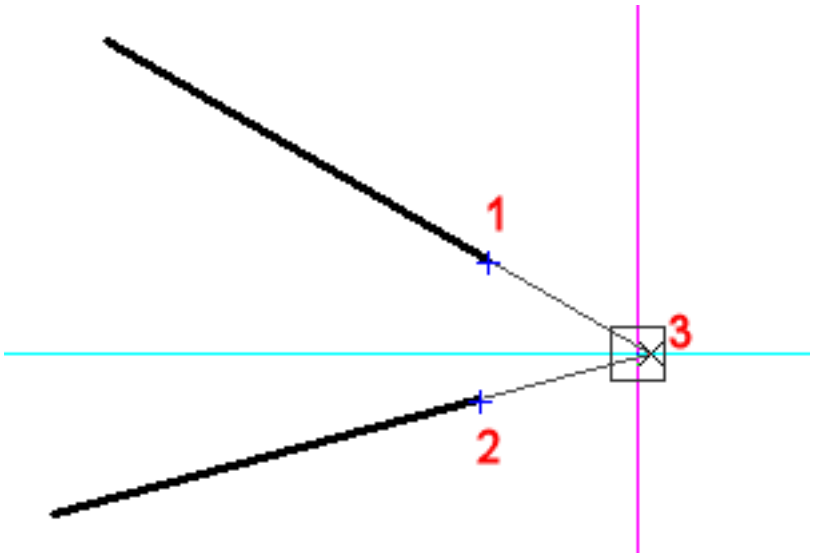
- Do not move the mouse while pressing the TAB key.
- Entity snap cycling is not possible when Dynamic Dimensions (1.21.9) are active. Click the **DYNMODE** field in the **Status Bar (1.15.2)** to toggle Dynamic Dimensions on/off.

To snap to the extension of two entities

1. If not already on, turn on the **Extension** Entity Snap mode ().
2. Launch a drawing tool, e.g. Draw Line.
3. Move the cursor over the endpoint of the first entity (1). A small cross () indicates the entity is marked for extension.
4. Move the cursor over the endpoint of the second entity (2). A small cross () indicates the entity is marked for extension.
5. Move the cursor near the intersection of the extensions of the two entities. An X indicates the intersection (3). (1.546 on the facing page)
6. Click to accept the snap point.

Note: You can snap to the extension of lines, polylines, arcs and elliptical arcs.

Figure 1.546



Using temporary tracking points

When using temporary tracking points, Polar Tracking (1.21.18) must be on and it is recommended to have dynamic dimensions (1.21.9) active as well.

1. Whenever a command prompts for a point, do one of the following:

   - Click the mouse wheel.
   - Click the **Temporary tracking points** tool button ( ) on the Entity Snaps toolbar.
   - Hold down the Shift key, then right click and choose **Temporary tracking points** in the context menu.
   - Type **TK** in the command bar, then press Enter.

   The command is suspended temporarily. You are prompted: Specify first temporary tracking point:

2. Enter a point, e.g. use an entity snap to specify a point. You are prompted: Specify next temporary tracking point (press ENTER to end)

3. Do one of the following:

   - Enter a point.
   - Press Enter to accept the last temporary tracking.

   The command resumes.

Using 'Middle of 2 points' snap

1. When prompted to specify a point, do one of the following:

   - Click the **Snap to the middle of 2 points** button ( ) on the Entity Snaps toolbar.
   - Type **mtp** or **m2p** in the command bar, then press Enter.
   - Press and hold the Shift key, then right click and choose **Snap to middle of 2 points** in the context menu.

   You are prompted: First point of mid:

2. Specify the first point You are prompted: Second point of mid:

3. Specify the second point. The point in the middle of the two points is snapped.

Using the Parallel entity snap

1. Make sure Entity Snap Tracking (1.21.17) is active.

2. Launch an entity create command to create a linear entity (e.g. Line).

3. Specify the first point of the entity. The line displays dynamically.

4. Do one of the following:

- Press and hold the Shift key, then right click and choose **Snap to parallel** in the context menu.

- Click the **Snap to parallel** tool button ( ) in the Entity Snaps toolbar.

5. Hover the cursor over the entity you want to draw parallel to. The **Parallel Entity Snap** marker () displays on the selected entity. Wait until a small cross (+) indicates the entity is recognized.

6. Move the cursor in order to place the dynamics of the line more or less parallel to the selected entity. A tracking line displays from the start point of the line.

7. Do one of the following to specify the second point while the tracking line displays:
   - Click a point.
   - Enter the desired length and press Enter.
   - Use a second entity snap tracking point, then move the cursor to the intersection of the parallel tracking line and the second entity snap tracking line.

Geometric Relations

When dragging a grip (1.32.3) of a line, polyline, arc or a circle the geometric relation (perpendicular or tangent) of the entity being edited with crossing or nearby other lines, polylines, arcs or circles is indicated. A snap marker displays and the other entity highlights when the current position of the dragged entity is perpendicular or tangent within the distance defined by the APERTURE (1.17.10) system variable. This feature is controlled by the GEOMRELATIONS (1.17.10) system variable. In the images below the red grip of the line is dragged. Depending on the position of the dragged grip the line is nearly perpendicular to the other line (top) or the circle (middle) or tangent to the circle (bottom). Click when the desired position is reached. (1.547 on the next page) (1.548 on the facing page) (1.549 on page 636)

Figure 1.547

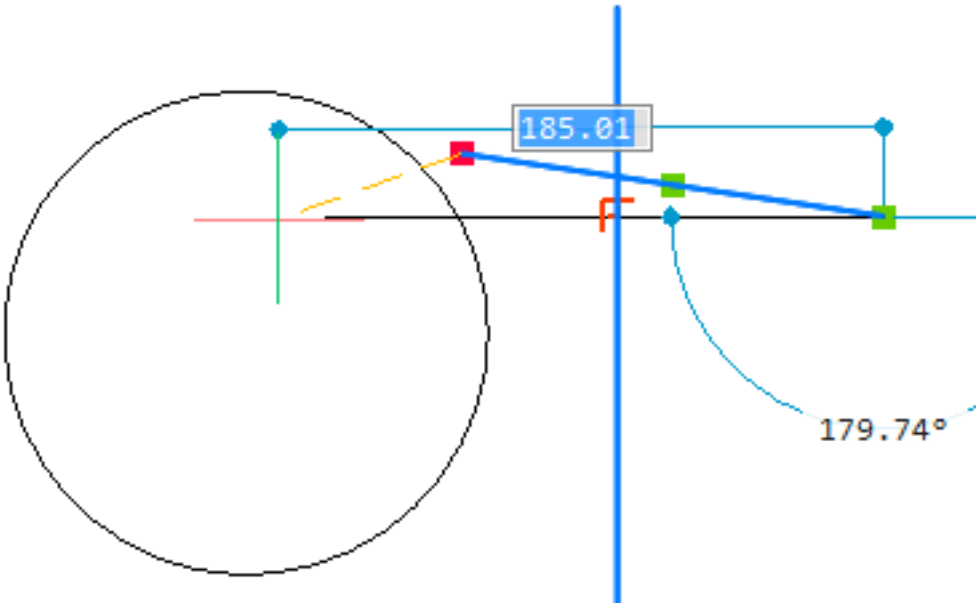


Figure 1.548

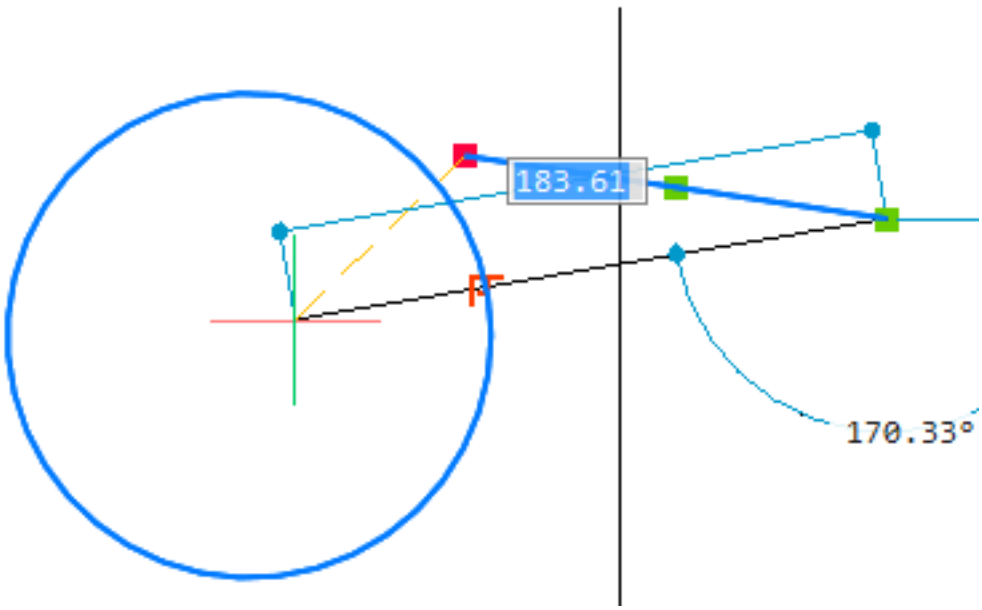

Figure 1.549

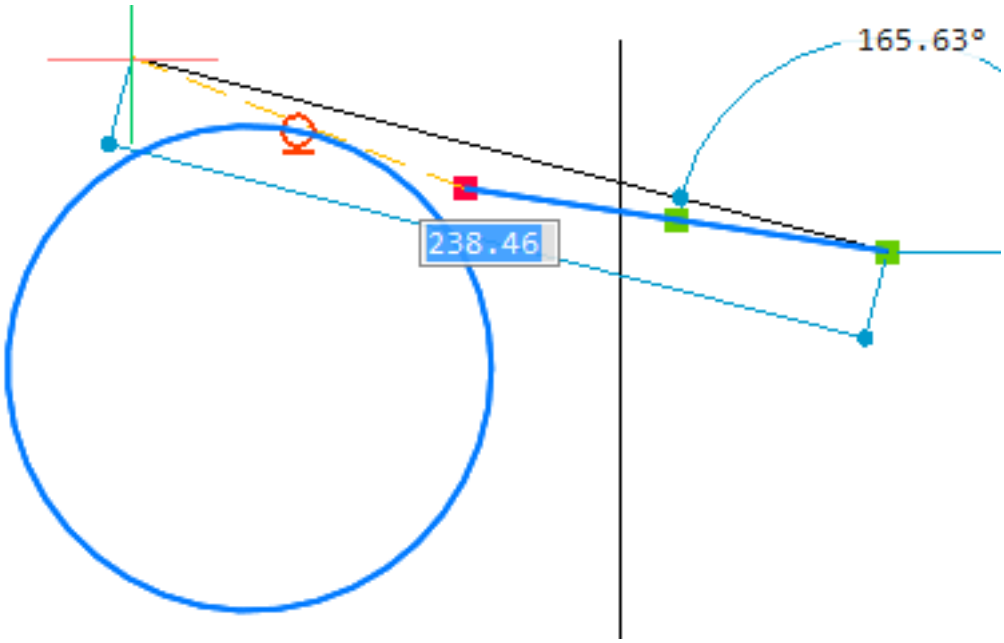

Figure 1.550

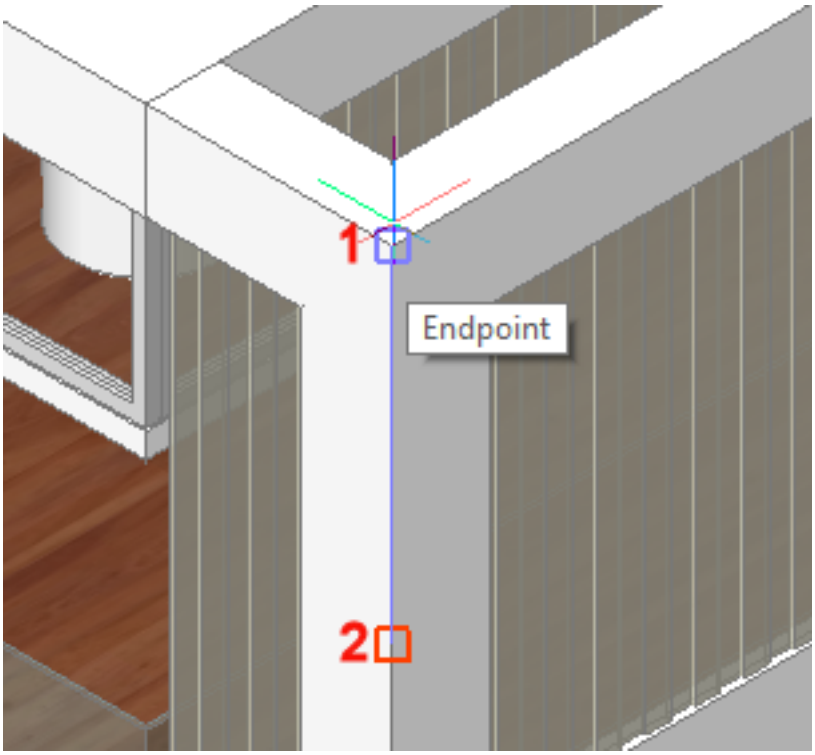

1.21.16 3D Entity Snaps

Commands: 3DOSNAP (6.3.8), -3DOSNAP (6.3.11), ZCENTER (6.35.1), ZINTERSECTION (6.35.2), ZKNOT (6.35.3), ZMIDPOINT (6.35.4), ZNEAREST (6.35.5), ZNONE (6.35.6), ZPERPENDICULAR (6.35.8), ZVERTEX (6.35.9) In addition to the 2D Entity Snaps (1.21.15), a series of 3D entity snap modes apply to points on 3D entities such as solids, surfaces, splines and meshes. The current 3D Entity Snap modes are saved through the 3DOSMODE system variable as the sum of the bitcodes of the selected snap modes.

Name	Icon	Marker	Description
Center			Snaps to the center of 3D faces.
Intersection			Snaps to the intersections of linear entities, edges, and polar or entity snap tracking lines with faces.
Knot			Snaps to knots (fit points) on splines (6.27.63).
Midpoint			Snaps to the midpoint of a face edge.
Nearest			Snaps to a point on the face of a 3D entity that is nearest to the cursor.
None			Disables all 3D snap modes.
Perpendicular			Snaps to a point perpendicular to a face on a 3D entity.
Vertex			Snaps to the closest vertex of a 3D entity and the control vertices of splines (6.27.63).
Point Cloud			Snaps to point cloud points.

To set the 3D Entity Snap modes

- Click the buttons on the **3D Entity Snaps** toolbar. The buttons of the currently active entity snap modes are pressed. (6.29 on page 3363)
  - When no command is running clicking a tool button toggles the snap mode on/off.
  - When executing a command clicking a tool button sets the snap mode for the next point, temporarily disabling all other selected snap modes.
- Run the 3DSONAP (6.3.8) or -3DOSNAP (6.3.11) the commands.
- Shift + Right click, then hover over **3d Entity Snap** and click the 3D entity snap option. (1.552 on the next page)

Figure 1.551

Figure 1.552

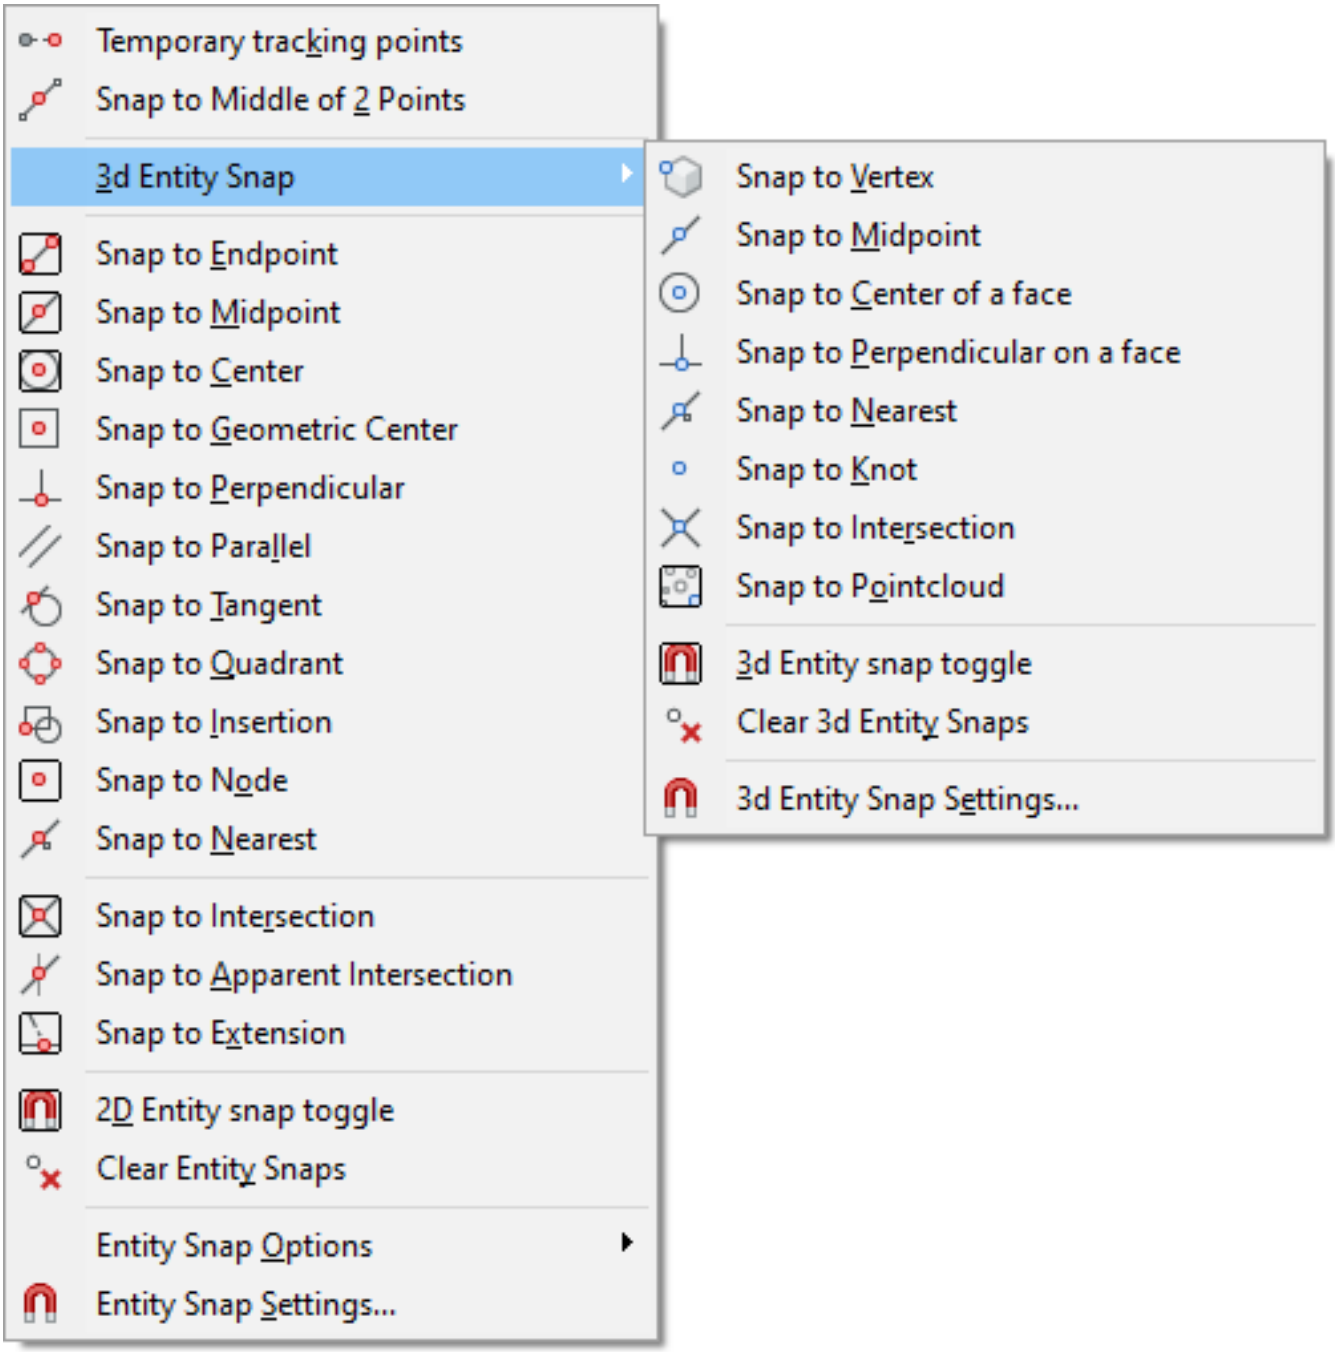

Figure 1.553

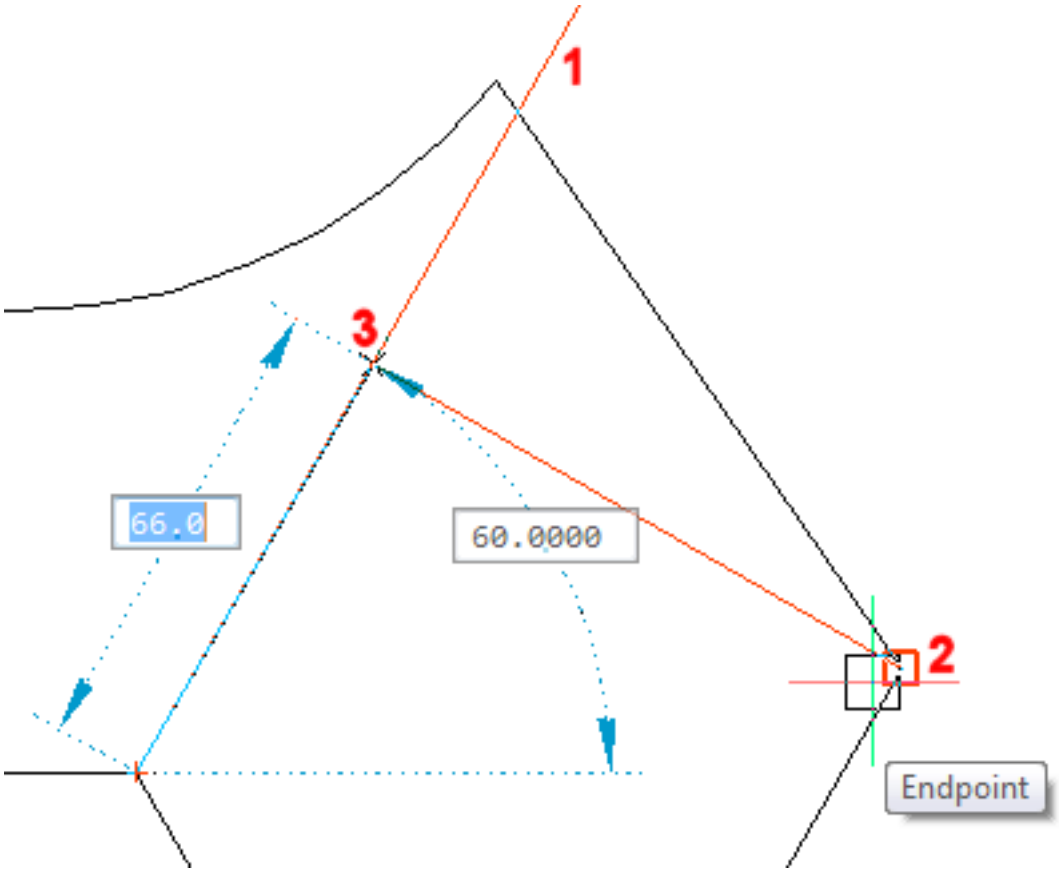


1.21.17 Entity Snap Tracking

Entity Snap Tracking assists you to draw entities with respect to other entities. When **Entity Snap Tracking** is turned on, BricsCAD displays temporary alignments based on entity snap points. **Entity Snap Tracking** works in combination with **Entity Snap** tools. At least one **Entity Snap** mode must be on if you want to use **Entity Snap Tracking.** Click the **STRACK** field in the Status bar (1.15.2) to enable/disable **Entity Snap Tracking** . **Entity Snap Tracking** alignments are parallel to the X- and Y-axis of the current UCS by default. If the Polar mode > (1.21.18) 0x0002 setting is checked, the polar angles used in Polar Tracking (1.21.18) (interval and additional angles) are also used in **Entity Snap Tracking** . Alignment points are acquired when you hover over a point, using entity snaps. Acquired points display a small plus sign (+). To remove an acquired point, hover over the point again. The small plus sign (+) is then removed. If the Polar mode > (1.21.18) 0x0008 is checked, you must press and hold the Shift key to acquire entity tracking points. Alignments relative to an acquired point are displayed as you move the cursor over their tracking paths. You can then define points either on the alignments or at the intersection of two alignments. Esnap track markers: to distinguish between regular esnap markers and markers drawn together with related snap tracking lines, esnap track markers display in the color of the tracking lines. Hitting the Shift key when a tracking line displays, locks the tracking line. Locked tracking lines display in red (1). Entity snaps (2) or specified points are projected perpendicularly onto the tracking line (3). Hit the Shift key again to unlock a tracking line. (1.553) More options with locked tracking lines are:

- If the Intersection entity snap is active, it is possible to snap to the intersections of a locked tracking line and entities in the drawing.
- Acquire additional tracking lines and snap to the locations where these intersect with the locked tracking line.

Using Entity Snap Tracking

1. Launch a drawing tool, e.g. **Draw Line** .
2. Hover the cursor over the first tracking point (1). A small plus sign (+) displays to indicate the tracking point is active.
3. Hover the cursor over the second tracking point (2) A small plus sign (+) displays to indicate the tracking point is active.

4. Move the cursor close to position 4.

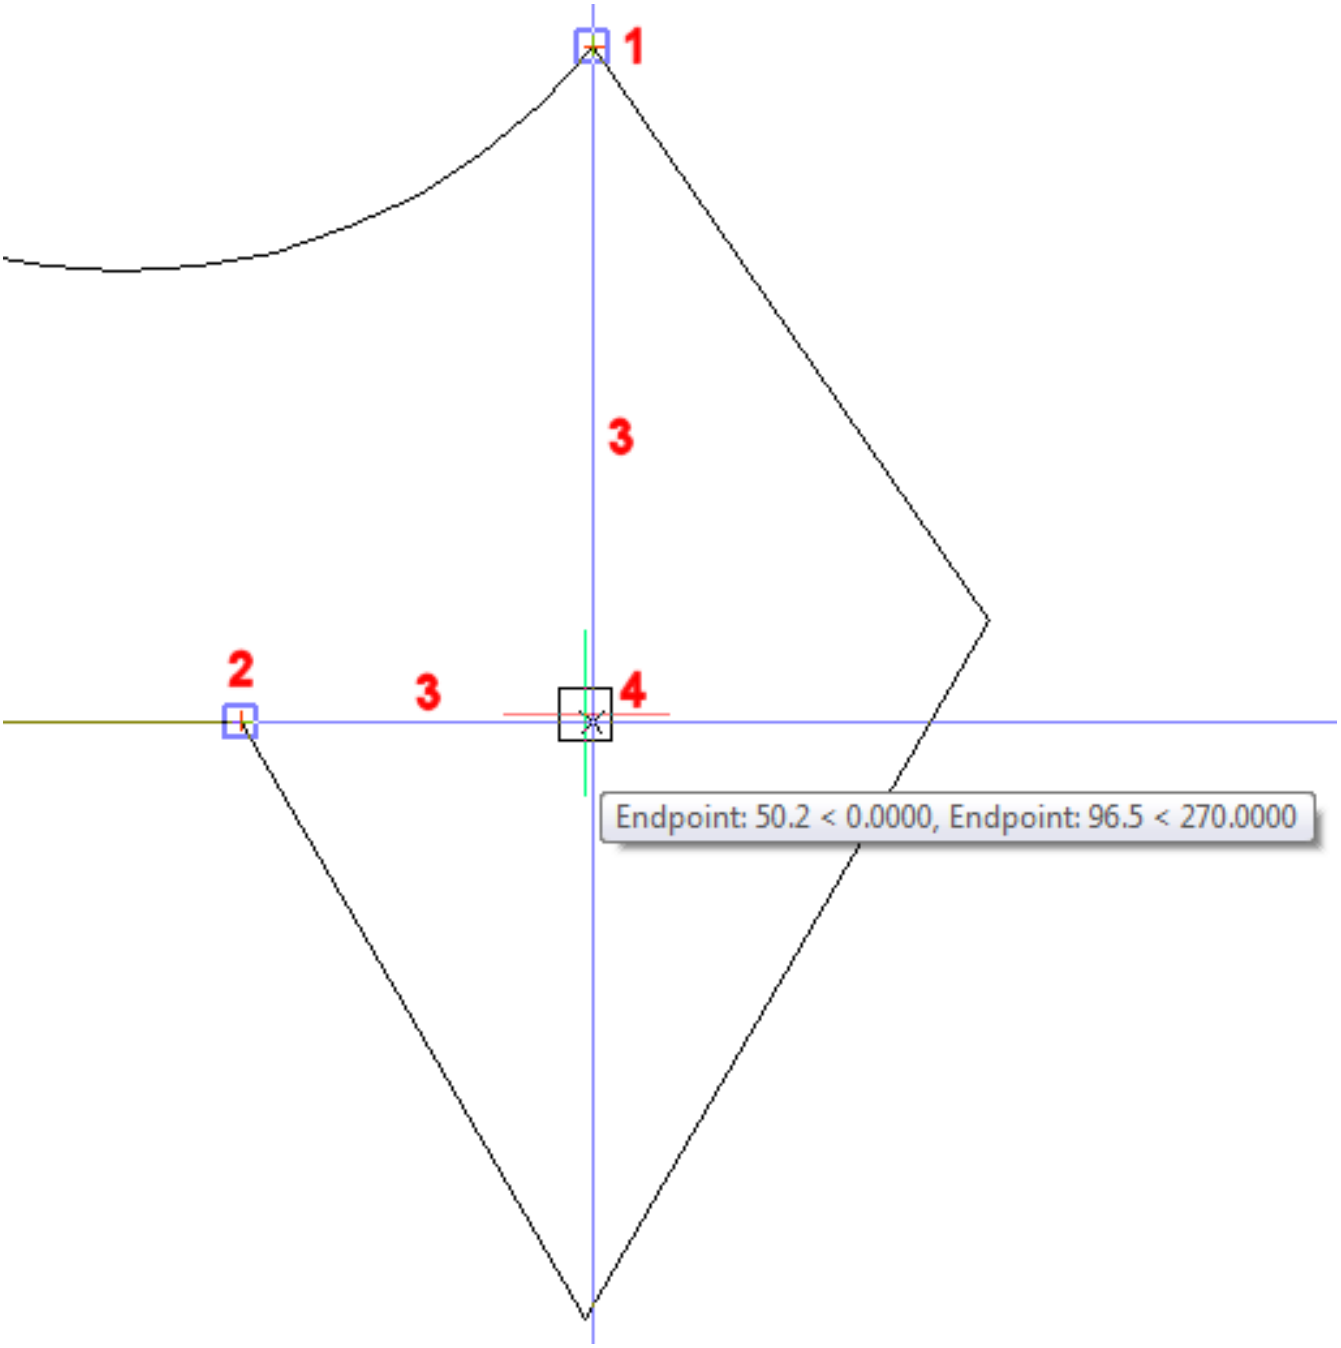
   - Tracking lines display from both tracking points (3).
   - A cross marker (X) indicates the intersection of the tracking lines.
   - Snap markers display at the tracking points.
   - An **Entity Snap Tracking** tooltip at the intersection of the tracking lines shows the angles and distances from the tracking points.

   (1.554 on the next page)

5. Click to accept the **Entity Snap Tracking** point.

Tutorial: Drawing Accurately: Snap and Grid Click here (1.14.1) to watch

Figure 1.554



1.21.18 Polar Tracking

Tutorial: Drawing Accurately : Polar and Snap Tracking Click here (1.14.2) to watch Polar tracking assists you to draw at exact angles:

- at fixed intervals, starting from 3 O'clock (or East)
- at specific additional angles

A polar tracking path line displays from the origin point when you move the cursor close to one of the polar tracking angles. The tracking path lines display as long as the **Snap Aperture** box overlaps the polar tracking line. In 3D views an additional tracking line displays parallel to the Z-axis of the current UCS. Snap track lock: to lock a snap track path hit the Shift key. To unlock a track path, hit Shift again: it works as a toggle. Locked tracking paths display in the **color defined by the** SnapMarkerColor (1.17.10) user preference..

NOTE	The display of the tracking path line is controlled through the **TRACKPATH** system variable. The color of the tracking path line is controlled through the **AutoTrackingVecColor** user preference. Tracking paths parallel to the X-, Y- or Z-axis of the current coordinate system (WCS or UCS) display in the color of the axis they are parallel with (defined by **COLORX** , **COLORY** or **COLORZ** variables)..

To define the Polar Tracking settings

1. Do one of the following:
   - Right click on the **POLAR** field in the Status Bar (1.15.2), then right click and choose **Settings** in the context menu.
   - Open the **Settings** dialog, then expand the **Coordinate input** sub-category under **Drafting** in the **Drawing** settings class. Expand the **Snap Tracking** settings group. **(1.555 on the facing page)**
2. Adjust the settings:
   - 1: Autosnap marker: If checked displays markers at the snapped locations.
   - 2: Autosnap tooltips: If checked tooltips display.
   - 4: Autosnap magnet (not used, required for AutoCad® compatibility only)
   - 8: Polar tracking: If checked, **Polar Tracking** is on.
   - 16: Entity snap tracking: If checked, **Object Snap Tracking** is on.
   - 32: Tooltips: If checked, tooltips display for polar tracking and entity snap tracking.
3. Polar angle: Sets the polar angle increment.
4. Polar add angles: Sets the additional polar angles. Separate angles by semicolons.
5. Polar mode: Controles the behavior of Polar Tracking.
   - 1: If checked, polar angles are measured relatively from selected entities.
   - 2: If checked, the polar angles (interval and additional angles) are also used in entity snap tracking.
   - 4: If checked, the additional angles for polar tracking are used.
   - 8: If checked, press and hold the Shift key to acquire entity tracking points.
6. Track path: Controls the display of the polar and entity snap tracking paths. (1.556 on the next page)

Do not display polar tracking path
Do not display polar or object snap tracking paths

Using Polar Tracking to draw a line

1. (option) Check the **Polar Tracking** settings.
2. (option) If not already on, click the POLAR field in the Status Bar (1.15.2).
3. Launch the Draw Line (6.20.31) tool.
4. Specify the start point of the line. Polar tracking lines display at the specified intervals and additional angles. If the cursor is on or next to a tracking line:
   - The current distance and angle from the start point display next to the cursor when
   - A cross marker (X) indicates the current point.
5. When the appropriate tracking line displays, do one of the following to define the endpoint of the line:
   - Click when the cursor is at the desired position.
   - Type the length of the line in the command bar and press Enter.

Note: Turning on **Polar Tracking** automatically disables Orthogonal Mode (1.21.2).

Using Snap Track Lock

Hit the Shift key while a snap track marker line is displayed to lock a tracking path, any (snap)point that is picked will be projected perpendicularly onto the tracking path. Hit the Shift key again to unlock. A locked tracking path changes to the color defined by the SnapMarkerColor (1.17.10) user preference.

Using temporary tracking points

When **Polar Tracking** is ON, temporary tracking points can be used to pick points at locations where no existing geometry is available to snap directly to, while you know the desired offset distance(s) from snap points on existing geometry in the neighborhood. **TT option: whenever prompted to enter a point, type TT** on the command line, then press Enter to define a single temporary tracking point. After the tracking point has been picked, normal command execution continues. Repeat typing **TT** to enter additional temporary tracking points. **TK option** : whenever prompted to enter a point, type **TK** on the command line, then press Enter to define one or more temporary tracking points. When eventually the desired location has been reached, enter the point by pressing the Right Mouse button or the Enter key.

Using the TT option

1. Launch a draw command, e.g. Line. You are prompted: ENTER to use last point/Follow/<Start of line>:
2. Type **TT** in the command bar, then right click or press Enter. You are prompted: Specify temporary tracking point:
3. Use an Entity Snap (1.21.15) to pick a point on existing geometry. A small red cross indicates the temporary tracking point.
4. Move the cursor in the desired direction. Depending on the value of the POLARANG (1.17.10) and POLARADDANG (1.17.10) system variables tracking lines display from the first temporary tracking point.
5. When a tracking line in the appropriate direction displays, type the distance from the temporary tracking point.
6. Specify the endpoint of the line.

Using the TK option

1. Launch a draw command, e.g. Line. You are prompted: ENTER to use last point/Follow/<Start of line>:
2. Type **TK** in the command bar, then right click or press Enter. You are prompted: Specify first temporary tracking point:
3. Use an Entity Snap (1.21.15) to pick a point on existing geometry. A small red cross indicates the temporary tracking point. You are prompted: Specify next temporary tracking point (press ENTER to end):
4. Move the cursor in the desired direction. Depending on the value of the POLARANG (1.17.10) and POLARADDANG (1.17.10) system variables tracking lines display from the first temporary tracking point.

5. When a tracking line in the appropriate direction displays, type the distance from the temporary tracking point. A small red cross indicates the second temporary tracking point. You are prompted: Specify next temporary tracking point (press ENTER to end):
6. Do one of the following:
7. Right click or press Enter to accept the second tracking point as the start point of the line.
8. Repeat steps 4 and 5 until the desired point is specified, then right click or press Enter to accept the point.
9. Specify the endpoint of the line.

1.21.19 Measuring

Commands: DIST (6.10.36), AREA (6.4.18), MASSPROP (6.21.2), ID (6.17.4) and LIST (6.20.34) The **Dist** command reports the distance and angle between two points. The **Area** command finds the area and perimeter (or length) of 2D entities. The **Massprop** command reports the area, perimeter, and other mathematical properties of 3D solids and 2D regions (short for "mass properties"). The **ID** command reports the x,y,z coordinates of picked points. The **List** command lists the properties of selected entities.

Measuring distances

To measure a distance between two points:

1. Do one of the following:

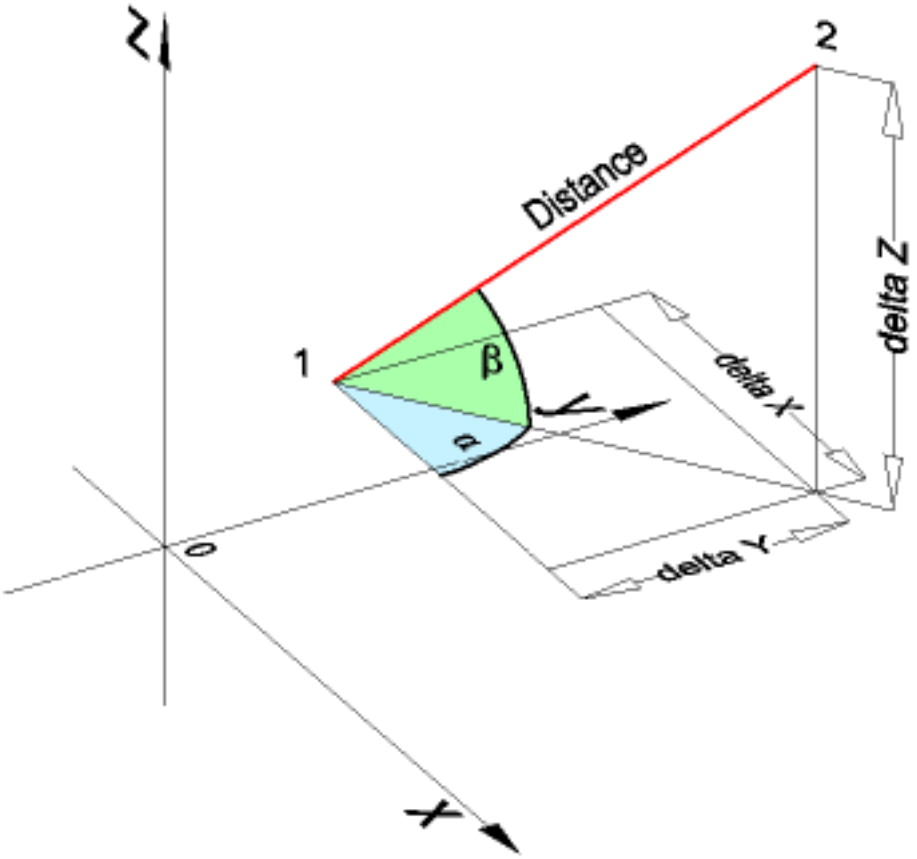
   - Click the **Distance** tool button () on the Inquiry toolbar.
   - Type **dist** in the command bar and press Enter.

   You are prompted: Starting point for distance.

2. Identify the first point. You are prompted: End point.

3. Identify the second point. If DRAGSNAP (1.21.15) = 1, the distance displays in the dynamic dimension (1.21.9) field. The following information displays in the command bar (see image below): Distance, Angle in XY Plane (alpha), Angle from XY Plane (beta), Delta X, Delta Y, Delta Z. The values are calculated with respect to the current **coordinate system**. (1.557 on the facing page)

Figure 1.557



Measuring lengths

To measure the length of single linear entity, click the entity then read the **Length** field in the **Properties Bar**. To add the lengths of a series of linear entities:

1. Do one of the following:

   - Click the **Area** tool button ( ) on the Inquiry toolbar.
   - Type area in the command bar and press Enter.

   You are prompted: Entity/Add/Subtract/<First point>: A prompt menu displays: (1.560 on the next page)

2. Do one of the following:

   - Choose **Add areas together** in the prompt menu.
   - Type **A** in the command bar and press Enter.

   You are prompted: Adding: Entity/Subtract/<First point>: A prompt menu displays: (1.561 on page 649)

3. Do one of the following:

Figure 1.558

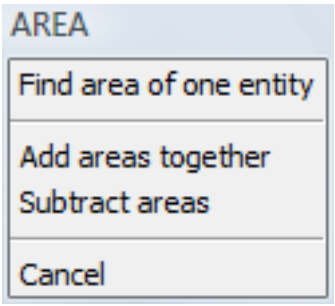


Figure 1.559

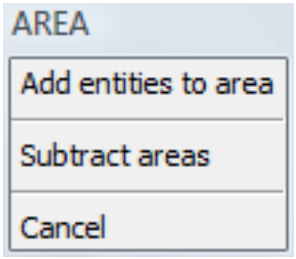

- Choose **Add entities to area** in the prompt menu.
- Type **E** in the command bar and press Enter.

You are prompted: Adding area<Select entities>:

4. Click the first entity. The area and length of the first entity display in the command bar. You are prompted: Adding area<Select entities>:

5. Click the second entity. The area and length of the second entity and the total area and total length display in the command bar. Optionally press the **F2** function key to display the Prompt History window; press **F2** again to close the Prompt History window. You are prompted: Adding area<Select entities>:

6. Repeat step 5 to add more entities or press the **Esc** key to stop.

Measuring areas

To measure the area and length of single closed entity, click the entity then read the **Area** and **Length** fields in the **Properties Bar**. To measure areas and perimeters by specifying points in a drawing:

1. Do one of the following:

   - Click the **Area** tool button ( ) on the Inquiry toolbar.
   - Type area in the command bar and press Enter.

   You are prompted: Entity/Add/Subtract/<First point>: A prompt menu displays: (1.560)

2. Do one of the following:

   - Choose **Add areas together** in the prompt menu.
   - Type **A** in the command bar and press Enter.

   You are prompted: Adding: Entity/Subtract/<First point>: A prompt menu displays: (1.561 on the facing page)

3. Click the first corner point of the area. A dashed line displays dynamically from the first corner point. You are prompted: Adding: <Next point>:

4. Click the second corner point of the area. A dashed polygon displays dynamically, indicating the currently defined area. You are prompted: Adding: <Next point>:

5. Click the third corner point of the area. You are prompted: Adding: <Next point>:

Figure 1.560

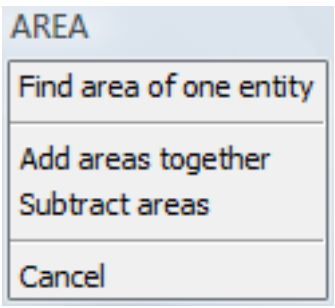

Figure 1.561

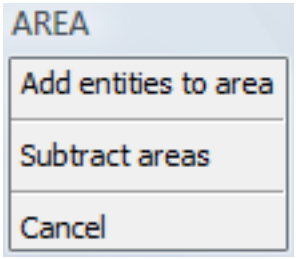

6. Repeat step 5 to add more corner points or Right click to stop adding corner points. The **Total length** and **Total area** display in the command bar. Optionally press the **F2** function key to display the Prompt History window; press **F2** again to close the Prompt History window.

7. Do one of the following:
   - Repeat steps 3 through 6 to add another area.
   - Press the **Esc** key to stop.

1.21.20 Dynamic UCS

With the Dynamic UCS feature enabled, the coordinate system is aligned automatically with the entity under the cursor. The UCSDETECT (1.17.10) system variable controls the supported entity types:

- **1** : faces of 3d Solids (the default)
- **2 :** other entity types: point, line, polyline, 2D polyline, 3D polyline, ray, xline, arc, circle, ellipse, spline, text, mtext, solid, 3Dface, trace, block insert, viewport, mline, leader, mleader, hatch, helix, camera, light, section, shape, pdf underlay and image.

UCSDETECT is an integer type with values in the range [-3;3]. The DUCS status bar control (1.15.2) allows toggle the feature and to select the supported entity types. This feature is controlled by system variables.

- The RedHilite_DUCSLocked_Face_Color (1.17.10) user preference controls the highlight color for the face to which the Dynamic UCS has been locked by pressing the Shift key.
- The RedHilite_DUCSLocked_Face_Alpha (1.17.10) user preference controls the highlight transparency for the face to which the Dynamic UCS has been locked by pressing the Shift key.

To toggle the dynamic UCS

Do one of the following:

- Press the **F6** function key.
- Click the **DUCS** field in the status bar. (1.15.2)

Using the Dynamic UCS

1. With the Dynamic UCS feature active, launch an entity creation command, e.g. Draw.
2. Move the cursor over an entity or 3D solid face.

   - The entity or face highlights.
   - If ON, the grid is aligned with the hovered entity or face.
   - If UCSICON (1.17.10) = 3 (On at Origin), the UCS icon displays. (1.562 on the next page)
   - The dynamic UCS is oriented depending on how the cursor touches the hovered entity or face, thus providing users a way to manipulate the orientation of the DUCS. On 3D solid faces the origin of the DUCS is set to the start point of the solid edge and the X-axis is chosen codirectional to the tangent at the start point of the edge. On curved faces, the the X-acis is tangent to the face, the Y-axis lies in the face and the Z-axis is perpendicular to the face.

3. (option) Tap the Shift key to lock the DUCS, which allows you to start drawing outside the hovered entity or face. Tap the Shift key again to unlock the DUCS.
4. Pick a point to start drawing.
5. When the drawing command concludes, the WCS or previously defined UCS is restored.

Tutorial: DUCS on Curved Surfaces Click here (1.18.28) to watch

Figure 1.562

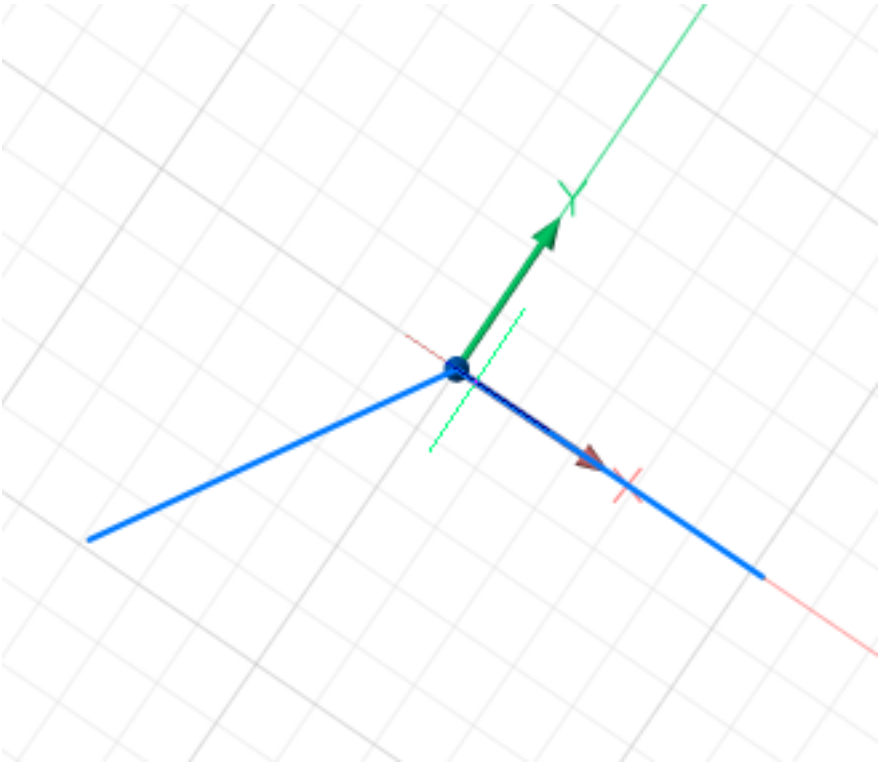

Figure 1.563

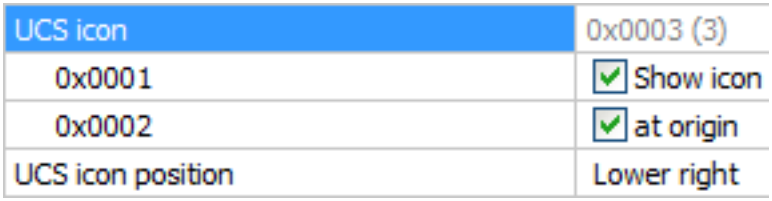


1.21.21 User Coordinate Systems

When you create entities in a drawing, they are located in relation to the drawing's underlying Cartesian coordinate system. The **ELEVATION** system variable specifies the distance from the xy-plane of the current coordinate system. If **ELEVATION** = 0 (zero), entities are created in the xy-plane of the current coordinate system. Every drawing has a fixed coordinate system called the World Coordinate System (WCS). You can also define arbitrary coordinate systems located anywhere in three-dimensional space. These are called user coordinate systems (UCS) and can be located anywhere in the WCS and oriented in any direction. You can create as many UCS as you want, saving or redefining them to help you construct three-dimensional entities. By defining a UCS within the WCS, you can simplify the creation of most three-dimensional entities into combinations of two-dimensional entities. When you create a new drawing the WCS is the current coordinate system by default, which is indicated by the letter W in the UCS icon. When you display a drawing in plan view, you see the coordinate system icon from the top, with the z-axis directed straight toward you. When you display a three-dimensional drawing in a view other than plan view, the coordinate system icon changes to reflect your new viewpoint. **Note:** You cannot delete or modify the WCS. To help you keep your bearings in the current coordinate system, BricsCAD displays a coordinate system icon (UCS icon). The visible portions of the axes are the positive directions. **2D Wireframe visual style** (1.566 on page 655) (1.567 on page 656) (1.568 on page 656) (1.569 on page 656) WCS Top View UCS Top View WCS Isometric View UCS Isometric View **Rendered Visual Styles** (1.571 on page 657) (1.571 on page 657) (1.572 on page 657) (1.573 on page 657) Three colors represent the three axes, making it easier for you to recognize the orientation in three-dimensional space:

- x-axis: red
- y-axis: green
- z-axis: blue

The colors of the axes are controlled by the COLORX (1.17.10), COLORY (1.17.10) and COLORZ (1.17.10) system variables. The Plan View (6.24.26) command restores the Plan view or Top view of the current UCS or WCS. The **UCSICON** settings variable controls the display and location of the UCS icon: (1.563) **Show icon** : Controls whether the icon shows or not. **At origin** : Controls the location of the UCS icon: if on, the icon indicates the origin point of the current coordinate system (UCS or WCS). However, if the origin is not within the viewport borders, the UCS icon moves to the corner of the viewport, as defined by the **UCSICONPOS** (UCS Icon Position) settings variable. When the **at origin** option is not checked, the icon always displays in the corner of the viewport defined by **UCSICONPOS**.

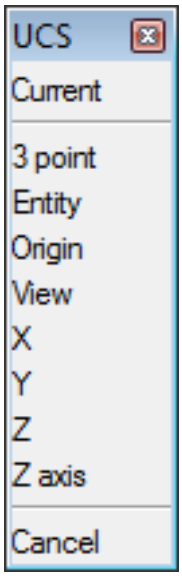
To move the origin of the current coordinate system

1. Type **ucs** at the command prompt. You are prompted: Specify origin of UCS or [Face/NAmed/Entity/Previous/View/X/Y/Z/Axis/Move/World] <World>:
2. Identify the new origin, then press Enter to confirm.

To define a User Coordinate System

1. Choose **Drawing Explorer > Coordinate Systems** in the **Tools** menu. The **Drawing Explorer - Coordinate Systems** dialog opens.
2. Click the **New** tool button ( ) on the **Drawing Explorer** dialog. The **BricsCAD Explore** dialog closes. **You are prompted**: Current/Entity/Origin/View/X/Y/Z/ZAxis;3point;:; A prompt menu displays: (1.564 on the next page)
3. Press Enter to define the UCS using points. You are prompted: New origin <current origin>:
4. Specify the origin point of the UCS. You are prompted: Point of positive X axis <current point>:
5. Specify a point to define the positive X-axis. The command window reads: Point in X-Y plane with positive Y value <current point>:

Figure 1.564



6. Specify a point to define the positive Y-axis. The UCS is defined. The **BricsCAD Explorer** dialog reopens.
7. Click in the **UCS Name** field of the newly defined UCS to replace the <NewUCS> default name.
8. Close the **BricsCAD Explorer** dialog.

Command Options

See the EXPUCS (6.13.24) and UCS (6.30.1) commands.

To restore the WCS

1. Type **UCS** in the command bar, then press Enter. You are prompted: ?/3point/Delete/Entity/Origin/Previous/Restore/Sa
   A prompt menu displays.
2. Do one of the following:
3. Press Enter to accept the default option.
4. Choose **World** in the prompt menu.
5. Type **W** in the command bar and press Enter.

To restore a UCS

1. Choose **Drawing Explorer > Coordinate Systems** in the **Tools** menu. The **Drawing Explorer - Coordinate Systems** dialog opens.
2. Click the blank tile in front of the UCS name to make it current.
3. Close the **BricsCAD Explorer** dialog.

Note: If no UCS is marked, the WCS is the current coordinate system.

To set a relative UCS

1. Do one of the following:
   - Click the **UCS...** tool button ( ) on the **Settings** toolbar.
   - Choose **UCS...** in the **Settings** menu.

   The **User Coordinate System** dialog opens. (1.565 on the following page)
2. Choose one of the following:
   - Set the selected UCS relative to the **Current UCS** .
   - Set the selected UCS relative to the **World coordinate system (WCS)** .
3. (option) Enable the **Change view to plan view of the selected UCS** option.
4. Click one of the **Planar UCS's** buttons. The User Coordinate System dialog closes.

NOTES

- If the UCSORTHO (1.17.10) system variable is ON an orthographic UCS is restored automatically when the related orthographic view is restored by the -VIEW (6.31.3) command or selected on the Look From (1.23.7) control. An orthographic UCS has its origin at the WCS origin.
- The UCSVP (1.17.10) (UCS viewports) system variable controls whether the UCS in a viewport is fixed (UCSVP = ON) or changes to match the UCS in the current viewport (UCSVP = Off). As a result, in a multiple viewport drawing, the UCS of all viewports that have UCSVP = Off matches the orthographic UCS of the current viewport if UCSORTHO = On.

Command Options

See the SETUCS (6.27.26) command.

1.22 Printing & Plotting

1.22.1 Output As Pdf

https://www.youtube-nocookie.com/embed/ASdk3O07T48

How to save single drawings or groups of drawings in PDF format.

PDF is the most popular way to view drawings, because they can be viewed on just about any computer or mobile device today. PDF allows viewing in a way that can't be edited. BricsCAD provides two ways to convert drawings to PDF: 1) One drawing at a time through the Export command 2) Groups of drawings through the Publish command. This video shows you both approaches. Back to Tutorial Overview

1.22.2 Paper Space Layouts in BricsCAD

https://www.youtube-nocookie.com/embed/tIwY8xao-Q0

Creating Paper Space Layouts in BricsCAD

Why use paper space? Here's the #1 Rule of CAD: all geometry gets created at full (1:1) scale. You draw in model space (MSPACE), and you can use the VPORTS command to create different views of your drawing / model on the screen. This is a great strategy when you're creating a drawing. It's not so easy when you need to fit your finished drawings into a standard sized title block. Yes, it is possible to create a drawing in model space and make it fit on a printed page. But why? **Using paper space (PSPACE) is the correct way to create accurate, reusable drawing layouts!** Creating drawing sheet layouts is super easy in paper space. In this short video by CAD expert Ralph Grabowski, you'll get started creating layouts that update automatically as your model geometry changes. This alone is a huge reason to use PSPACE. Think of a layout as a scale-able, zoom-able set of windows ("viewports") that help you see your model from different points in space. You can control the view, the scale, the orientation and the properties of each viewport in a layout. Ralph's video starts simply, helping you create and move viewports in a new layout tab. Next, you'll see how to change what you see in each new viewport. Then, he'll show you how you can modify, scale or change the properties of each individual viewport in a layout tab. You'll use visual styles to change the way that your drawing is displayed in each PSPACE viewport. Then, he will show you how to non-rectangular and clipped viewports, how to turn any closed entity into a viewport border and how to hide viewport boundaries using LAYERs. Back to Tutorial Overview

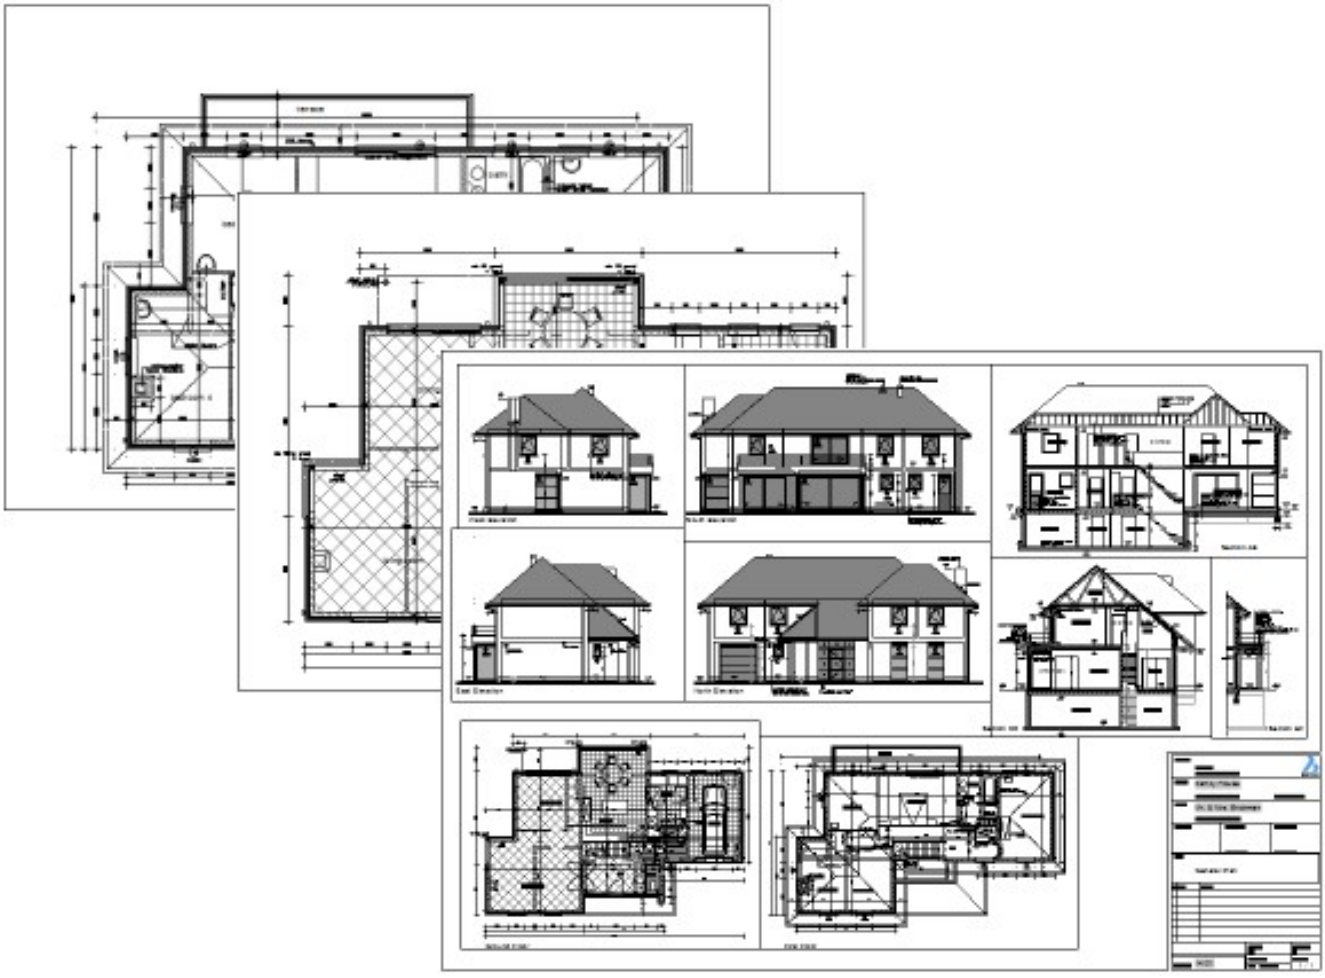
1.22.3 Printing in BricsCAD: Paper Space Layouts

https://www.youtube-nocookie.com/embed/t6zwMl8xmLI This is a four series tutorial about printing in BricsCAD. We'll start with the paper space layouts. Although it is perfectly possible to print a drawing from model space, paper space layouts are especially designed for printing purposes.

Multiple layouts

Each drawing can have multiple layouts, with multiple viewports in each layout. The print settings are controlled by a page setup, while viewports define the portion of the model space to be printed. The layer visibility and scaling can be different for each viewport. (1.574 on the next page)

Figure 1.574



Publish to PDF

Print all layouts in a drawing to a single, multi-page pdf. (1.575 on the facing page) Back to Tutorial Overview

1.22.4 Printing in BricsCAD: Viewports

https://www.youtube-nocookie.com/embed/cGFD_GOuc7w

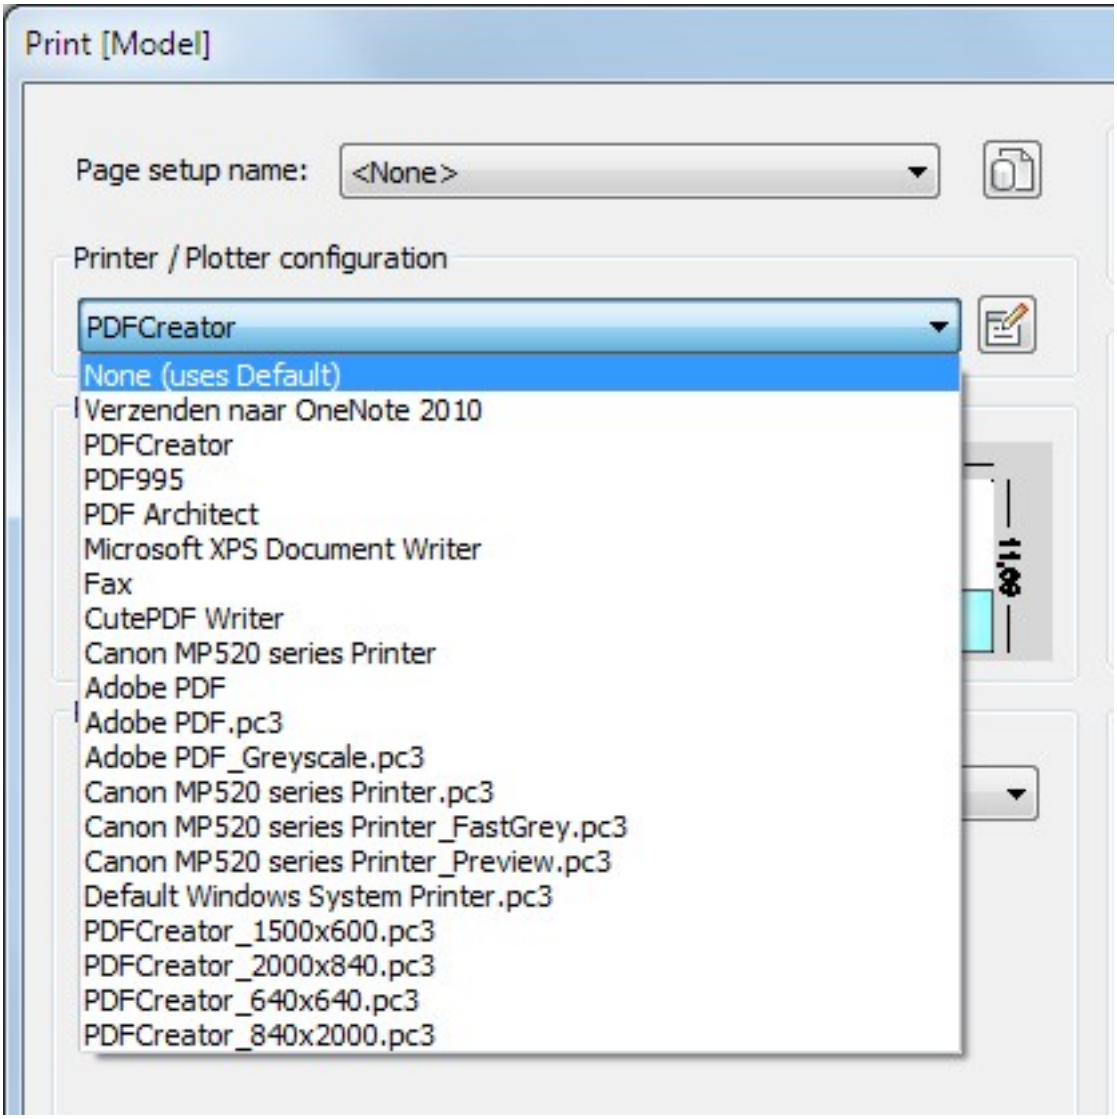
Create page setups and layouts using viewports.

Use page setups to define print settings Page Setups control:

- Printer configuration
- Paper size and orientation
- Plot style table, which specifies how entity colors are used to control color and line weights.

Freeze layers in a viewport In the VPFreeze column of the Drawing Explorer – Layers dialog, select the layers you do not want to be printed in the current viewport. Back to Tutorial Overview

Figure 1.576



1.22.5 Printing in BricsCAD: Plotter Configurations

https://www.youtube-nocookie.com/embed/TqJVK0GE2SY When printing a layout, the available paper sizes and print settings are controlled by a Plotter Configuration File. The Printer/Plotter Configuration list is composed of all printer drivers that are installed on your computer. The Printer Configuration are the files in the folder which is specified by the 'Plotter Configuration Path' user preference. (1.576)

Create a new plotter configuration

To create or edit a Plotter Configuration click the 'Edit Plotter Configuration' button on the Print or Page Setup dialog. (1.577 on the following page)

1.22.6 Creating Plot Stamps

https://www.youtube-nocookie.com/embed/wxbc5RCivms Plot stamps are text that appears on drawings only when plotted. They provide information like the date and time the plot was made, the file name, and so on. BricsCAD adds plot stamps through an option in the Print dialog box. For greater flexibility, however, consider using field text. This video shows you how to use both methods. Back to Tutorial Overview

1.23 Viewing your Drawing

1.23.1 View Commands Overview

BricsCAD provides various tools to control the display and view orientation of your drawing. These tools can be found either in the **View** menu or the **View** toolbar or both.

(1.581 on page 676)
(1.582 on page 676)
(1.583 on page 676)
(1.584 on page 676)

View toolbar and its flyouts

The Look From control (1.23.7)

Icon	Tool name	Command	Description
	Redraw (1.23.4)	REDRAW (6.26.9)	Refreshes the screen display in the current viewport.
	Redraw All (1.23.4)	REDRAWALL (6.26.10)	Refreshes the screen display in all open viewports.
	Regenerate (1.23.4)	REGEN (6.26.23)	Recalculates the screen display in the current viewport.
	Regenerate (1.23.4) All (1.23.4)	REGENALL (6.26.24)	Recalculates the screen display in all open viewports.
	Update Fields (1.29.23)	UPDATEFIELD (6.30.10)	Updates the selected fields.
	Real Time Pan (1.23.8)	RTPAN (6.26.36)	Pans the view dynamically.
	Pan (1.23.8)	PAN (6.24.3)	Pans the view.
	Real Time Zoom (1.23.5)	RTZOOM (6.26.42)	Zooms in/out dynamically.
	Zoom (1.23.5) In (1.23.5)	ZOOM (1.23.5) **+ I(*)**	Zooms in on the center of the window by a factor of 2.
	Zoom Out (1.23.5)	ZOOM (1.23.5) **+ O(*)**	Zooms out from the center of the window by a factor of 1/2.
	Zoom Extents (1.23.5)	ZOOM (1.23.5) + **E(*)**	Displays all the entities in the drawing (referred to as the drawing extents).
	Zoom Window (1.23.5)	ZOOM (1.23.5) **+ W(*)**	You are prompted to pick two corners of a box on the existing view in order to enlarge that area to fill the display.
	Zoom Previous (1.23.5)	ZOOM (1.23.5) **+ P(*)**	Restores the displayed view prior to the current one.

	**Zoom All (1.23.5)**	ZOOM (1.23.5) **+ A(*)**	Displays the whole drawing as far as its drawing limits or drawing extents (whichever is the greater of the two).
	**Zoom Left (1.23.5)**	ZOOM (1.23.5) **+ L(*)**	Pick the lower left corner of the next view, then specify the magnification factor or the view height.
	**Zoom Center (1.23.5)**	ZOOM (1.23.5) **+ C(*)**	Pick the center of the next view, then specify the magnification factor or the view height.
	**Zoom Right (1.23.5)**	ZOOM (1.23.5) **+ R(*)**	Pick the upper right corner of the next view, then specify the magnification factor or the view height.
	Look Around	RTLOOK (6.26.40)	Look around in a 3D scene.
	Look Up and Down	RTUPDOWN (6.26.46)	Move up / down and left / right in a 3D scene.
	Walk	RTWALK (6.26.47)	Walk left / right and forward / backward in a 3D scene.
	Real-Time Constrained Sphere (1.23.7)	RTROT (6.26.37)	Rotates the view dynamically in 3D. • Moving the mouse horizontally (parallel to the screen x-axis) rotates the view about the world z-axis. • Moving the mouse vertically (parallel to the screen y-axis) rotates the screen x-axis.
	Real-Time Sphere Center (1.23.7)	RTROTCTR (6.26.38)	Rotates the view dynamically in 3D about a user-defined center point. Behaves like RTROT.

	Real-Time Free Sphere (1.23.7)	RTROTF (6.26.39)	Rotates the view dynamically in 3D. • Moving the mouse horizontally (parallel to the screen x-axis) rotates the view about the screen y-axis. • Moving the mouse vertically (parallel to the screen y-axis) rotates the view about the screen x-axis.
	Real-Time X (1.23.7)	RTROTX (6.26.50)	Rotates the view dynamically about the screen x-axis.
	Real-Time Y (1.23.7)	RTROTY (6.26.41)	Rotates the view dynamically about the screen y-axis.
	Real-Time Z (1.23.7)	RTROTZ (6.26.44)	Rotates the view dynamically about the screen z-axis.
	Set View Point (1.23.7)	**DDVPOINT (6.10.23)**	Opens the **Preset Viewpoints** dialog.
	Plan View (1.23.7)	PLAN (6.24.26)	Restores the plan view with respect to the WCS, the current UCS or a saved UCS.
	Define View (1.23.15)	DVIEW (6.10.53)	Defines parallel and visual perspective views.
	Save/Restore view (1.23.10)	VIEW (6.31.2)	Saves and restores named views.
	Viewports (1.23.11)	VPORTS (6.31.26)	Manages viewports in model space.
	Paper Space Views (1.23.16)	MVIEW (6.21.37)	Creates viewports in paper space.
	Generate Drafting Views	**BMGENDRAFT**	Generates associative orthographic and standard isometric views of a 3D solid model in a paper space layout.
	Generate Section	**BMGENSECTION**	Creates a cross section view based on a standard drafting view generated by the **BmGenDraft** command in a paper space layout.
===ERROR WITH DOWNLOADED IMAGE===	**2D Context**	**2DCONTEXT**	Switches the drawing to a 2D drafting context.
	3D Context	**3DCONTEXT**	Switches the drawing to a 3D modeling context.

(*) <command> <option>: type zoom followed by Enter, then type the command option letter, followed by Enter.

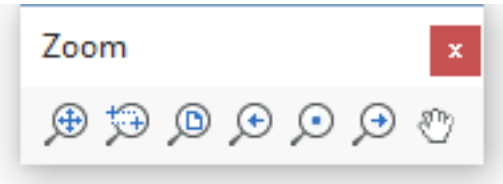

Figure 1.584

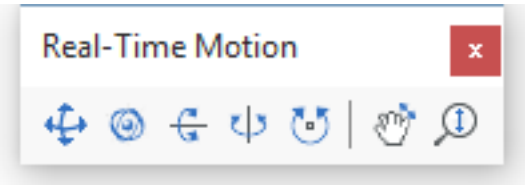

Figure 1.585

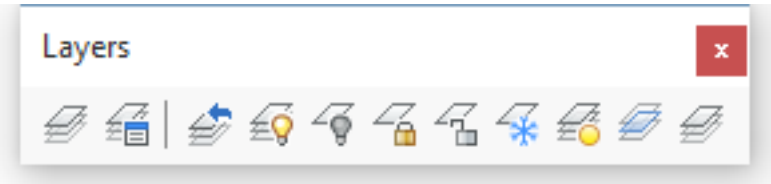


1.23.2 Layer Utilities

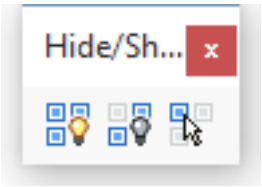
The layer utility commands help you to easily manipulate the **On/Off** , **Thaw/Freeze** and **Unlocked/Locked** layer properties by selecting entities. You can then save the result in a Layer State (1.23.9). (1.585)

Command	Description
LAYON (6.20.13)	Turns on all layers that have been turned off
LAYOFF (6.20.14)	Turns off layers associated with selected entities.
LAYFRZ (6.20.12)	Freezes layers associated with selected entities.
LAYTHW (6.20.16)	Thaws all frozen layers.

LAYLCK (6.20.18)	Locks layers associated with selected entities.
LAYULK (6.20.19)	Unlocks layers associated with selected entities.
LAYISO (6.20.17)	Isolates layers associated with selected entities. If no entity on the current layer is selected, the layer of the entity that is selected first temporarily becomes the current
LAYUNISO (6.20.20)	Restores layers isolated by the LAYISO command.

See also Hide and Show Entities (1.23.3).

1.23.3 Hide and Show Entities



The tools on the **Hide/Show Entities** toolbar allow to temporarily hide or isolate a selection of entities.

Command	Icon	Description
UNISOLATEOBJECTS		Brings back all previously hidden entities.
HIDEOBJECTS		Hides the selected entities.
ISOLATEOBJECTS		Displays the selected entities only.

The OBJECTISOLATIONMODE (1.17.10) system variable controls whether hiding and isolating entities is saved or not. See also Layer Utilities (1.23.2).

1.23.4 Redrawing and Regenerating a Drawing

Commands: REGEN (6.26.23), REGENALL (6.26.24), REGENAUTO (6.26.17), REDRAW (6.26.9) and REDRAWALL (6.26.10) The **Regen** command regenerates the current viewport (short for "regenerate"). The **Regenall** command regenerates all viewports (short for "regenerate all"). The **Regenauto** command controls when BricsCAD regenerates the drawing automatically. The **Redraw** command redraws the current viewport to clean it up. The **Redrawall** command redraws all viewports to clean them up. As a matter of fact the screen display of a drawing is a simplified version of the drawing database. From time to time it is necessary to synchronise the screen display and the drawing database. The **REGENMODE** system variable controls whether BricsCAD regenerates the drawing automatically. You can change the status of **REGENMODE** through the **RegenAuto** command. If **REGENMODE** is ON BricsCAD regenerates the display automatically, but in a few cases a forced regeneration of the drawing might be necessary. This is done by the **Regen** command. Don't confuse the **Regen** command with the **Redraw** command, which simply repaints the screen, without attempting to synchronize the screen display with the drawing database.

Regenerate the current viewport

Do one of the following:

- Click the **Regen** tool button () on the **View** toolbar.
- Choose **Regen** in the **View** menu.
- Type **re** or **regen** in the command bar, then press Enter.

The current viewport is regenerated.

Regenerate all viewports

Do one of the following:

- Click the **Regenall** tool button () on the **View** toolbar.
- Type **rea** or **regenall** in the command bar, then press Enter.

All viewports are regenerated.

Redraw the current viewport

Do one of the following:

- Click the **Redraw** tool button () on the **View** toolbar.
- Choose **Redraw** in the **View** menu.
- Type **r** or **redraw** in the command bar, then press Enter.

The current viewport is refreshed.

Redraw all viewports

Do one of the following:

- Click the **Redraw Al** l tool button () on the **View** toolbar.
- Type **ra** or **redrawall** in the command bar, then press Enter.

All viewports are refreshed.

1.23.5 Zooming

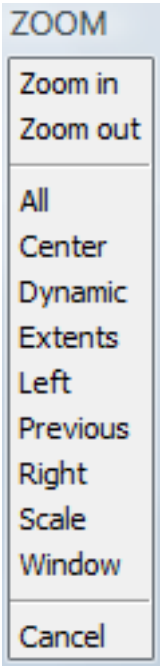
Command: ZOOM (6.35.7) and RTZOOM (6.26.42) The **Zoom** command visually changes the size of the drawing within the current viewport. The **Rtzoom** command zooms the drawing in real-time. You can change the magnification of your drawing at any time by zooming. The cursor changes to a magnifying glass () when a **Zoom** tool is active. Zoom out to reduce the magnification so you can see more of the drawing, or zoom in to increase the magnification so you can see a portion of the drawing in greater detail. Changing the magnification of the drawing affects only the way the drawing is displayed; it has no effect on the dimensions of the entities in your drawing. See also : View manipulation using the mouse (1.23.6).

Using the zoom command

1. Do one of the following:
   - Choose **zoom** in the **View** menu.
   - Type **zoom** in the command bar.
   - Type **Z** in the command bar.

   You are prompted: In/Out/All/Center/Dynamic/Extents/Left/Previous/Right/Window/<Scale(nX/nXP)>: A prompt menu opens: (1.586 on the next page)
2. Do one of the following:
   - Type the zoom factor, followed by **X** . E.g. type **2x** to magnify the display 2 times; typing **0.5x** changes the display to half its original size.
   - In paper space viewports (1.23.16), type the zoom factor followed by **XP** to define the zoom factor relative to the viewport, thus defining the scale of the viewport (1.23.16) content.
   - Pick two corners of a box on the existing view in order to enlarge that area to fill the display.

Figure 1.586



Real-time zooming

1. Do one of the following:

   - Click the **Real-Time Zoom** tool button ( ) in the View toolbar.
   - Type **rtzoom** in the command bar, then press Enter.

   You are prompted: »ENTER, Right click or Esc to complete.

2. Press and hold the left mouse button. Move the mouse forward to zoom in. Move the mouse backward to zoom out.

3. To abort the **Real-Time Zoom** command, do one of the following:

   - Right click.
   - On the keyboard, press Enter, space bar or Esc.

Dynamic zooming

1. Do one of the following:

   - Choose **zoom** in the **View** menu.
   - Type **zoom** in the command bar.
   - Type **Z** in the command bar.

   A prompt menu displays. **You are prompted:**In/Out/All/Center/Dynamic/Extents/Left/Previous/Right/Window/<Scale(r

2. Do one of the following:

   - Choose **Dynamic** in the prompt menu.
   - Type **D** , then press Enter. A view extents or view limits (if larger) is executed first. A view box displays. The original size of the view box matches the size of the previous view. (1.587 on the facing page) A dashed rectangle indicates the area of the previous view.

3. (option) To resize the view box:

   - Click to switch to resize mode. A right pointing arrow indicates you are in resize mode. (1.588 on the next page)
   - Move the mouse to adjust the size.
   - Click to leave resize mode.

Figure 1.587

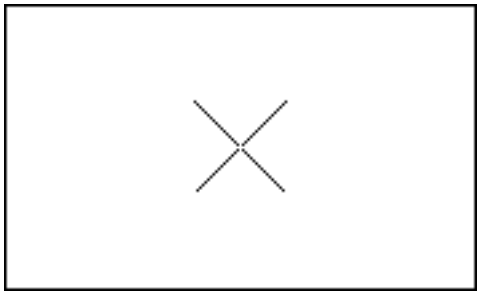


Figure 1.588

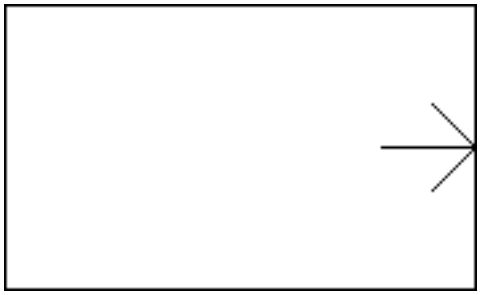


4. Move the view box to the area you want to enlarge, then right click. The drawing is zoomed in on the selected area.
5. Repeat steps 1 through 4 to zoom in on another part of the drawing.

1.23.6 View manipulation using the mouse and keyboard

In BricsCAD you can navigate through a 3D model using the mouse and keyboard shortcuts. In perspective mode (1.23.15) you can walk inside the 3D model. In isometric mode you can only zoom in very close, but not go inside.

Mouse / Key	Action	Result
Wheel	scroll	Zoom in / out. The incremental change in zoom with each mouse-wheel action is controlled through the **Zoom Factor** variable (ZOOMFACTOR (1.23.6)). Default = 60. Values between 3 and 100 are accepted. When zooming in the incremental step decreases gradually allowing to focus on a particularly detail easily. In a 3D model the entity under the cursor has the zoom focus. The ZOOMWHEEL (1.17.10) system variable controls the zoom direction: • 0 or OFF: scrolling forwards zooms in, backwards zooms out. • 1 or ON: scrolling forwards zooms out, backwards zooms in.
Middle Button or wheel (**)	press and hold while moving the mouse	Real-time pan (RTPAN (6.26.36) command)
Middle Button or wheel (**)	double click	Zoom extents
Ctrl + Shift + Left Button	press and hold while moving the mouse	Real-time zoom in / out (RT-ZOOM (6.26.42) command)
Ctrl + Shift + Right Button	press and hold while moving the mouse	Constrained real-time pan (RTPAN (6.26.36) command). Release the Shift key for free panning.
Ctrl + Shift + Middle Button or wheel	press and hold while moving the mouse	Real-time sphere (RTROTF (6.26.39) command)
Shift + Middle Button or wheel	press and hold while moving the mouse	Real-time constrained sphere (RTROT (6.26.37) command)
Ctrl + Right Button	press and hold while moving the mouse	Real-time rotate about the screen Z-axis (RTROTZ (6.26.44) command)
Walk through navigation		
Alt + Left Button	press and hold while moving the mouse	Walk left / right and forward / backward (RTWALK (6.26.47) command)
Alt + Middle Button	press and hold while moving the mouse	Move up / down and left / right (RTUPDOWN (6.26.46) command)
Ctrl + Middle Button	press and hold while moving the mouse	Look around (RTLOOK (6.26.40) command)
Ctrl + Arrow Keys	press the arrow keys while holding the Ctrl key	Walk left / right and forward / backward (RTWALK (6.26.47) command)
Ctrl + Shift + Arrow Keys	press the arrow keys while holding the Alt + Ctrl keys	Look up / down and left / right (RTUPDOWN (6.26.46) command)
Ctrl + Home		Sets the view direction horizontal
Alt + Home		Moves target point to center of scene

Alt + plus/minus	Increase / decrease movement speed
Ctrl + plus/minus	Increase / decrease rotation speed

(**) On condition the **Middle Button Pan** (MBUTTONPAN (1.17.10)) variable is set **ON**.

Setting the Zoom Factor variable

1. Type **zoomfactor** in the command bar, then press Enter. You are prompted: New current value for ZOOMFACTOR (3 to 100) <current value>:
2. Type a value between 3 and 100 in the command bar, then press Enter.

Or

1. In the Settings (1.17.10) dialog, open the **Drawing** category, then expand the **Display/Viewing** sub-category. In the **Viewing** group, select the **ZOOMFACTOR** variable.
2. Type a value between 3 and 100 in the **zoomfactor** field.

NOTE	Increase the zoom factor to speed up scroll wheel zooming in large drawings.

Setting the Middle Button Pan variable

1. Type in **mbuttonpan** the command bar, then press Enter. You are prompted: New current value for MBUTTONPAN (Off or On) <current value>:
2. Type **On** or **Off** in the command bar.

Or

1. In the Settings (1.17.10) dialog, open the **Program Options** category, then expand the **User Preferences** subcategory and select the **MBUTTONPAN** variable.
2. Choose either **Support panning** or **Support action defined in menu file** .

1.23.7 View Rotation

Commands: LOOKFROM (6.20.41), RTROT (6.26.37), RTROTCTR (6.26.38), RTROTF (6.26.39), RTROTX (6.26.50), RTROTY (6.26.41), RTROTZ (6.26.44), DDVPOINT (6.10.23), -VIEW (6.31.3), PLAN (6.24.26), VPOINT (6.31.21), ACTIVATESECTIONVIEW (6.7.5)

- The **LookFrom** command controls the display of the Look From control (1.23.7).
- The **Rtrot** (Real-Time Constrained Sphere) command rotates 3D drawings in real-time.
- The **Rtrotctr** (Real-time Sphere Center) command freely rotates 3D drawings in real-time about a user-defined center point.
- The **Rtrotf** (Real-time Free Sphere) command freely rotates 3D drawings in real-time.
- The **Rtrotx** , **Rtroty** and **Rtrotz** commands rotates 3D drawings in real-time about the x, y or z screen axis.
- The **Ddvpoint** command sets 3D viewpoints or plan view, through a dialog box (short for "dynamic dialog view point").
- The **Plan** command displays the plan viewpoint of drawings.
- The **Vpoint** command changes the 3D viewpoint.
- In order to view your 3D drawings from any angle, you can rotate a view. The **Real-Time Motion** tools of BricsCAD allow you to rotate a view in real-time. You can rotate the view about the X, Y or Z screen axis or in any direction (real-time sphere). If the **Continuous Motion** variable is set, the view rotation continues until you conclude the **Real-Time Motion** command.
- The **ActivateSectionView** command allows to look at a BIM model from a section plane's perspective, without actually generating the section.

See also : View manipulation using the mouse (1.23.6).

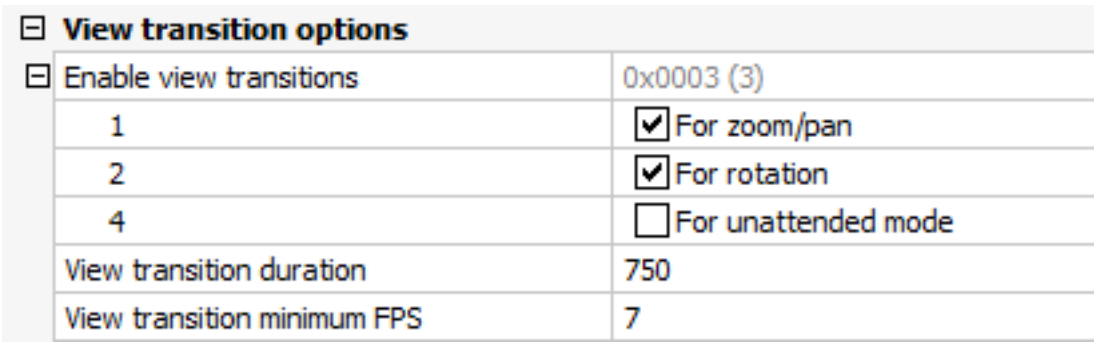
NOTE	'Real-time' commands should not be used when drawing in 2D. Use the Plan View (1.23.7) tool to restore top view.

View Transition options

(1.589)

- VTENABLE: determines whether animated view transitions are enabled for zoom/pan and/or for view rotation operations.
- VTDURATION: determines the duration of view transition animations in milliseconds.
- VTFPS: defines the minimum frame rate required to allow animation. That is 7 by default, which means that the redraw time should take less than 143 (=1000/7) milliseconds. If the computer is not capable to redraw the view fast enough, no animation will be available.

Figure 1.589



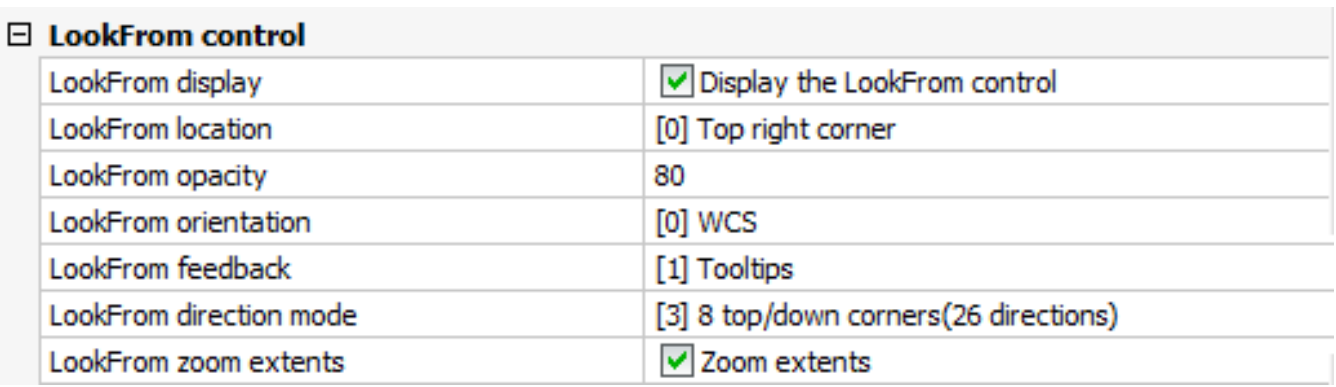
The Look From control

The **Look From** control allows to select a number of preset views such as orthographic views and isometric views. By default the **Look From** control displays in the top right corner of the graphic screen. If the UCSORTHO (1.17.10) system variable is **ON** an orthographic UCS is restored automatically when the related orthographic view is chosen on the **Look From** control.

System variables and user preferences The behavior of the **Look From** control depends on a number of system variables and user preferences (1.590)

Name	Title	Description / Options
NAVVIEWCUBEDISPLAY	Look From Display	Controls whether the **Look From** control displays.
NAVVIEWCUBELOCATION	Look From Location	Controls the location of the **Look From** control in the drawing area. The options are: 0: Top right corner. 1: Top left corner 2: Bottom left corner 3: Bottom right corner
NAVVIEWCUBEOPACITY	Look From Opacity	Sets the opacity of the **Look From** control when not active. Values between 1 (invisible) and 100 (no dimming) are accepted.
NAVVIEWCUBEORIENT	Look From Orientation	Specifies the view orientation reference: either the WCS (World Coordinate System or the current UCS (User Coordinate System).
LookFromFeedback	Look From Feedback	Controls the display and location of tooltips. 0: No tooltips 1: Tooltips next to the **Look From** control. 2: Tooltips in the status bar.

Figure 1.590

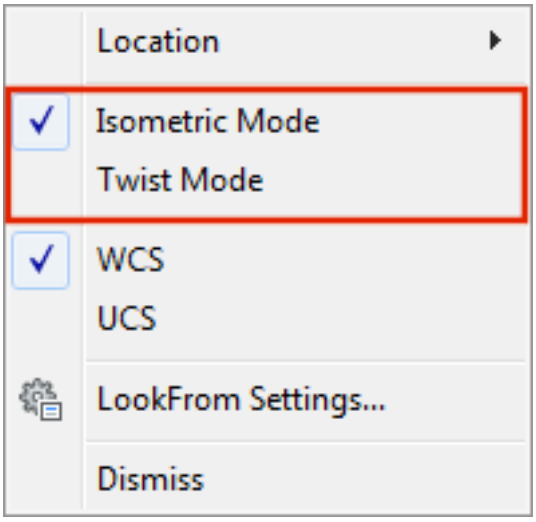


LookFromDirectionMode	Look From Direction Mode	Specifies the number of available view directions. Holding down the Ctrl-key switches between top-down and bottom-up view directions 0: Orthogonal views only (6 directions). (1.602 on page 699) 1: 6 Orthogonal views and 8 Isometric views (14 directions). (1.603 on page 699) 2: 4 Rotated orthogonal, 6 Orthogonal and 8 Isometric views (18 directions) (1.604 on page 700) 3: 8 Rotated isometric, 4 Rotated orthogonal, 6 Orthogonal and 8 Isometric views (26 directions). (1.605 on page 700)
LookFromZoomExtents	Look From Zoom Extents	Determines whether a 'zoom extents' is performed whenever a new view direction is selected.

Setting the Look From mode

1. Move the cursor to the **Look From** control.
2. Right click, then select either **Isometric Mode** or **Twist Mode** in the context menu. (1.591 on the facing page)

Figure 1.591

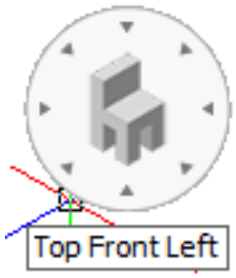


Using the Look From control in Isometric mode Isometric mode is best used in 3D models.

1. Move the cursor to the **Look From** control. The **Look From** control becomes active.
2. Position the cursor on the **Look From** control to choose a view orientation. A preview image and a tooltip indicate the currently selected view orientation. (1.592)
3. Click to confirm. The view is updated.

NOTE	VTENABLE setting determines whether animated view transitions are enabled for zoom/pan and/or for view rotation operations. VTDURATION setting determines the duration of view transition animations in milliseconds. VTFPS setting defines the minimum frame rate required to allow animation. That is 7 by default, which means that the redraw time should take less than 143 (=1000/7) milliseconds. If the computer is not capable to redraw the view fast enough, no animation will be available.

Figure 1.592



Using the Look From control in Twist mode

Twist mode is best used in 2D drawings. In **Twist** mode, the **Look From** control allows to rotate the view around the screen Z-axis

1. Move the cursor to the **Look From** control. The **Look From** control becomes active.
2. Do one of the following:
3. Move the cursor on the edge of the the **Look From** control. Left half for counterclockwise, right half for clockwise rotation. Click when the arrow is at the desired rotation angle. The following angles are available: 15°, 30°,45°, 60°, 90°, 120°, 135° and 180°, both clockwise and counterclockwise. If **LookFromFeedback** = 1, the angle displays in a tooltip. Click again to rotate over the same angle again. (1.593)
4. Move the cursor to the center of the **Look From** control, then click to restore the view (= unrotated state).

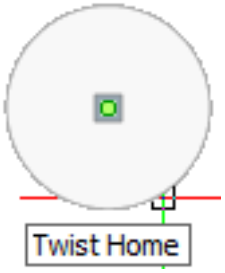


Figure 1.593

Rotating a view freely

1. Do one of the following:

   - Click the **Real-Time Constrained Sphere** tool button ( ) or the **Real-Time Sphere** tool button ( ) on the **Real-Time Motion** toolbar.
   - Choose **Real-Time Motion** > **Real-Time Constrained Sphere** or **Real-Time Motion** > **Real-Time Sphere** in the **View** menu.
   - Type **rtrot** , **rtrotf** or **rtrotctr** in the command bar, then press Enter.

   You are prompted: » Press ENTER or Esc to complete, or right click to display context menu.

2. Press and hold the left mouse button. Move the mouse to rotate the view.

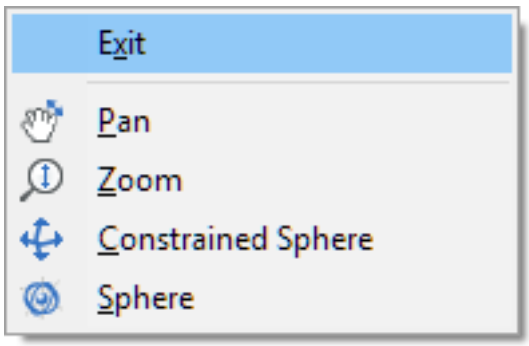
   - Using the **Real-Time Constrained Sphere** command horizontal mouse movement (parallel to the screen X-axis) rotates the 3D model about the world Z-axis.
   - Using the **Real-time Sphere Center** command you are prompted to specify a center point for the rotation first.

3. (option) Right click to display a context menu: (1.597 on page 694)

4. To abort the **Real-Time Sphere** commands, do one of the following:

   - Right click, then choose **Exit** in the context menu..
   - Press Enter, space bar or Esc.

Figure 1.594



Rotating a view about the view X-axis

1. Do one of the following:

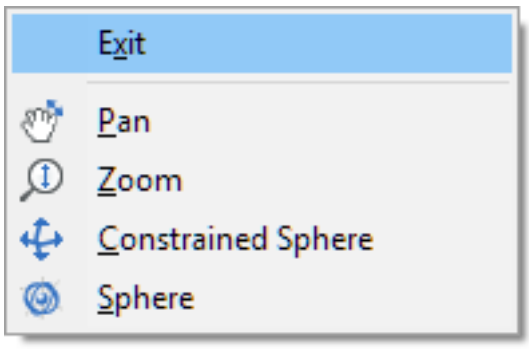
   - Click the **Real-Time X** tool button ( ) on the **Real-Time Motion** toolbar.
   - Choose **Real-Time Motion** > **Real-Time X** in the **View** menu.
   - Type **rtrotx** in the command bar, then press Enter.

   You are prompted: » Press ENTER or Esc to complete, or right click to display context menu.

2. Press and hold the left mouse button. Move the mouse to rotate the view.
3. (option) Right click to display a context menu: (1.597 on page 694)
4. To abort the **Real-Time X** command, do one of the following:

   - Right click.
   - Press Enter, space bar or Esc.

Figure 1.595



Rotating a view about the view Y-axis

1. Do one of the following:

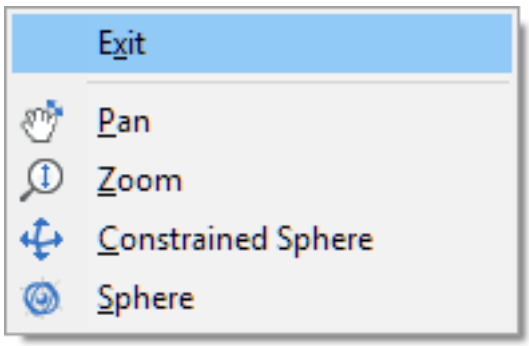
   - Click the **Real-Time Y** tool button ( ) on the **Real-Time Motion** toolbar.
   - Choose **Real-Time Motion** > **Real-Time Y** in the **View** menu.
   - Type **rtroty** in the command bar, then press Enter.

   You are prompted: » Press ENTER or Esc to complete, or right click to display context menu.

2. Press and hold the left mouse button. Move the mouse to rotate the view.
3. (option) Right click to display a context menu: (1.597 on the next page)
4. To abort the **Real-Time Y** command, do one of the following:

   - Right click.
   - Press Enter, space bar or Esc.

Figure 1.596



Rotating a view about the view Z-axis

1. Do one of the following:

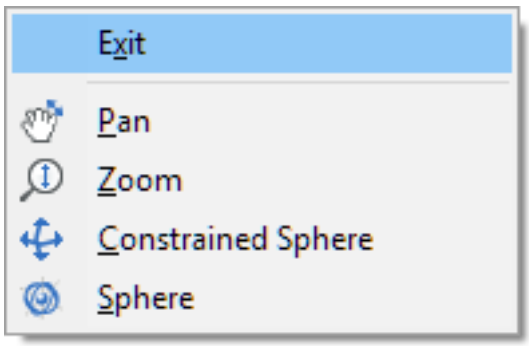
   - Click the **Real-Time Z** tool button ( ) on the **Real-Time Motion** toolbar.
   - Choose **Real-Time Motion** > **Real-Time Z** in the **View** menu.
   - Type **rtrotz** in the command bar, then press Enter.

   You are prompted: » Press ENTER or Esc to complete, or right click to display context menu.

2. Press and hold the left mouse button. Move the mouse to rotate the view.
3. (option) Right click to display a context menu: (1.597)
4. To abort the **Real-Time Z** command, do one of the following:

   - Right click.
   - Press Enter, space bar or Esc.

Figure 1.597



Using Preset Viewpoints

1. Do one of the following:

   - Click the **Set Viewpoint ...** tool button ( ) on the **View** toolbar.
   - Choose **Set Viewpoint** in the **View** menu.
   - Type **ddvpoint** in the command bar, then press Enter.

   The **Preset Viewpoint** dialog opens.

2. Click the **Angle Precision** button (45°) to choose a different display mode for the **Set Viewpoint** dialog. Then choose either **45°** , **15°** or **5°** . (1.598 on the next page)

   45° display mode In **15°** or **5° mode** click in the inner area of the **Horizontal** and **Vertical** fields to choose a **45°** display mode viewpoint. Click in the outer area of the **Horizontal** and **Vertical** fields to choose another angle.

3. To set the **Vertical** view angle, do one of the following:

   - Skip this step to accept the default vertical view directions:
   - Horizontal for East, North, West and South.
   - Downwards for the other directions

   If both the down- and left-arrow show in the **Vertical** field, the default vertical view directions are active.

   - Select a **45° mode** angle in the inner area, then click to confirm your choice. A single arrow indicates the selected vertical view direction.
   - If in **15°** or **5° mode** in, select a view direction in the outer area, then click to confirm your choice. The selected angle displays in bold.

   (1.599 on the following page) The view is updated as you click.

4. To set the **Horizontal** view angle, do one of the following:

   - Select a **45° mode** angle in the inner area, then click to confirm your choice. An arrow indicates the selected horizontal view direction. The perspective of the arrow reflects the vertical view direction.

   (1.600 on page 697)

   - If in **15°** or **5° mode** in, select a view direction in the outer area, then click to confirm your choice. The selected angle displays in bold.

   The view is updated as you click.

NOTE	Use the **Isometric Views** toolbar for standard view rotations: top, front, back, left, right and isometric views.

Figure 1.598

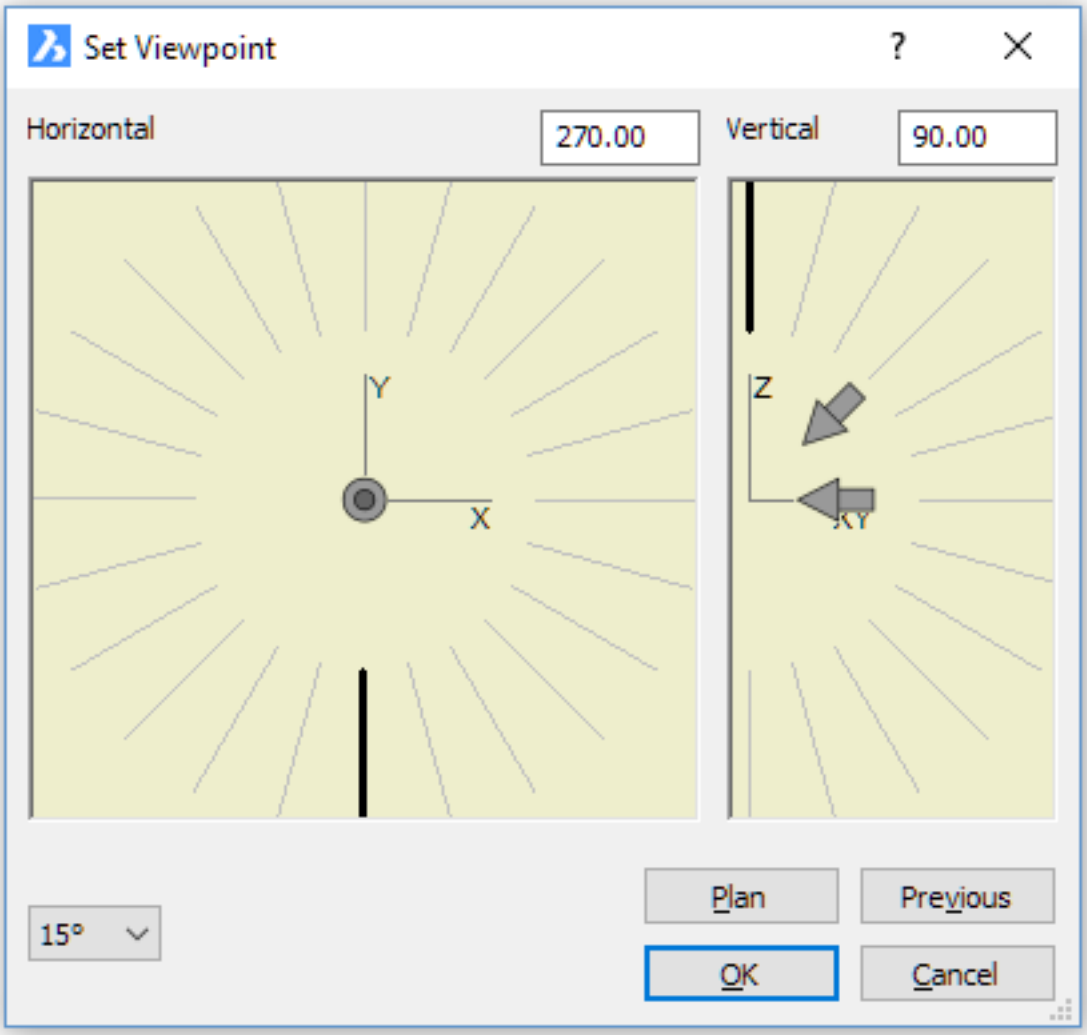


Figure 1.599

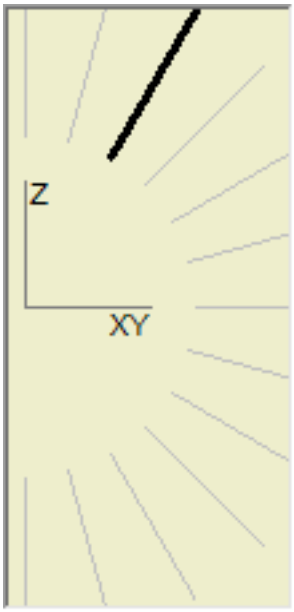

Figure 1.600

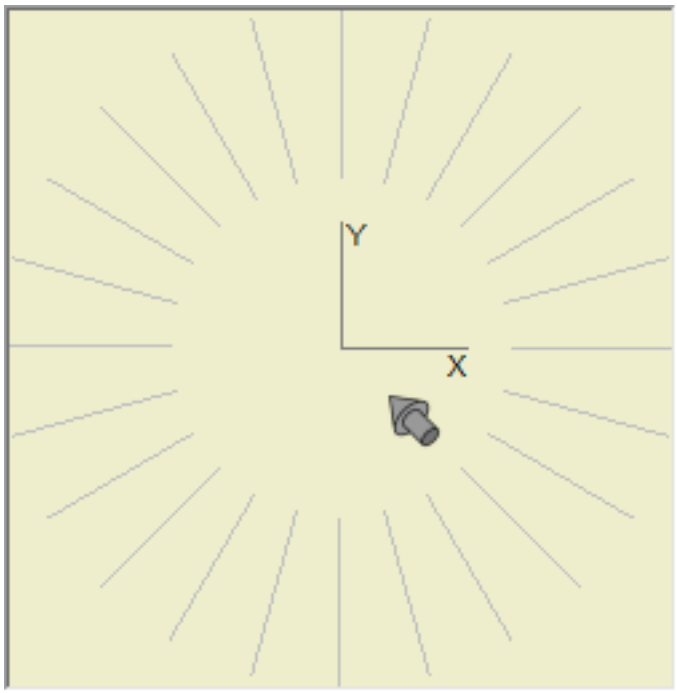
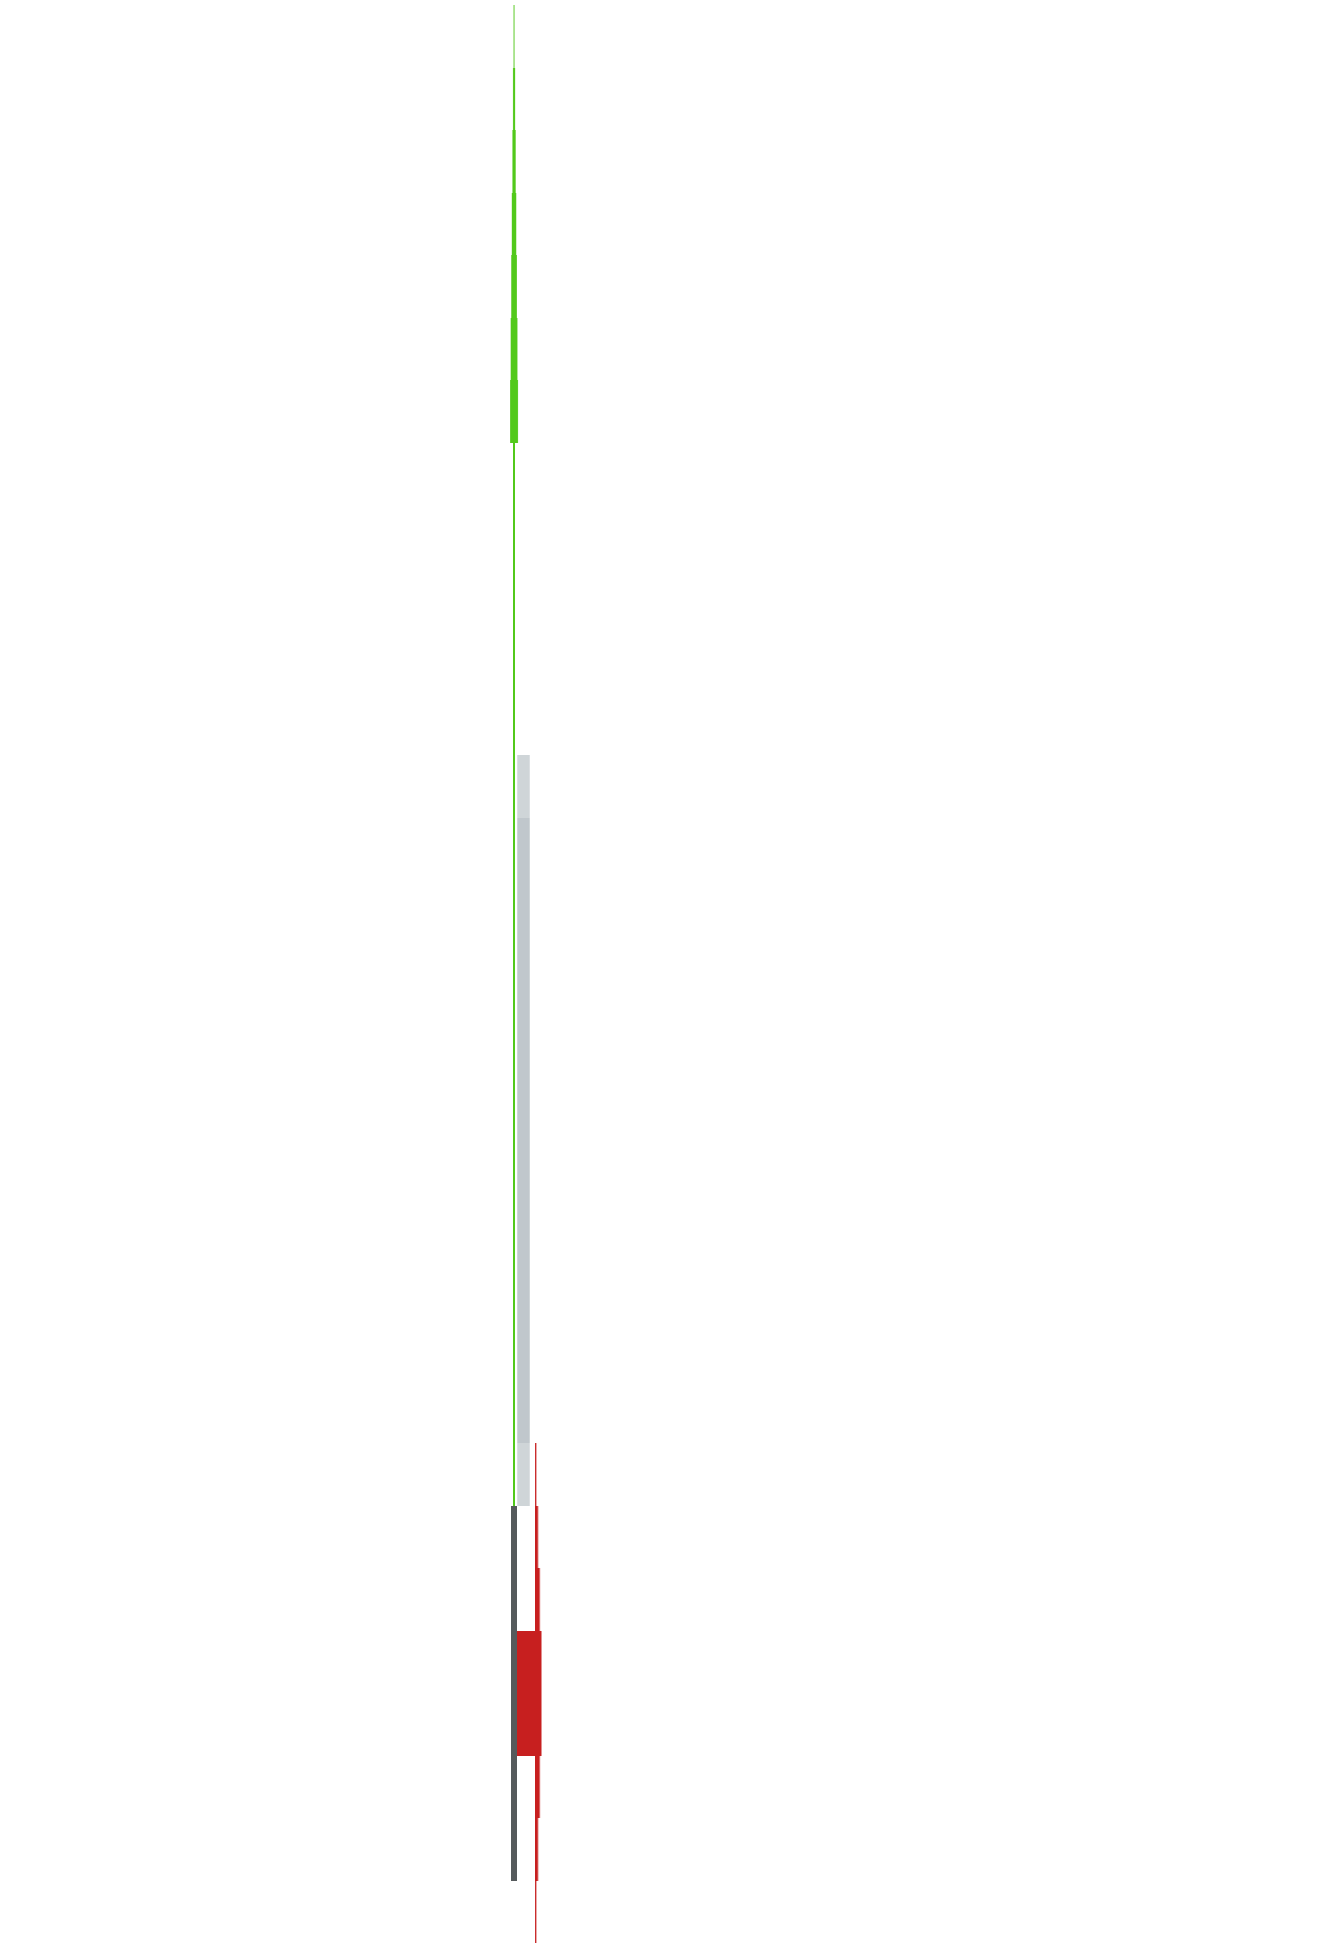


Restoring Plan View

1. Do one of the following:



- Click the **Plan View** tool button ( ) on the **View** toolbar.

Figure 1.601

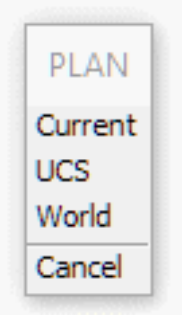


Figure 1.602

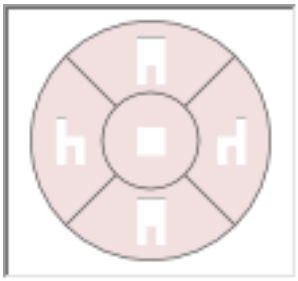

- Choose **Plan View** in the **View** menu.
- Type **plan** in the command bar, then press Enter.

You are prompted: Plan view of: UCS/World/<current UCS>: A prompt menu opens: (1.601)

2. Press Enter to restore the plan view with respect to the current coordinate system.

NOTES

- If the WCS is the current coordinate system, the **Current** and **World** options have the same result.
- If the **UCSFOLLOW** variable is set to **ON** , the plan view is generated whenever the UCS changes.

Figure 1.603

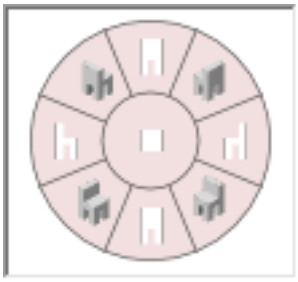

Figure 1.604

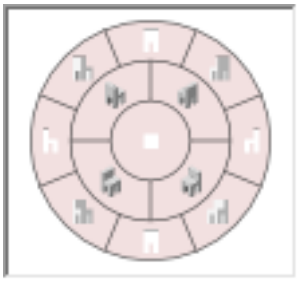

Figure 1.605

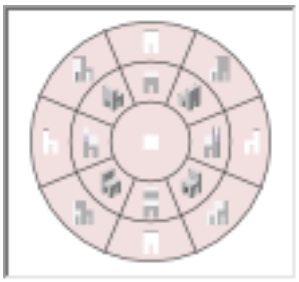


1.23.8 Panning

Commands: PAN (6.24.3) and RTPAN (6.26.36) The **Pan** command moves the drawing in any direction: horizontally, vertically, or diagonally. The magnification of the drawing remains the same, as does its orientation in space.

The only change is the portion of the drawing being displayed. The cursor changes to a hand () when a **Pan** tool is active. The **Rtpan** command pans the drawing in real-time. See also : View manipulation using the mouse (1.23.6).

Using the pan command

1. To launch the Pan command do one of the following:

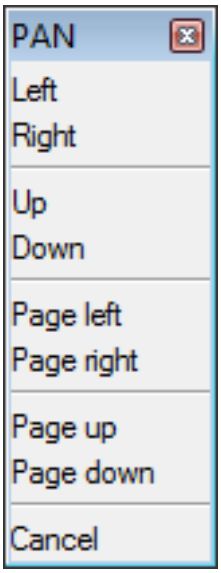
   - Click the **Pan** tool button () on the **View** toolbar (**Zoom** flyout).
   - Choose **Zoom > Pan** in the **View** menu.
   - Type **p** or **pan** in the command bar, then press Enter.

   You are prompted: Left/Right/Up/Down/PGLeft/PGRight/PGUp/PGDown/<Pan base point>: A prompt menu opens: (1.606 on the next page)

2. Specify the **Pan base point** . **You are prompted:** Pan displacement point:

3. Specify the **Pan displacement point** . The display shifts over the specified distance and in the specified direction.

Figure 1.606



Using real time panning

1. To launch the Real-time Pan command do one of the following:

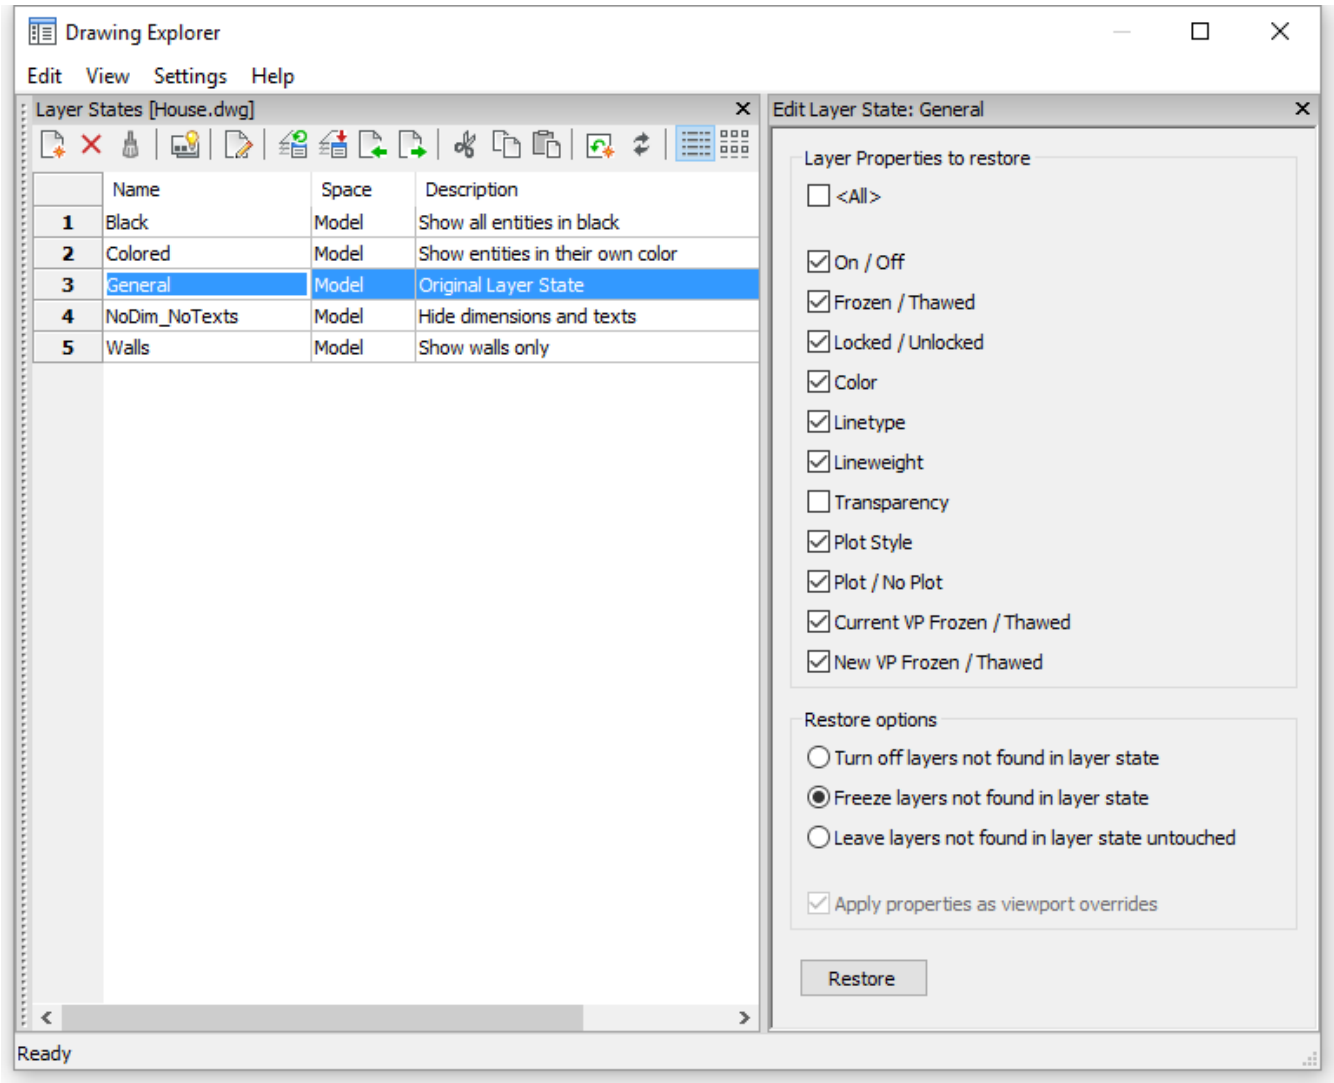
   - Click the **Real-Time Pan** tool button ( ) on the **Real-Time Motion** toolbar
   - Choose **Real-Time Motion** > **Real-Time Pan** in the **View** menu.
   - Type **Rtpan** in the command bar, then press Enter.

   You are prompted: »ENTER, Right click or Esc to complete.

2. Press and hold the left mouse button to pan the view.
3. To abort the **Real-Time Pan** command, do one of the following:

   - Right click.
   - On the keyboard, press Enter, space bar or Esc.

Figure 1.607



1.23.9 Layer States

Command: LAYERSTATE (6.20.9) Layer states let you save and restore configurations of layer properties and states. You might want a layer to display in blue sometimes and green at other times, or you need some layers to be off or frozen or locked when editing a specific part of a drawing. After spending a lot of time adjusting all layer settings you can use layer states to save your settings. You can save multiple layer states in a each drawing. Layer states can be copied between drawings and you can save a layer state to an external file, which can then be imported in another drawing. To easily create layer states, the Layer Utility (1.23.2) commands might be useful. (1.607) **Drawing Explorer: Layer States (Detail view)**

Tutorial: Use Layer States instead of Clicking Bulbs Click here (1.9.7) to watch

Opening the Layer States Explorer

1. In the **Tools > Drawing Explorer** menu choose **Layer States...**.
2. (option) Do one of the following:
   - Click the **Detail View** button ( ). (1.608 on the next page)
   - Click the **Icon View** button ( ). (1.609 on the following page)

Figure 1.608

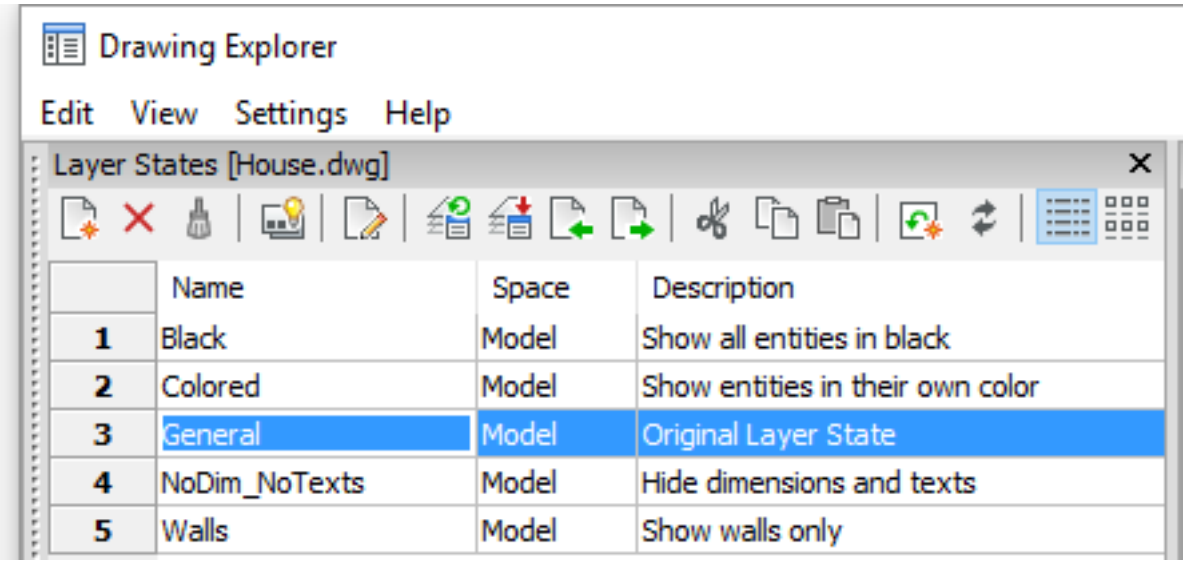


Figure 1.609

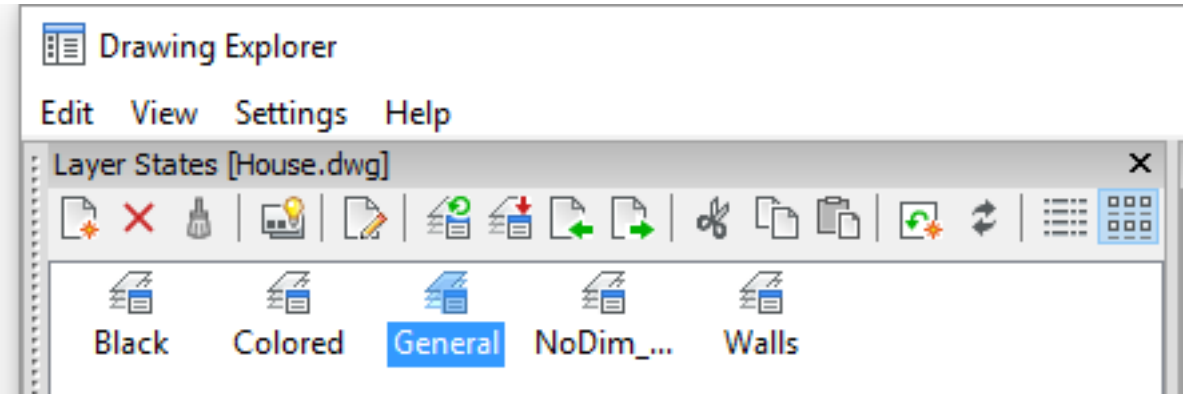
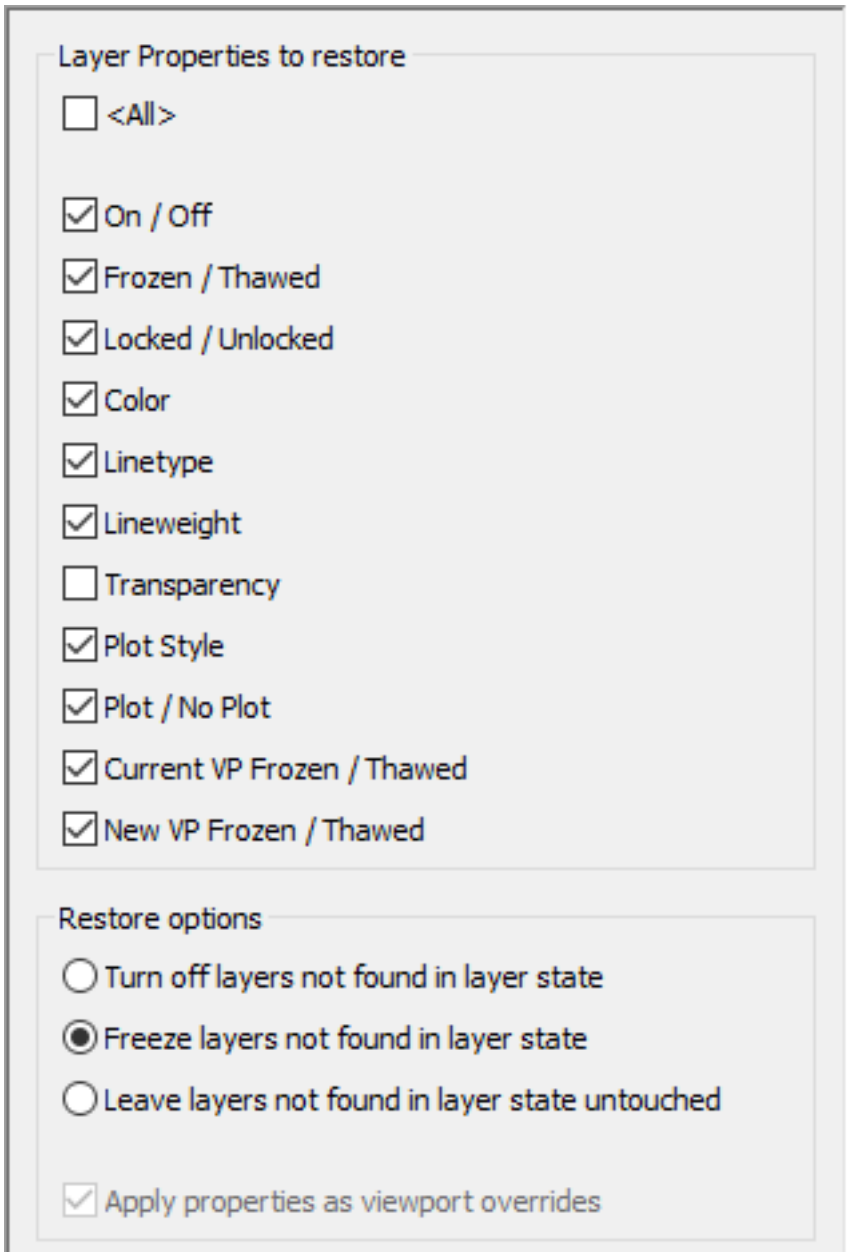


To save the current layer state

1. Open the Layer States explorer (1.23.9).
2. Click the **New** button. (). A new layer state is created.
3. Type a name for the layer state, replacing the **NewLayerState1** default name.
4. (option) When in **Detail View** type a description in the **Description** field.
5. Select the **Layer Properties to restore** . Click the check box to select a layer property, click again to remove the selection. (1.610 on the next page)

NOTE	By default in a new layer state all layer properties are selected to be restored.

Figure 1.610



Layer Properties to restore
<All>

Plot / No Plot
Current VP Frozen / Thawed
New VP Frozen / Thawed
Restore options
Turn off layers not found in layer state
Freeze layers not found in layer state
Leave layers not found in layer state untouched
Apply properties as viewport overrides

To edit a layer state

1. Open the Layer States explorer (1.23.9).

2. (option) Click the **Overwrite** button () to overwrite the layer state with the current layer settings.

3. If necessary, click the **Tree View** button ().

4. Click the expand button of the layer state.

5. (option) Rename the layer state.

6. (option) Edit the layer state description.

7. (option) Expand the **Layer Properties to restore** list. Click the check box to select a layer property, click again to remove the selection.

To restore a layer state

1. Open the Layer States explorer (1.23.9).

2. Select the layer state you want to restore.

3. Select a **Restore Option**. The restore option applies to layers which are added after the selected layer state was created. The options are:

   - Turn Off.
   - Freeze.
   - Do nothing.

4. Optionally check the **Apply properties as viewport overrides** option, which applies the layer state as viewport overrides (VP layer properties (6.13.17)) to the current layout viewport. This option is available only on a layout within a layout viewport.

5. Do one of the following:

   - Click the **Restore** button ().
   - Right click, then choose **Restore** in the context menu.

6. Click the **Regen** button ( )

- If **REGENAUTO** is on ( ), it is not necessary to press the **Regen** button in step 4.

To copy layer states to another drawing

1. Open both, the source and the target drawing.
2. Make the source drawing the current drawing.
3. Open the Layer States explorer (1.23.9).
4. If the layer states display in **Tree View** , choose either **Detail View** () or **Icon View** ().
5. Do one of the following
   - Select the layer state you want to copy.
   - Press and hold the Ctrl key to select multiple layer states.
6. With the cursor on a selected layer state, press and hold the left mouse key, then drag the selection to the target drawing in the **Open Drawings** section of the Drawing Explorer (1.19.2) dialog window.
7. When on the target drawing, release the left mouse button. The selected layer states are copied to the target drawing.

To export a layer state

1. Open the Layer States explorer (1.23.9).
2. Select the layer state.
3. Click the **Export** button (). The **Export Layer States** dialog opens.
4. In the **File Name** field, type a name for the layer state.
5. Choose a folder to save the layer state in.
6. Click the **Save** button.

To import a layer state

1. Open the Layer States explorer (1.23.9).
2. Click the **Import** button (). The **Import Layer States** dialog opens.
3. Browse to the folder where you have saved the layer state file.
4. Select the layer state.
5. Click the **Open** button. The layer state is imported.

NOTE	If a layer state of the same name already exists in the drawing a warning displays. It is not possible to overwrite a layer state definition.

Tutorial: Employing the Display Power of Layer States Click here (1.12.17) to watch

1.23.10 Named Views

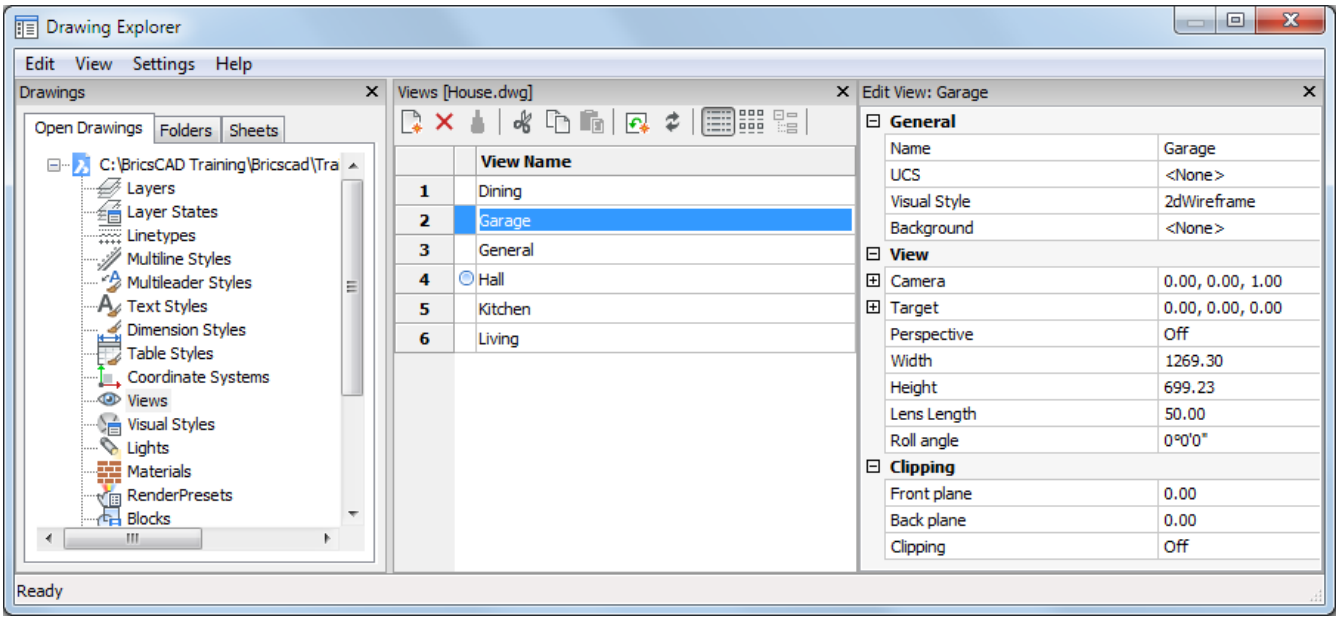
Commands: -VIEW (6.31.3), VIEW (6.31.2), CAMERA (6.9.1) You can save the view in the current window as a named view. Saved views can be restored at any time. A Background can be assigned to a named view, which will be used when the view is rendered (1.34.3)

Exploring views

1. Do one of the following:
   - Choose **Drawing Explorer > Views...** in the **Tools** menu.
   - Type either **view** or **V** in the command bar, then press Enter.

   The **Drawing Explorer - Views** window opens.
2. (option) Click the blank tile in front of the **View Name** to restore a saved view. The current view is marked (). (1.611 on the following page)
3. (option) Click the **New** button () in the **Drawing Explorer** toolbar to save the current view.
4. (option) Click the **Delete** button () in the **Drawing Explorer** toolbar to delete the selected view.
5. (option) Click the **View Name** , then right click and choose Rename in the context menu. Type a new name for the saved view.
6. (option) Check the **Perspective** property to make the view a visual perspective view. If not checked the view is a parallel perspective view. See also Define a View (1.23.15).
7. (option) Click the **Background** column of a view to choose a background. The background definition of the view is applied during rendering.

Figure 1.611



Saving a view

1. Do one of the following:

   - Click the **Save/Restore View** tool button ( )
   - Choose **Save/Restore View** in the **View** menu.
   - Type **-view** in the command bar, then press Enter.

   You are prompted: View: ? to list saved views/Delete/Restore/Save/Window: (1.613 on the next page)

2. Do one of the following:

   - Choose **Save** in the **View** prompt menu.
   - Type **S** in the command bar, then press Enter

3. Type a name for the view in the command bar, then press Enter. The current view is saved.

NOTE	If you type a name that is already used, the current view is saved, replacing the previously saved view. There is no warning when overwriting a saved view.

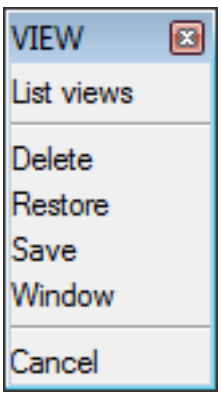
Figure 1.612



Restoring a view

1. Do one of the following:

   - Click the **Save/Restore View** tool button ( ) on the **View** toolbar.
   - Choose **Save/Restore View** in the **View** menu.
   - Type **-view** in the command bar, then press Enter.

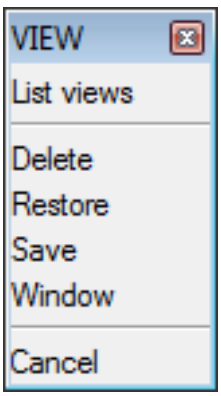
   You are prompted: View: ? to list saved views/Delete/Restore/Save/Window: (1.613)

2. Do one of the following:

   - Choose **Restore** in the **View** prompt menu.
   - Type **R** in the command bar, then press Enter

3. Type the name of the saved view you want to restore in the command bar, then press Enter. The saved view is restored.

Figure 1.613



Defining the view background

1. In the Drawing Explorer - Views dialog window, select **Background** in the **Edit** grid of the view.
2. Click the settings field to display the **Background** options. (1.617 on page 719)
3. Choose an option in the list. The **Background** dialog box displays: (1.615 on the facing page)
4. (option) Select **Solid** in the **Type** list. Click the **Color** button to define the color (1.25.5).
5. (option) Select **Gradient** in the **Type** list.
   - Set the rotation angle
   - Choose **Two** or **Three** colors.
   - Click the **Top** , **Middle** and **Bottom** color buttons to define the color (1.25.5).
6. (option) Select **Image** in the **Type** list. (1.616 on page 718)
   - Click the browse button next to the Image settings field to select a raster image file.
   - Choose an alignment. The options are: **Center** , **Stretch** and **Tile** .
7. (option) Right click, then choose **Set Current** in the context menu if you want to use the newly defined background in a rendering right away.

1.23.11 Model Space Viewports

Command: VPORTS (6.31.26) The display in model space (Model Space, with tiled viewports) can be divided into multiple viewports, each of which can contain a different view of the current drawing. All viewports are displayed in a tiled manner. You can work in only one of these viewports at a time but all viewports are updated simultaneously. When no command is active click in a viewport to make it the current viewport. You can print the current viewport only. The following settings can be defined differently for each viewport:

- grid display and snap
- coordinate system: WCS or UCS

(1.618) **Model Space divided in 3 viewports**

Creating viewports in model space

1. Do one of the following:

   - Click the **Viewports** tool button ( ) on the **Views** toolbar.
   - Choose **Viewports** in the **Views** menu.
   - Type **vports** in the command bar.

   You are prompted: Viewports: ? to list/Save/Restore/Delete/SIngle/Join/2/3/4/<3>: A prompt menu opens. (1.619 on the facing page)

2. (option) To create 2 viewports, do one of the following:

   - Choose **Create 2 viewports** in the prompt menu.
   - Type **2** in the command bar, then press Enter.

   You are prompted: Two viewports: Horizontal/<Vertical>:

Option	Result
Horizontal	(1.647 on page 754)
Vertical	(1.648 on page 754)

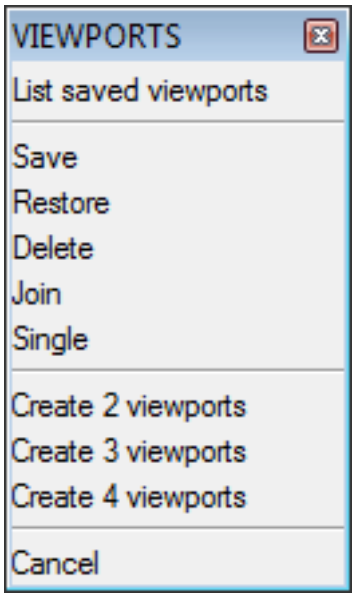
3. (option) To create 3 viewports, do one of the following:

   - Choose **Create 3 viewports** in the prompt menu.
   - Type **3** in the command bar, then press Enter.

   You are prompted: Three viewports: Horizontal/Vertical/Above/Below/Left/<Right>:

Option	Result

Figure 1.619



Drawing in multiple viewports

1. Click in a viewport to make it current. The border of the current viewport highlights.
2. Draw the entities in the current viewport.
3. (option) Repeat step 1 to make a different viewport current.

NOTES

- The crosshairs show in the current viewport only.
- You can start a command in the current viewport, and finish the operation in a different viewport.

Joining adjacent viewports

1. Launch the **Viewports** command.
2. Select the **Join** command option. You are prompted: Select inside dominant viewport <Current>:
3. Click in the dominant viewport or press Enter to choose the current viewport. The border of the selected viewport highlights. You are prompted. Select inside viewport to join:
4. Click the viewport to join again to confirm. The two selected viewports are joined.

NOTE You can join viewports which share an edge of equal length only.

1.23.12 Model space and paper space

Understanding paper space and model space

When you start a drawing session, your initial working area is called **Model Space** . Model Space is an area in which you create two-dimensional and three-dimensional entities based on either the World Coordinate System (WCS) or a user coordinate system (UCS). You view and work in model space while using the **Model** tab. In general model space consists of a single view that fills the screen. If needed, you can create additional views, called viewports, which can show different views of your drawing or 3D model. All viewports are displayed in a tiled manner. You can work in only one of these viewports at a time but all viewports are updated simultaneously. Click in a viewport to make it the current viewport. You can print the current viewport only. The Viewports (1.23.11) command lets you manage your viewports in model space. BricsCAD provides an additional work area, called **Paper Space** . Paper space represents a paper layout of your drawing. In this work area, you can create and arrange different views of your drawing similar to the way you arrange drawings on a sheet of paper. In paper space you can also add keynotes, annotations, borders, title blocks, and other print-related entities, which you don't want to see in model space. Each drawing has at least one **Layout** in which you can have one or more **Layout Viewports** . Such layout viewports are to be considered as a view window on your drawing in model space. Layout viewports can be placed anywere in a paperspace layout. Each viewport has its own scale and layer visibility. All viewports in the same layout can be printed simultaneously. The Mview (1.23.16) command lets you manage your viewports in paper space. Although not necessary to print your drawing, paper space offers a lot of advantages:

- Create multiple layouts to print the same drawing with different print settings, such as pen widths, printer configuration files, lineweight settings, drawing scale, and more.
- Add print-related entities that are not essential to the model itself, such as keynotes, annotations, title blocks, etc.
- For a single layout, create multiple layout viewports to print multiple views of your drawing at different scales.

Switching between model space and paper space

- To switch between Model Space and Paper Space Layouts use the Model and Layout tabs (1.23.12) at the bottom of the drawing window.
- When working in a layout, use the MSPACE (6.21.32) and PSPACE (6.24.59) commands to toggle between paper space and model space (1.23.12).

Tutorial: Paper Space Layouts in BricsCAD Click here (1.22.2) to watch

Using the model and layout tabs

1. To open model space, click the **Model** tab (2) at the bottom of the drawing window.
2. To open a paper space layout, click the corresponding **Layout** tab (3) at the bottom of the drawing window.
3. Use Ctrl-PgUp or Ctrl-PgDn to switch to the previous or next layout tab.
4. Click the navigation buttons to shift the tab display (1):
5.  : Display the model tab.
6.  : Shift one tab to the left.
7.  : Shift one tab to the right.
8.  : Shift to the last tab.

(1.629 on the facing page)

NOTE	A drawing contains at least one layout, which is named **Layout1** by default.

Toggle between model space and paper space in a layout

Commands: MSPACE (6.21.32) and PSPACE (6.24.59)

1. (option) When in **model space** (Model Space, with floating viewports) do one of the following to switch to **paper space** :

- Type either **pspace** or **ps** , then press Enter
- Double click outside a viewport.

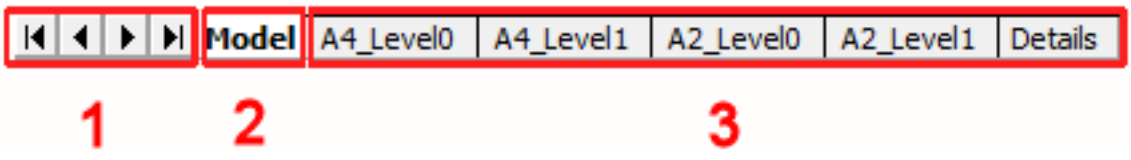
2. (option) When in **paper space** do one of the following to switch to **model space** (Model Space, with floating viewports):

- Type either **mspace** or **ms** , then press Enter.
- Double click inside a viewport.

NOTE	**MSPACE** and **PSPACE** commands are available when working in a layout only.

Tutorial: Copying Layouts to Model Tab Click here (1.16.3) to watch

Figure 1.629



1.23.13 Layouts

Commands: LAYOUT (6.20.14), LAYOUTMANAGER (6.20.15) In BricsCAD, you can create up to 255 layouts in a single drawing. Each layout represents a sheet of paper. For each layout you can specify the print area, print scale, lineweight scale, pen mappings, and add viewports, dimensions, a title block, and other geometry specific to the layout. The entities you add to a layout in paper space do not appear in model space. Each layout requires at least one layout viewport. If the CREATEVIEWPORTS (1.17.10) system variable is ON a viewport is added automatically in a new layout. If this variable is OFF, newly created viewports are empty. To add new layouts you can either define them yourself or your can import layouts from another drawing: template file (.dwt), drawing file (.dwg) or drawing interchange file (.dxf). Viewports can display all or part of the drawing's model space entities. The CACHELAYOUT (1.17.10) system variable controls whether the content of layouts is cached. The extra memory required for caching is made up for by improvements to the memory requirements for displaying entities, the net result being that the memory needed to display drawings has been reduced. As a result of this switching between layouts is up to 10 times faster now. The Ctrl-PgUp or Ctrl-PgDn keyboard shortcuts allow to open the next or previous layout.

Creating a new layout

1. Do one of the following:

   - Click the **New Layout** tool button () on the **Layout** or the **Insert** toolbar.
   - Choose **New Layout** in the **Insert** menu.
   - Type **layout** in the command bar, press Enter, then type **N** and press Enter.

   You are prompted: Enter a layout name. <Layout1>:

2. Do one of the following:

   - Type a unique name for the layout, then press Enter. The name can be up to 255 characters in length and can contain letters, numbers, the dollar sign ($), hyphen (-), and underscore (_), or any combination.
   - Right click or press Enter to accept the default name (e.g. Layout1).

   The new layout tab is added.

3. Create at least one viewport (see Creating viewports in a layout (1.23.16)). If the CREATEVIEWPORTS (1.17.10) system variable is ON a viewport is added automatically in a new layout.

Copying layouts

1. Right click the layout tab you want to copy. A context menu displays.
2. Choose **Copy** in the context menu. **You are prompted:** Enter new layout name:
3. Type a new unique name in the command bar, then press Enter. A copy of the selected layout is added.

Arranging the layout tabs

Drag the layout tab to the desired position **Or**

1. Right click the layout tab you want to move. A context menu displays.
2. Do one of the following:

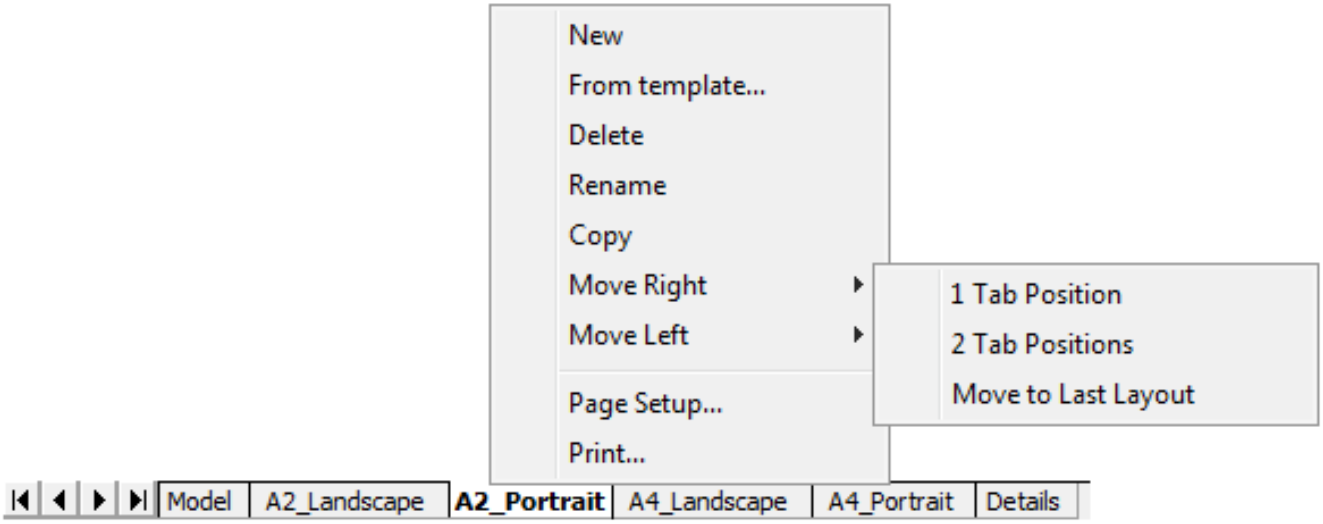
   - Choose **Move Right** .
   - Choose **Move Left** .

3. To move the selected layout tab do one of the following:

   - Select the number of tab positions.
   - Choose **Move to Last Layout** or **Move to First Layout** .

(1.630 on the next page)

Figure 1.630



Importing layouts

1. Right click the **Model** tab or one of the layout tabs. A context menu displays.
2. Choose **From Template...** in the context menu. The **Select Template From File** window opens.
3. Browse to the drawing that you want to import layouts from.
4. Click the **Open** button on the **Select Template From File** window. The **Insert Layout(s)** window opens.
5. Select the layout(s) you want to import. Press and hold the Ctrl key to select multiple layouts.
6. Click the OK button on the **Insert Layout(s)** window. The selected layouts are imported.

Renaming layouts

1. Double click the layout tab you want to rename. The **Rename Layout** dialog opens.
2. Type a new unique name in the **Name** field of the **Rename Layout** dialog.
3. Click the **OK** button on the **Rename Layout** dialog.

Deleting a layout

1. Right click the layout tab you want to move. A context menu displays.
2. Choose **Delete** in the context menu. The selected layout is deleted.

Deleting multiple layouts

1. Do one of the following:
2. Choose **Drawing Explorer > Page Setups...** in the **Tools** menu.
3. Choose **Page Setup...** in the **File** menu. The **Drawing Explorer - Page Setups** dialog displays.
4. Select the layouts you want to delete. To select a series of layouts: select the first layout, then press and hold the Shift key and select the last layout. Press and hold the Ctrl-key to add/remove layouts.
5. Click the **Delete** tool button (✕) in the toolbar on the **Drawing Explorer - Page Setups** toolbar. An alert box displays: (1.631 on the following page)
6. Press the **Yes** button on the **Delete Layouts** alert box.

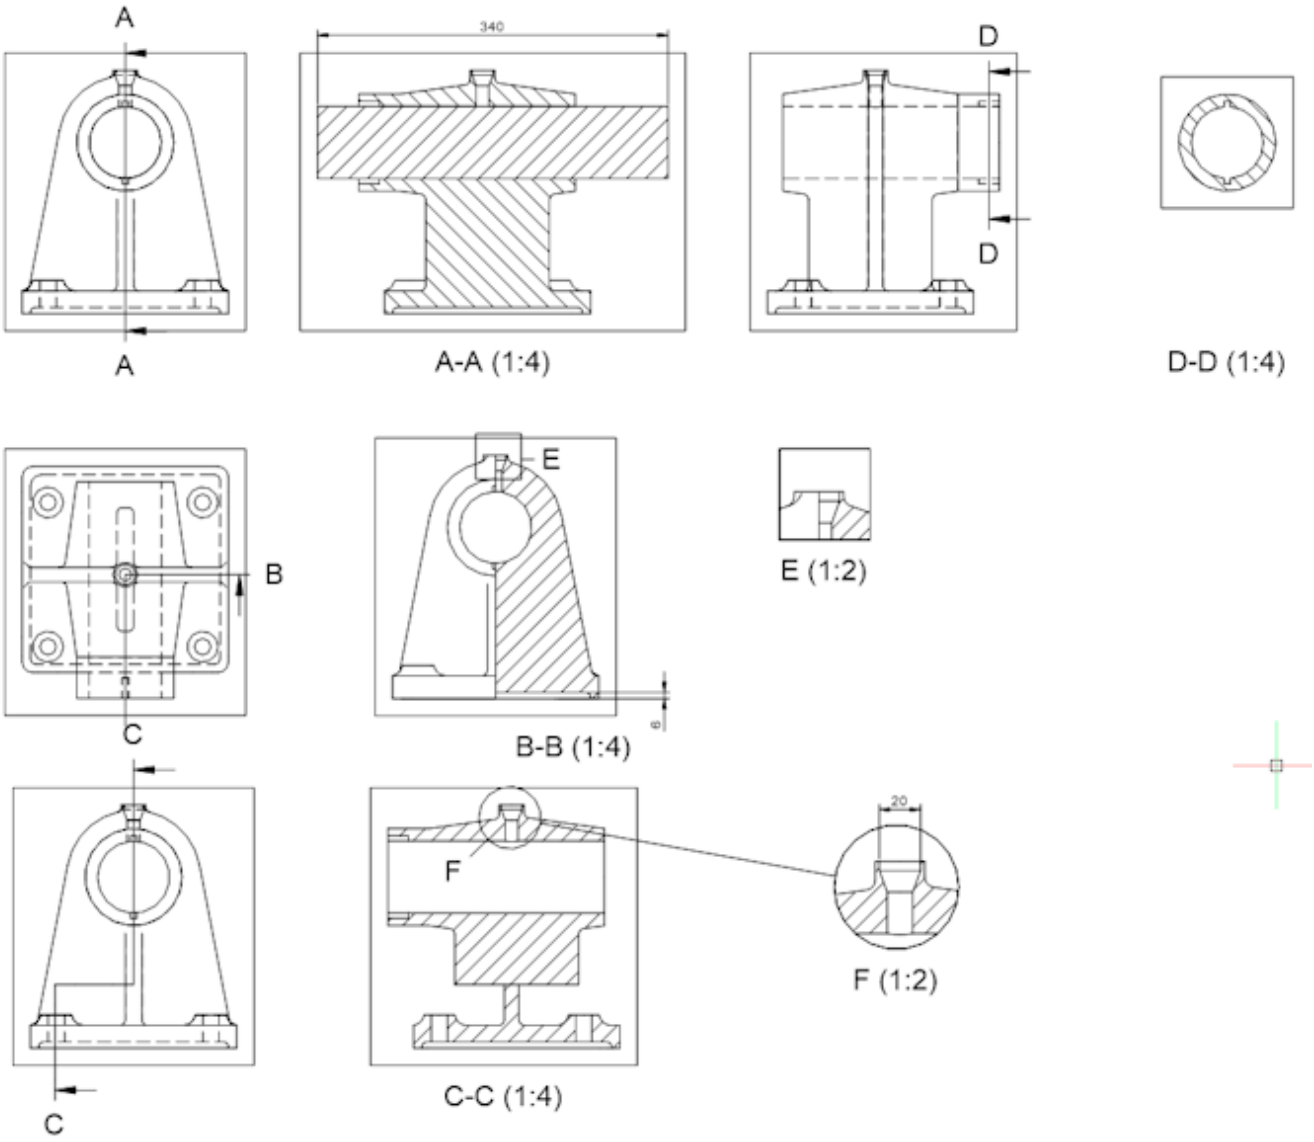
Figure 1.632



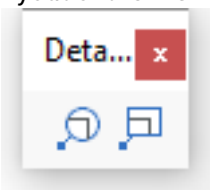
1.23.14 Generated Drawing Views

Commands: VIEWBASE (6.31.4), VIEWSECTION (6.31.12), VIEWSECTIONSTYLE (6.31.22), VIEWPROJ (6.31.9), VIEWDETAIL (6.31.6), VIEWDETAILSTYLE (6.31.7), VIEWUPDATE (6.31.13), VIEWEXPORT (6.31.11) and VIEWEDIT (6.31.8)
The Generated Drawing Views functionality allows to automatically generate associative orthographic and standard isometric views of a 3D solid model. All drawing views are placed in a paper space layout (1.23.13), they are not visible in model space (1.23.12). Analytical hidden line removal (HLR) procedures are used to create the drawing views using standard 2D entities, mostly lines and arcs. Much like the result of the FlatShot (6.14.10) command. Drawing views created in V14.1 will be automatically converted into HLR geometry by the ViewUpdate (6.31.13) command. (1.632)
The **ViewBase** command generates associative orthographic and standard isometric views of a 3D solid model in a paper space layout (1.23.13). The **ViewSection** command creates a cross section view based on a standard drawing view generated by the **ViewBase** command in a paper space layout (1.23.13). The **ViewSectionStyle** command allows to modify the appearance of the section views created by the **ViewSection** command. The **ViewProj** command generates additional projected views from an existing generated drawing view. The **ViewDetail** command creates a detail view of a portion of a standard generated drawing, at a larger scale. The **ViewdetailStyle** command allows to modify the appearance of the detail views created by the **ViewDetail** command. The **ViewUpdate** command Updates a selection of drawing views obtained by **ViewBase** and **ViewSection** when VIEWUPDATEAUTO (1.17.10) = 0. The **ViewExport** command exports the content of drawing views obtained by **ViewBase** and **ViewSection** to the Model Space (1.23.12) of the drawing. This command can be used in Paper Space (1.23.12) only. The **ViewEdit** command allows changing the scale and the hidden line visibility of drawing views.

NOTE	Drawing views generated in V14.2 or higher will show correctly in BricsCAD V13. The most recent V13.2 version is recommended. Drawing views generated in V14.2 or higher do not display in V12 and older BricsCAD versions.

Commands and Toolbars

Tools to generate drawing views of your 3D solid model are available on: The **Drawing Views** toolbar, which is a flyout of the **View** toolbar: (1.633) The **Section Types** and **Detail Section Types** toolbars: (1.634 on the next page)



The **View | Drawing Views** menu: (1.635 on the facing page) The **Drawing Views** panel of the **Annotate** Ribbon tab. (1.636 on the next page)

Figure 1.633

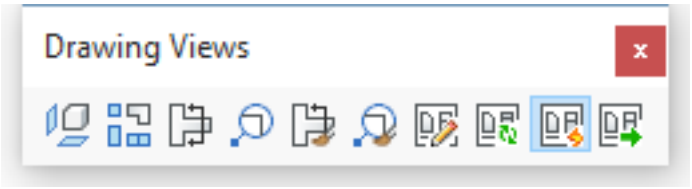


Figure 1.634

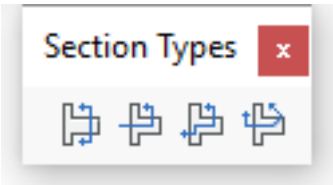

Figure 1.635

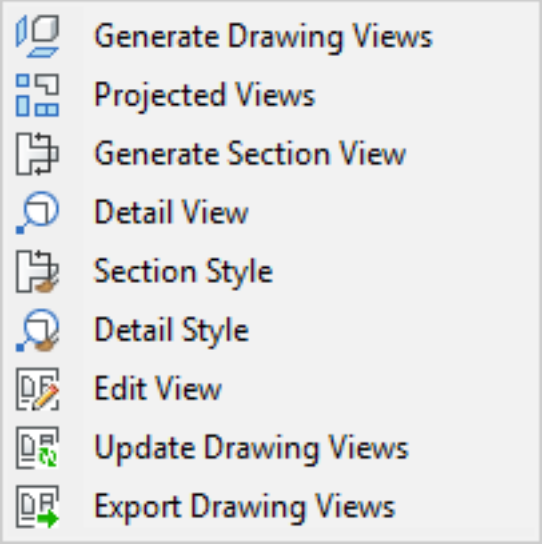

Figure 1.636

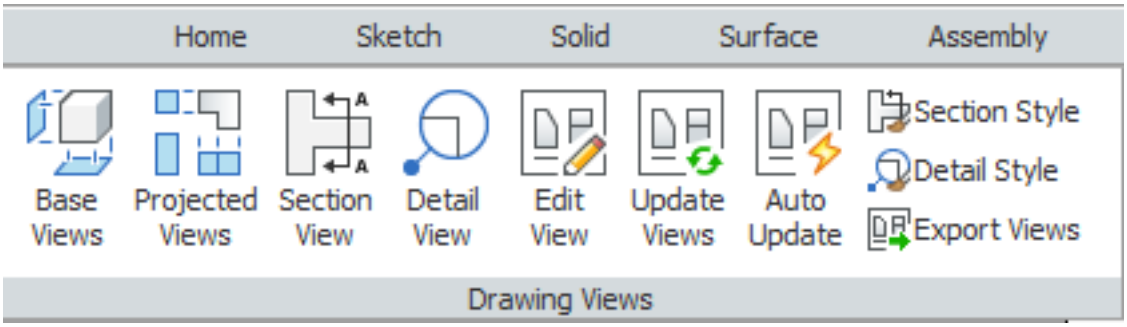

Standard Drawing Views

Standard views include multiview orthographic and isometric projections. In a technical drawing, a multiview orthographic projection is an illustration technique in which up to six images of an object are generated, with each projection plane parallel to one of the coordinate axes of the object. Isometric projection is a method to represent three-dimensional objects in two dimensions in technical and engineering drawings. It is an axonometric projection in which the three coordinate axes appear equally foreshortened and the angles between any two of them are 120 degrees. To generate the standard views of your 3D solid model, run the ViewBase (6.31.4) command from Model Space (1.23.12). You can choose between first angle (European) projection or third angle (American) projection. Orthographic projection (or orthogonal projection) is a means of representing a three-dimensional object in two dimensions. It is a parallel projection, where all the projection lines are orthogonal to the projection plane, resulting in every plane of the scene appearing in affine transformation on the viewing surface. It is further divided into multiview orthographic projections and axonometric projections. Two projection planes, one horizontal (H.P.) and one vertical (V.P.) divide the space in four quarters.

- In the first angle projection system the model is placed in the first quarter space (first angle).
- In the third angle projection system the model is placed in the third quarter (third angle).

(1.637 on the facing page) With multiview orthographic projections, up to six pictures of a 3D model are produced, with each projection plane parallel to one of the coordinate axes of the model. The views are positioned relative to each other according to either of two schemes: first-angle or third-angle projection. In each, the appearances of views may be thought of as being projected onto planes that form a 6-sided box around the model. (1.638 on page 734) The projection type is set by the **Projection Type** option of the ViewBase (6.31.4) command or by editing the PROJECTIONTYPE (1.17.10) system variable:

- 0 = First angle projection
- 1 = Third angle projection

The value of the PROJECTIONTYPE (1.17.10) system variable is saved in the drawing. Generated drawing view lines are created on default layers:

- BM_Isometric_Hidden;
- BM_Isometric_Visible;
- BM_Ortho_Hidden;
- BM_Ortho_Visible.

The display of the **BM_Isometric_Hidden** layer is turned off by default. Additional projected views can be added using the ViewProj (6.31.9) command. A projected view inherits the scale, display settings and alignment from the parent view.

Figure 1.637

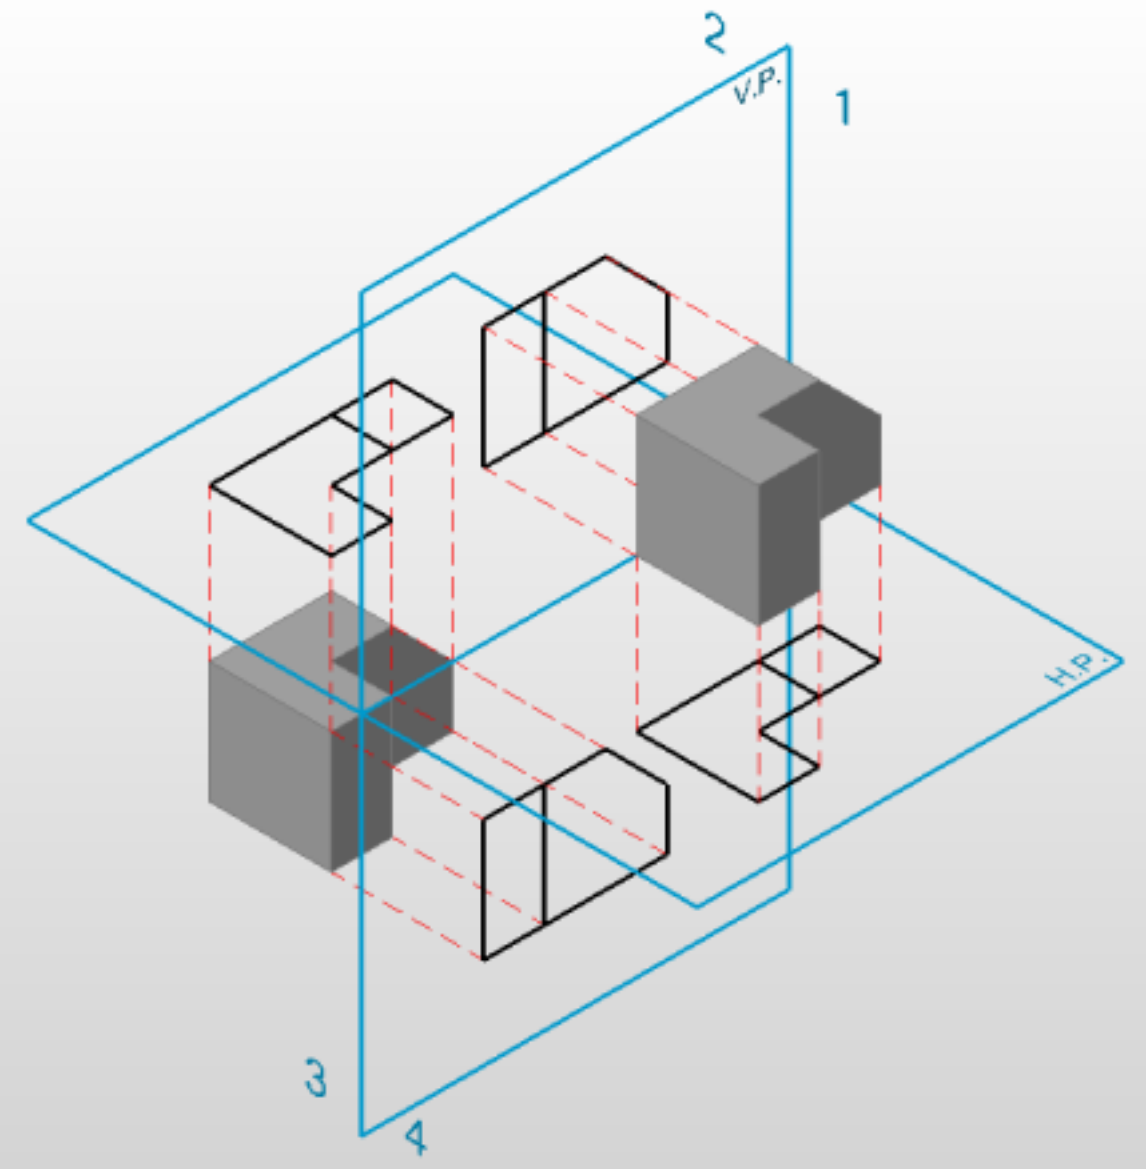

Figure 1.638

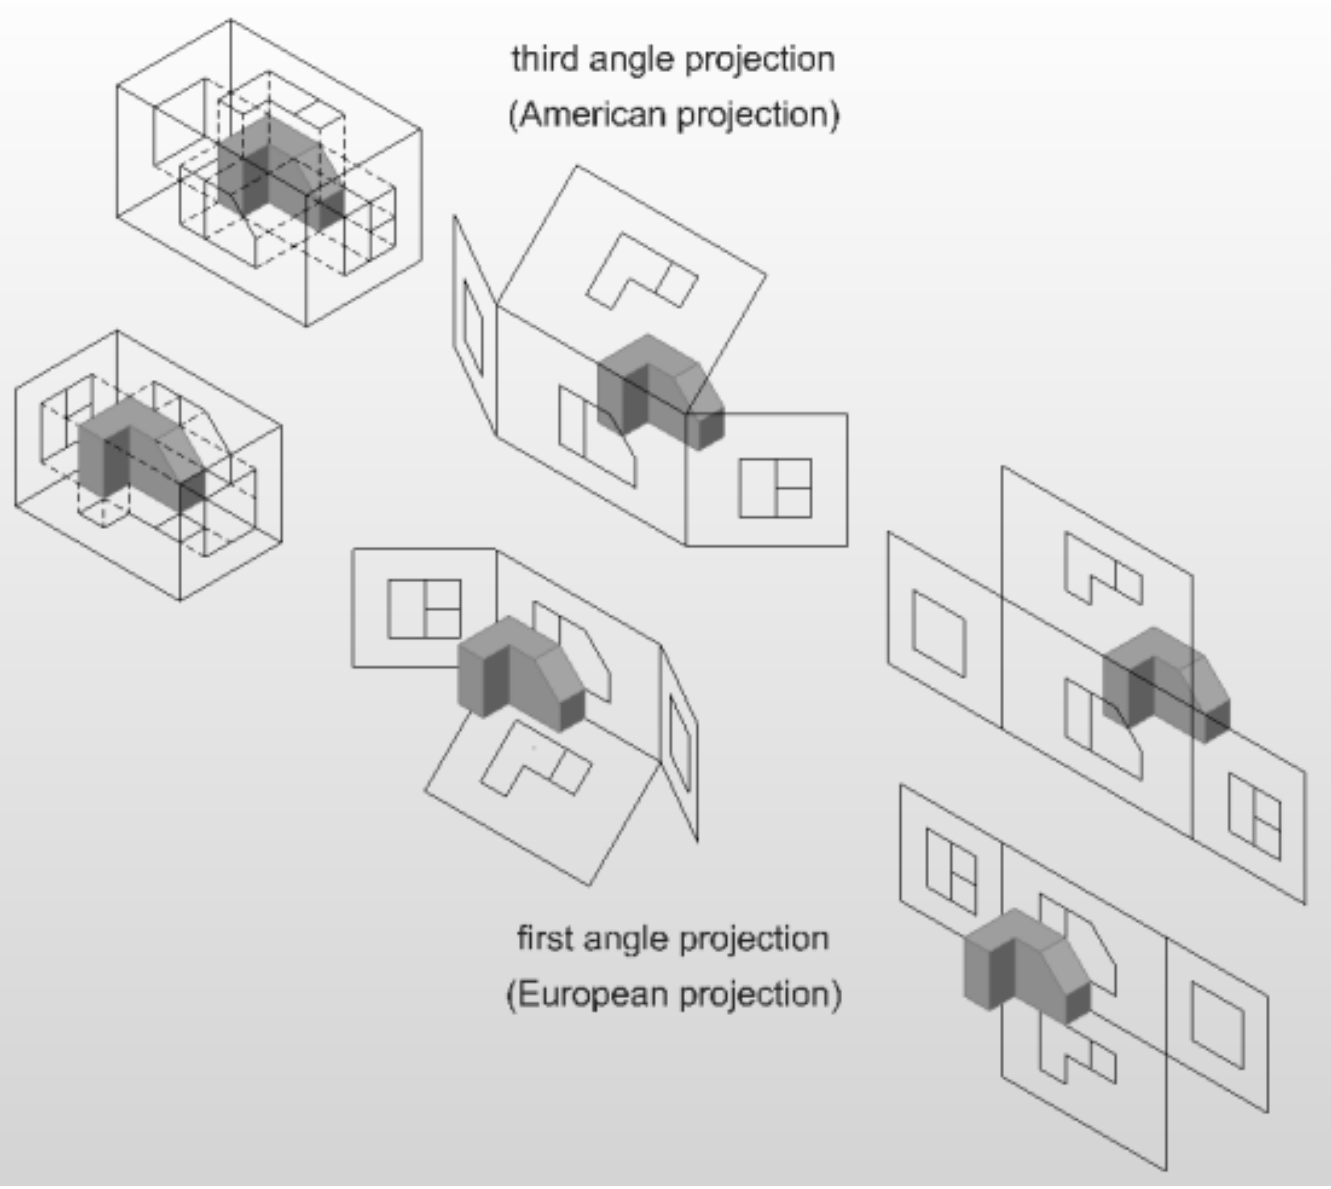
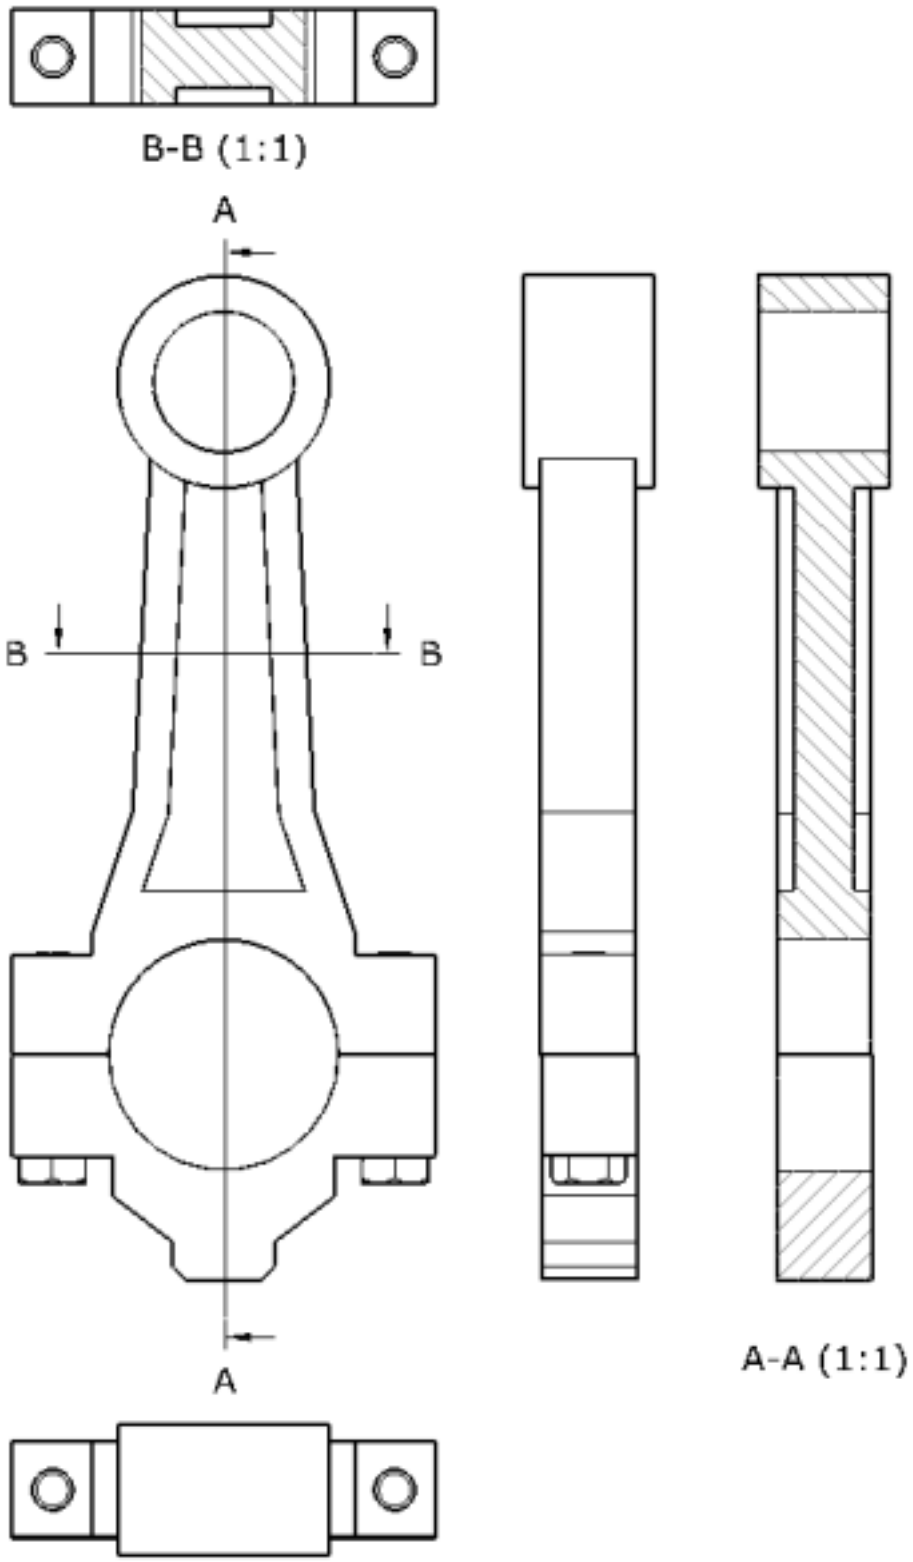


third angle projection
(American projection)
first angle projection
(European projection)

Generating Cross Section Views

A cross section is the intersection of a 3D solid model with a section plane. In technical drawings, the internal parts of the 3D model are hatched in cross sections. To generate section views of a 3D solid model, run the ViewSection (6.31.12) command from the paper space layout (1.23.13) where the standard drawing views exist. (1.639 on the following page)

Figure 1.639



Special views

(1.640 on the next page) It is possible to generate drawing views for a selected exploded representation (3.7.8). Normally, an orthogonal projection is used for that; however, BricsCAD allows to create any standard projection for exploded representations. Sections and detailed views are also supported. To create a view for an exploded representation, run the ViewBase (6.31.4) command with the Special views option, select the Exploded view option and then select the required exploded representation from the dialog box. Generated views for exploded representation can be associative with the original model, so annotations and balloons (3.11.2) can be placed. To do that, the views should be created or updated with GENERATEASSOCVIEWS (1.17.10) = ON.

Figure 1.640

Updating Drawing Views

By default BricsCAD checks whether the source 3D solid model or the associated exploded representation was modified and automatically recalculates the drawing when:

- opening a paper space layout (1.23.13) containing out-of-date views if the VIEWUPDATEAUTO (1.17.10) system variable is ON.
- running the ViewUpdate (6.31.13) command.
- running the BmUpdate (6.8.29) command (BricsCAD Platinum only).

NOTES

- Hidden line removal calculation might take some time for complex 3D models. In such cases it is recommended to set VIEWUPDATEAUTO (1.17.10) = OFF. The viewport border of out-of-date drawing views turns red to indicate an update is needed. When executing the ViewUpdate (6.31.13) command, BricsCAD prompts you to either select the drawing views to be updated or update all drawing views.
- If GENERATEASSOCVIEWS (1.17.10) = ON, associative dimensions (1.29.2) will be updated according to the modified 3D geometry.

Exporting Views to Model Space

The associativity mechanism of drawing views in a paper space layout (1.23.13) allows limited control by the user. Such views can be moved or scaled, but you cannot edit the geometry. In order to get the full control to the drawing views geometry, the ViewExport (6.31.11) command allows to move or copy drawing views to model space (1.23.12) or to a separate drawing. Exported drawing views lose their associativity with the 3D model and become standard blocks, which can be exploded, edited, erased, etc.

Tutorial: Copying Layouts to Model Tab Click here (1.16.3) to watch

Customizing Drawing Views

- style, color, height of identified text, and the type of identifier
- symbol, and its color and size
- color, type, and weight of detail view boundary

1.23.15 Perspective Views

Commands: DVIEW (6.10.53) and CAMERA (6.9.1) The **Define View** command dynamically defines parallel perspective or visual perspective views of your 3D models. The **Camera** command creates perspective views. The projection method of a view is controlled by the **Perspective** property of the view:

- If ON, the view is a visual perspective view.
- If OFF, the view is a parallel perspective view.

(1.641 on page 742) Parallel Perspective View	(1.642 on page 742) Visual Perspective View

The following parameters are used in the **Define View** procedure:

- **Target Point** : Defines the center of the view (1)
- **Camera Point** : Defines the view point and view direction (2).
- **Distance to Target** : Distance between the camera position an the target point (3).

(1.643 on page 742)

NOTE	View manipulation tools, such as zoom, pan, real-time motion, are not available in visual perspective views. However, you can use the mouse to manipulate the view (1.23.6).

Defining a camera view

The **Camera** command creates a named view (1.23.10). Do one of the following:

- Click the **Camera** tool button ( ) on the **View** toolbar.
- Choose **Camera** in the **View** menu.
- Type **Camera** in the command bar

You are prompted: Specify camera location: Do one of the following:

- Click a point in the drawing.
- Type the coordinates of the camera location in the command bar and press Enter.

You are prompted: Specify target location: Do one of the following:

- Click a point in the drawing.
- Type the coordinates of the target location in the command bar and press Enter.

You are prompted: Enter an option: ?/Name/LOcation/Height/Target/LEns/Clipping/View/<eXit>: Do one of the following:

- Press Enter to create the camera view using a default name (e.g. Camera1).
- Enter an option:
  - Name : **Prompts you:** Enter name for new camera <Camera1>: Type a name at the command prompt, then press Enter.

- Location : **Prompts you:** Specify camera location <current location>: Click a point or enter new coordinates of the camera location, then press Enter.

- Height : **Prompts you:** Specify camera height <current height>: Enter a new height (Z-coordinate) for the camera location.

- Target : **Prompts you:** Specify target location <current location>: Click a point or enter new coordinates of the target location, then press Enter.

- Lens : **Prompts you:** Specify lens length in mm <50.00>: Enter an new lens length, then press Enter.

- Clipping : **Prompts you:** Enable front clipping plane? <Yes>/No: Choose Yes to define the front clipping plane. **Prompts you:** Specify front clipping plane offset from target plane <0.00>: Type value in the command bare or specify the distance by clicking two points. **Prompts you:** Enable back clipping plane? Yes/<No>: Choose Yes to define the front clipping plane. **Prompts you:** Specify front clipping plane offset from target plane <0.00>: Type value in the command bare or specify the distance by clicking two points.

- View : **Prompts you:** Switch to camera view? Yes/<No>: Choose Yes to display the camera view. This option concludes the **Camera** command.

NOTE	Choose **Drawing Explorer > Views...** in the **Tools** menu to edit a camera view.

To toggle the perspective property of view

Do one of the following

- Click the **Perspective** tool button () on the **View** toolbar. The state of the tool button, pressed or not, indicates the current value of the PERSPECTIVE system variable.
- Choose **Perspective** in the **View** menu.
- Type **perspective** in the command bar. **You are prompted:** New current value for PERSPECTIVE (Off or On) <On>: A prompt menu displays. Do one of the following:
  - Type **off** or **on** in the command bar, then press Enter.
  - Choose **Off** or **On** in the prompt menu.

NOTE	In named views you can set the **Perspective** property in the Drawing Explorer - Views (1.23.10) dialog.

Tutorial: How to navigate quickly around your drawing Click here (1.9.1) to watch

Figure 1.641

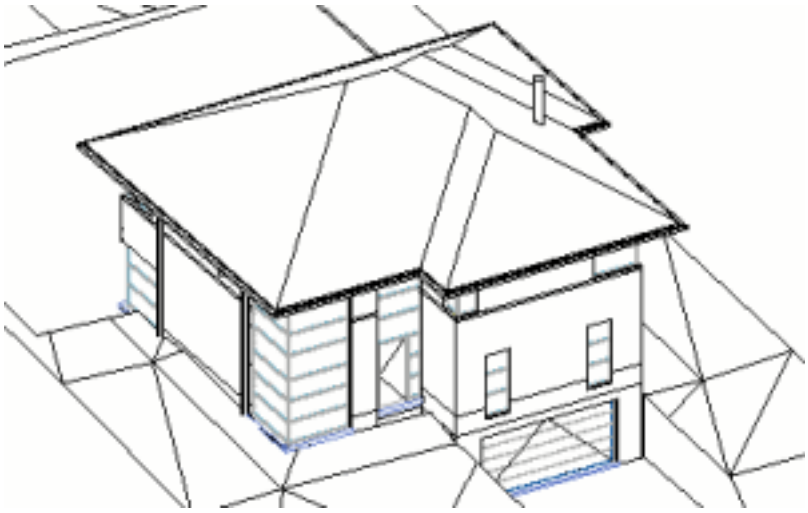

Figure 1.642

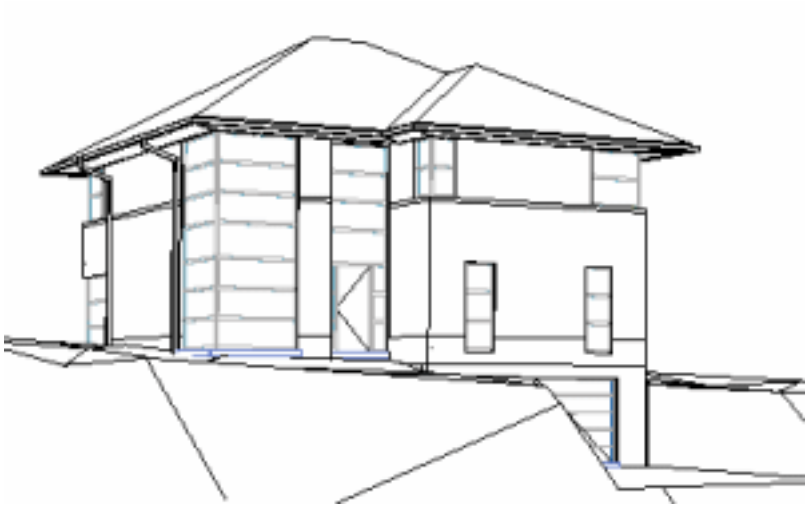

Figure 1.643

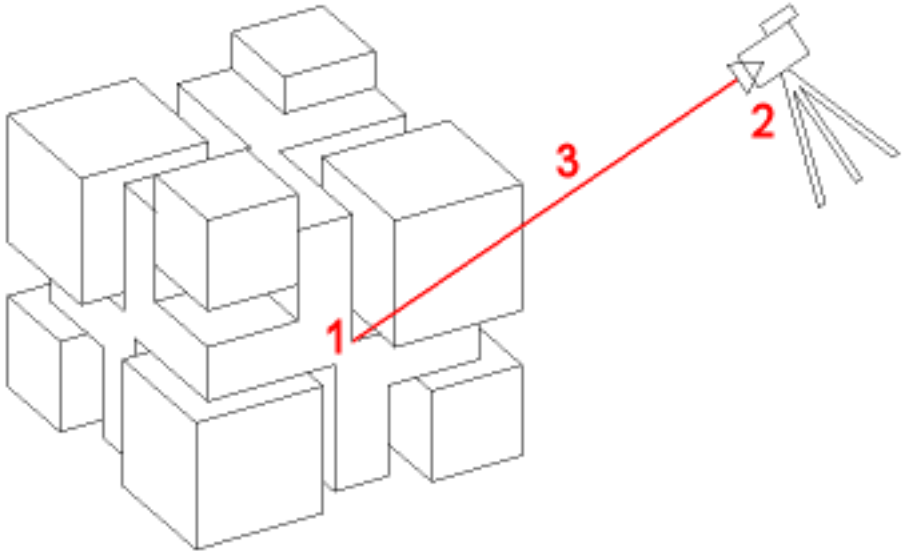


1.23.16 Paper space viewports

Commands: MVIEW (6.21.37), MVSETUP (6.21.34), ALIGNSPACE (6.4.10) and VPCLIP (6.31.18) The **Mview** command creates one or more viewports in layout tabs (short for "make viewports"). The **MvSetup** command creates multiple viewports; in model space the command creates a rectangle, representing a paper sheet with respect to a specified scale. The **AlignSpace** command adjusts viewport angle, zoom factor and pan position based on alignment points specified in model space and paper space. The **Vpclip** command clips viewports in layouts (short for "view port clipping"). In a layout you can create multiple viewports each of which displays a unique view of the entities created in model space. Each layout viewport functions as a window into your model space drawing. You can control the view, scale, and content of each layout viewport separately. A layout viewport is created as a separate entity that you can copy, delete, move, scale, and stretch as you would any other drawing entity. You can snap to the viewport borders using entity snap. When you are working in model space with floating viewports (see Toggle between model space and paper space (1.23.12)), click any layout viewport to make it the current viewport, and then add or modify model space entities in that viewport. Any changes you make in one layout viewport are immediately visible in the other viewports (if the other layout viewports are displaying that portion of the drawing). Zooming or panning in the current viewport affects only that viewport. Each viewport has its own layer visibility settings. You can also turn off the display of the content of a viewport. To preserve the scaling of a viewport you can lock the display. It is no longer possible to zoom or pan in a locked viewport. Apart from viewports, you can add print-related entities in a paper space layout that are not essential to the model itself, such as keynotes, annotations, title blocks, etc. Such entities are part of a specific paper space layout and do not appear in other layouts or in model space. When you are working in a layout, either **Model Space** or **Paper Space** is your current workspace. The **Workspace** field in the Status Bar (1.15.2) indicates which workspace is current: **M:<Layout Name>** indicates you are working in **Model Space** , while **P:<Layout Name>** means **Paper Space** is the current workspace.

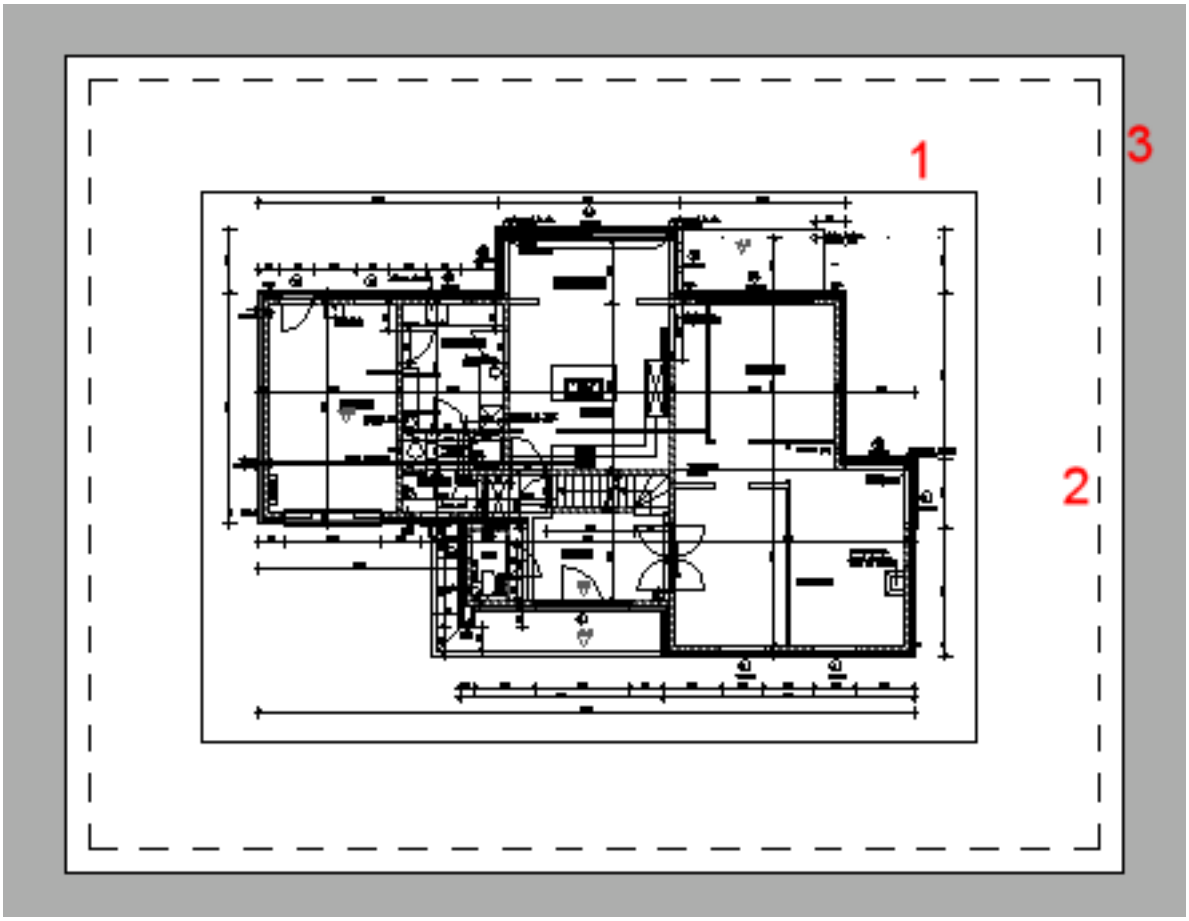
	Model Space, with floating viewports of layout PLAN
	Paper Space of layout PLAN

Displaying the paper sheet and the printable area

(1.644 on the next page)

1. Viewport
2. Printable area. The display of the printable area is controlled through the DISPPAPERMARGINS (1.17.10) system variable.
3. Paper sheet. The display of the paper sheet is controlled through the DISPPAPERBKG (1.17.10) system variable.

Figure 1.644



Creating viewports in a layout

Command: MVIEW (6.21.37)

1. Click the appropriate layout tab (1.23.12) at the bottom of the drawing window.
2. Do one of the following:
   - Click the **Paper Space Views** tool button ( ) on the **Views** toolbar.
   - Choose **Paper Space Views** in the **Views** menu.
   - Type **mview** at the command prompt, then press Enter.
3. (option) To add 1 viewport. do one of the following:
   - Click to specify the first corner of the viewport, then specify the opposite corner. A single viewport which fits in the specified rectangle is created.
   - Choose **Fit to view** in the prompt menu or type **F** , then press Enter. A single viewport which fits in the current drawing display window is created.
4. (option) To create 2 viewports, do one of the following:
   - Choose **Create 2 viewports** in the prompt menu.
   - Type **2** in the command bar, then press Enter.

   You are prompted: Two viewports: Horizontal/<Vertical>:

Option	Result
Horizontal	(1.647 on page 754)
Vertical	(1.648 on page 754)

You are prompted: Fit to screen/<First corner of bounding rectangle>:

- Click to specify the first corner of the bounding rectangle, then specify the opposite corner. Two viewports which fit in the specified bounding rectangle are created.
- Choose **Fit to view** in the prompt menu or type **F** , then press Enter. Two viewports which fit in the current drawing display window are created.

Option	Result
Create 4 viewports	(1.655 on page 755)

You are prompted: Fit to screen/<First corner of bounding rectangle>:

- Click to specify the first corner of the bounding rectangle, then specify the opposite corner. Four viewports which fit in the specified bounding rectangle are created.
- Choose **Fit to view** in the prompt menu or type **F** , then press Enter. Four viewports which fit in the current drawing display window are created.

7. (option) To create a non-rectangular (clipped) viewport using an existing polyline or circle, do one of the following:

   - Choose **Object** in the prompt menu.
   - Type **O** in the command bar, then press Enter.

   You are prompted: Select Object to clip viewport. Select a closed polyline or a circle in the layout.

8. (option) To create a non-rectangular (clipped) viewport, do one of the following:

   - Choose **Polygonal** in the prompt menu.
   - Type **P** in the command bar, then press Enter.

   You are prompted: Specify start point: Specify the vertices of the non-rectangular viewport. Right click or press Enter to create the viewport.

NOTES

- Make sure no other viewports display when choosing the **Fit to view** option because they will be hidden behind the newly created viewport.
- Each newly created viewport shows all entities on the layers which are currently visible in model space.
- Since a new viewport is created on the current layer it is recommended to use a dedicated layer for viewport entities. Make this layer current when you want to add a new viewport. If you don't want the viewport outlines to be printed, set the **Do Not Plot** property of the viewport layer.
- Only circles and closed polylines can be used to create a clipped viewport. If you want to create an elliptical viewport, use the Polyline Ellipse (1.25.21) variable to create a polyline representation of an ellipse.
- To select a clipped viewport do the following: Click the viewport border. Both the viewport and the clipping polygon are selected then, as indicated in the Properties Bar (1.15.4): the list button caption reads: **All (2)** . Press the list button and select **Viewport** to see the properties of the viewport.

Tutorial: Printing in BricsCAD: Paper Space Layouts Click here (1.22.3) to watch

Tutorial: Paper Space Layouts in BricsCAD Click here (1.22.2) to watch

Creating an array of layout viewports

Command: MVSETUP (6.21.34)

1. Type **mvsetup** in the command bar. You are prompted: Enter an option [Align/Create/Scale viewports/Undo]:
2. Do one of the following:
   - Type **C** in the command bar, then press Enter.
   - Choose **Create** in the context menu.

   You are prompted: Enter an option [Delete objects/Create viewports/Undo]<Create>:
3. Press Enter to accept the default option. You are prompted: Enter choice for layout options <0-3> [none(0)/single(1)/std of viewports(3)] <0>:
4. Do one of the following:
   - Type **3** in the command bar, then press Enter.
   - Choose **Array of Viewports** in the prompt menu.

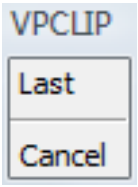
   You are prompted: Specify first corner of bounding area for viewport(s):
5. Pick a point in the layout. **You are prompted:** Other corner of rectangle:
6. Pick a second point in the layout. **You are prompted:** Enter number of viewports in X direction <1>:
7. Specify the number columns in the array. **You are prompted:** Enter number of viewports in Y direction <1>:
8. Specify the number of rows in the array. **You are prompted:** Specify distance between viewports in X direction <0.000>:
9. Press Enter, to create contiguous viewport columns. **You are prompted:** Specify distance between viewports in Y direction <horizontal distance>:
10. Do one of the following:
    - Press Enter to set the vertical spacing equal to the horizontal spacing.
    - Type **0** (zero) to create contiguous viewport rows.
    - Specify the vertical spacing between the viewports.

    The viewports are created.
11. Press Enter to conclude the command.

To clip a viewport

Command: VPCLIP (6.31.18)

1. Type **vpclip** in the command bar, then press Enter. **You are prompted:** Select viewport to clip:
2. Select the viewport. **You are prompted:** Polygonal <Select clipping object>: A prompt menu displays.



3. Do one of the following:
   - Select the clipping object.
   - Choose **Polygonal** in the prompt menu or type **P** , then press Enter. **You are prompted** to draw a polyline (1.25.12).

   The viewport is clipped.

NOTE

- Only closed polylines and circles are accepted as clipping boundaries.
- If you want elliptical viewports, use the polyline representation (1.25.21) to create the ellipses.

To remove the clipping boundary of a viewport

Command: VPCLIP (6.31.18)

1. Type **vpclip** in the command bar, then press Enter. **You are prompted:** Select viewport to clip:
2. Select a clipped viewport. **You are prompted:** Polygonal/Delete<Select clipping entity>:
3. Do one of the following:
   - Type **D** , then press Enter.
   - Choose **Delete** in the prompt menu.

Defining viewport properties

1. Select the viewport. The viewport properties display in the **Properties Bar**. (1.645 on the next page)
2. Click the settings field of a property to modify.

Properties

Name	Description
Center	XYZ coordinates of the center point of the viewport. To specify the center of the viewport graphically, drag the center handle of the viewport.
Height (*)	Height of the viewport in **drawing units** . To specify the height of the viewport graphically, drag the top or bottom handle of the viewport.
Width (*)	Width of the viewport in **drawing units** . To specify the width of the viewport graphically, drag the left or right handle of the viewport.
On	Controls the display of the content of the viewport.
Clipped	Allows to create non-rectangular viewports.
Display locked	Locks the scaling of the viewport content to preserve the scaling factor. The VPLOCK field in the Status bar (1.15.2) displays the Display Locked status of the selected viewport(s). Click the field to toggle the Display Locked property.
Scale	The SCALELISTEDIT (6.27.7) command allows to edit the available scales in the current drawing. Annotation scale Sets the annotation scale for the viewport. If the ANNOALLVISIBLE (1.17.10) system variable is OFF, annotative entities which do not supoort the annotation scale do not display. Standard scale The **Standard scale** field automatically matches the **Annotation scale** field. Although you can set the **Standard scale** field different from the **Annotation scale** field manually, it is not recommended if annotative entities (1.29.25) exist in the drawing. The **Standard scale** field reads 'Custom' if the value in the **Custom scale** field is not available in the drawings scale list. Custom scale Displays the viewport scale factor. Allows to set the viewport scale to a scale which is not available in the drawings scale list.
Standard scale (*)	Lets you choose a standard scaling factor.
Custom scale (*)	Lets you define the scaling factor in a decimal format. Displays the current scaling factor.
UCS per viewport	If Yes, lets you define a UCS for this viewport.
Shade Plot	Defines how the viewport will be plotted. The options are: (1.656 on page 756)

(*) You must choose the width and height of a paperspace viewport with respect to the viewport scale (1.23.16).

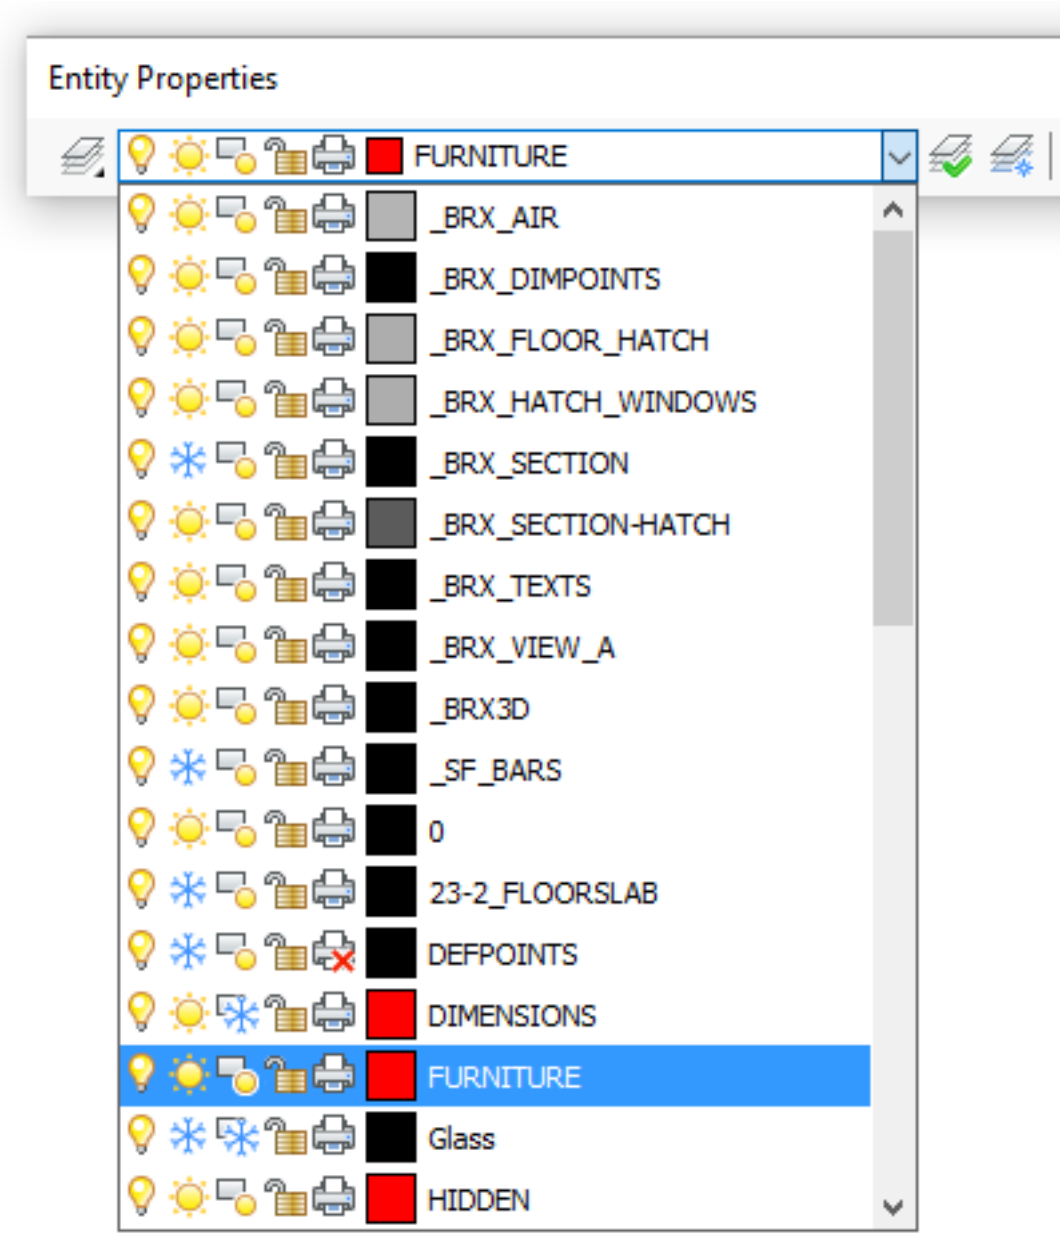
Navigating in a paper space layout

View manipulation commands, such as zoom, pan and view manipulation using the mouse, act slightly different in a paper space layout compared to model space (with tiled viewports). If you are working in paper space (no viewport selected), view manipulation commands act on the complete paper space layout. If you are working in a viewport (model space with floating viewports), view manipulation commands act on the active viewport only. Except if the display of the current viewport is locked, then the view manipulation commands act on the complete paper space layout.

NOTE	It is not possible to rotate the display of a paper space layout. View Rotate (1.23.7) commands are available in viewports of which the display is not locked only.

Tutorial: How to navigate quickly around your drawing Click here (1.9.1) to watch

Figure 1.646



Setting the layer visibility in a viewport

Using the Entity Properties toolbar

1. Do one of the following:
   - If **Paper Space** is the current workspace: double click inside the viewport to make it the current viewport.
   - If **Model Space with floating viewports** is the current workspace: click inside the viewport to make it the current viewport.
2. Select the layer in the layer list of the **Entity Properties** toolbar. (1.646)
3. Do one of the following:
   - Click the **Thawed** icon ( ) of the layer(s) you want to freeze in the current viewport.
   - Click the **Frozen** icon ( ) of the layer(s) you want to thaw in the current viewport.
4. (option) Repeat the previous steps to set the layer visibility in another viewport.

Using the Drawing Explorer / Layers dialog

1. Do one of the following:

- If **Paper Space** is the current workspace: double click inside the viewport to make it the current viewport.
- If **Model Space with floating viewports** is the current workspace: click inside the viewport to make it the current viewport.

2. Do one of the following.

   - Click the **Layers...** tool button on the **Settings** toolbar.
   - Choose **Layers...** in the **Settings** menu.
   - Type **layer** in the command bar, then press Enter.

   The **Drawing Explorer - Layers** window opens.

3. In the **VP Freeze** column:

   - Click the **Thawed** icon ( ) of the layer(s) you want to freeze.
   - Click the **Frozen** icon ( ) of the layer(s) you want to thaw.

4. Close the **Drawing Explorer - Layers** window.
5. (option) Repeat the previous steps to set the layer visibility in another viewport.

NOTE Use the **Viewports / Vpfreeze** option of the LAYOFF (6.20.11) and LAYFRZ (6.20.12) commands to freeze layers in a viewport by clicking entities.

Setting the scale of a viewport

1. Make sure the Plot Scale (1.33.1) property of the layout is set correctly.
2. Switch to **paperspace** . (See Toggle between model space and paper space (1.23.12))
3. Click the viewport border. The viewport properties display in the BricsCAD Properties Bar (1.15.4).
4. Do one of the following:

   - Select the **Annotation scale** field, then click the **Browse** button ( ) and select a scale in the scale list. The **Standard scale** and **Custom scale** fields are updated automatically.
   - Select the **Standard scale** field, then click the **Browse** button ( ) and select a scale in the scale list. The **Custom scale** field is updated automatically.
   - Select the **Custom scale** field and type the scale factor. If the scale factor is not available in the drawings scale list, the **Standard scale** field reads 'Custom'.

5. (option) If necessary, adjust the size of the viewport to the new scale.
6. (option) Set the **Display Locked** property to **Yes** . The scale fields are greyed out and cannot be edited anymore.

NOTE In a **locked viewport** it is impossible to:

- zoom, pan or rotate the view
- modify the scale

Setting the scale of a selection of viewports

Command: MVSETUP (6.21.34)

1. Make sure the Plot Scale (1.33.1) property of the layout is set correctly.
2. Type **mvsetup** in the command bar. You are prompted: Enter an option [Align/Create/Scale viewports/Undo]:
3. Do one of the following:

- Type **S** in the command bar, then press Enter.
- Choose **Scale viewports** in the prompt menu.

You are prompted: Select entities

4. Select the viewports.
5. Press Enter or right click to stop selecting viewports. **You are prompted:** Set the scaling mode of viewports: Interactively/<Uniform>:
6. Do one of the following:
   - Press Enter to set the scale of the selected viewports uniformly. You are prompted: Enter the number of paper space units <1.0>:
     - Press Enter to accept the number of paper space units. You are prompted: Enter the number of model space units <1.0>:
     - Type the desired scaling factor: e.g. 50 to apply a 1/50 scale.
     - Press Enter to apply the scale to all selected viewports.
     - Press Enter to conclude the command.
   - Choose **Interactively** in the prompt menu or type **I** , then press Enter. The first viewport in the selection set highlights. You are prompted: Enter the number of paper space units <1.0>:
     - Press Enter to accept the number of paper space units. You are prompted: Enter the number of model space units <1.0>:
     - Type the desired scaling factor: e.g. 50 to apply a 1/50 scale.
     - Press Enter to apply the scale to the viewport. The next viewport highlights. You are prompted: Enter the number of paper space units <1.0>:
     - Repeat the previous steps for each of the selected viewports.
7. Press Enter to conclude the command.

To rotate the display in a viewport

The display of a layout viewport can be rotated only if the display of the viewport is not locked. If the VPROTATE-ASSOC (1.17.10) system variable is ON, the ROTATE (6.26.29) command rotates the content of a viewport over a specified angle. The **Align > Rotate** option of the MVSETUP (6.21.34) command rotates the content of a viewport relative to the X-axis of the world coordinate system (WCS).

Rotating the viewport display

1. Select the viewport, then right click and choose **2D Rotate** in the context menu. **You are prompted:** Rotation point.
2. Use the **Center** () entity snap to select the center point of the viewport as the rotation point. **You are prompted:** Copy/Base angle/<Rotation angle> <0>:
3. Type the rotation angle, then press Enter.
4. The content of the viewport is rotated over the specified angle.

Defining the rotation angle of the viewport display

1. Type **mvsetup** in the command bar. **You are prompted:** Enter an option [Align/Create/Scale viewports/Undo]:
2. Do on of the following:
   - Type **A** in the command bar, then press Enter.
   - Choose **Align** in the prompt menu. **You are prompted:** Enter an option [Angled/Horizontal alignment/Vertical alignment/Rotate view/Undo]:
3. Do one of the following:
   - Type **R** in the command bar, then press Enter.
   - Choose **Rotate view** in the prompt menu. **You are prompted:** Specify basepoint in the viewport to be rotate:

4. Specify the rotation point in the viewport. **You are prompted:** Specify rotation angle:
5. Type the rotation angle in the command bar, then press Enter. The viewport display is rotated over the specified angle with respect to the X-axis of the WCS.

NOTE	Type 0 (zero) in the final step of the above procedure to undo the rotation of the viewport display.

To align viewports

Command: MVSETUP (6.21.34)

1. Type **mvsetup** in the command bar. **You are prompted:** Enter an option [Align/Create/Scale viewports/Undo]:
2. Do on of the following:
   - Type **A** in the command bar, then press Enter.
   - Choose **Align** in the prompt menu. **You are prompted:** Enter an option [Angled/Horizontal alignment/Vertical alignment/Rotate view/Undo]:
3. Do one of the following:
   - To align two viewports horizontally:
     - Choose **Horizontal alignment** in the context menu or type **H** in the command bar, then press Enter. **You are prompted:** Specify basepoint:
     - Pick a point in the reference viewport. **You are prompted:** Specify point in viewport to be panned:
     - Pick a point in the viewport to be aligned. The display in the viewport is moved vertically to align the two points horizontally.
   - To align two viewports vertically:
     - Choose **Vertical alignment** in the context menu or type **V** in the command bar, then press Enter. **You are prompted:** Specify basepoint:
     - Pick a point in the reference viewport. **You are prompted:** Specify point in viewport to be panned:
     - Pick a point in the viewport to be aligned. The display in the viewport is moved horizontally to align the two points vertically.

Tutorial: Printing in BricsCAD: Viewports Click here (1.22.4) to watch

To align model space and paper space points

Command: ALIGNSPACE (6.4.10)

Aligning 1 point

1. Type **alignspace** in the command bar, then press Enter. **You are prompted:** First alignment point in Model space:
2. Click inside a layout viewport, then pick a point. **You are prompted:** Second alignment point in Model space or <Return> for none:
3. Right click or press Enter. **You are prompted:** Alignment point in Paper space:
4. Pick a point in the layout. **You are prompted:** Activate the viewport which will be used for alignment.
5. Click inside the viewport you want to align.
6. Right click or press Enter to confirm. The display in the selected viewport is moved to make the two points coincident.

Figure 1.647

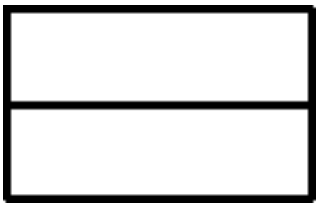


Figure 1.648

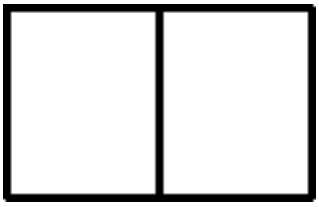

Aligning 2 points

1. Type **alignspace** in the command bar, then press Enter. **You are prompted:** First alignment point in Model space:
2. Click inside a layout viewport, then pick a point. **You are prompted:** Second alignment point in Model space or <Return> for none:
3. Pick a second point in the layout viewport. **You are prompted:** First alignment point in Paper space:
4. Pick a point in the layout. **You are prompted:** Second alignment point in Paper space:
5. Pick a second point in the layout. **You are prompted:** Activate the viewport which will be used for alignment.
6. Click inside the viewport you want to align.
7. Right click or press Enter to confirm. The display in the selected viewport is moved, rotated and/or scaled to make the points two by two coincident.

1.24.1 Unlock BricsCAD's extra features

https://www.youtube-nocookie.com/embed/7Pg4OEQRwN4 BricsCAD has quite a lot of commands that don't appear on the menu, ribbon, or toolbars. If you don't know about these, then you're missing out on features. In this video we'll show you how to find these commands, and then highlight a couple that you may find useful.

Don't miss out on features!

Back to Tutorial Overview

1.24.2 The Case for Using LISP Today, Part 2

Copy & rotate the easy way with LISP

In contrast to the .NET example I pointed you to in the last episode of this blog, here is a simple example of a LISP command used to Copy & Rotate objects: Now that's a short program! Like I mentioned above, this “command" combines the Move and Rotate commands in to a single command.

The same program, with comments:

In LISP, the semi-colon marks a comment line, so anything after is not processed. To improve the usability of our function, we could add a “while" loop (to keep asking for more selections), and give angular options, turn Osnaps or Ortho on/off, etc…

Is a LISP routine too much?

Having presented this, I will tell you that there are many cases where a LISP routine can be over-kill. If you are simply executing a string of commands that don't require “manipulation" of the data between functions, or where the entry of data is consistent, then menu macros can be even more efficient than LISP. But, menu macros can't be designed with choices and they can be “brittle" – that is, easy to break – as they can't handle errors. My recommendation? Here's a bit of a hybrid – it's a one-line LISP routine: ***^c^c(command “Select" pause “copy" “p" “ " “@" “@" “move" “p" “ " pause pause “rotate" “p" “ " “@" pause)** This simple, yet elegant LISP “macro" functions exactly as the program above, with the added automatic function repeat (*^c^c), and gives all the dynamic graphical user feedback of a sophisticated program. Simply add an icon to one of your menus using the CUI interface and plug the line above into the command string, and you have a super cool copy / rotate function.

The right tool for the job

You might be thinking that it's just as easy to use Grips in BricsCAD and right-click to cycle through all the options. My reply would be to remind you that I'm (really) old school, and while I use Grips often, I also know the Esc key has always been the first key to die from abuse on my keyboard (OK, not really). The main point here is to make sure you are using the right tool for the job, and while there are certainly valid uses for .NET applications, I can't bring myself to write pages of compiled code when I can do the job cleanly with a few lines of LISP. Hopefully, this introduction has peaked your interest. I think that you will find some useful tips/suggestions as you dive into the world of LISP. Remember, it's all about getting your design work done quickly and accurately. What better way than using the features built into BricsCAD to make it work your way? Back to Tutorial Overview

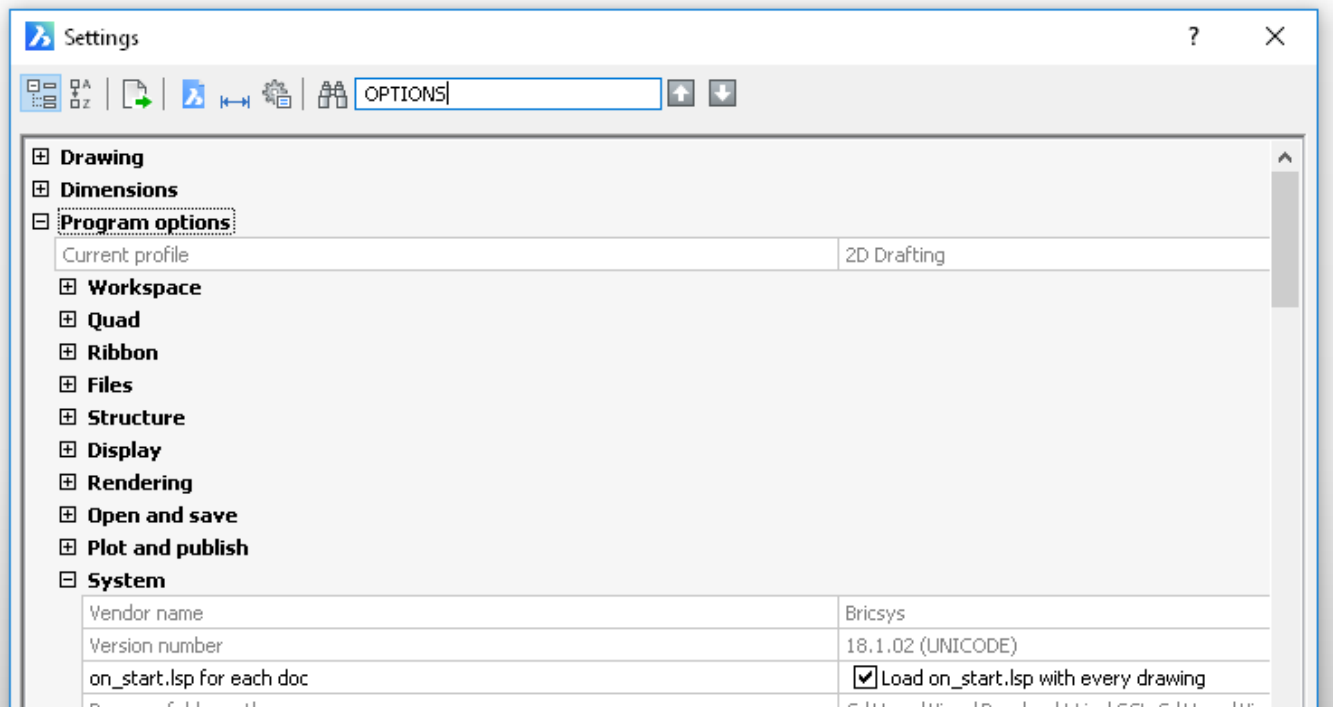
1.24.3 BricsCAD Lisp – Migrating from OtherCAD

BricsCAD LISP versus OtherLISP

If you've read my previous posts (**part 1** and **part 2**), you know that BricsCAD fully supports the LISP tools that you and your company have relied upon for years (perhaps decades). Now, as you move to BricsCAD, you are ready to migrate your environment and standards. What are some of the items to consider? For the sake of this discussion, we are going to focus on LISP customization and not on menu and custom user interface (CUI) modifications. However, I would first recommend using the default BricsCAD interface for a week or so before you make any changes to the menus. For me, I found that I actually preferred the standard layout and command access of BricsCAD over the "other" environment. Once I discovered where all commands were located, I found that I wasn't toggling between tool menu palates as often as I did in OtherCAD. As a side note… you know you are truly "old school" when you prefer to type short-cut commands with your non-mouse hand, rather than picking through 2 or 3 levels of menus. The more I use BricsCAD, the less I seem to rely on those keyboard short-cuts. The streamlined user interface and the quad cursor actually make it easier to use menus than to type. Try it, you'll love it.

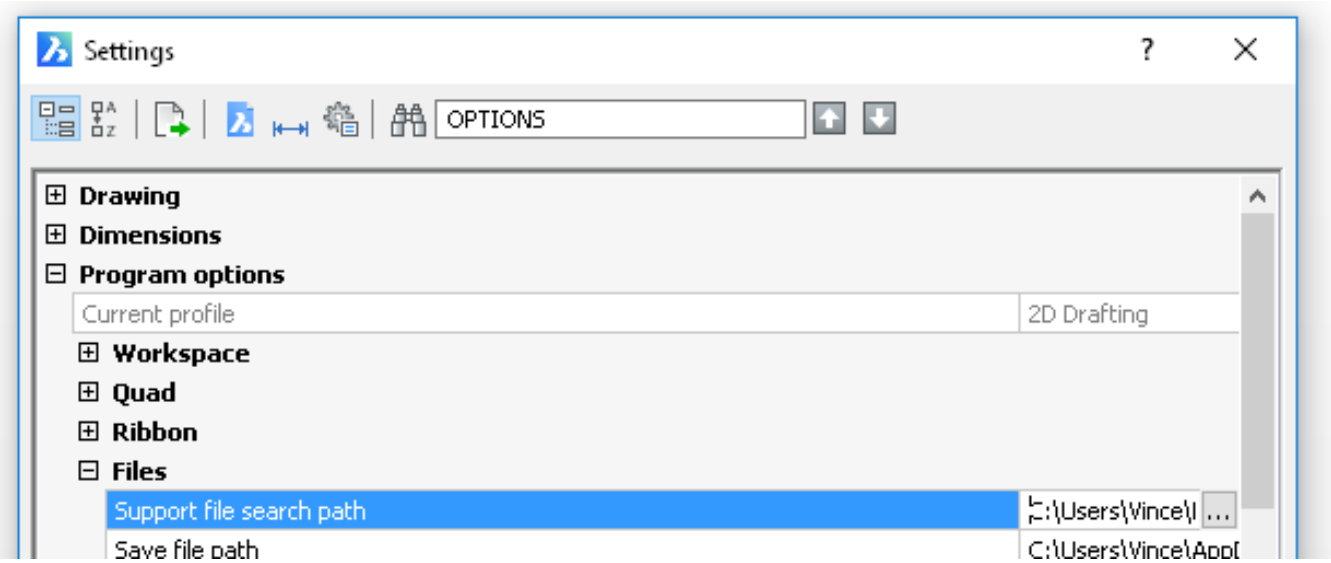
Almost no differences When you're ready to start migrating, you'll find that there are virtually no differences in BricsCAD LISP versus OtherLISP. Your code loads and runs, and the functionality is identical. The primary differences when "porting" your apps will be a few minor setup steps, command line structure, and possibly file locations. To start, let review the setup and launch of your existing programs in BricsCAD. If you are auto-launching your programs using **Acad.lsp** or **Acaddoc.lsp**, you will simply need to rename and or combine those files into a single file named "**on_start.lsp**". To enable this feature, simply toggle the option in Settings / Program options / System: (1.657 on the following page) I prefer to always enable this option.

Figure 1.657



Enjoy the BricsCAD Settings Panel I would also recommend that you prepare to spend a little time familiarizing yourself with the Options/Setting menu in BricsCAD. As you dive in, you will find a ton of settings and options you probably wish you had in your "other" CAD environment. Welcome to BricsCAD! The next step in the settings dialog would be to add your support folders to the Files search path, which is found within Settings / Program Options / Files: (1.658 on the next page) As a rule, I never hard code any paths unless absolutely necessary. The support paths I use will typically be added as in the manner above and/or located one level below the current project folder. Typically, I will use a "findfile" function to validate the file exists before proceeding with my commands, as in the method below: `(if (findfile "custom-code.lsp") (load "custom-code"))` In fact, this is one of the methods I've used to demand-load my functions within the **on_start.lsp** file: `(defun c:my-function () ; this defines the command(if (findfile "custom-code.lsp") ; check if the file exists(load "custom-code") ; if True, launch(alert "Custom-code not in Support Path!") ; not True, so alert) ; end If statement) ; end function` The command defun (DEfine FUNction) is the same name as the function inside of your **on_start.lsp** file and that function redefines the calling function when it's launched. This is another cool reason for using this method, as it demonstrates how dynamic LISP can be!

Figure 1.658



Take advantage of your move to BricsCAD... When your engineering workflow is running, you usually build a long list of maintenance items that you keep putting off. Migrating to a new CAD environment offers an opportunity to make some of those updates and update your documentation standards. Almost every client that I've helped to migrate need to address old-style hard-coded paths, 8.3 syntax filenames, old layer naming conventions and other no-nos within their standards. As we move forward in this series, I will share some of the methods I use to store user settings and defaults external to your LISP code, so that they can be updated more easily. Until next time, happy coding! Back to Tutorial Overview

1.24.4 The Case for Using LISP Today, Part 1

LISP: What is old is still very new

Welcome to Part 1 of my first post on the Bricsys Blog! I'll be writing about LISPprogramming and transitioning your existing code into the BricsCAD environment. I'll review implementation, differences from other environments, tips & tricks, and other topic requests from our readers. Or, if you haven't started looking at LISP, maybe I can give a little encouragement and let you know that LISP is alive and well. It is definitely a language worth considering for BricsCAD customization. First, let me state that I've written a couple hundred thousand lines of LISP over the last few decades. But I still would not call myself an expert. I don't know all of the vl-commands, or some of the more "advanced" functions. Please forgive me if I present a method that isn't the most efficient, or if I suggest a paragraph of code that could be replaced by a single function. Chances are good that I had no idea that the "better" function existed! I still stumble across "new" (to me) commands on a regular basis. When I do, I often wonder how much time that newly-discovered function might have saved me. A while back I was questioned by a client about my continued coding in LISP. I actually thought it may have become a skill set that had become obsolete. Think about (manual) drafting skills and mastery of the Vemco Drafting Machine – now, those are obsolete! But when I looked at my customer's real needs, I found more and more reasons to update or develop new LISP functions. I think that it will be fun to share some of these concepts with you to help you get started.

Is LISP the Rosetta Stone of CAD customization?

The name "LISP" comes from the words "List Processing". Data is stored in .dwg files as lists, and LISP reads, writes, changes and stores that data. Best of all, this code is platform independent. It's efficient, small and flexible. I prefer the simplicity of developing code in a non-compiled language. While LISP code does not need to be compiled, you can encrypt your programs to protect your source code. Many programs that I wrote twenty years ago on "vintage" hardware/software/OSes still work today in current versions of BricsCAD with little or no modifications. Recently, I was asked to solve a migration issue for a client who was transitioning from AutoCAD™ 2014 to 2016. This company's standard CAD setup included over 400 program files with 123,000 lines of LISP code, with around 4,000 functions defined. After a bit of research, I discovered that the primary issue was related to a couple of (compiled) ARX applications that were not compatible with AutoCAD™ 2016. **Their LISP code, much of which was written in the late 90s, ran perfectly.** When I'm asked to consult on CAD standards migration, I first determine how much of a company's workflow is dependent on 3rd party tools. Then, I check to see if their tools need specific software versions or platforms. Often, the only issues revolve around hard-coded folder paths that need to be updated.

Why use LISP for custom CAD programs?

So, what are some reasons to create custom programs in your CAD environment? Typically, I write code to improve process or workflow automation, relating to specific CAD entities or CAD standards. Routines can be as simple as a few lines of code. These functions can perform layer manipulations, change entity properties, automate drawing and XREF relationships, or help standardize plotting and publishing workflows. Or, these routines can be as complex as a parameter-driven design process, or an application to automate database access. As I mentioned earlier, a key benefit to using LISP is simply the small size and great efficiency of the language in a CAD environment. In the example we'll explore in Part 2 of this post, the LISP code to do simple geometry manipulation (move and rotate) can be a fraction of what one might have to write in a compiled language (.NET, C, C++, et al). For the sake of page space, I'm not including a .NET example here. But, if you really want to see what I'm talking about, just Google: **"Create a move command with .NET API"** and you'll see a few examples. These compiled languages often require hundreds to thousands of lines of code to create the graphical behaviors and intuitive interfaces that users expect in a day-to-day CAD environment. (This post will be continued in Part 2 (1.24.2)) You can customize BricsCAD by adding custom programs written in any of several programming languages that run within BricsCAD. See here which API's are available**. Back to Tutorial Overview**

1.25 2D Drafting

1.25.1 Drawing Entities Overview

In a drawing you can create a variety of different entity types. Drawing entities can be very simple such as lines, circles, arcs, points and rays or complex such as polylines, splines and planes. Apart from 2D entities you can also create 3D surface entities or 3D solids in BricsCAD. To further complete your drawing BricsCAD provides a series of tools to add text, hatching and dimensions. To create an entity you can choose between selecting the command in the Draw menu, using the tools on the Draw, Draw 3D and Solids toolbars or typing the command in the command bar. When you use a tool or a drawing command, the program prompts you to enter coordinate points, such as endpoints or insertion points. You can enter the points or distances either using a mouse or by typing coordinate values in the command bar. As you draw, BricsCAD also displays a context-sensitive prompt menu with appropriate additional options for the type of entity you are drawing. New entities are created on the current layer (1.25.3), using the current color (1.25.5), linetype (6.20.32) and lineweight (1.25.7).

1.25.2 Settings for Drawing Entities

The default values and preferences to create many of the fundamental 2D drawing entities are specified by system variables. You can view and modify variables in BricsCADusing the SETVAR command at the Command line. If you prefer to change variables through the user interface, you can use the Settings dialog. It offers a single, central location to view and modify all the variables in BricsCAD. There are more than 900 of them!

BricsCAD Settings

Access Settings from the General menu on the Quad or via other methods including the Command line (SETTINGS, OPTIONS). (1.659 on the facing page) With so many variables, I can't possibly cover them all in this post. Instead, I'll focus on the ones for entity creation. After opening the Settings dialog box, expand the Drafting node and then expand Entity Creation. These properties apply to new entities you create. At the top of the list are general properties including color, linetype, and layer. Below that are entity-specific properties. (1.660 on the next page) Expand an entity node, such as Hatches, to view and modify its relevant properties. Select a property to display the name of the variable it controls in the lower left corner of the dialog box. (1.661 on page 766) Some of the entity controls are available from other locations, such as the Entity Properties toolbar. But, you will find ALL of them in the Settings dialog box. You don't have to navigate through multiple dialog boxes in search of the control you want. And, the best part is the search capability. Enter a relevant term in the search box, such as HATCH or PICK. Relevant properties highlight as you click your way through each occurrence of the term. Even if you are completely new to BricsCAD, you can easily find the settings you're looking for! (1.662 on page 766)

Figure 1.659

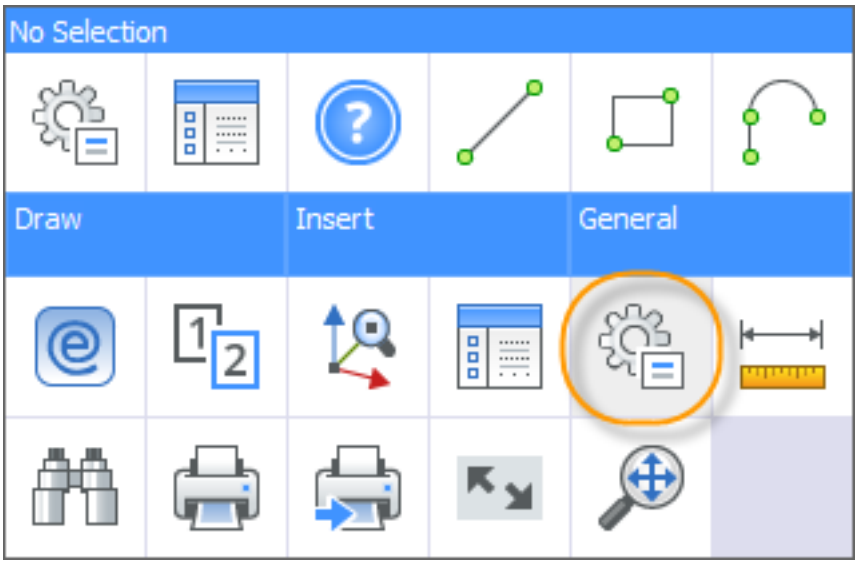


Figure 1.660

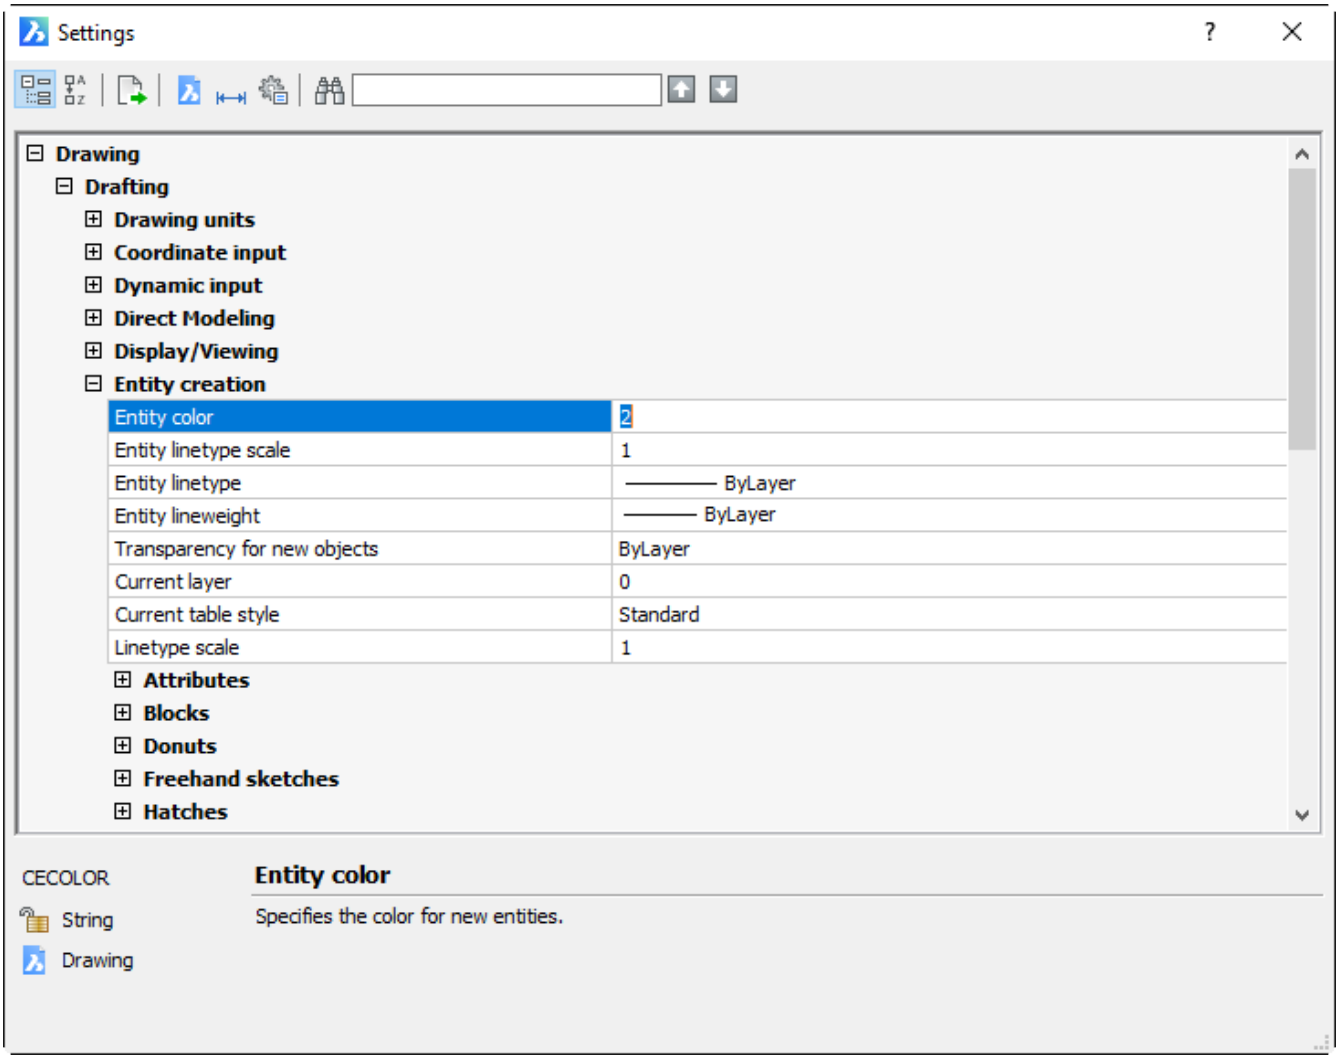

Figure 1.661

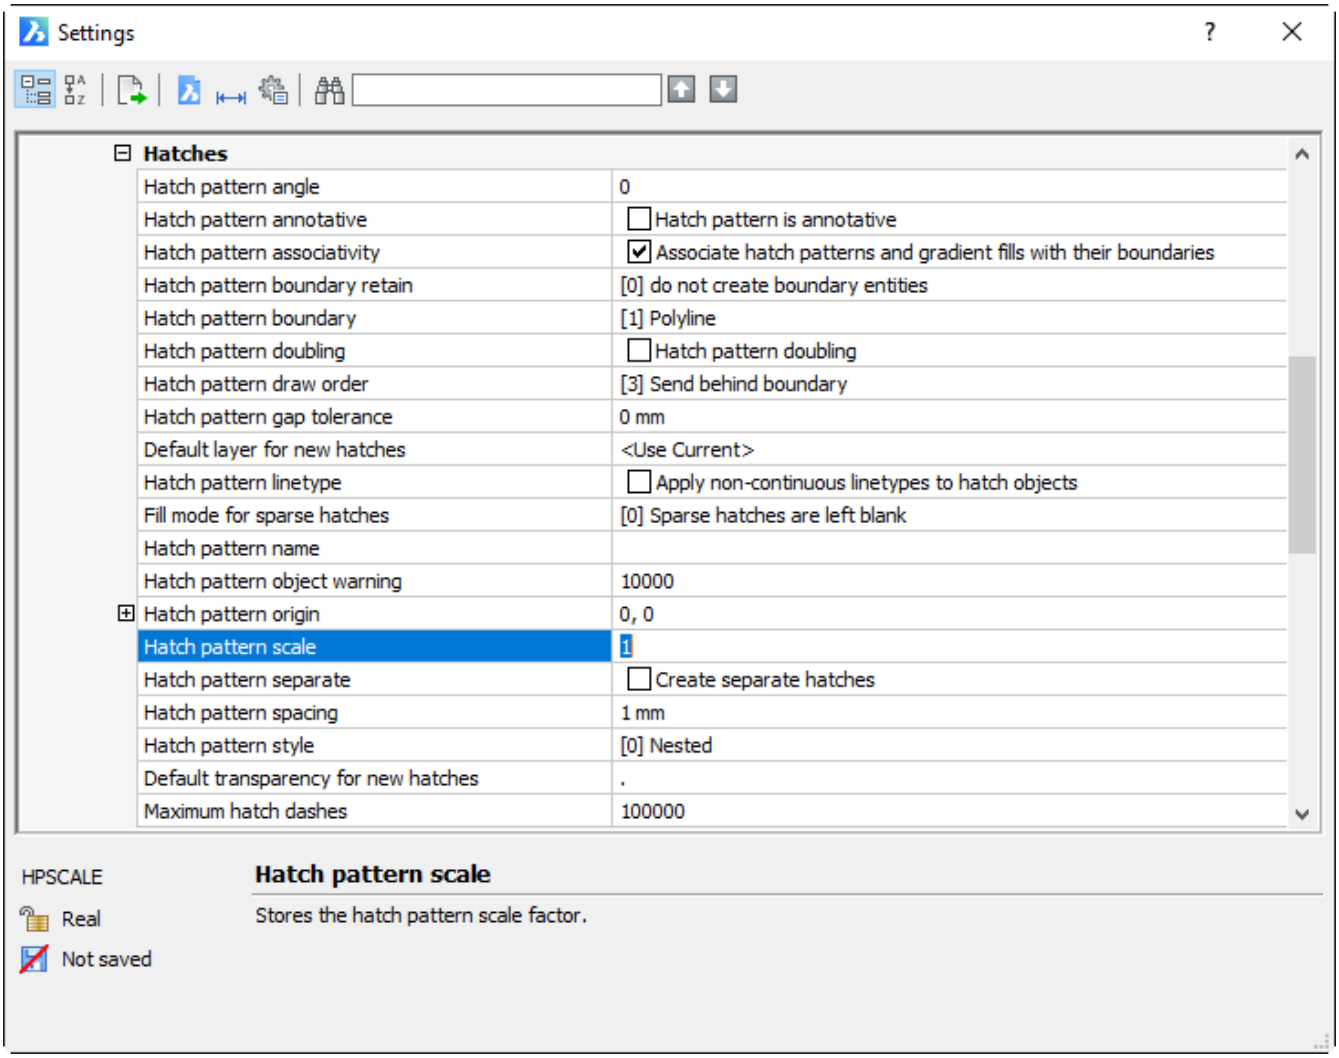

Figure 1.662

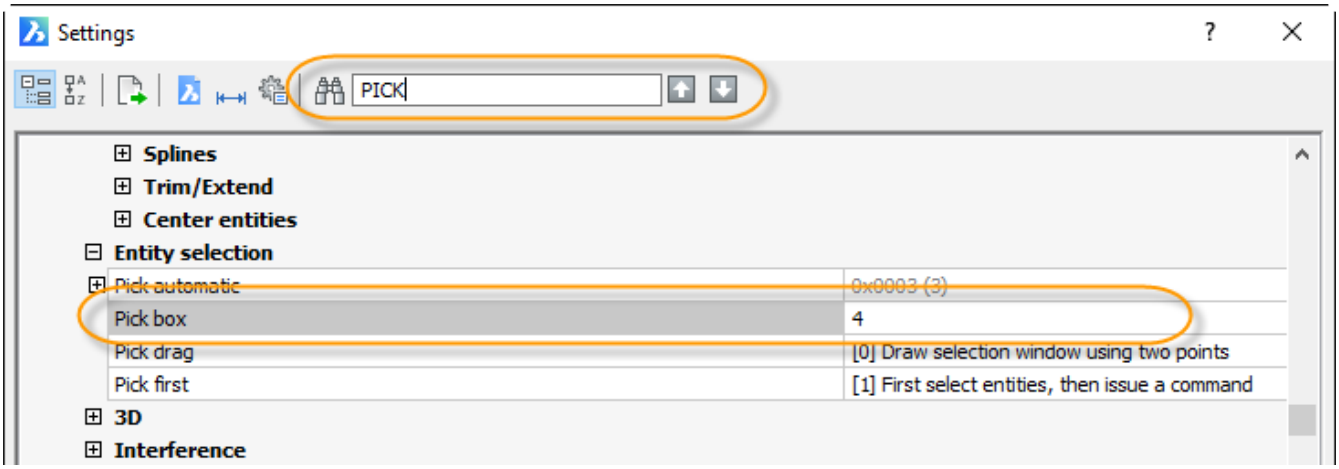

1.25.3 Current Layer

When you create new entities, they are drawn on the current layer. To draw new entities on a different layer, you must first make that layer the current layer.

- The current layer is saved through the CLAYER system variable.
- The CENTERLAYER* system variable controls the layer where centerlines and centermarks created by the DIMCENTER (6.11.7) command are placed on.
- The DIMLAYER* system variable controls the layer for dimension entities created by the dimensioning commands (1.29.1).
- Entities created by the INTERFERE (6.17.17) command are created on the layer which is specified by the INTERFERELAYER system variable.

* The default value is <Use Current>

Setting the current layer

Do one of the following:

- On the BricsCAD Properties Bar (1.15.4), select **Layer** . Make sure, no entity is selected. Choose a layer in the drop down list. (1.663 on the following page)
- On the Entity Properties toolbar, click the down arrow next to the **Layer** field, then choose a layer in the drop down list.
- Right click on the **Layer** field in the Status Bar (1.15.2), then choose a layer in the context menu.

NOTES

- It is possible to turn the display of the current layer off ( ). As a result, everything you draw will be invisible until the display of the current layer is turned on ( ) again. A warning displays if you try to turn off the current layer.
- The LAYISO (6.20.7) command allows to isolate layers by either lock or turn off other layers. If no entity on the current layer is selected, the layer of the entity that is selected first temporarily becomes the current layer until the LAYUNISO (6.20.20) command is executed.
- It is not possible the freeze ( ) the current layer.

1.25.4 Working with Layers and Linetypes

Drawing Explorer

The default method to create and manage layers in BricsCAD is via Drawing Explorer. Because, like everything else in Drawing Explorer, layers are named drawing content. You can, of course, launch Drawing Explorer from the Quad and other methods including the command line. You can also launch it with the LAYER command (LA alias). Doing so automatically displays the Layers panels in Drawing Explorer. (1.665 on the next page) One of the primary benefits of managing layers in Drawing Explorer is the ability to preview layer geometry as you manage layer properties. It is similar to the LAYWALK tool in AutoCAD®. However, unlike AutoCAD, BricsCAD enables you to view geometry on any number of layers and then, with those layers already selected, you can change their properties. It's very cool and eliminates the need for a separate LAYWALK command. (1.665 on the following page) The toolbar and right-click menu provide access to additional tools relevant for layer management. For example, you can merge layers or open and close the Filters panel. (1.666 on page 771) Drawing Explorer is incredibly useful as a central location for managing all the named content in your drawings. However, it is a dialog box and cannot remain open while you use other commands.

Figure 1.664

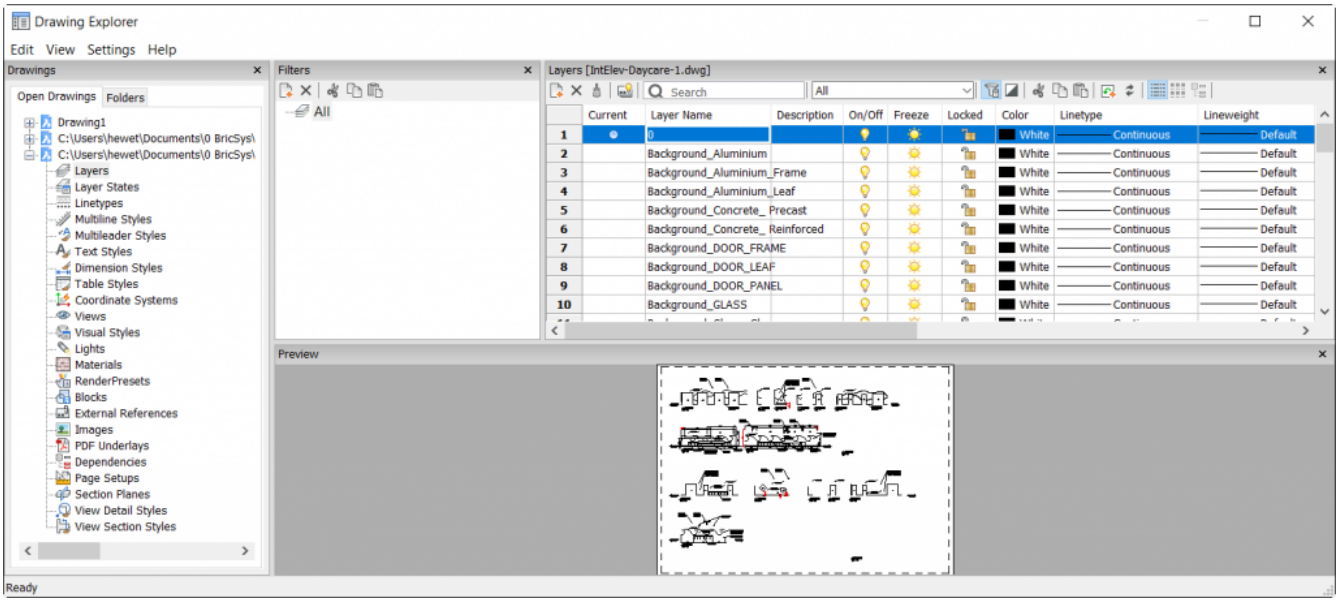

Figure 1.665

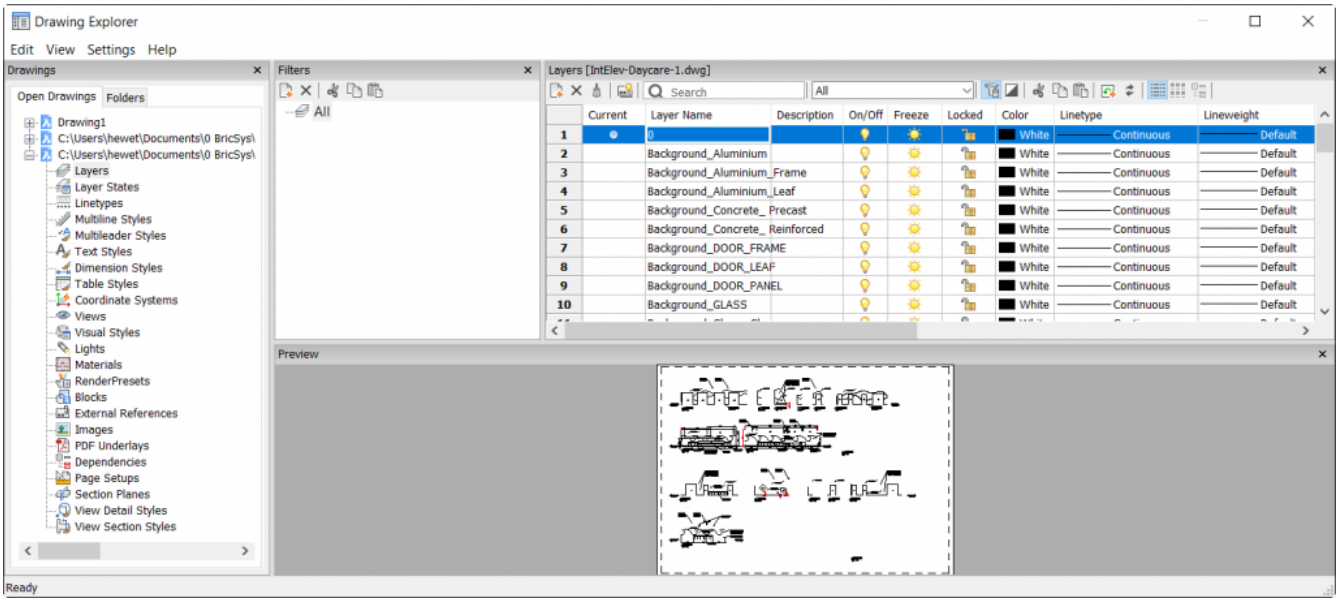

Figure 1.666

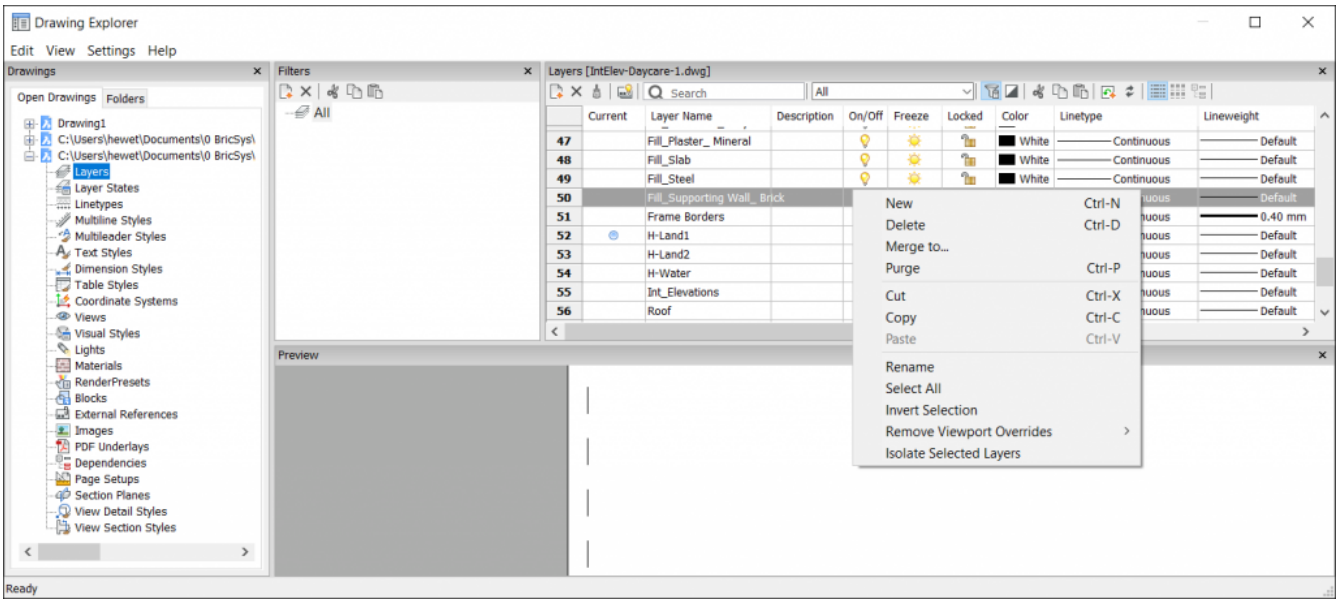
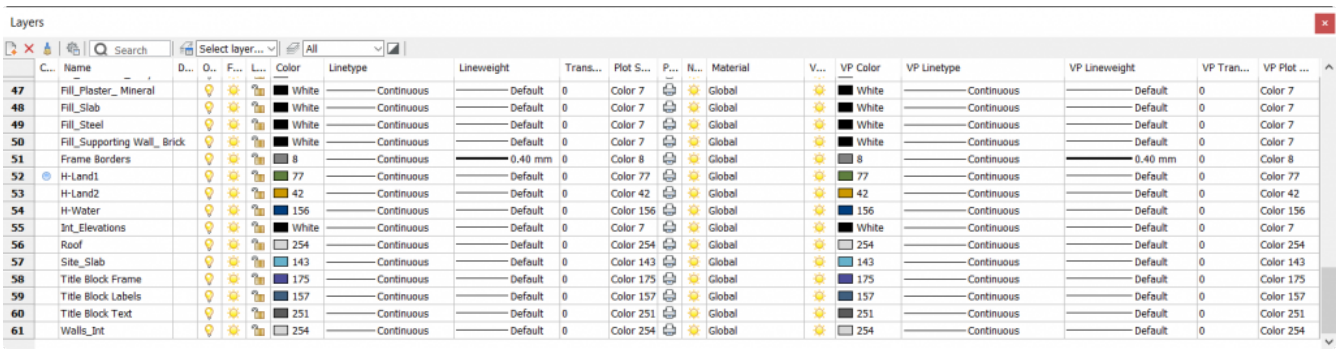


Layers Panel

If you frequently access the Layers panel, you may want to leave it open while you work. No problem! Use the LAYERSPANELOPEN command to display only the Layers panel from the Drawing Explorer. Move and resize it as you wish, and even move it to a second monitor. If you find old habits hard to break and prefer for the LAYER command and LA alias to open the Layers panel instead of the Drawing Explorer. It's easy to change and I'll show you how in a future post! (1.667)

Figure 1.667

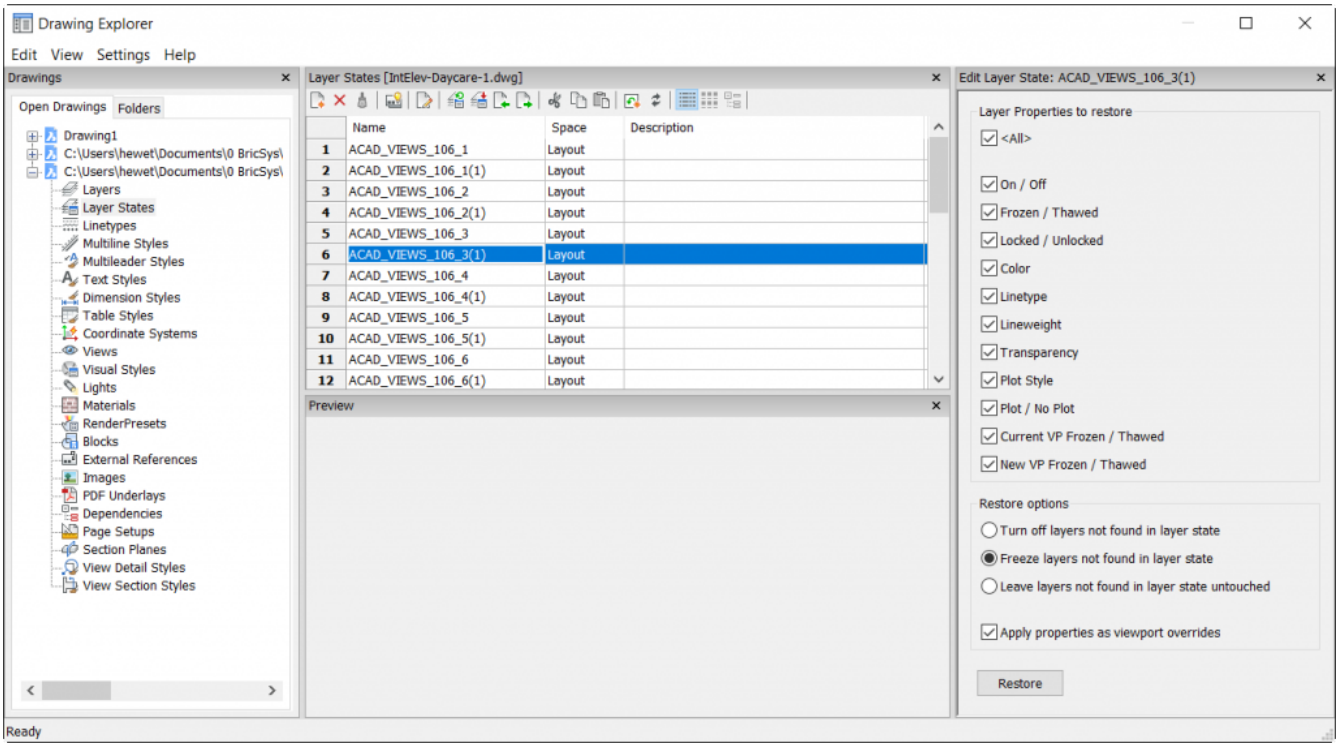


Layer States

Layer states are named content stored in a drawing. How do you think you access them in BricsCAD? If you answered, “Drawing Explorer", you're correct! You can, of course, open Drawing Explorer via typical methods. Or you can launch it with the LAYERSTATE command (LAS alias) to open it with the Layer States panels already displayed. It includes one panel to access layer states and another panel to modify properties for the selected state. (1.668 on the next page)

Tutorial: Employing the Display Power of Layer States Click here (1.12.17) to watch

Figure 1.668



Linetypes

The LINETYPE command (LT alias) in BricsCAD opens the Drawing Explorer with the Linetypes panel displayed. This is where you can load new linetypes or delete existing ones. It's like the Linetype Manager in AutoCAD. However, in BricsCAD you won't find controls for linetype scaling (LTSCALE and CELTSCALE) in the Drawing Explorer because those aren't named content. (1.669 on the following page) Instead, you can specify Linetype scales in the Settings dialog box or at the Command line like any other system variable. (1.670 on the next page)

Figure 1.669

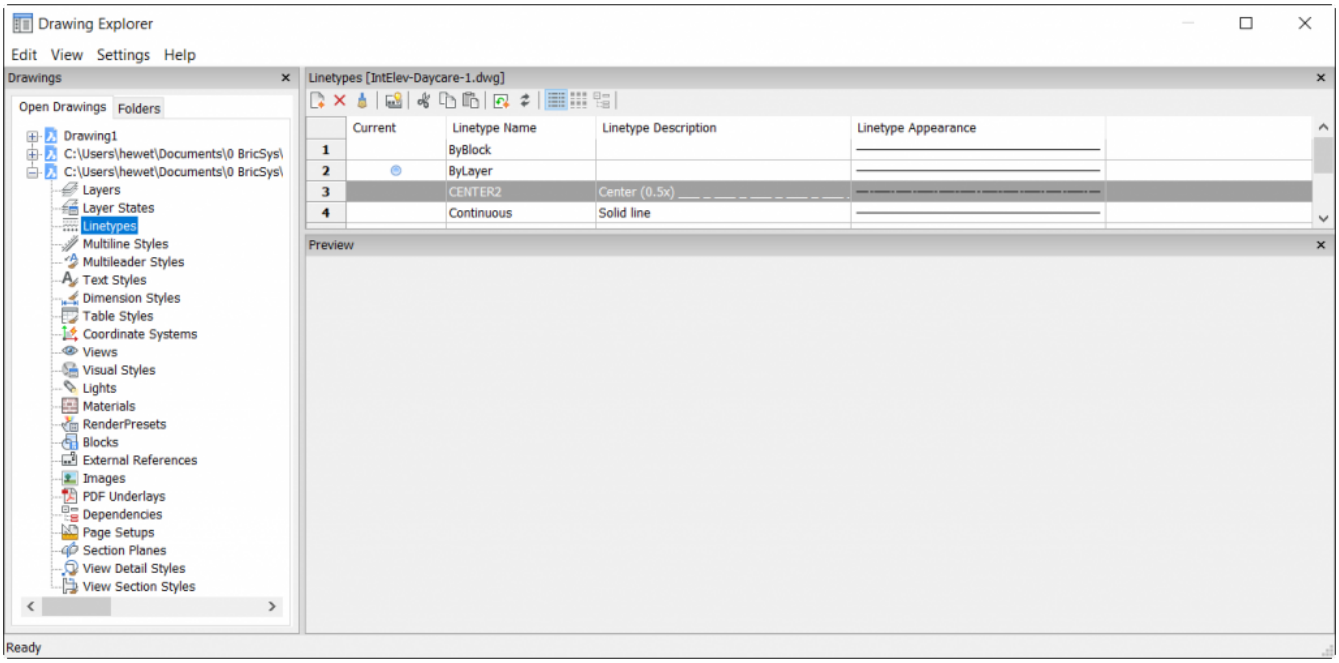


Figure 1.670

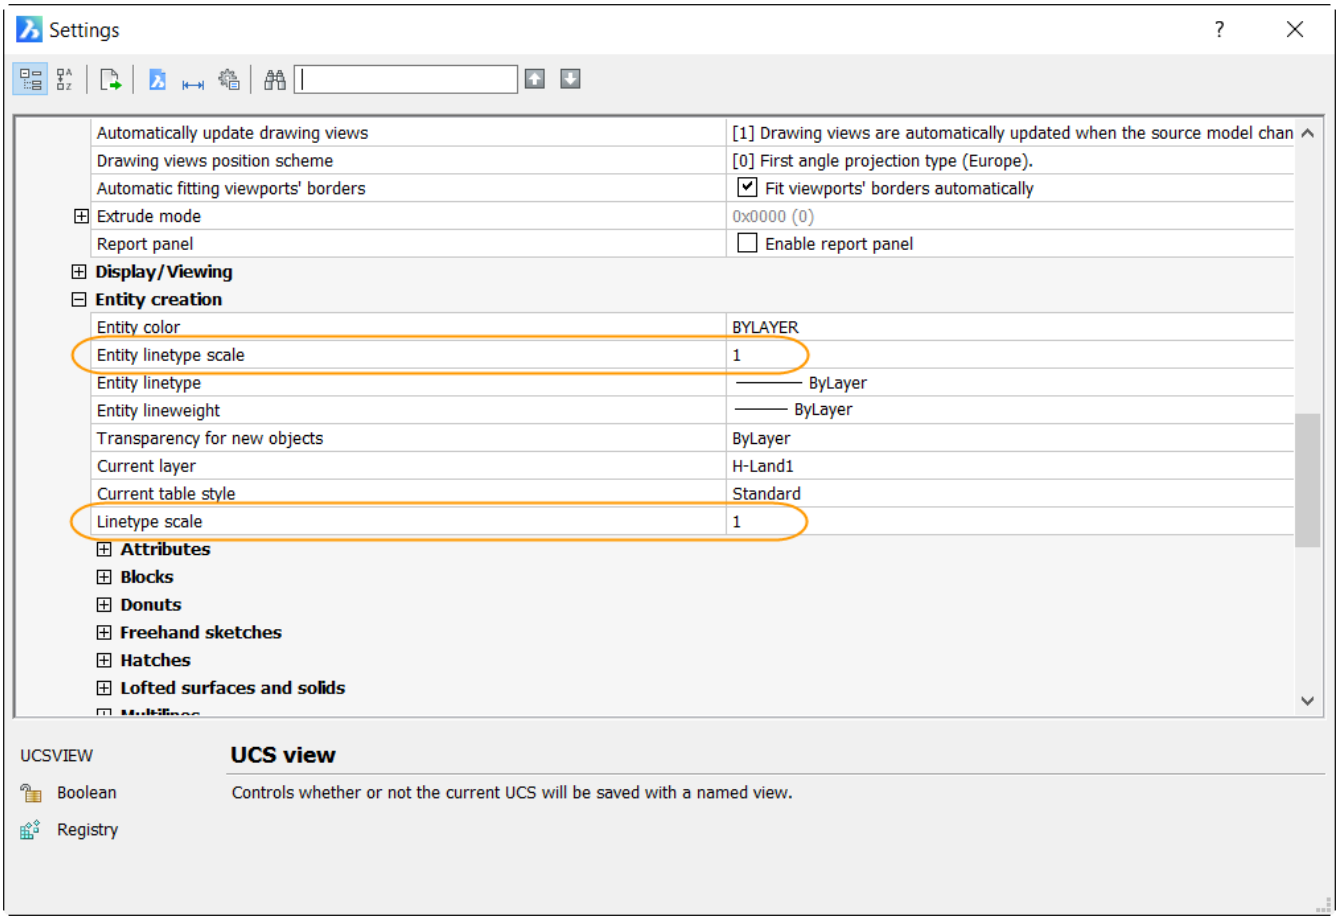

1.25.5 Entity Color

Commands: COLOR (6.9.19) and -COLOR (6.9.20) The **Color** command specifies the current color, through a dialog box. The **-Color** command sets the current color, through the command bar. An entity's color determines how it is displayed and how it prints. Entities are created in the current color. You can choose between 255 **index colors** or define a **true color.**

Index Colors

Index color is the specification of the color of a pixel on a display screen using a an 8-bit color value, allowing up to 256 possible colors. Each of the Index Colors has a unique number from 1 to 255. Seven of the index colors can also be referred to by name: red (1), yellow (2), green (3), cyan (4), blue (5), magenta (6) and white/black (7). Index color 7 displays white on a black screen background and black on a white screen background. Index color 7 always prints in black. The two additional color properties are BYLAYER and BYBLOCK. These color properties cause an entity to adopt the color either of the layer or of the block in which it is a member. BYLAYER is color number 256, and BYBLOCK is color number 0. In all commands where you would use a color, you can indicate BYLAYER and BYBLOCK as well as by numbers 256 and 0, respectively.

Color BYLAYER: Entities which have a color **BYLAYER** adopt the color of their layer. This allows you to change the color of all such entities by adjusting the color of the layer.

Color BYBLOCK: Entities which have a color **BYBLOCK** are drawn in index color 7 (black or white, depending on the screen background color). When included in a block definition, such entities adopt the color of the block. **Note:** Whether entities using an index color will print in this color, depends on the **Color Table** (CTB) or **Style Table** (STB) that is used for printing. Only if the **Color** setting in the CTB or STB definition file is set to **Use Object Color** , the printed color matches the entity color.

True Colors

True color is the specification of the color of a pixel on a display screen using a 24-bit value, which allows up to 16 777 216 possible colors. The number of bits used to define a pixel's color shade is its **bit-depth**. True color is sometimes known as **24-bit color**. Some new color display systems offer a 32-bit color mode. The extra byte, called the **alpha channel**, is used for control and special effects information. True colors use a **RGB** color definition (**R**ed, **G**reen, **Bl**ue). Each of these parameters has a range from 0 to 255. The RGB definition for black is (0,0,0), the RGB definition for white is (255,255,255).

NOTES

- In drawings that use **Style Tables** (STB) to set up plotting configurations, entities in a true color will only be printed in this color if the **Color** setting in the STB definition file is set to **Use Object Color.**
- In drawings that use **Color Tables** (CTB) to set up plotting configurations, entities in a true color always print in this color.

Setting the current entity color

1. To open the Select Color dialog, do one of the following:
   - In the **Color** field of the Entity Properties toolbar, choose **Select Color** .
   - Click the **Select Color** tool button () on the Settings toolbar.
   - In the BricsCAD Properties (1.15.4) Bar click **Color** , then choose **Select Color** in the drop down list.
   - Double click the **Color Field** in the Status Bar (1.15.2).
   - Type **color** in the command bar, then press Enter.
2. (option) To select an index color, click the **Index Color** tab on the Select Color dialog, then do one of the following:
   - Click one of the colored tiles.
   - Type the color number in the **Color Number** field.
3. (option) To define a true color, click the **True Color** tab on the Select Color dialog, then do one of the following:
   - Click the in **Color Selection** pane.
   - Set the color parameters in the **Color Parameter** fields.
3. Click the **OK** button to confirm.

1.25.6 Entity Linetype

You use different linetypes to differentiate the purpose of one line from another. A linetype consists of a repeating pattern of dots, dashes, or blank spaces. Linetypes determine the appearance of entities both on the screen and when printed. By default, every drawing has at least three linetypes: CONTINUOUS, BYLAYER and BYBLOCK. Your drawing may also contain an unlimited number of additional linetypes. Linetype definitions are saved in the drawing. New linetypes are either imported from other drawings or loaded from a linetype file (*.lin). Which linetype file is used is controlled by the MEASUREMENT system variable:

- MEASUREMENT = ON uses **Iso.lin**: Linetype definitions are expressed in mm.
- MEASUREMENT = OFF: **Default.lin**: Linetype definitions are expressed in inch.

New entities are drawn using the current linetype.

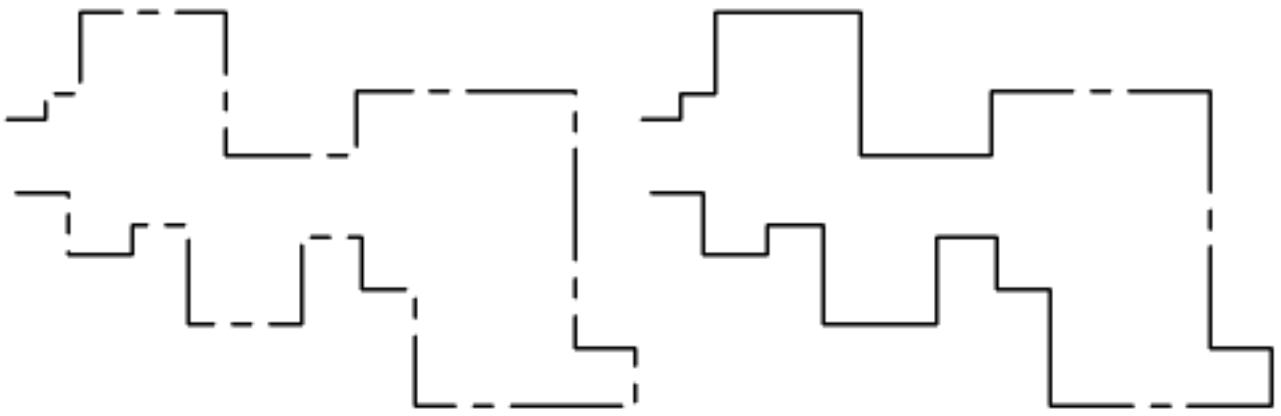
Linetype BYLAYER: Entities which have a linetype BYLAYER adopt the linetype of their layer. This allows you to change the linetype of all such entities by adjusting the linetype of the layer.

Linetype BYBLOCK: Entities created using linetype BYBLOCK, are drawn as continuous lines until you include them into a block. The entities then inherit the block's linetype setting when you insert the block into a drawing.

Linetype scale (LTSCALE) Non-continuous linetypes consist of lines, gaps and dots put together in a variety of patterns. In complex linetypes also text or shapes can be included. In the linetype definition the length of the lines and gaps are either defined in inch (default.lin) or mm (iso.lin). If the drawing units are different from inch or mm, linetypes need to be scaled. The linetype scaling is controlled by the **Linetype Scale** (LTSCALE) system variable, which must be set with respect to the drawing units (DU): **Drawing Unit LTSCALE** Imperial (MEASUREMENT = OFF) Inch 1 Foot 1/12 Metric (MEASUREMENT = ON) mm 1 cm 0.1 m 0.001 BricsCAD will always put a dash at the start and end of a line, polyline, arc or spline. The linetype pattern is also nicely centered, so that both ends of the entity look the same.

Polyline Generation (PLINEGEN) Linetypes are normally generated from vertex to vertex. Polylines of which the vertices are very close together might be rendered as a continuous line, if the linetype pattern does not fit between two subsequent vertices. The **Polyline Generation** (PLINEGEN) system variable addresses this problem: when set to 1 or ON, the linetype is drawn from one end of the polyline to the other end, instead of from vertex to vertex. (1.1297 on page 1446) The same polyline drawn with PLINEGEN on (left) and off (right).

Figure 1.673



Paper space linetype scale (PSLTSCALE) PSLTSCALE controls linetype scaling in paperspace layouts. If ON, linetype scaling is independent from the viewport scale. In general, PSLTSCALE is best set ON. Remember that this variable can be set per layout.

Model space linetype scale (MSLTSCALE) If MSLTSCALE is ON, the current annotation scale (1.29.25) (CANNOSCALE) is applied to linetypes in model space. MSLTSCALE is best set OFF. It might be usefull to switch it ON when printing from model space.

Setting the Global Linetype Scale

1. Choose **Settings** in the **Settings** menu. The Settings (1.17.10) dialog opens.
2. Select the **Drawing settings** category.
3. Expand the **Entity Creation** settings sub-category.
4. Select the **Linetype Scale** setting (LTSCALE). (1.674 on the next page)
5. Type a new value in the **Global Linetype Scale** field, then press Enter. The drawing is regenerated.
6. Close the **Settings** dialog.

Adding a new linetype

1. In the **Tools > Drawing Explorer** choose **Linetype...** The **Drawing Explorer - Linetypes** dialog displays. (1.676)
2. Click the **New** tool button ( ) in the **Details** toolbar. The **Linetypes** dialog opens. (1.677 on the following page)
3. (option) Click the **File** button on the **Linetypes** dialog to load a different linetype file (*.lin).
4. Select a linetype, then click the **OK** button. The linetype is added.
5. (option) Click the linetype name to rename the linetype.
6. (option) click the linetype description to edit the description of the linetype.

Figure 1.676

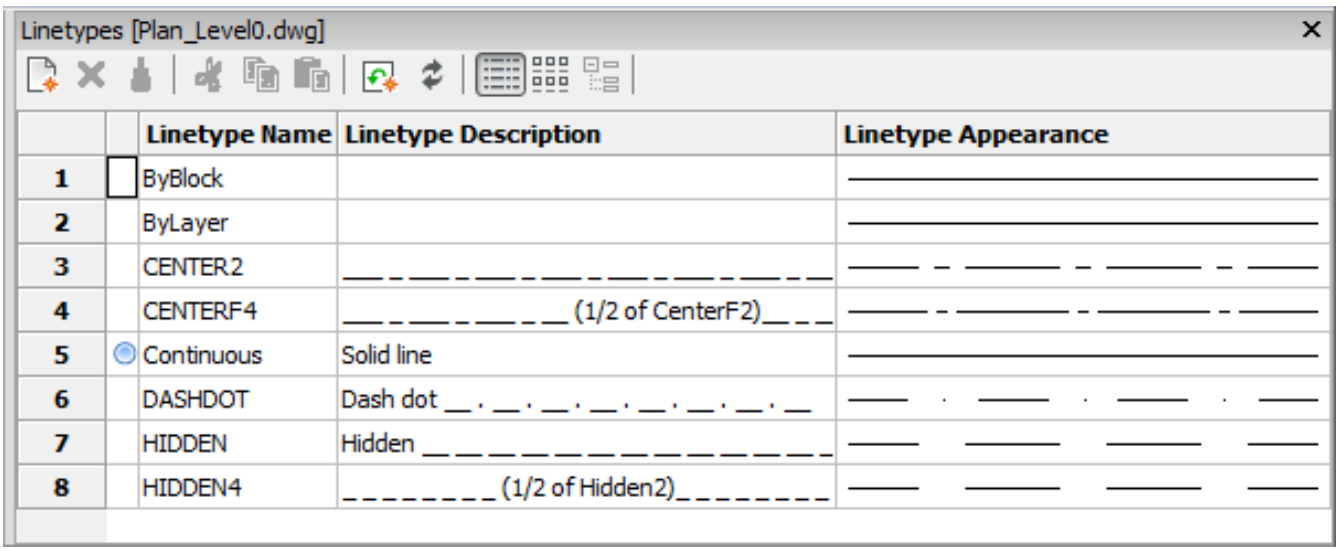

Figure 1.677

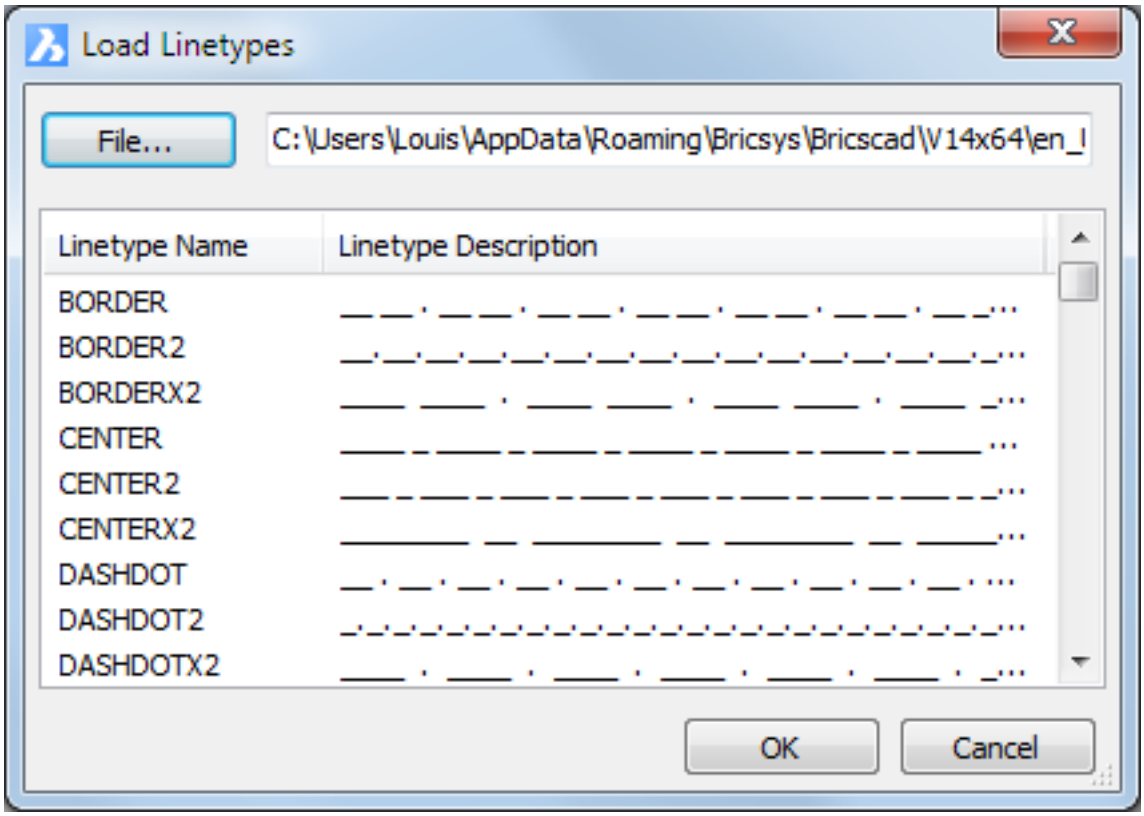
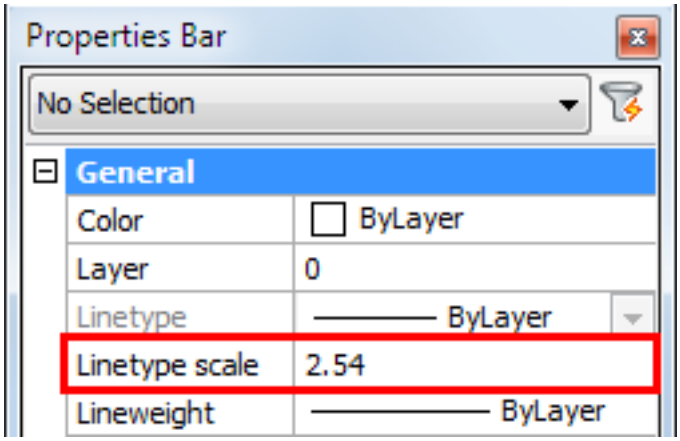


Setting the Entity Linetype Scale

The CELTSCALE system variable sets the value of the Linetype Scale property for new entities. This variable is best set to 1, except for special linetypes, such as BATTING or GAS_LINE, which most likely need to be scaled.

1. On the BricsCAD Properties Bar (1.15.4), select **Linetype scale** . Make sure, no entity is selected.
2. Type a new value in the Linetype scale field. (1.678)

Figure 1.678



1.25.7 Lineweight

Lineweights determine how thick or thin entities appear on the screen and / or when printed. The following lineweights are available: BYLAYER, BYBLOCK, DEFAULT and many additional lineweights in millimeters or inches, depending on the **Lineweight Units** (LWUNITS) system variable. You cannot assign lineweights to planes, points, TrueType fonts, and raster images. New entities are drawn using the current lineweight (1.25.7).

Lineweight BYLAYER: When you create an entity, it is created using the current lineweight. By default, the current lineweight for a new entity is BYLAYER. This means that the entity lineweight is determined by the current layer. When you assign BYLAYER, changing a layer's lineweight changes the lineweight of all such entities on that layer.

Lineweight BYBLOCK: Entities created using lineweight BYBLOCK, are drawn using the DEFAULT lineweight until include them into a block. The entities then inherit the block's lineweight setting when you insert the block into a drawing.

DEFAULT lineweight: The default lineweight is saved in the **Default Lineweight** (LWDEFAULT) system variable. Entities created using the default lineweight will be adjusted if the **Default Lineweight** setting is redefined.

NOTE	For entities using an index color (1.25.5), lineweights will be used for printing only if the **Color Table** (CTB) or **Plot Style** (STB) is defined as 'Use object lineweight'. Otherwise the line weight is defined by the objects color or plot style. Entities which are created in a true color (1.25.5) always use the object line weight when printed.

Setting the current lineweight

1. (option) On the BricsCAD Properties Bar (1.15.4), select **Lineweight**. Make sure, no entity is selected. Choose a lineweight in the drop down list. (1.679 on the following page)
2. (option) On the **Entity Properties** toolbar, click the down arrow next to the **Lineweight** field, then choose a lineweight in the drop down list.

1.25.8 Fill Mode

Command: FILL (6.14.5) The **Fill** command toggles the display of filled and hatched areas. Specifies whether multilines, traces, solids, hatches (including solid-fill) and wide polylines are filled in. If **FILLMODE** is OFF, all filled entities display and print as outlines. You can reduce the time it takes to display or print a drawing by turning FILLMODE off.

	Polyline	**Donut**	**Trace**	**Plane (Solid)**
Fill On	(1.681)	(1.682 on the next page)	(1.683 on the following page)	(1.684 on the next page)
Fill Off	(1.685 on the following page)	(1.686 on page 793)	(1.687 on page 793)	(1.688 on page 793)

Setting Fill Mode

1. To toggle **Fill Mode** on / off do one of the following:
   - Choose **Fill** in the **Settings** Menu.
   - Type **fill** or **fillmode** in the command bar, then type **T** + Enter.
2. Regenerate (1.23.4) the viewport.

Note: If multiple viewports are open, click the Regen All (1.23.4) tool button ( ) on the **View** toolbar (**Redraw/Regen** flyout) to regenerate all open viewports simultaneously.

1.25.9 Transparency

The Transparency property allows to control the transparency of drawing entities. You can set the transparency for a selection of entities or for all entities on the same layer. The default transparency for new entities is controlled by the CETRANSPARENCY system variable. The default transparency for Hatches and Gradient Fills is controlled by the HPTRANSPARENCY system variable. Transparency can be used to enhance the display of your drawings, e.g. to de-emphasize less important details or entities that are used for reference only. Transparencies will only be printed if the Plot Transparencies option is checked on the Print or Page Setup dialog boxes. The options to set the Transparency are:

- **ByLayer** - apply the value of the transparency property of the layer.
- **ByBlock** - the transparency value is controlled by block.
- **Value** - values between 0 (fully opaque) and 90 are accepted. The transparency level is limited to 90 % to avoid confusion with layers that are frozen or turned off.

Tutorial: Making Entities Transparent in BricsCAD Click here (1.16.2) to watch

1.25.10 Lines

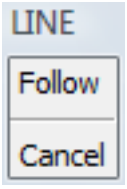
Command: LINE (6.20.31) A line consists of two points: a start point and an endpoint. Using the **Line** command you can draw a series of connected lines, but each line is considered a separate line entity.

Drawing lines

1. Do one of the following

   - Click the **Line** tool button ( ) on the **Draw** toolbar.
   - Choose **Line** in the **Draw** menu.
   - Type **line** in the command bar, then press Enter.
   - Type **L** in the command bar, then press Enter.

   You are prompted: ENTER to use last point/Follow/<Start of line>: A prompt menu displays:



2. Specify the start point. The line displays dynamically.
3. Specify the end point. The line is drawn and the following line displays dynamically starting in the endpoint of the first line.

   - Using Ortho Mode (1.21.2) or Polar Tracking (1.21.18) you can type the length of the line in the command bar.
   - Using Snap Tracking (1.21.17) you can position the end point with respect to the start point and one or two snap points on entities in the drawing.

   The prompt menu changes: (1.689)

4. (option) Repeat step 3 to draw a series of connected lines. When the second line is drawn, the options in the prompt menu are: (1.690 on the next page) After the third line, the options in the prompt menu are: (1.691 on the following page)
5. Right click to stop drawing lines.
6. (option) Right click to restart.

Figure 1.689

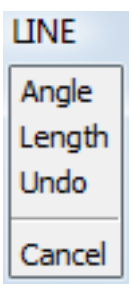


Figure 1.690

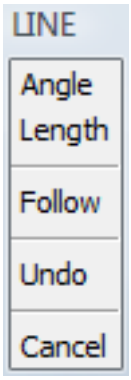

Figure 1.691

1.25.11 Rays

Command : RAY (6.26.1) A **Ray** is a line that starts at a point and extends to infinity. Because rays extend to infinity, they are not calculated as part of the drawing extents. The default method for drawing a ray is to select the start point of the ray, and then specify its direction. Rays and Infinite Lines (1.25.13) or sometimes referred to as construction lines.

Drawing rays

1. Do one of the following:

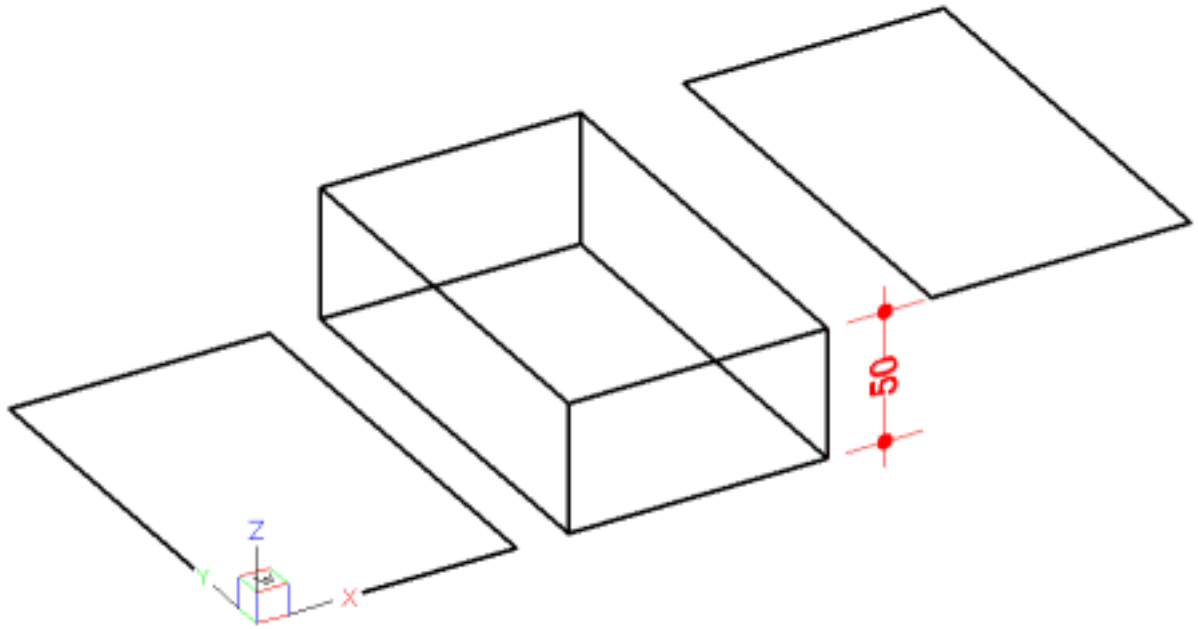
   - Click the **Ray** tool button ( ) on the **Lines** flyout of the **Draw** toolbar.
   - Choose **Ray** in the **Draw** menu.
   - Type **ray** in the command bar, then press Enter.

   You are prompted: Infinite ray: Bisect/Horizontal/Vertical/Angle/Parallel/<Start of Ray>: A prompt menu opens: (1.692)

2. Specify the start point of the ray. The ray displays dynamically.
3. Specify the direction of the ray. The next ray displays dynamically.
4. (option) Keep specifying directions to draw a series of rays, starting from the same point.
5. Right click to stop drawing rays.

Figure 1.692

Figure 1.693



1.25.12 Polylines

Commands: PLINE (6.24.27), BOUNDARY (6.6.15) and -BOUNDARY (6.6.16) A **polyline** is an open or closed sequence of connected line and/or arc segments, which are treated as a single entity. Each segment of a polyline can have a width that is either constant or tapers over the length of the segment. The **Pline** command interactively creates open and closed polylines entering points. The **Boundary** and **- Boundary** commands create closed polylines from an enclosed area, defined by other entities. The **THICKNESS** system variable specifies the height of a polyline. If **THICKNESS** = 0 (zero) there is no visual difference between polylines and a series of lines and/or arcs. (1.693) **THICKNESS** = 0 (left), **THICKNESS** = 50 (middle), **ELEVATION** = 50 (right) When a polyline is edited, you can modify the entire polyline or change individual segments and you can add or remove vertices. (1.700 on page 809) (1.701 on page 809) zero width polyline constant width polyline (1.702 on page 810) tapered width polyline **Note:** When Fill Mode (1.17.10) is turned OFF, all filled entities, such as wide polylines and planes, display and print as outlines. Depending on the value of the GRIPS (1.17.10) system variable have grips on their endpoints and vertices and/or at the midpoint of each segment. The value of GRIPS can be 0, 1 or 2.

Value	Grips display
0	No grips
1	Endpoint grips only
2	Endpoint and midpoints grips

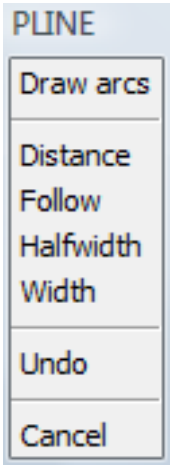
Drawing polylines

1. Do one of the following:

- Click the **Polyline** tool button ( ) on the Draw toolbar.

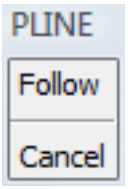
Figure 1.694

Figure 1.695



- Choose **Polyline** in the Draw menu.
- Type **pline** in the command bar, then press Enter.
- Type **PL** in the command bar, then press Enter.

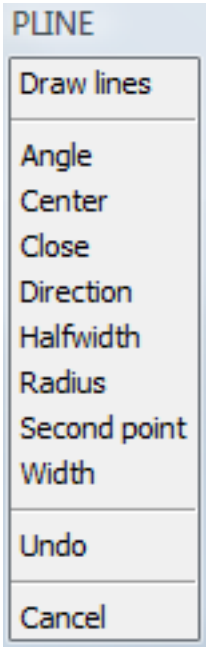
You are prompted: ENTER to use last point/Follow/<Start of polyline>: A prompt menu displays:



2. Specify the start point of the polyline. The prompt menu changes: (1.694)
3. Specify the second point of the polyline. The prompt menu changes: (1.695)
4. (option) Repeat step 3 to add more straight segments.
5. (option) Do one of the following to start drawing arc segments:
   - Type **A** , then press Enter.
   - Choose **Draw arcs** in the prompt menu.

   The prompt menu changes: (1.696 on the facing page) An arc segment displays dynamically. The arc is tangent to the previous line segment.
6. Specify the endpoint of the arc.
7. (option) Repeat step 6 to add more arc segments.
8. (option) Do one of the following to start drawing line segments:
   - Type **L** , then press Enter.
   - Choose **Draw lines** in the prompt menu.

Figure 1.696



9. Specify the endpoint of the line segment.

10. Right click or choose **Done** in the prompt menu to stop.

11. (option) Right click to restart.

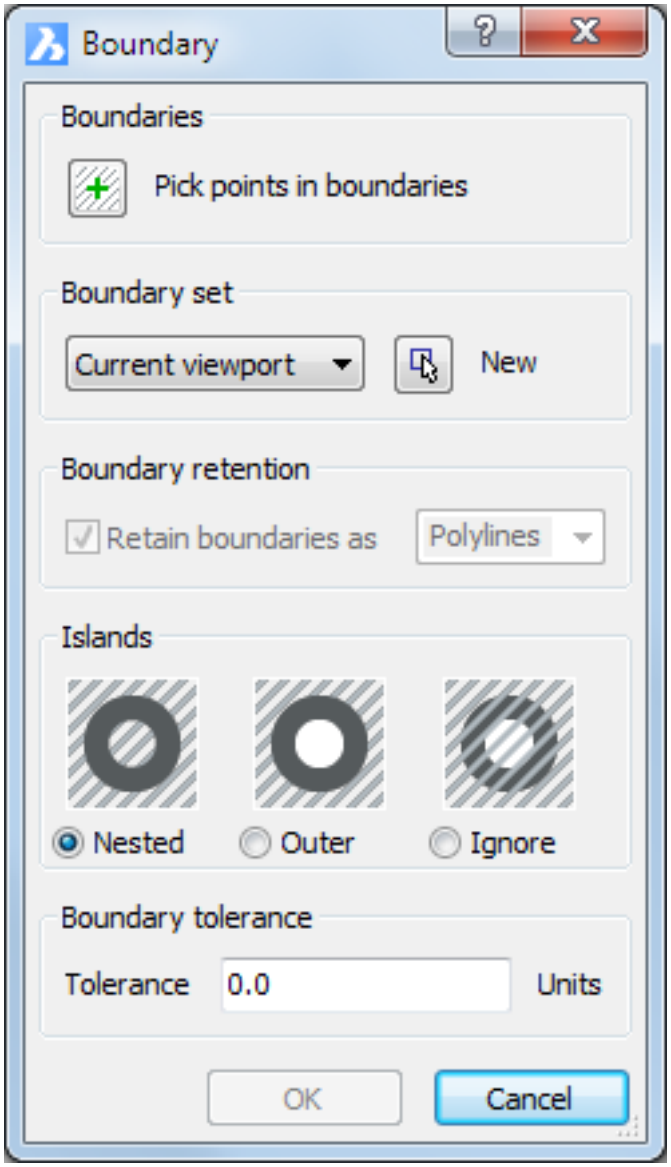
Note: Polylines have a direction, which can be modified by the **Reverse Direction** option of the PEDIT (6.24.24) (polyline edit) command.

Creating boundary polylines

1. Do one of the following:

- Click the **Boundary Polyline** tool button ( ) on the Draw toolbar.

Figure 1.697



- Choose **Boundary Polyline** in the Draw menu.
- Type **boundary** in the command bar, then press Enter.

The Boundary dialog box opens. (1.697)

2. (option) Click the **Select** button ( ) The Boundary dialog closes. Select the boundary entities in the drawing, then Press Enter. The Boundary dialog opens.

Figure 1.698

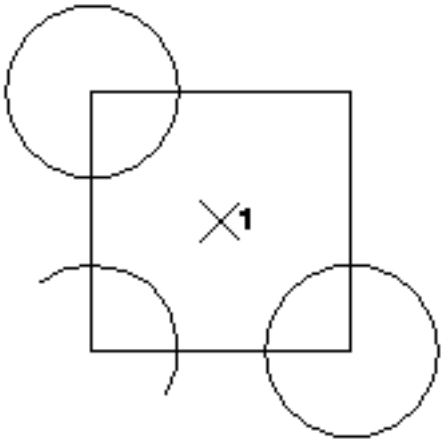


Figure 1.699

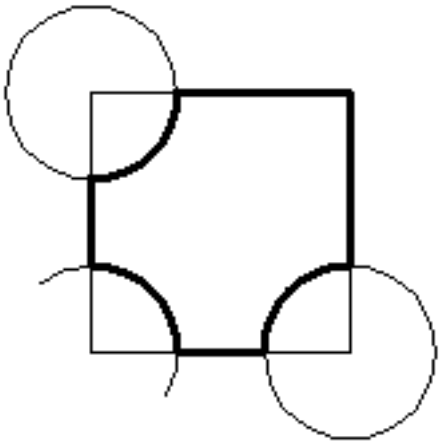

3. Click the **Pick points in boundaries** button on the Boundary dialog box. The dialog box closes.
4. Click in the area where you want to create the boundary polyline: point 1 in the image below. (1.698)
5. The boundary polyline displays in dashed lines.
6. (option) Keep picking points to create more boundary polylines.
7. Right click to accept the polyline(s). The Boundary dialog box opens again.
8. Click the **OK** button on the Boundary dialog box. The polyline(s) is (are) created. (1.699)

NOTES

- If you select the boundary entities before launching the **Boundary Polyline** tool, you can make the selection set active by pressing the

Figure 1.700

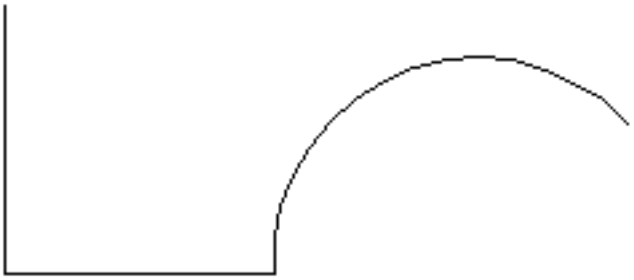

Figure 1.701

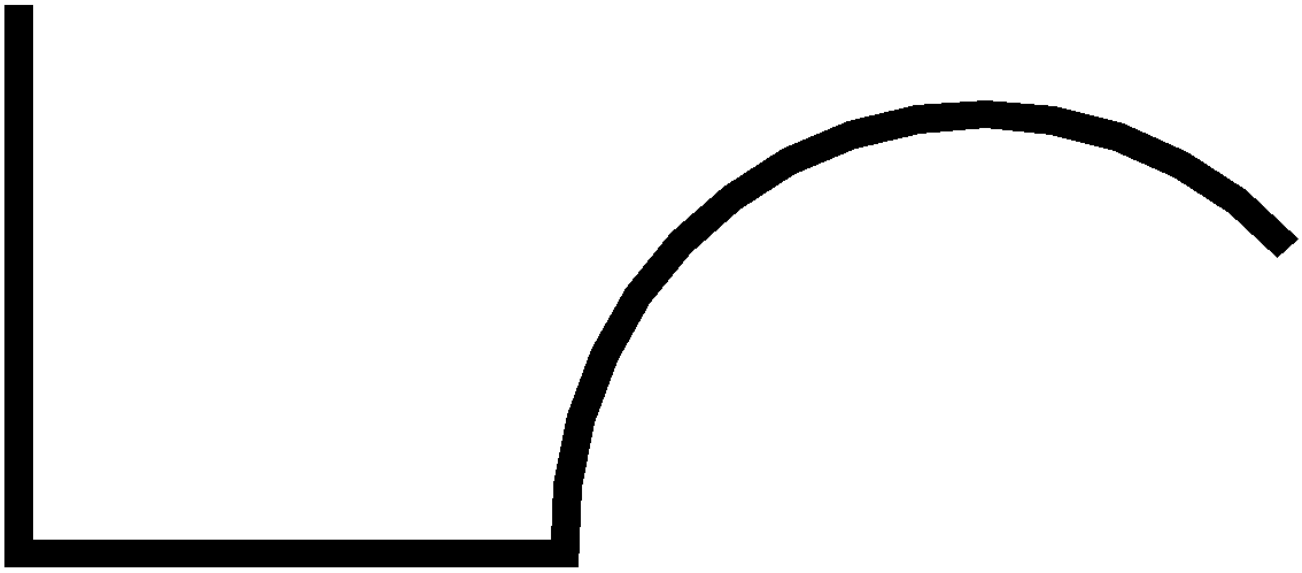

Figure 1.702

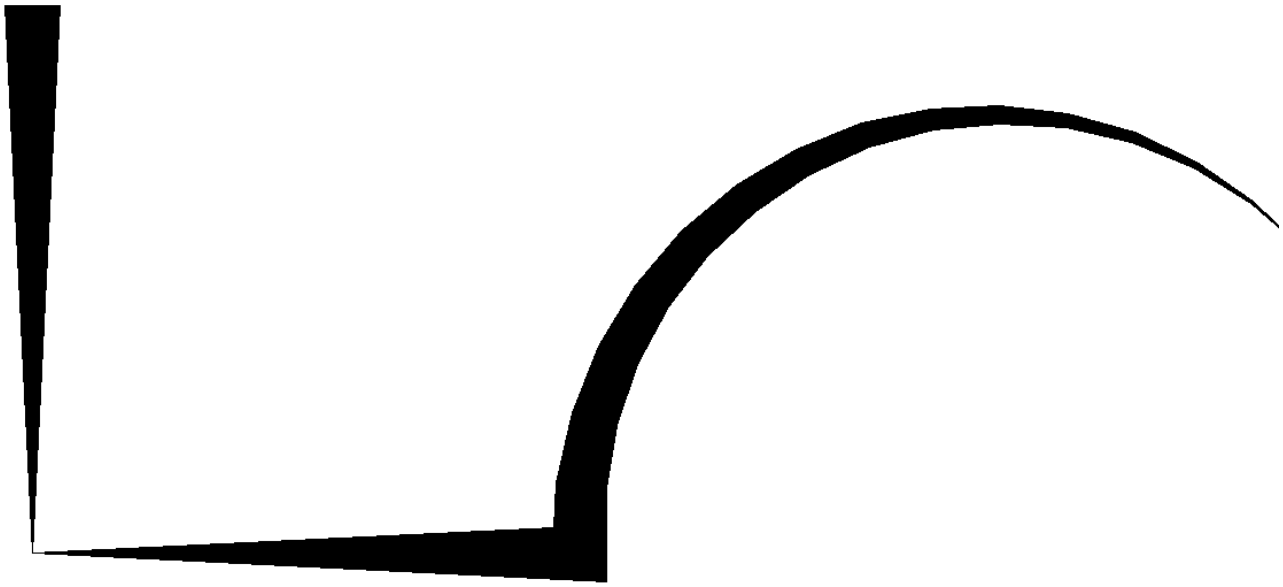


1.25.13 Infinite Lines

Command : XLINE (6.34.6) The **Xline** command creates infinite lines. An **Infinite Line** is a line through a given point, oriented at a specified angle and extending to infinity in both directions. Because infinite lines extend to infinity, they are not calculated as part of the drawing extents. The default method for drawing an infinite line is to select a point and then specify its direction. Rays (1.25.11) and Infinite Lines or sometimes referred to as construction lines.

Drawing infinite lines

1. Do one of the following:

   - Click the **Infinite Line** tool button ( ) on the **Lines** flyout of the Draw toolbar.
   - Choose **Infinite Line** in the Draw menu.
   - Type **xline** in the command bar, then press Enter.

   You are prompted: Xline: Bisect/Horizontal/Vertical/Angle/Parallel/<Point along line>: A prompt box displays: (1.703)

2. Specify the start point of the infinite line. The infinite line is created. A new infinite line through the same start point displays dynamically.

3. (option) Specify the direction of the infinite line. The infinite line is created. A new infinite line through the same start point displays dynamically.

4. (option) Repeat step 3 to draw a series of infinite lines, through the same start point.

5. Right click to stop drawing infinite lines.

6. (option) Right click to restart.

Figure 1.703

1.25.14 Circles

Command: CIRCLE (6.9.12), AI_CIRCTAN (6.5.2) The default method for drawing a circle is to specify a center point and radius. Other methods to draw circles can be found in the **Circle** submenu of the Draw menu and in the **Circles** toolbar (1.15.3). The **Ai_CircTan** command draws circles tangent to three entities.

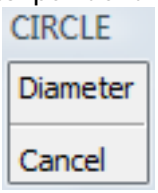
General procedure to draw a circle

1. Do one of the following.

   - Click the **Circle** tool button ( ) on the Draw toolbar.
   - Type **circle** in the command bar, then press Enter.
   - Type **C** in the command bar, then press Enter.

   You are prompted: 2Point/3Point/RadTanTan/Arc/Multiple/<Center of circle>: A prompt menu displays: (1.704)

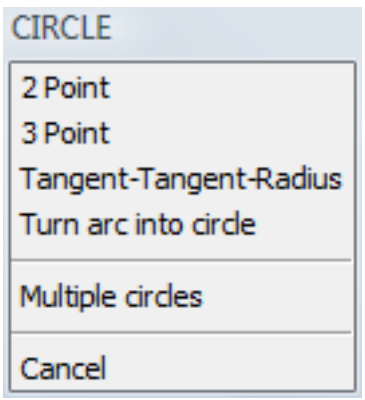
2. Specify the center point of the circle. You are prompted: Diameter/<Radius> <current radius>: The prompt menu changes:



3. Do one of the following:

   - Press Enter to accept the current radius.
   - Type a new radius and press Enter.
   - Click to define the radius graphically.

Figure 1.704



Drawing a circle tangent to three entities

1. Type **ai_circtan** in the command bar. You are prompted: Enter Tangent spec:
2. Click a linear entity. Lines, arcs, circles, polyline segments, xlines and rays are accepted. You are prompted: Enter second Tangent spec:
3. Click the second linear entity. You are prompted: Enter third Tangent spec:
4. Click the third linear entity. A circle tangent to the three selected entities is created.

Editing a circle

1. Select the circle. The properties of the circle display in the Properties bar (1.15.4). (1.705 on the following page)
2. Type a new value in the **Center** , **Radius** , **Diameter** , **Circumference** or **Area** field, then press Enter.
3. Press the Esc key to stop editing the circle.

Figure 1.705

1.25.15 Arcs

Command: ARC (6.4.21) The default method for drawing circular arcs is to specify three points: the start point, a second point and the endpoint. Other methods to draw arcs can be found in the Arc submenu of the Draw menu and in the Arcs toolbar (1.15.3).

General procedure to draw an arc

1. Do one of the following.

   - Click the **Arc** tool button ( ) on the Draw toolbar.
   - Type **arc** in the command bar, then press Enter.
   - Type **A** in the command bar, then press Enter.

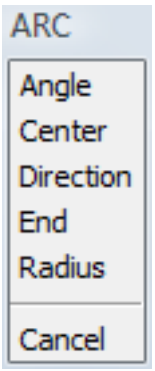
   
   You are prompted: Enter to use last point/Center/Follow/<Start of arc>: A prompt menu displays:

2. Specify the start point of the arc. You are prompted: Angle/Center/Direction/End/Radius/<Second point>: The prompt menu changes: (1.706)

3. Specify the second point of the arc. You are prompted: End point:

4. Specify the end point of the arc.

Figure 1.706



Editing an arc

1. Select the arc. The properties of the arc display in the Properties bar (1.15.4). (1.707 on the facing page)
2. Type a new value in the **Center** , **Radius** , **Start angle** or **End angle** , then press Enter.
3. Press the Esc key to stop editing the arc.

1.25.16 Elliptical Arcs

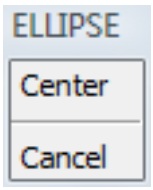
Command: ELLIPSE (6.13.5) + A An elliptical arc is a portion of an ellipse. The default method for drawing an elliptical arc is to specify the endpoints of one axis of the ellipse, and then specify a distance representing half the length of the second axis. Then you specify the start and end angles for the arc, measured from the center of the ellipse in relation to its major axis. Other methods to draw elliptical arcs can be found in the Ellipse submenu of the Draw menu and in the Elliptical Arcs toolbar.

General procedure to draw an elliptical arc

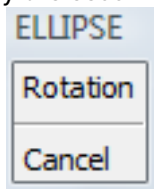
1. Do one of the following:

   - Click the **Elliptical Arc** tool button ( ) on the Draw toolbar.
   - Launch the Ellipse (1.25.21) command using the **Arc** option.

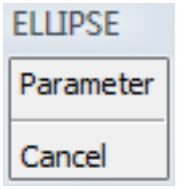
   You are prompted: Center/<First end of ellipse axis>: A prompt menu displays:

2. Specify the first end or the ellipse axis. You are prompted: Second end of axis:
3. Specify the second end of the ellipse axis. You are prompted: Rotation/<Other axis> A prompt menu displays:

4. Specify the length of half the other axis of the ellipse. You are prompted: Parameter/<Start angle of arc>: The prompt menu changes:

5. Specify the start angle of the elliptical arc. The elliptical arc is drawn dynamically when you move the crosshairs. You are prompted: Parameter/Included/<End angle>: The prompt menu changes: (1.709 on page 821)
6. Specify the end angle of the elliptical arc.

1.25.17 Freehand sketches

Command: SKETCH (6.27.69) A freehand sketch consists of a series of straight line segments, created either as individual line entities or as a polyline. Before you begin creating a freehand sketch, you must set the length, or increment, of each segment. The smaller the segments, the more accurate your sketch, but small segments increase the file size. After you specify the length of the sketch segments, the crosshairs change to a pencil tool (). A freehand sketch line is not added to the drawing until you "write" the sketch into your drawing.

Setting the Sketch Poly (SKPOLY) system variable

Whether a chain of individual lines or a polyline is created by the **Sketch** tool is controlled through the **Sketch Poly** (SKPOLY) system variable. When the setting is **ON** the **Sketch** tool creates polylines Do one of the following:

- In the command bar type **skpoly** , then press Enter.
- In the Settings (1.17.10) dialog, go to **Drawing > Drafting > Entity Creation > Freehand Sketches**.

(1.710)

Figure 1.710

Creating a freehand sketch

1. Do one of the following:

   - Click the **Sketch** tool button ( ) on the Draw toolbar.
   - Choose **Sketch** in the Draw menu.
   - Type **sketch** in the command bar, then press Enter.

   You are prompted: Length of segments <current length>:

2. Do one of the following to define the length of the segments:

   - Press Enter to accept the current length.
   - Type a new value in the command bar.
   - Click two points to define the length graphically.

   The length of the segments is saved to the **Sketch Increment** (SKETCHINC) system variable.

3. Click to start sketching (pen down). The crosshairs are replaced by the **Pencil** tool ( ) You are prompted: Press ENTER or click to toggle Pen/Quit without save/Record (save)/Erase/Connect/Straight/eXit with save:: A prompt menu displays: (1.711)

4. Move the cursor to sketch. The sketched line displays in light green.

5. (option) Click to stop sketching (pen up), then click again (pen down) to resume.

6. (option) Choose **Erase** on in the prompt menu or type **E** + Enter in the to start erasing sketch lines. The cursor changes to the **Erase** tool ( ).

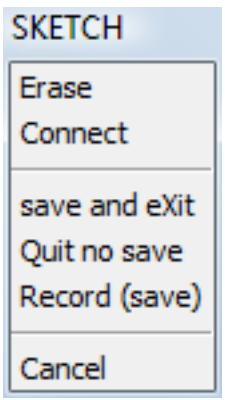
   - Move the cursor to the end of a sketch line to start erasing.
   - Click to stop erasing and resume sketching.

7. (option) Choose **Record (save)** in the prompt menu or type **R** + Enter to save the sketch lines, and keep sketching.

8. (option) Choose **save and eXit** in the prompt menu or type **X** + Enter to save the sketch lines and exit the sketch command.

9. (option) Choose **Quit no save** in the prompt menu or type **Q** + Enter to exit the sketch command without saving.

Figure 1.711



1.25.18 Rectangles

Command: RECTANG (6.26.6) A rectangle is created as a closed, four sided polyline (1.25.12). A rectangle is drawn by specifying two opposite corners. The **Dimensions** option allows to specify the width and height of the rectangle. Unless the **Rotated** option is chosen, the sides of a rectangle are always parallel to the x-axis and y-axis of the current coordinate system (1.21.21). **Note:** When Fill Mode (1.25.8) is turned off, all filled entities, such as wide polylines (1.25.12) and solids (1.25.23), display and print as outlines.

Drawing rectangles

General Procedure

1. Do one of the following

   - Click the **Rectangle** tool button ( ) on the Draw toolbar.
   - Choose **Rectangle** in the Draw menu.
   - Type **rectang** in the command bar, then press Enter.
   - Type **rec** in the command bar, then press Enter.

   You are prompted: Chamfer/Elevation/Fillet/Rotated/Square/Thickness/Width/Area/Dimensions<select first corner of rectangle>: A prompt menu opens: (1.712 on the next page)

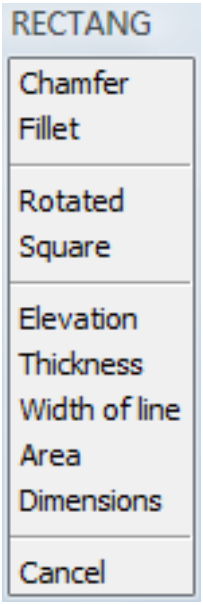
2. Specify the first corner of the rectangle. The rectangle displays dynamically when you move the cursor.

3. Specify the opposite corner of the rectangle. The rectangle is created.

4. (option) Right click to draw more rectangles.

NOTE	Because a rectangle is created as a closed polyline, rectangles have a direction. The direction of a closed polyline is positive if it is drawn counter-clockwise and negative if it is drawn in a clockwise direction. Rectangles have a counter-clockwise direction if both the X- and Y-coordinate of the second point are higher or lower than the coordinates of the first point (= movement of the cursor is positive or negative along both X- and Y-axis). Rectangles have a clock-wise direction if the X- or Y-coordinate is higher or lower than the X- or Y-coordinate of the first point (= movement of the cursor is positive along the X-axis and negative along the Y-axis or vice versa). The **Reverse Direction** option of the PEdit (6.24.24) (Edit Polyline) command changes the direction of a polyline.

Figure 1.712

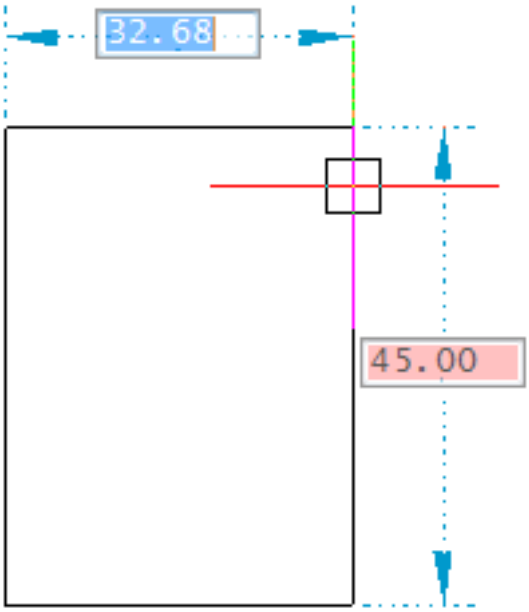


Using Dynamic Dimensions

Using Dynamic Dimensions (1.21.9) the width and length of the rectangle can be controlled dynamically.

1. Launch the **Rectang** command. You are prompted: Chamfer/Elevation/Fillet/Rotated/Square/Thickness/Width/Area/D first corner of rectangle>:
2. Specify the first corner of the rectangle. The rectangle displays dynamically when you move the cursor. The width and height display in the dynamic dimension fields.
3. Type a value in the **Height** field.
4. Press the TAB key. The **Height** field is locked and turns red.
5. Type a value the **Width** field. (1.713 on the following page)
6. Do one of the following:
   - Press Enter to create the rectangle.
   - Press the TAB key until the desired field is active, then type a different value.
7. Press Enter to create the rectangle.

Figure 1.713



1.25.19 Splines

Command: SPLINE (6.27.63) A spline is an open or closed smooth curve defined by a set of points. You can use splines to draw curved shapes, which cannot be drawn as a polyline.

Drawing splines

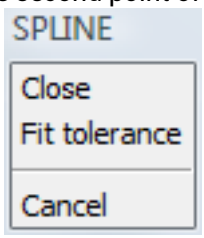
1. Do one of the following

   - Click the **Spline** tool button ( ) on the Draw toolbar.
   - Choose **Spline** in the Draw menu.
   - Type **spline** in the command bar, then press Enter.

   You are prompted: First point of spline:

2. Specify the first point of the spline.

3. Define the second point of the spline. You are prompted: Close/Fit Tolerance/<next point>: A prompt menu displays.



4. (option) Repeat step 3 to define more points.

5. Right click to stop adding more points. You are prompted: Select starting tangent point: A line that is tangent to the spline displays dynamically from the start point of the spline. (1.714)

6. Click to define the curve of the spline. You are prompted: Select ending tangent point: A line that is tangent to the spline displays dynamically from the start end of the spline. (1.715 on the following page)

7. Click to conclude the spline command. (1.716 on the next page)

8. (option) Right click to restart.

Figure 1.714

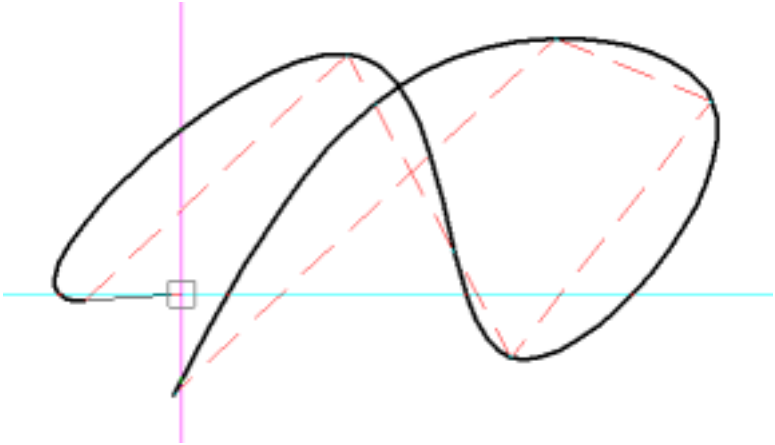


Figure 1.715

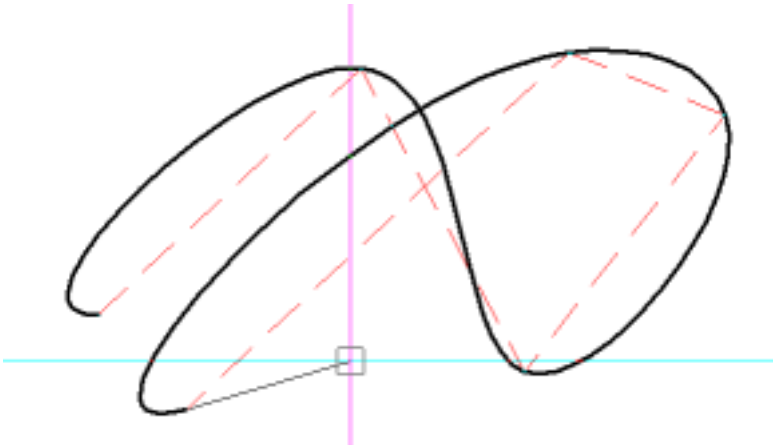

Figure 1.716

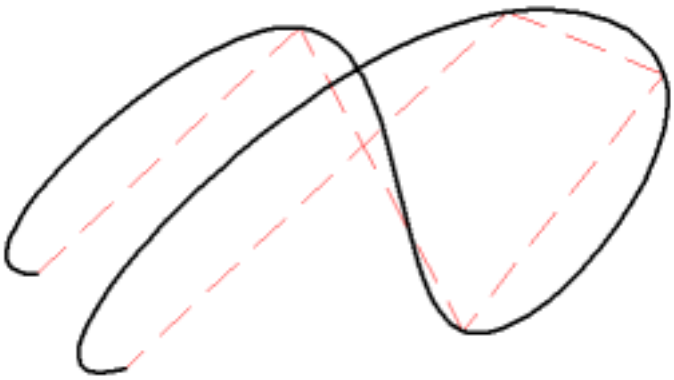


NOTES

- The red dashed lines in the above images represent the polyline through the control points of the spline.
- The **SPLFRAME** (Spline Frame) settings variable defines whether the control polygon displays for splines and spline-fit polylines.

1.25.20 Polygons

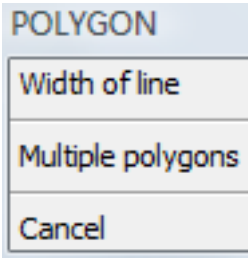
Command: POLYGON (6.24.61) Polygons are closed polylines (1.25.12) comprised of a minimum of three and a maximum of 1,024 equal-length sides. In BricsCAD you can draw polygons using the following methods:

- **Centre - Vertex** ( ): first define the center point, then the vertex (= radius of the circumscribed circle method).
- **Center - Side** ( ): first define the center point, then the midpoint of a side (= radius of the inscribed circle method).
- **Edge** ( ): define the length of the side of the polygon.

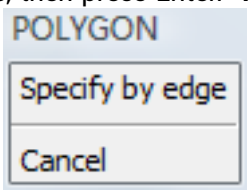
Drawing polygons

1. Do one of the following:
   - Click the **Polygon, Center - Vertex** tool button ( ) on the **Polygons** flyout of Draw toolbar.
   - Choose **Polygon** in the Draw menu.
   - Type **polygon** in the command bar, then press Enter.

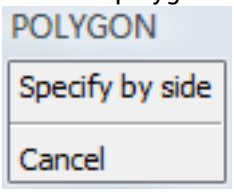
   You are prompted: Polygon: Multiple/Width of line/<Number of sides> <4>: A prompt menu opens:



2. Specify the number of sides, then press Enter. **You are prompted:** Specify by: Edge/<Center of polygon>: The prompt menu changes:



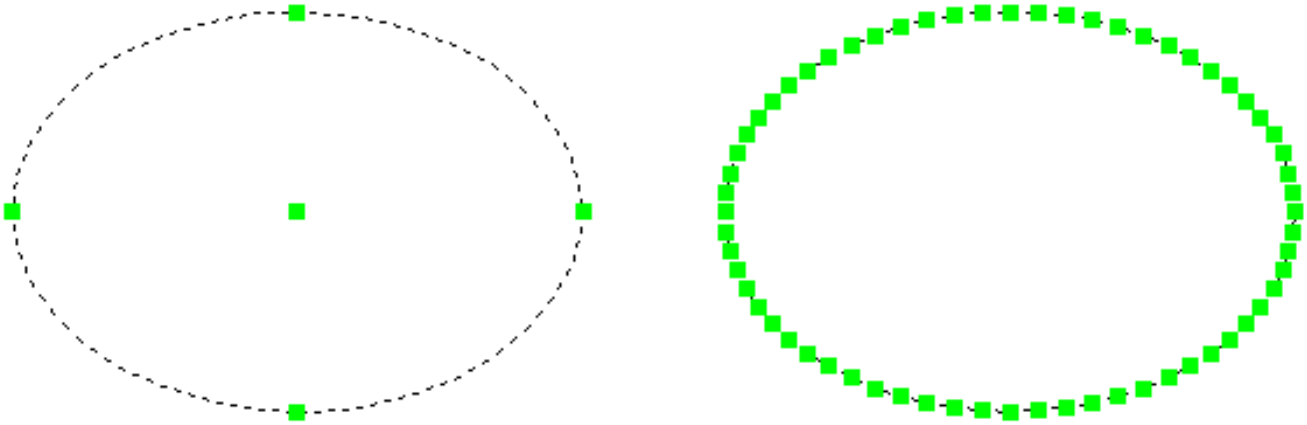
3. Specify the center of the polygon. **You are prompted:** Specify by: Side/<Select vertex point>: the prompt menu changes:



4. Specify a vertex point of the polygon. The polygon is created.

Note: When Fill Mode (1.25.8) is turned off, all filled entities, such as wide polylines and planes, display and print as outlines.

Figure 1.717



1.25.21 Ellipses

Command: ELLIPSE (6.13.5) The default method for drawing an ellipse is to specify the endpoints of one axis of the ellipse and then specify a distance representing half the length of the second axis. The endpoints of the first axis determine the orientation of the ellipse. The longer axis of the ellipse is called the major axis, and the shorter one is the minor axis. The order in which you define the axes does not matter. The program determines the major and minor axes based on their relative lengths. Half the major axis is called the major radius, half the minor axis is the minor radius. The ratio (minor radius divided by the major radius) defines the eccentricity of the ellipse. A circle is an ellipse with an eccentricity of 1. Other methods to draw ellipses can be found in the **Ellipse** submenu of the Draw menu and in the Ellipses toolbar. The **Polyline Ellipse** (PELLIPSE) settings variable: controls whether real ellipses or a polyline representation is created. If the variable is ON, the **Ellipse** tool creates a closed polyline, if the variable is OFF real ellipses are created. The difference between a real ellipse and a polyline representation of an ellipse is visible when you select the ellipse. A real ellipse has five handles: center point and the endpoints of the axes. A polyline representation of an ellipse is a closed polyline composed of arc segments. (1.717) real ellipse (left) and the polyline representation of an ellipse (right) **Note:** Since ellipses cannot be used as a clip boundary for **external references** or to create clipped paperspace viewports (1.23.16), you must use a polyline representation to do these jobs.

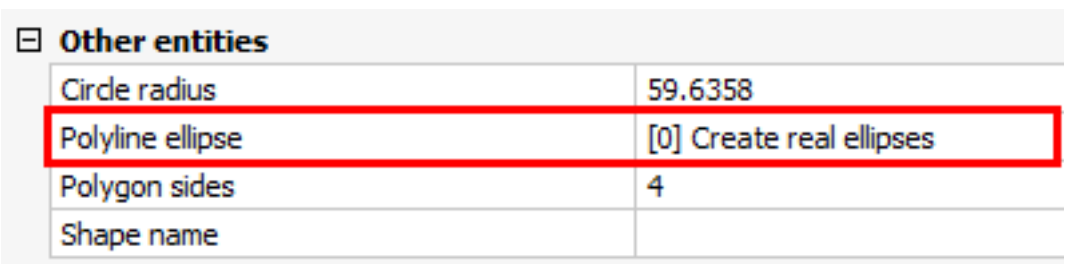
Setting the Polyline Ellipse (PELLIPSE) system variable

Do one of the following:

- In the command bar type **pellipse**, then press Enter.
- In the Settings (1.17.10) dialog, go to **Drawing > Drafting > Entity Creation > Other entities** .

(1.718)

Figure 1.718

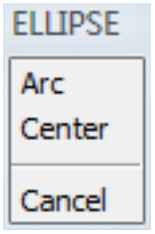


General procedure to draw an ellipse

1. Do one of the following.

   - Click the **Ellipse** tool button ( ) on the Draw toolbar.
   - Type **ellipse** in the command bar, then press Enter.
   - Type **EL** in the command bar, then press Enter.

   You are prompted: Arc/Center/<First end of ellipse axis>: A prompt menu displays:



2. Specify the the first end of the ellipse axis. You are prompted: Second end of axis:
3. Specify the second end of the ellipse axis. You are prompted: Rotations/<Other axis>: A prompt menu displays: ===ERROR WITH DOWNLOADED IMAGE===
4. Specify the length of half the other axis of the ellipse.

Note: If the **Polyline Ellipse** variable is off, the **Arc** option is not available.

Editing an ellipse

1. Select the ellipse. The properties of the ellipse display in the Properties bar (1.15.4). (1.719 on the facing page)
2. Type a new value in the **Center**, **Major radius**, **Minor radius**, **Radius ratio**, **Start angle** or **End angle** field, then press Enter.
3. Press the Esc key to stop editing the ellipse.

1.25.22 Traces

Command: TRACE (6.29.32) Traces are 4-sided filled entities, created with two parallel sides. When you create a series of traces, they are L-connected to each other.

Drawing traces

1. Do one of the following:

   - Click the **Trace** tool button () on the **Polygons** flyout of the Draw toolbar.
   - Choose **Trace** in the Draw menu.
   - Type **trace** in the command bar, then press Enter.

   You are prompted: Width of trace <current width>:

2. Do one of the following:

   - Right click to accept the current width.
   - Type a new current width in the command bar.
   - Define a new current width graphically by clicking two points.

   You are prompted: Start of trace:

3. Specify the start point of the trace. **You are prompted:** Next point:

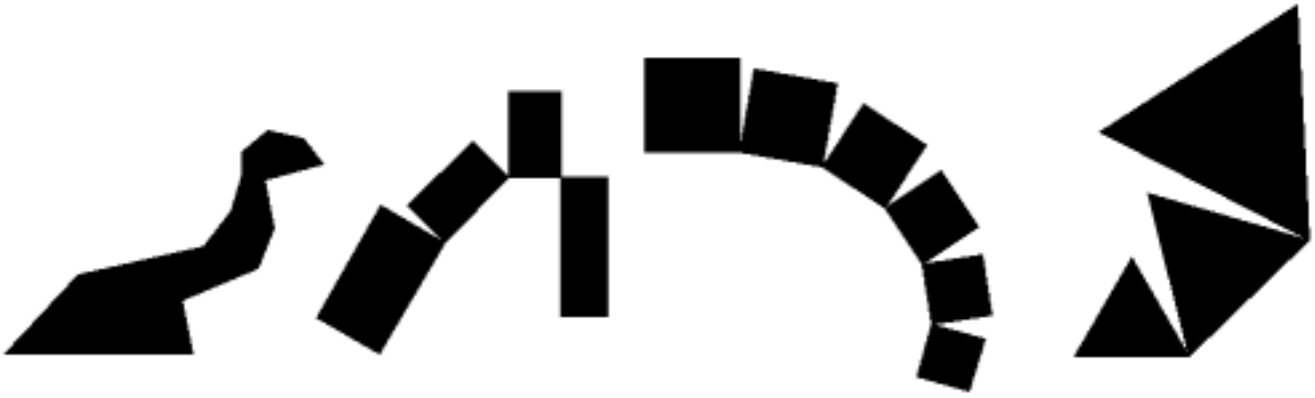
4. Specify the end point of the first trace. A line indicates the direction of the first trace. The direction of the second trace displays dynamically.

5. Do one of the following:
   - Right click to create the trace.
   - Specify the endpoint of the next trace.

6. (option) Repeat step 5 to keep adding traces.

Note: When Fill Mode (1.25.8) is turned off, all filled entities, such as traces, display and print as outlines.

Figure 1.720



1.25.23 Solids

Command: SOLID (6.27.45) 2D Solids are rectangular, square, triangular or quadrilateral areas filled with a solid color. (1.720) Left to right: quadrilateral, rectangular, square and triangular solids

Drawing solids

1. Do one of the following:

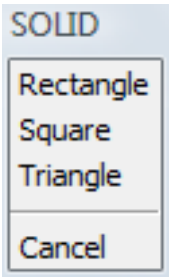
   - Click the **Solid** tool button ( ) on the **Polygons** flyout of **Draw** toolbar.
   - Choose **Solid** in the **Draw** menu.
   - Type **solid** in the command bar, then press Enter.

   You are prompted: Rectangle/Square/Triangle/<First point of solid>: A prompt menu displays: (1.721)

2. Specify the first point of the solid.
3. Specify the second point of the solid.
4. Specify the third and fourth point of the solid. The solid is created.
5. (option) Repeat step 4 to add more solids. A series of connected solids is created.
6. Right click to conclude.

Note: When Fill Mode (1.25.8) is turned off, all filled entities, such as wide polylines and solids, display and print as outlines.

Figure 1.721



1.25.24 Revision Clouds

Command: REVCLOUD (6.26.33) A **Revision Cloud** is an open or closed polyline (1.25.12) composed of arcs. Revisions clouds are used to for reviewing or redlining purposes to indicate the parts of the drawing that need to be adjusted or annotated. Before you start drawing revision clouds, first define the **Arc length** and **Style** .

Drawing revision clouds

1. Do one of the following:

   - Click the **Revision Cloud** tool button ( ) on the Draw toolbar.
   - Choose **Revision Cloud** in the Draw menu.
   - Type **revision cloud** in the command bar, then press Enter.

   You are prompted: Specify start point or [Arc length/Object/Style] <Object>: A prompt menu opens: (1.722)

2. (option) To define the **Arc length** , do one of the following:

   - Choose **Arc length** in the prompt menu.
   - Type **A** in the command bar, then press Enter.

   You are prompted: Specify minimum length of arc <current minimum length>: Do one of the following:

   - Press Enter or right click to accept the current minimum length.
   - Type a new value in the command bar, then press Enter.
   - Define a new minimum length graphically by specifying two points.

   You are prompted: Specify maximum length of arc <current maximum length>: Do one of the following:

   - Press Enter or right click to maximum length equal to the minimum length.
   - Type a new value in the command bar, then press Enter.
   - Define a new maximum length graphically by specifying two points.

3. (option) To define the revision cloud **Style** , do one of the following:

   - Choose **Style** in the prompt menu.
   - Type **S** in the command bar, then press Enter.

   
   You are prompted: Select arc style [Normal/Calligraphy] <current style>: A prompt menu opens: Do one of the following:

   - Press Enter or right click to accept the current style
   - Select a new style in the prompt menu.
   - Type **N** or **C** in the command bar, then press Enter.

4. (option) To convert an existing polyline, arc or circle to a revision cloud, do one of the following:

   - Press Enter, then select the entity you want to convert.
   - Choose Object in the prompt box, then select the entity you want to convert.

Figure 1.722

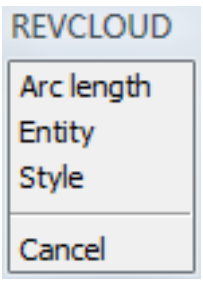


Figure 1.723

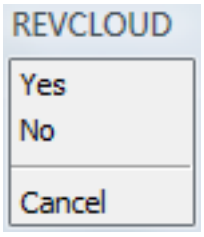
5. (option) To draw the revision cloud, click where you want to start and move the cursor. Each time the cursor movement exceeds the minimum length, an arc is added. To stop do one of the following:

   - Move the cursor over the start point to close the revision cloud.
   - Right click.

   You are prompted: Reverse direction [Yes/No] <No>: A prompt menu opens:



6. To create the revision cloud, do one of the following:

   - To accept the revision cloud, right click.
   - To reverse the direction, type **Y** or choose **Yes** in the prompt menu.
   - To leave the command without creating the revision cloud, choose **Cancel** in the prompt menu or press the Esc key.

(1.723) Revision Clouds: 1. Normal 2. Calligraphy 3. Reversed calligraphy (based on a rectangle)

1.25.25 Wipeouts

Command: WIPEOUT (6.33.10) A **wipeout** is a polygonal area that hides the underlying objects using the current background color. Most commonly wipeouts are used to mask part of a drawing for clarity. For example, you may want to add text to a complicated part of a drawing. A wipeout could be used then to mask an area behind the text to increase the readability of the text. The **Frames** option of the **wipeout** command determines whether the edges of all wipeout entities in the current drawing are displayed or hidden.

To create a wipeout using points

1. Do one of the following:
   - Click the **Wipeout** tool button ( ) on the Draw toolbar.
   - Choose **Wipeout** in the Draw menu.
   - Type **wipeout** in the command bar, then press Enter.

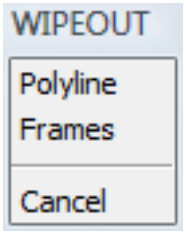
   You are prompted: Frames/Polylines/<Start point>:
2. Specify the first vertex of the wipeout. **You are prompted:** Next point.
3. Specify the second vertex of the wipeout. **You are prompted:** Undo/<Next Point>:
4. Do one of the following:
   - Specify the third vertex of the wipeout.
   - Type **U** , then press Enter or choose **Undo** in the context menu to delete the previous vertex.

   You are prompted: Undo/Close/<Next Point>:
5. Do one of the following:
   - Specify the next vertex of the wipeout.
   - Type **U** , then press Enter or choose **Undo** in the context menu to delete the previous vertex.
   - Type **C** , then press Enter or choose **Close** in the context menu to create the wipeout.
   - Right click to create the wipeout.
6. Repeat step 5 to create more vertices of the wipeout.

To create a wipeout from a polyline

1. Do one of the following:
   - Click the **Wipeout** tool button ( ) on the Draw toolbar.
   - Choose **Wipeout** in the Draw menu.
   - Type **wipeout** in the command bar, then press Enter.

   You are prompted: Frames/Polylines/<Start point>: The **Wipeout** context menu displays:



2. Do one of the following:
   - Choose **Polyline** in the context menu.
   - Type **P**, then press Enter.

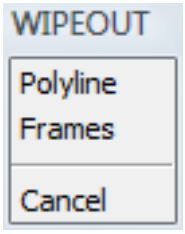
   You are prompted: Select a closed polyline:
3. Click a closed polyline. Only polylines composed of line segments can be selected. You are prompted: Delete selected polyline? Yes/<No>:
4. Do one of the following:
   - Type **Y** , then press Enter or choose **Yes** in the context menu to create the wipeout and delete the selected polyline.
   - Press Enter or choose **No** in the context menu, to create the wipeout and delete the selected polyline.

To control the display of the edges of wipeouts

1. Do one of the following:

   - Click the **Wipeout** tool button ( ) on the Draw toolbar.
   - Choose **Wipeout** in the Draw menu.
   - Type **wipeout** in the command bar, then press Enter.

   You are prompted: Frames/Polylines/<Start point>: The **Wipeout** context menu displays:



2. Do one of the following:

   - Choose **Frames** in the context menu.
   - Type **F** , then press Enter.

   You are prompted: Enter display mode: OFF/<ON>:

3. Do one of the following:
   - Choose **OFF** in the context menu or type **off**, then press Enter, to hide the edges of all wipeouts in the drawing.
   - Choose **ON** in the context menu or type **on**, then press Enter, to display the edges of all wipeouts in the drawing.

1.25.26 Hatching Overview

Commands: HATCH (6.16.3), -HATCH (6.16.1), GRADIENT (6.15.20), HATCHEDIT (6.16.2), -HATCHEDIT (6.16.4)
When you add hatching to a drawing, BricsCAD fills entities or enclosed areas with a predefined pattern or lines. First you specify the hatch pattern and other options, and then you choose which entities or enclosed areas that you want to hatch.

NOTES

- Depending on the pattern, hatchings are memory intensive and might take a considerable amount of time to draw and display. To improve performance, add hatching as one of the last steps when you create a drawing, or insert hatches on a separate layer that you can freeze as you continue to work on your drawing. Or use the **FILLMODE** system variable to switch off the display of hatches, gradient fills and filled entities.
- The maximum number of dashes is controlled by the **MAXHATCH** settings variable. When the number of dashes is higher than the current MAXHATCH value, the hatch cannot be created. A warning box displays offering possible choices for subsequent actions: (1.726 on page 842) By default the maximum number of dashes is 100 000.

The predefined and user pattern files sit in the **Support** folder of the current user. The **MEASUREMENT** setting controls which predefined hatch pattern file will be used.

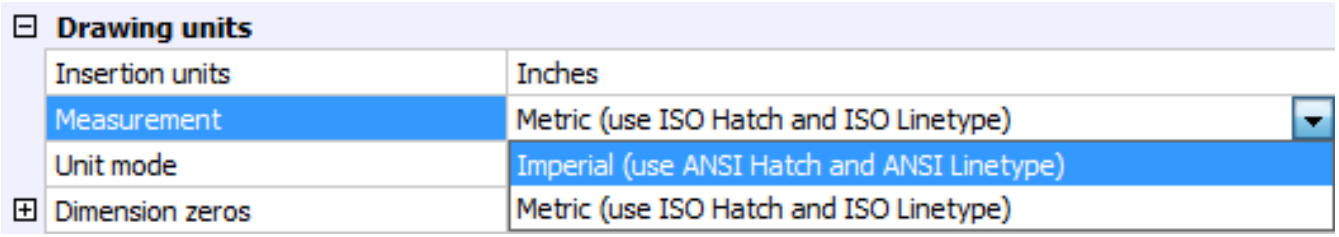
- **Imperial**: uses Default.pat
- **Metric**: uses Iso.pat

Defining the MEASUREMENT setting

Do one of the following:

- In the command bar type **measurement** , then press Enter. Type **ON** , then press Enter to set **measurement** to **Metric**. Type **OFF** , then press Enter to set **measurement** to **Imperial**.
- In the Settings (1.17.10) dialog go to **Drawing > Drafting > Drawing units.** Choose either **Metric** or **Imperial** in the combo box. (1.724)

Figure 1.724



Defining the MAXHATCH setting

Do one of the following:

- In the command bar type **maxhatch**, then press Enter. Type a new value and press enter.
- In the Settings (1.17.10) dialog, go to **Drawing > Drafting > Entity Creation > Hatches** . Type a new value in the Maximum hatch dashes settings field. (1.725)

Figure 1.725

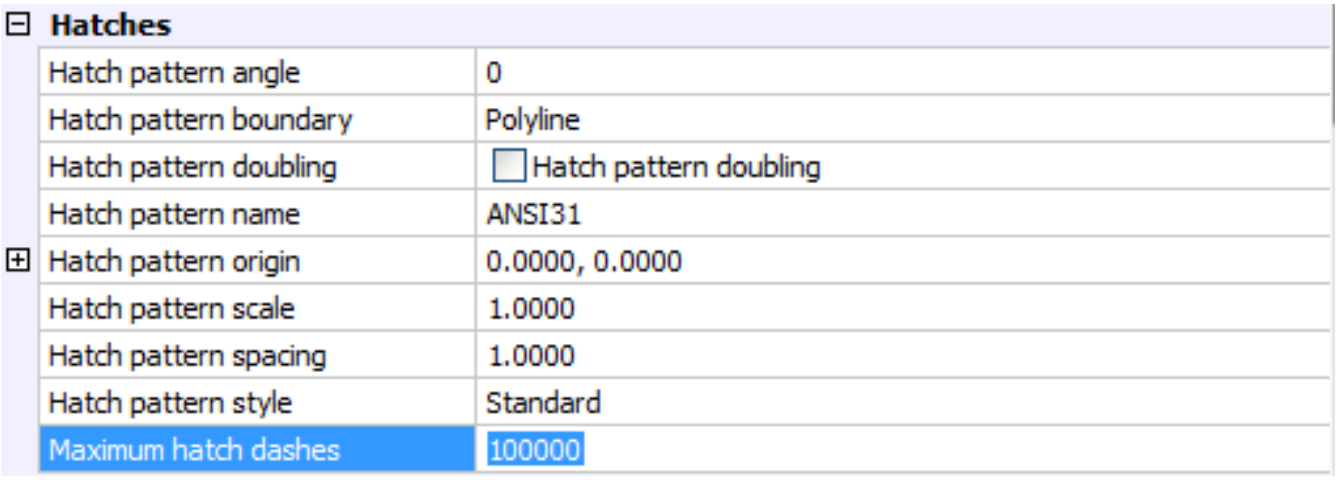


Figure 1.726

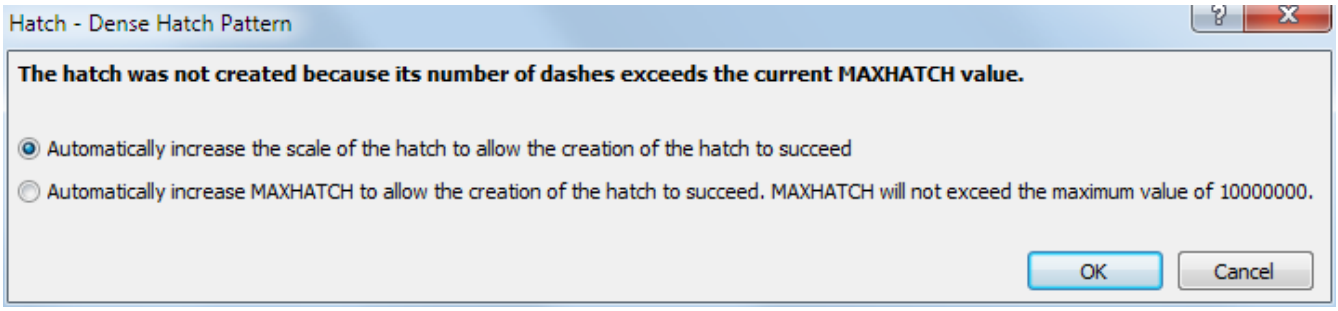

Hatch - Dense Hatch Pattern
The hatch was not created because its number of dashes exceeds the current MAXHATCH value.
Automatically increase the scale of the hatch to allow the creation of the hatch to succeed
Automatically increase MAXHATCH to allow the creation of the hatch to succeed. MAXHATCH will not exceed the maximum value of 10000000.

Cancel

1.25.27 Creating Hatches and Gradient Fills

Commands: HATCH (6.16.3), -HATCH (6.16.1) and GRADIENT (6.15.20) The **Hatch** command fills an enclosed area in your drawing with a pattern. The **Gradient** command creates solid fills in nine different patterns and one or two colors. The area can either be a single entity such as a circle or a closed polyline or an area enclosed by a selection of entities. To create the hatch you can click inside the closed perimeter of a boundary or you can select entities.

General procedure to create hatches and gradient fills

1. Do one of the following:
   - Click the **Hatch** tool button ( ) or the **Gradient** tool button ( ) on the Draw toolbar.
   - Choose **Hatch...** or **Gradient...** in the Draw menu.
   - Type **hatch** or **gradient** in the command bar, then press enter.

   The Hatch and Gradient dialog displays.
2. Do one of the following:
   - Click the **Hatch** tab to create a hatch, then define the hatch properties.
   - Click the **Gradient** tab to create a gradient fill, then define the gradient fill properties.
3. Define the boundary for the hatch or gradient fill.
4. Set the options for the hatch or gradient fill.
5. Click the **OK** button to create the hatch or gradient fill.

To define hatch properties

1. On the Hatch and Gradient dialog click the Hatch tab. (1.727 on the following page)
2. (option) Click the **Inherit properties** button ( ).
   - The **Hatch and Gradient** dialog closes temporarily. Prompts you: Select hatch entity to copy properties from:
   - Select a hatch entity. The **Hatch and Gradient** dialog reopens, displaying the properties of the selected hatch entity.
3. (option) Select the **Pattern Type** . (1.728 on page 845)
   - User Defined - uses the pattern defined in this dialog box with the Angle, Spacing, and Cross Hatch options.
   - Predefined - uses patterns defined in **iso.pat** (metric units - MEASUREMENT (1.17.10) = ON) and **default.pat** (imperial units - MEASUREMENT = OFF).
   - Custom - uses patterns defined in *.pat files (one pattern definition per file).

   BricsCAD searches for *.pat files in the folders that are defined in the SRCHPATH (1.17.10) (Support File Search Path) system variable.
4. (option) If the **Pattern Type** is **Predefined** or **Custom** select a **Pattern Name** in the **Hatch pattern** palette, then double click the pattern or click the **OK** Button. (1.729 on page 845)
5. (option) If the **Pattern Type** is **Predefined** or **Custom**, do one of the following:
   - Type a scale in the **Scale** settings field.
   - Choose the scale from the drop down list.
6. (option) Do one of the following:
   - Type an angle in the **Angle** settings field.
   - Choose the angle from the drop down list.
7. (option) If the **Pattern Type** is **User defined** , specify the **Pattern Spacing**.
8. (option) If the **Pattern Type** is **User defined** , select the **Cross Hatch** option.
9. Define the Hatch Origin. The options are:

- **Use current origin** : The origin as defined by the HPORIGIN (1.17.10) system variable is reused.
- **Specified origin** : Click the **Pick new origin** button (), then pick a point in the drawing. The new origin is stored in the HPORIGIN (1.17.10) system variable.

Note: The BACKGROUNDCOLOR property of a hatch can be modified in the **Pattern / Background Color** field in the Properties (1.15.4) panel.

To define gradient fill properties

1. On the Hatch and Gradient dialog click the Gradient tab. (1.730 on the next page)
2. (option) Click the **One color** radio button to create a 'color to white' or 'color to black' gradient fill.
   - Click the colored tile to open the Select color dialog, to pick a different base color.
   - The color slider sets the transition from color to white or black. Press and hold the left mouse button to move the color slider ((1.731 on page 849)) . Move the slider to the far right to create a 'color to white' gradient fill. Move the slider to the far left to create a 'color to black' gradient fill.
3. (option) Click the Two color radio button to create 'two color' gradient fill. Click the colored tiles to open the Select color dialog to pick the base colors.
4. Select one of the 9 gradient patterns. The options are: linear, cylindrical, inverted cylindrical, spherical, hemispherical, curved, inverted spherical, inverted hemispherical and inverted curved.
5. (option) **Centered**: If centered, the gradient fill is created symmetrical; if not centered, the gradient fill is built up from the left of the boundary.
6. (option) **Angle**: Specifies the angle of the gradient fill, relative to the current UCS.

Figure 1.731

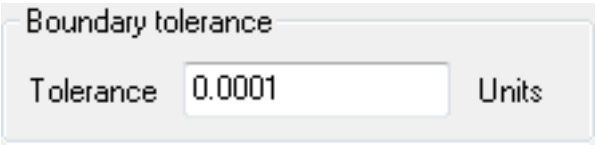
To define the boundary for a hatch or gradient fill

1. (option) Select the **Boundary retention** option.
2. (option) Select an **Island** option. (1.732)
3. (option) Adjust the **Boundary tolerance**. (1.733 on the following page)
4. (option) Click the **Select** button ( ) to select a **Boundary set**. The **Hatch and Gradient** dialog temporarily closes to let you select entities. (see also the note below)
5. (option) Click the **Specified Origin** radio button, then click the **Pick a new origin** button ( ). The **Hatch and Gradient** dialog temporarily closes to let you specify a new origin.
6. Do one or more of the following:
   - Click the **Pick Points** button ( ). The **Hatch and Gradient** dialog closes. You are prompted: Select a point to define a boundary or hatch area:
     - Specify a point in each of the areas you want to hatch. You are prompted: Select a point to define a boundary or hatch area:
     - Right click or press Enter to stop adding areas. The **Hatch and Gradient** dialog displays again.
   - Click the **Select Boundary Entities** button ( ). The **Hatch and Gradient** dialog closes. You are prompted: Select entities:
     - Select the entities you want to hatch.
     - Right click or press Enter to stop selecting entities. The **Hatch and Gradient** dialog displays again.
   - Click the **Remove Boundary Entities** button ( ). The **Hatch and Gradient** dialog closes. You are prompted: Select entities:
     - Select the current boundary entities to be removed from the selection.
     - Right click or press Enter to stop selecting entities. The **Hatch and Gradient** dialog displays again.
7. Define the Hatch Origin. The options are:
   - **Use current origin** : The origin as defined by the HPORIGIN (1.17.10) system variable is reused.
   - **Specified origin** : Click the **Pick new origin** button ( ), then pick a point in the drawing. The new origin is stored in the HPORIGIN (1.17.10) system variable.

Note: If a selection set was active when you launch the **Hatch** tool, this selection will be used as the **Boundary Set** if you click the **New** button in step 11 in the above procedure. In this case the Hatch and Gradient dialog closes and immediately reopens.

Figure 1.732

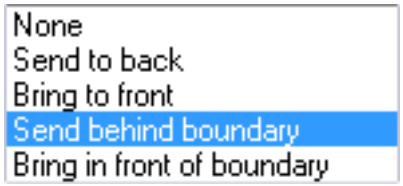
Figure 1.733



Set the Hatch and Gradient options

1. (option) Select the **Annotative** option to create an annotative hatch (1.29.27).
2. (option) Select the **Associative** option to associate the hatch with its boundary.
3. (option) Select the **Create Separate Hatches** option. In case multiple boundaries are detected or multiple entities are selected in step 9, separate hatches are created instead of a single hatch.
4. (option) Choose a **Draw order** option. (1.734) This option is reset to **Send behind boundary** when the drawing is closed and reopened.

Figure 1.734



1.25.28 Donuts

Command: DONUT (6.10.37) Donuts are solid, filled circles or rings created as closed, 2-segment, wide polylines. The default method to draw donuts is to specify its inside and outside diameters, and then specify its center. If the inside diameter is zero, a filled circle is created.

Drawing donuts

1. Do one of the following:

   - Click the **Donut** tool button ( ) Draw toolbar.
   - Choose **Donut** in the Draw menu.
   - Type **donut** in the command bar, then press Enter.

   You are prompted: 2Point/3Point/RadTanTan/<Inside diameter of donut> <current inside diameter>: A prompt menu opens: (1.735)

2. Do one of the following:

   - Right click to accept the current inside diameter.
   - Type a new inside diameter in the command bar.
   - Define a new inside diameter graphically by clicking two points.

   You are prompted: Outside diameter of donut <current outside diameter>:

3. Do one of the following:

   - Right click to accept the current outside diameter.
   - Type a new outside diameter in the command bar.
   - Define a new outside diameter graphically by clicking two points.

   You are prompted: Center of donut:

4. Specify the center of the donut. The donut is created.

5. (option) Specify the center point of another donut.

6. Right click to conclude the **donut** command. (1.736 on the next page)

NOTES

- When Fill Mode (1.25.8) is turned off, all filled entities, such as wide polylines and planes, display and print as outlines.
- Set the inside diameter to 0 (zero) to create filled circles.

Figure 1.735

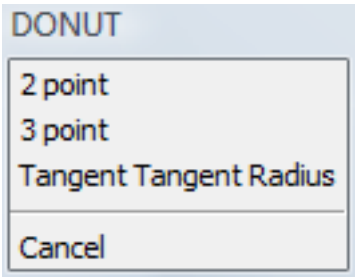


Figure 1.736

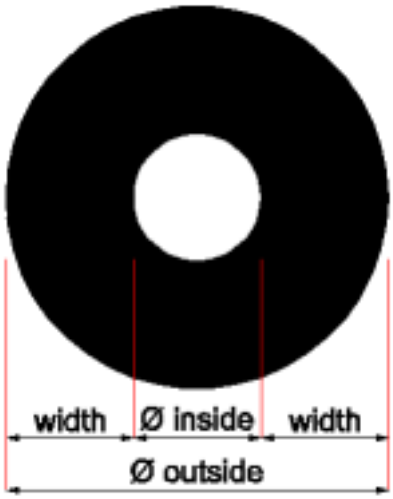

1.25.29 Editing a hatch or gradient fill

Commands: HATCHEDIT (6.16.2) and -HATCHEDIT (6.16.4) If you select a hatch or gradient fill, its properties display in the Properties bar.

To edit a hatch or gradient fill in the properties bar

1. Select the hatch or gradient fill in the drawing. The properties of the selected entity display in the Properties bar: (1.737 on the following page) Hatch properties (1.738 on page 855) Gradient fill properties.
2. Select the property you want to modify in the Properties bar. The selected property field is activated.
3. Modify the selected property
4. Do one of the following:
   - Repeat steps 2 and 3 to modify another property.
   - Press the Esc key to stop editing the hatch.

NOTES

- If you select multiple hatches you can you edit them simultaneously. Properties which are different display as ***varies*** in the BricsCAD Properties bar. If you edit such property, all edited hatches will then share this property.
- Linetype (1.25.6), Linetype scale (1.25.6) and Lineweight (1.25.7) apply to **User Defined** pattern types only .

To edit a hatch in a dialog box

1. Do one of the following:

   - Double click a hatch or gradient fill entity.
   - Type **hatchedit** at the command prompt, then select a hatch or gradient fill entity.

   The Hatch Edit dialog displays: (1.739 on the facing page)

2. (option) Select the Gradient tab to turn the Hatch into a Gradient fill.
3. Edit the Pattern settings (1.25.27).
4. Edit the Boundary settings (1.25.27).
5. Click the **OK** button to apply the changes.

To edit a gradient fill in a dialog box

1. Do one of the following:

   - Double click a hatch or gradient fill entity.
   - Type **hatchedit** at the command prompt, then select a hatch or gradient fill entity.

   The Hatch Edit dialog displays: (1.740 on the next page)

2. (option) Select the **Hatch** tab to turn the Gradient fill into a Hatch .
3. Edit the Color settings (1.25.27).
4. Edit the Boundary settings (1.25.27).
5. Click the **OK** button to apply the changes.

To edit a hatch or gradient fill using the Quad

1. If necessary, hit the F12 function key to activate the Quad cursor menu (1.15.5).
2. Pause the cursor of the hatch or gradient fill. The Quad displays.
3. Move the cursor to the Quad and expand the **2D Editing** command group. (1.741)
4. Do one of the following:
   - Click the **Add Loop** button ( ). You are prompted: Specify internal point or [Select entities]: Click inside a closed area, or Type **S** , then press Enter to select entities. Right click or press Enter to conclude.
   - Click the **Remove Loop** button ( ). The boundaries of the selected hatch highlight. You are prompted: Select entities: Click the boundaries you want to remove. Right click or press Enter to conclude.
   - Click the **Associate** button ( ). You are prompted: Specify internal point or [Select entities]: You are prompted: Specify internal point or [Select entities]: Click inside a closed area, or Type **S** , then press Enter to select entities. Right click or press Enter to conclude.
   - Click the **Generate Boundary** button ( ). The boundary of the hatch is generated.
   - Click the **Send all hatches to back** button ( ). You are prompted: # hatch entity(ies) sent to back.

   Note: To repeat a Quad command, right click when the Quad displays.

   Tutorial: Hatch made easy using the Quad Click here (1.16.1) to watch

Figure 1.741

1.25.30 Editing Entities

Editing in the Properties Panel

BricsCAD offers a Properties panel like the Properties palette in AutoCAD. You can access it with the PROPERTIES command (PR alias) as well as other methods such as double-clicking on an object. Since it's a panel, it can remain open while you work. The properties displayed in the panel vary depending on the type of object(s) that you've selected. In general, they match what you would expect from your AutoCAD experience. There are, however, a few notable differences. For example, the Properties panel in BricsCAD displays the Handle (read-only) of the selected entity. The entity's handle can be useful to store and recall for programing purposes. You'll find other valuable additions to the Properties panel for different objects. I can't possibly cover all of them, but below is an example of properties for a selected line. In BricsCAD you can edit a line by entering the x,y,z values of the start point, end point, or even the delta. It also displays the slope as a read-only value. While this is supposed to be a 2D drawing, it's obvious from the slope of the selected line, that this particular entity isn't flat. You could, of course, edit the z-value of its endpoint to match the start point. However, you may incorrectly assume its accuracy beyond the second decimal place. Instead, you can change the Delta z-value to 0 ensuring the line is truly flat!

Editing with Grips

BricsCAD supports traditional object grips like AutoCAD. For example, if you select a circle, you can use its center and quadrant grips to move or resize it. BricsCAD does not, however, support mutli-functional grips. Instead, much of that functionality is available on the Edit tab of the Quad. (1.742 on the next page)

Editing with the Quad

As I mentioned in a previous post, the Quad offers different edit tools based on the type of entity. Circle edit tools are quite different, for example, from Dimension edit tools. When you select a dimension, you're offered tools to modify the dimension or dimension text. For example, you can flip the dimension arrowhead nearest to where you selected the dimension. In contrast, Circle edit tab includes tools like Trim and Hatch. (1.743 on the following page) The default tool changes based on your most recent editing behavior for that type of entity. You can hover over the default tool to display additional recently used tools. The recent tools can vary depending if you select the entity or simply hovered over it. (1.744 on the next page) Pass the cursor over a tab at the bottom of the Quad to expand it with even more tools. You'll find the most common tools to edit that specific type of entity on the Edit tab. The tools may vary depending if you select the entity or simply hover over it. For example, if you select a line, the Edit tab displays the Lengthen, Break, Join, and Match tools. If you hover over a line, without selecting it, the Quad adds Trim and Extend to the tool set. (1.745 on the following page) In this example, if you hover over the line and use the Extend tool, BricsCAD automatically extends the highlighted entity to the nearest boundary based on where you hovered the cursor. It only takes one pick compared to three picks and two enters using traditional methods. Of course, traditional methods are still available. (1.746 on page 865)

1.25.31 Drawing with Styles

Draw Multilines

The default behavior to draw a multiline is just as you expect. In addition to the familiar command options, BricsCAD offers a Follow option. Follow enables you to create a new multiline that's adjacent and colinear to the last mline you created. (1.747 on the facing page)

Figure 1.747

Commandline

```
Set end point or [Angle/Length/Follow/Close/Undo]:
:
: MLINE
Current Settings: Justification = Top, Scale = 20.00, Style = Standard
Start of line or [Justification/Scale/STyle/Follow] <Last point>:f
Length of line:
```

Draw Single-line Text

Like AutoCAD®, BricsCAD includes two text tools: Single- and Multi-line. The default process to create single line text is just as you would expect. BricsCAD, however, displays all the available options on the Command line so you can view and specify options with minimal effort. (1.748)

Figure 1.748

Commandline

```
: TEXT
Text: Style/Align/Fit/Center/Middle/Right/Justify/<Start point>:
Height of text <50>:
Rotation angle of text <0>:
Text: NOTES:
```

Draw Multiline Text

You create mtext (multiline text) in BricsCAD much like in AutoCAD. However, after you pick the first corner to place the text box, you have the option to enter specific values for the width and height of the text box. (1.749) And, instead of displaying the text editing tools on the ribbon, BricsCAD displays a Text Formatting toolbar right above the mtext box. It includes familiar text formatting controls such as line spacing, columns, and numbering. (1.750 on the next page)

Figure 1.749

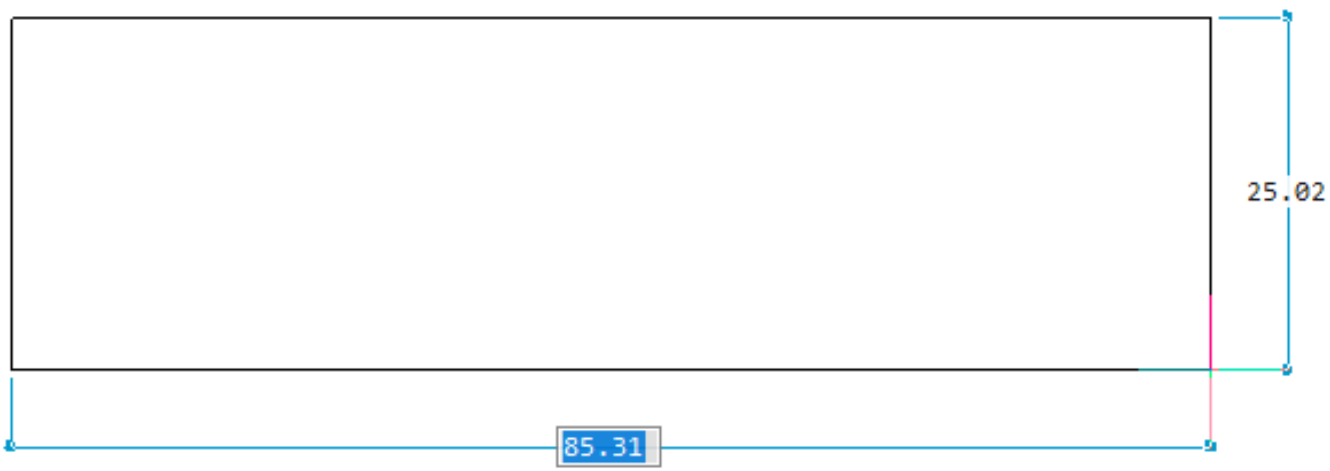

Figure 1.750

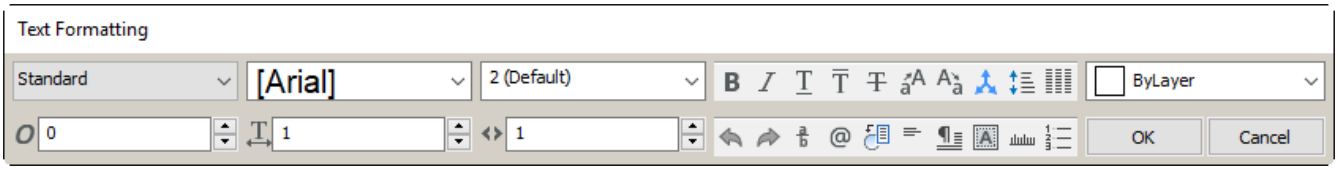

Draw Dimensions

BricsCAD includes the most common dimensioning tools, Linear and Aligned, in the Quad. You can access the entire set of familiar dimensions from other locations including the Command line. And, of course, you can add them to the Quad. (1.751 on the following page)

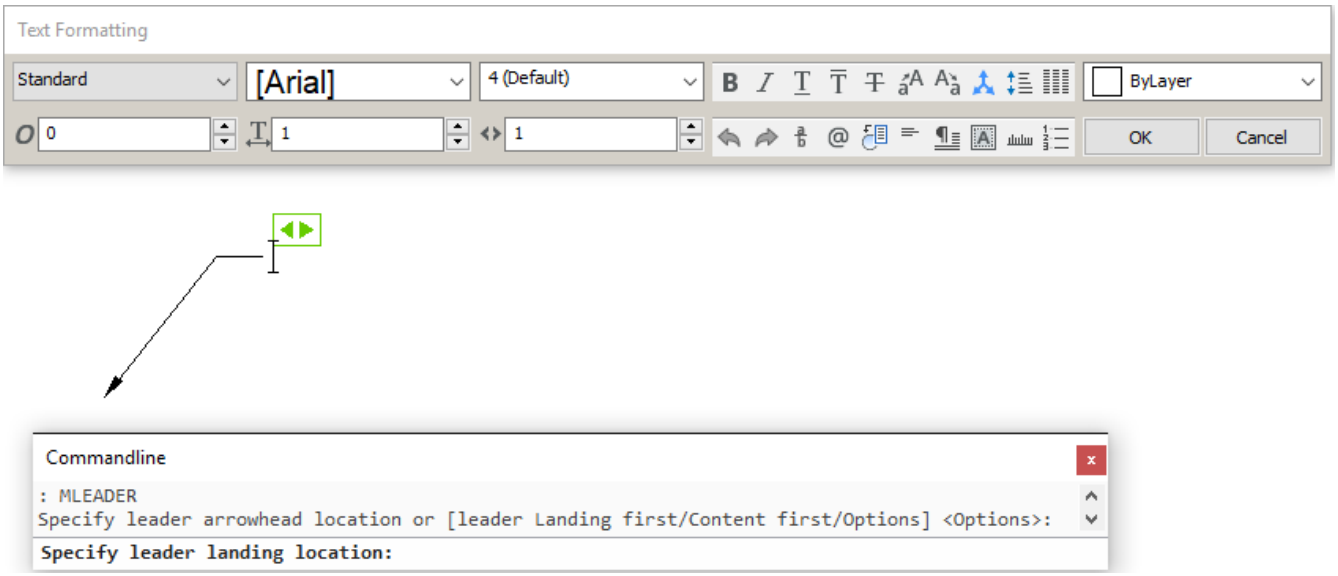
Dimension Variable Status

Draw Multileaders

You draw a multileader in BricsCAD very much like you draw one in AutoCAD. First you place the leader lines. And then you enter the text. However, after you pick points to place the leader, BricsCAD displays the Text Formatting tools near the leader rather than on the ribbon. The Text Formatting toolbar includes all the tools you need to format multiline text as part of your leader. (1.752 on the next page)

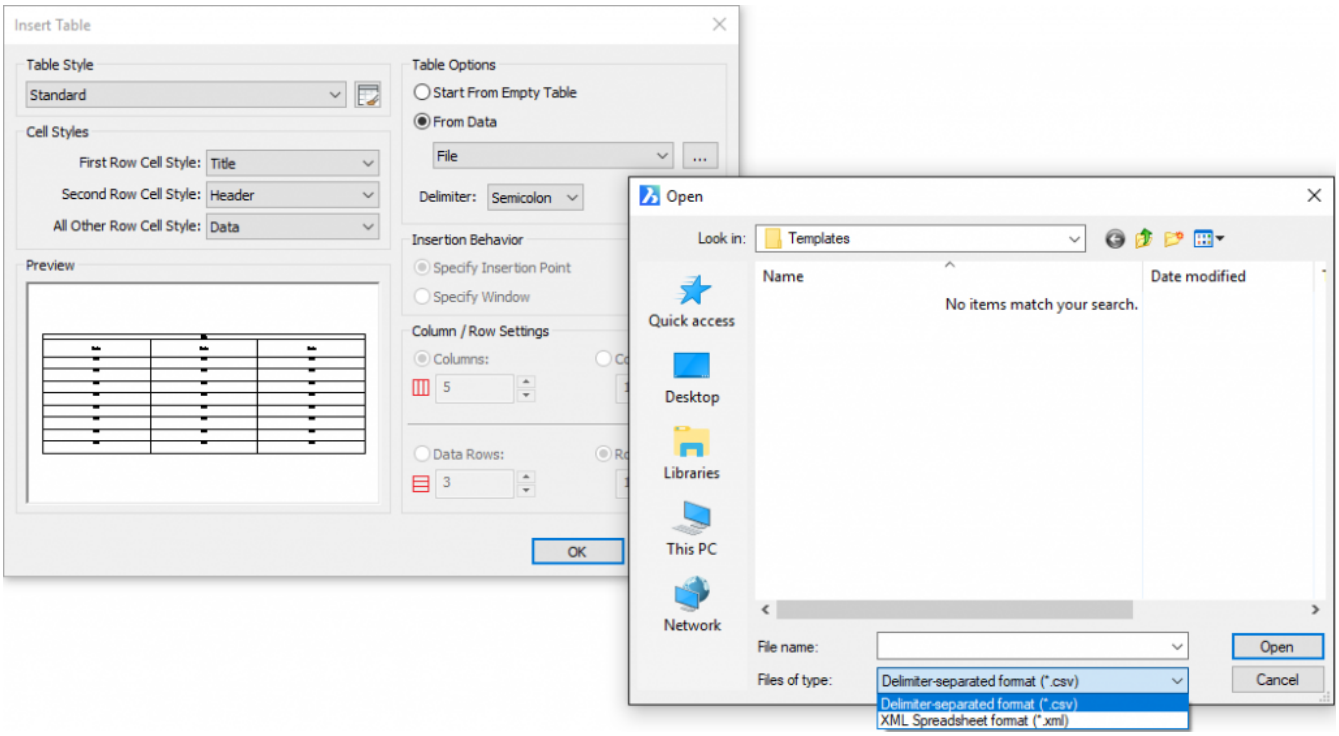
Figure 1.752



Draw Tables

The process to create a table in BricsCAD is similar to AutoCAD LT. The Insert Table dialog box offers the most popular table creation options. It includes the ability to import data from CSV and XML files. Note: BricsCAD does not support data linking directly from Excel spreadsheets. (1.753 on the facing page)

Figure 1.753



Defining Styles in the Drawing Explorer

All the drawing tools I covered in this post are dependent on style definitions. They work as you expect from your AutoCAD experience. However, the way you define styles is different. At first glance it may seem overwhelmingly different. But, if you take just a few minutes to explore the style definitions in BricsCAD I think you'll appreciate the differences! In BricsCAD all style definitions are managed from a central location, the Drawing Explorer. You can access the Drawing Explorer from the General menu on the Quad. It's also accessible via other methods including the Command line (EXPLORER). (1.754 on the next page) If you use familiar methods such as the MLSYTLE, STYLE, DDIM, MLEADERSTYLE, and TABLESTYLE commands, BricsCAD automatically expands the relevant style information in the Drawing Explorer. In the image below, Text Styles is expanded. Select any of the other styles to view and modify those definitions. (1.755 on the following page)

Tutorial: BricsCAD Spreadsheet Import Techniques Click here (1.9.8) to watch

Figure 1.754

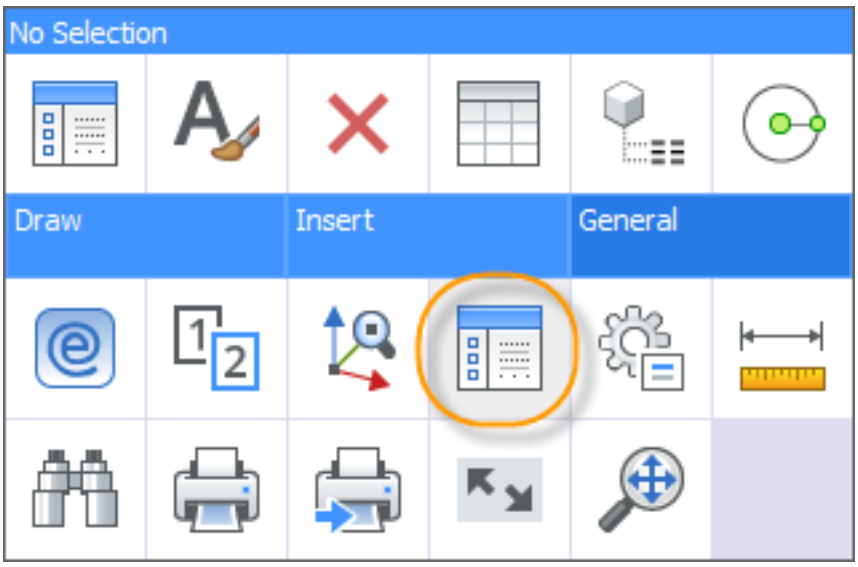


Figure 1.755

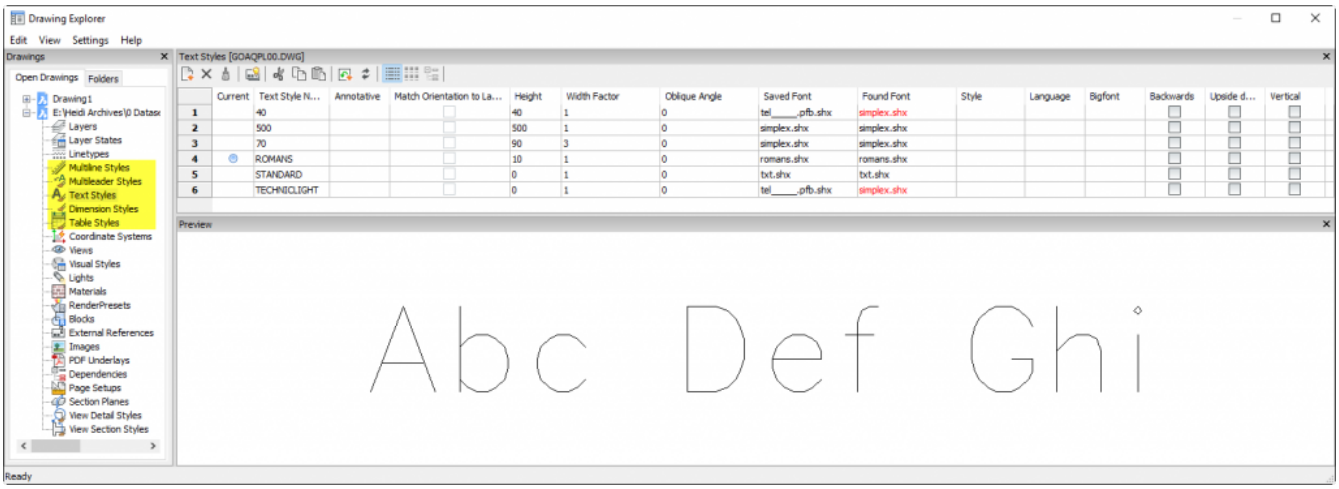


1.25.32 Drawing Entities

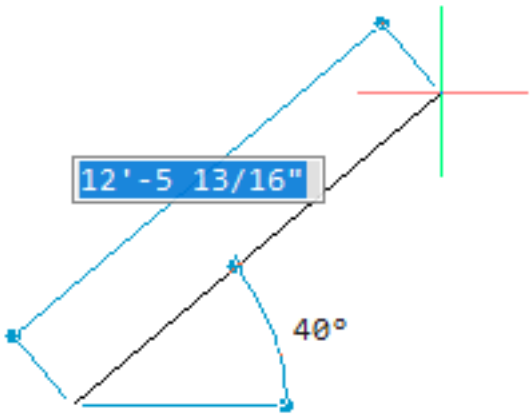
Draw Polylines, Splines, Ellipses, Elliptical Arcs, and Wipeouts

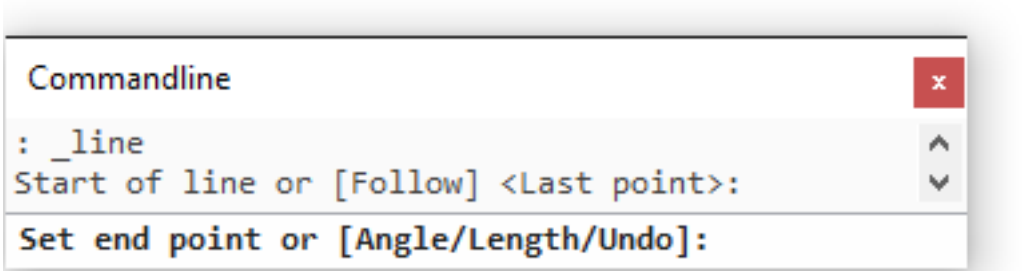
The processes to create Splines, Polylines, Ellipses, Elliptical Arcs, and Wipeouts in BricsCAD are just as you would expect in AutoCAD.

Draw Lines

The Line tool in BricsCAD works, by default, like you would expect. It includes the ability to enter the length and angle via dynamic input. However, BricsCAD also includes Command options to switch between Angle and Length. This offers you additional design flexibility even when Dynamic Input is turned off. Another minor difference is the terminology to continue a new line, arc or polyline from the last segment. In BricsCAD, the option is “Follow" instead of Continue. (1.756 on the next page)

Figure 1.756

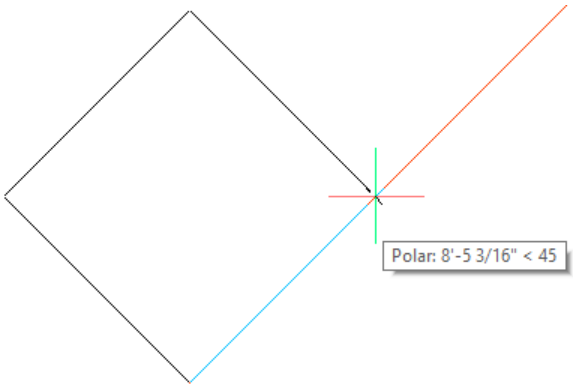




Draw Rectangles

The default behavior to draw a rectangle should be familiar to you. However, BricsCAD includes additional options offering maximum flexibility with minimal clicks. Creating a square is a great example! (1.757 on the facing page)

Figure 1.757



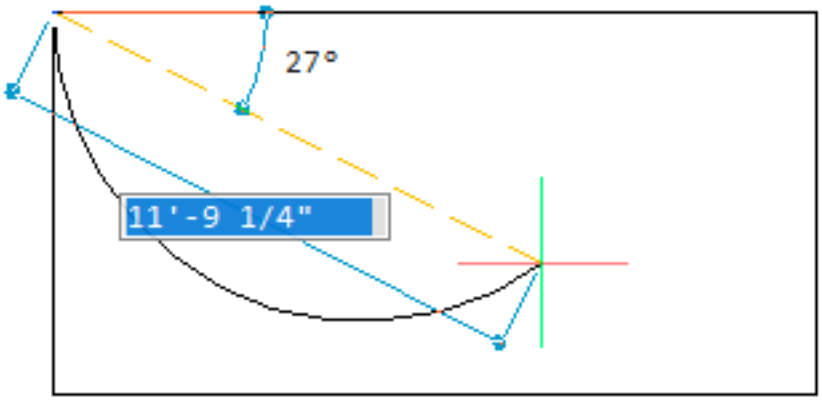
Commandline

```
: RECTANG
Select first corner of rectangle or [Chamfer/Fillet/Rotated/Square/Elevation/Thickness/Width of line/Area/Dimensions]:S
Select first corner of rectangle or [Chamfer/Fillet/Rotated/Elevation/Thickness/Width of line/Area/Dimensions]:
Second corner of square:
```

Draw Arcs

The methods to draw an Arc, by default, are as you would expect. However, BricsCAD includes all the arc creation options after the first pick. It provides more flexibility with fewer clicks. For example, you can pick the first point of an arc. Then, use the Direction option to specify its direction of tangency. (1.758 on the next page)

Figure 1.758



Commandline

```
Enter start of arc or [Center/Follow] <Last point>:
Enter second point or [Angle/Center/Direction/End/Radius]:D
Enter initial direction for arc <Follow>:
End point:
```

Draw Circles

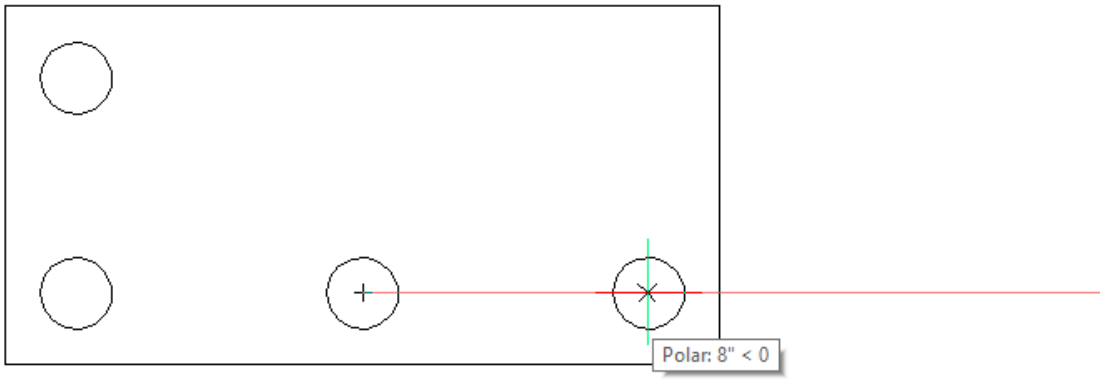
The options to draw a circle in BricsCAD should be familiar to you. However, the Circle command includes two extra options that you may not expect, but will certainly appreciate! One option allows you to quickly convert an arc to a circle. (1.759) The other option, Multiple, enables you draw a circle and then copy it as many times as you like. The center of each new circle is placed in relation to the previous one. This allows you to create many circles, quickly and accurately. Very handy! (1.760 on the next page)

Figure 1.759

Commandline

```
:
: CIRCLE
Select center of circle or [2 Point/3 Point/TangenT-tangent-Radius/turn Arc into circle/Multiple circles]:a
Select arc to convert to circle:
```

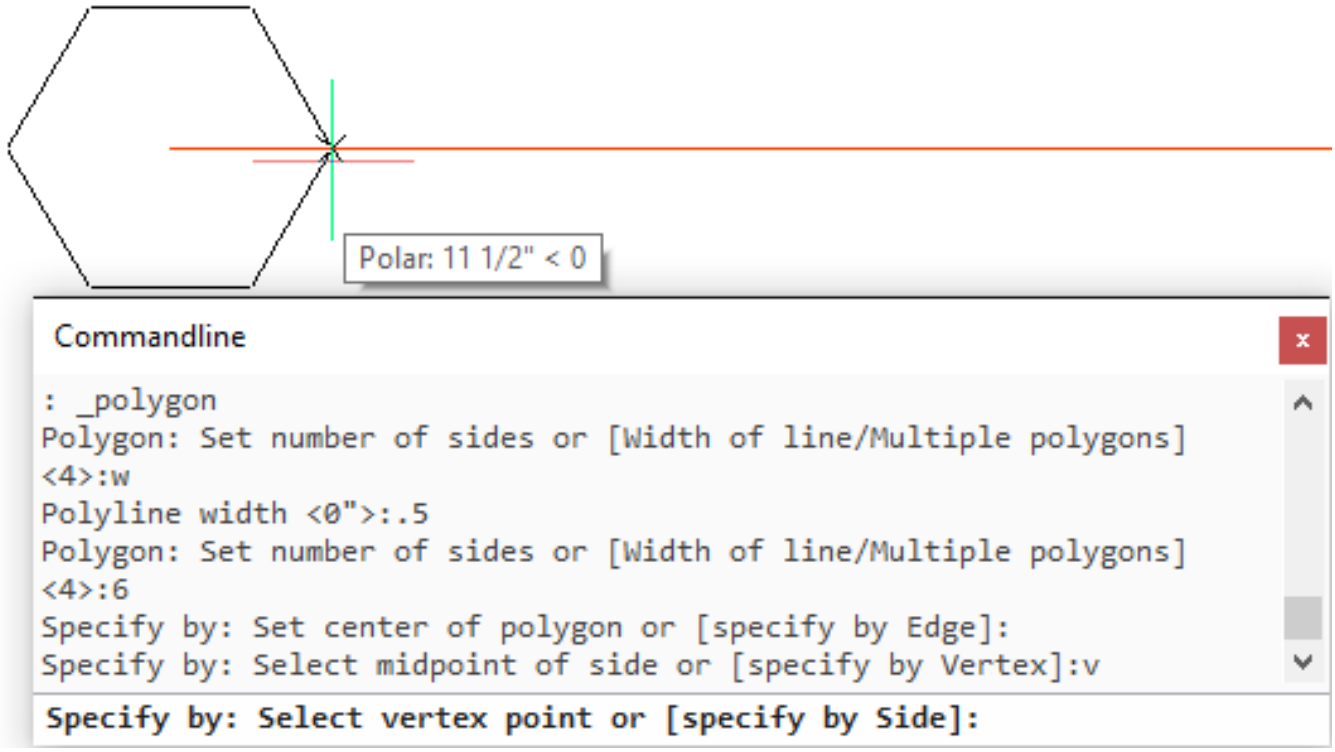
Figure 1.760



Draw Polygons

The default behavior to draw a polygon in BricsCAD works as you expect. However, it also includes an option for you to specify a line width while you draw the polygon. This reduces the need for you to modify the width property after it's created! When you create a polygon using the center option, you might notice a difference in terminology. Instead of prompting for inscribed or circumscribed, it asks if you want to select using the midpoint of the side or the vertex. Intuitive terminology! (1.761 on the following page)

Figure 1.761



Draw Hatches

The Hatch creation tool in BricsCAD is very much like using AutoCAD without the ribbon. It displays a familiar Hatch and Gradient dialog box with the controls you need to create a new hatch or gradient object. (1.762 on the next page)

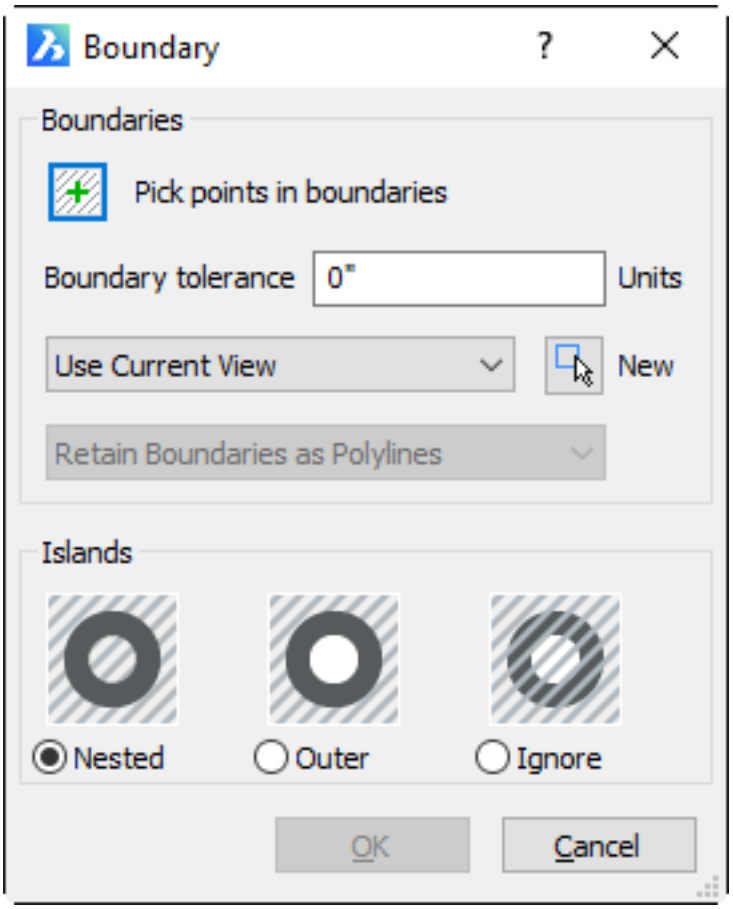
Draw Boundaries

The method to create a boundary in BricsCAD is very similar to AutoCAD. It displays a familiar Boundary dialog box with the controls to create a polygonal boundary. (1.763 on the facing page)

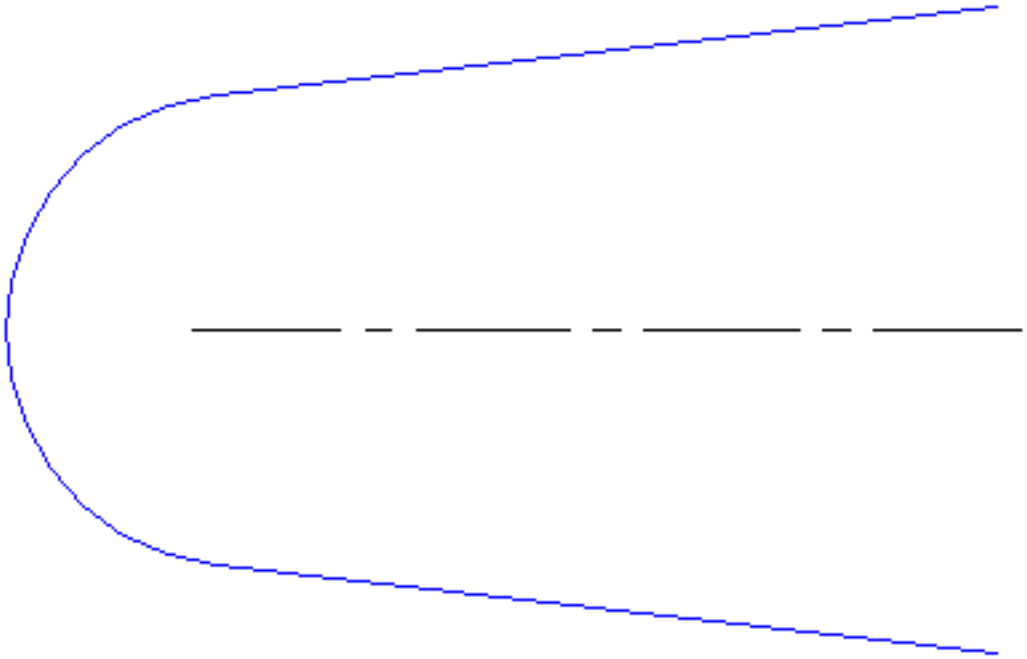
Figure 1.763



Draw Centerlines and Center marks

The process to add centerlines and center marks is as you expect. However, BricsCAD automatically applies a center linetype to centerlines. Note: The CL and CM command aliases don't launch CENTERLINE and CENTERMARK in BricsCAD. In a future post I'll show you how to easily change command aliases. (1.764 on the next page)

Figure 1.764



Draw Points

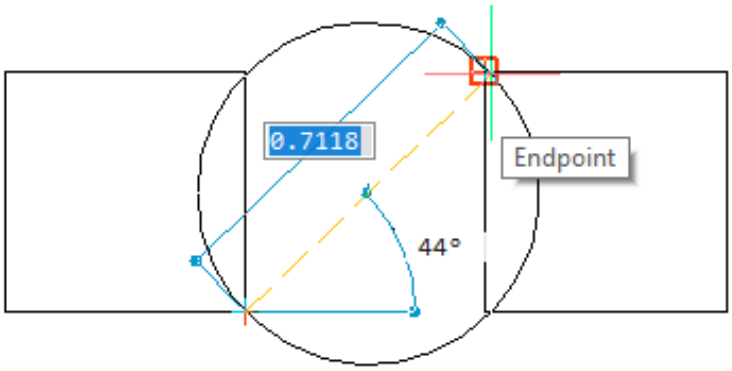
The default process to draw points in BricsCAD is simple and familiar. However, the POINT command in BricsCAD offers a Multiple option. This allows you to insert multiple points without having to relaunch the command each time.

Draw Donuts

You have never seen a donut like this before! By default, it behaves as you expect. But, unlike the donuts of your past, BricsCAD donuts come in many flavors! You're not required to create and place the donut only by its center point. You can choose from familiar circle creation options including 2 Point, 3 Point, and Tangent, Tangent, Radius. (1.765 on the facing page)

When you use any of those options, you are prompted to specify the width and diameter of the donut. That's more intuitive than specifying the inside and outside radius! (1.766 on the next page)

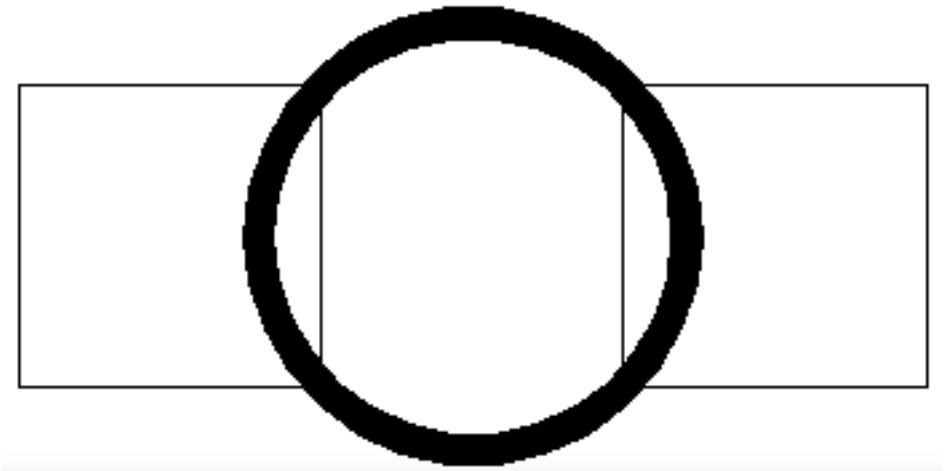
Figure 1.765



Commandline

```
: DONUT
Inside diameter of donut [2 Point/3 Point/Tangent Tangent Radius] <0.5000>:2p
Width of donut <0.2500>: .05
First point on diameter:
Second point on diameter:
```

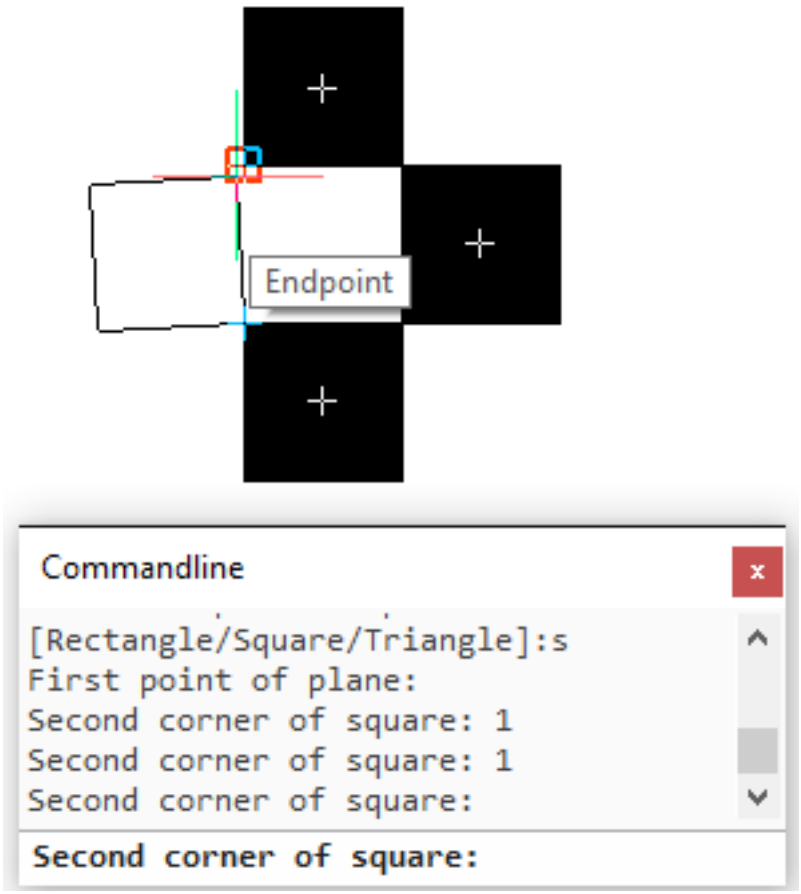
Figure 1.766



Draw Solids

BricsCAD offers three additional options in addition to the default expected behavior for drawing solids. You can create rectangular, square, or triangular solids. After you draw one of these shapes, you can create more of the same shapes with minimal clicks. (1.767 on the facing page)

Figure 1.767



Draw Xlines and Rays

Xline and Ray work as expected. You might, however, notice the Parallel option for Xlines. It's the same as the Offset option in AutoCAD.

1.25.33 Points

Command: POINT (6.24.30) Since points are dimensionless, a single pixel should be the (nearly) correct representation on the screen. But this is hardly visible, especially in a complex drawing. Therefore you can choose between a number of possible display styles. The point display style is chosen by means of the **Point Display Mode** (PDMODE) system variable. The size of the point representation style is controlled through the **Point Display Size** (PDSIZE) system variable.

Defining the point display settings

1. Open the Settings (1.17.10) dialog.
2. In the **Drawing** settings category, expand the **Entity Creation** sub-category.
3. Expand the **Points** settings group, then expand the **Point display mode** setting. (1.768) (1.769 on the facing page) Point display modes.
4. Set the **Point Display Mode** setting:
   - Choose the **point location marker** style: **point** , **none** , **X** or **|**
   - Choose to add a **circle** and/or a **square** .
5. Set the **Point Display Size** setting.
   - Relative: Type 0 (zero) to scale the point display style at 5% of the screen.
   - Absolute: Type the size of the point display style in drawing units.
6. Close the Settings dialog.

Note: If you need to draw a 'dot', use a Donut (1.25.28) with a zero inside diameter instead of a point entity.

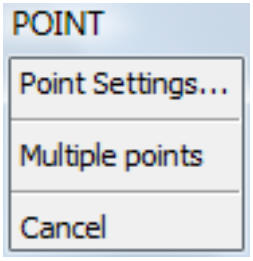
'

Drawing points

1. Do one of the following

   - Click the **Point** tool button ( ) on the Draw toolbar.
   - Choose **Point** in the Draw menu.
   - Type **point** in the command bar, then press Enter.

   You are prompted: Settings/Multiple/<Location of point>: A prompt menu displays:



2. Specify the location of the point. The point is created.

Note: If the **Point Display Size** setting is set to 0 (zero), use the Regen (1.23.4) tool to resize the display of the points to 5% of the screen size after zooming in or out.

1.26 3D Modeling

1.26.1 Direct Modeling Overview

BricsCAD provides advanced easy-to-use functions for working with ACIS solid and surface geometry, including:

- The creation of solid and surface geometry using Extrude (6.13.25) (dmExtrude (6.12.14)) and Revolve (6.26.45) (dmRevolve (6.12.21)) commands applied to 2D contours, 3D curves, and edges of existing solids.
- The creation of fillets (dmFillet (6.12.13)) and chamfers (dmChamfer (6.12.4)) on existing solid and surface geometry.
- Modifying (dmPushPull (6.12.25)) or deletion (Erase (6.13.8)) of fillets and chamfers.
- Direct interactive manipulation of solid and surface faces using PushPull (dmPushPull (6.12.25)), Move (6.21.29) (dmMove (6.12.16)) and Rotate (6.26.29) (dmRotate (6.12.24)) operations.
- The creation or removing of a volume when 2D contour attached to a face of a solid is being pushed or pulled.
- The removing of holes in surfaces by deleting its edges (Erase (6.13.8)).
- Deletion (Erase) and copying (dmCopyFaces (6.12.12)) of protrusion or depression features, such as holes, pockets, extrusions, ribs, and their combinations within the same 3D solid or from one 3D solid to another.

All these operations are performed in interactive mode: the intermediate result of the operation is shown dynamically, according to user input defined by mouse movement. Depending on the value of the DELOBJ (1.17.10) (Delete Entity) system variable, the defining entities are either retained or deleted or you are prompted whether to keep or delete the source entities (see table below).

Value	Result
0	Retain defining entities
1	Delete profile entities; retain paths and guide curves
2	Delete all defining entities
-1	Prompt to delete profile entities; retain paths and guide curves
-2	Prompt to delete all defining entities

The key feature of direct editing capabilities provided by BricsCAD consists in preserving of design intent. Design intent can be expressed by 3D dimensional and geometrical constraints which can be explicitly specified by user (see 3D Constraints (1.27.3)). 3D dimensional constraints (Distance, Radius, and Angle) imposed for faces and edges give user full parametric control over the solid model, different configurations and scales of the model can be obtained simply by changing the parameter of a dimensional constraint. Geometrical constraints (Coincident, Tangent, Parallel and others) define how these changes influence the geometry of the model. However, there is no need to introduce all the geometrical constraints manually since most of them can be recognized automatically by BricsCAD (see Design Intent (1.26.3)) to provide the expected result. Another feature of Direct Editing operations is that they can be easily applied with the Quad cursor menu (1.15.5). This tool provides a set of operations for the currently selected entities. At the same time the Quad provides the other basic solid editing operations such as copy, boolean union and subtract. Direct modeling operations apply to all ACIS solid geometry, whether created in BricsCAD or imported, and can be combined with regular solid modeling operations, for example, SOLIDEDIT (6.27.42).

1.26.2 Direct Modeling Operations

This section describes the direct modeling tools in BricsCAD. These tools are accessible in:

- The Quad (1.15.5) cursor menu.
- The **Direct Modeling** Menu.
- The **Direct Modeling, Fillet, Chamfer** and **Deform** toolbars. ===ERROR WITH DOWNLOADED IMAGE=== ===ERROR WITH DOWNLOADED IMAGE=== ===ERROR WITH DOWNLOADED IMAGE=== ===ERROR WITH DOWNLOADED IMAGE===

The **Align UCS** tool (===ERROR WITH DOWNLOADED IMAGE===) launches the UCS (6.30.1) command with the **Face** option selected. Click the **DUCS** field in the Status Bar (1.15.2) to toggle the dynamic UCS (1.21.21) feature ON and OFF. When ON the UCS aligns automatically to the solid face under the cursor and he UCS-icon changes accordingly. Press the TAB key to select an obscured face. The BricsCAD direct modeling tools are: **Icon Command Applies to Description**  dmPushPull (6.12.25) Any face of a 3D solid or surface. Adds volume to or removes volume from a solid via cursor movement or direct distance input.  dmMove (6.12.16) Cylindrical, spherical, conical, and toroidal faces of a 3D solid or surface. Linear and circular edges of a 3D solid or surface. Whole 3D solids, surfaces, and other entities. Moves the selected geometry with a vector in the XY- plane of the current UCS. When the face or edge of a solid or surface is moved, adjacent faces and edges are adjusted to preserve the correct solid/surface topology.  dmRotate (6.12.24) Planar, cylindrical, spherical, conical, and toroidal faces of a 3D solid or surface. Whole 3D solids, surfaces, and other entities. Rotates the selected geometry around an axis. When the face of a solid or surface is rotated, adjacent faces and edges are adjusted to preserve the correct solid/surface topology.  dmSimplify (6.12.27) 3D solids, surfaces, and their faces. Simplifies the geometry and topology of entities and subentities.  dmStitch (6.12.29) Surfaces Stitches touching surfaces into a single 3D solid or a single surface.  dmAudit (6.12.2) 3D solids and surfaces Checks and fixes geometrical and topological errors in ACIS solids and surfaces.  UCS (6.30.1) Planar faces of 3D solids and surfaces. Aligns the UCS to a face. ===ERROR WITH DOWNLOADED IMAGE=== dmExtrude (6.12.14) Closed 2D entities and detected closed boundaries.* Extrudes 2D entities or boundary to create solids. Planar faces of 3D solids and surfaces. Adds volume to or removes volume from a solid. (Optional): Create the new volume as a separate solid. Closed 2D entities and detected closed boundaries on a planar face of a solid. Extrudes 2D entities or boundaries to create solids or surfaces. (Optional): Create the new volume as a separate solid. ===ERROR WITH DOWNLOADED IMAGE=== dmRevolve (6.12.21) Closed 2D entities and detected closed boundaries.* Revolves a 2D entity on an axis to create a solid or a surface. Planar faces of solids and surfaces. Adds volume to or removes volume from a solid. (Optional): Create the new volume as a separate solid. Closed 2D entities and detected closed boundaries on the planar face of a solid. Revolves a 2D entity on an axis to create a solid or a surface. (Optional): Create the new volume as a separate solid. ===ERROR WITH DOWNLOADED IMAGE=== xFaces (6.34.3) Surfaces and faces of 3D solids. Extracts a set of 3D solids or surface faces as a new, 3D surface object.  dmCopyFaces (6.12.12) A set of 3D solid faces. Copies a feature (protrusion or depression), from one 3D solid to another or copies it to a different location on the same 3D solid.  dmThicken (6.12.30) Faces of 3D solids and surfaces. Thickens faces to create 3D solids. Surfaces Thickens surfaces to create 3D solids. Wire entities; lines, polylines, circles, ellipses, arcs, helices, and splines. Sweeps a circle along a wire to create a new 3D solid.  dmFillet (6.12.13) Sharp edges of a 3D solid or surface. Creates a fillet between adjacent faces sharing a sharp edge. ===ERROR WITH DOWNLOADED IMAGE=== dmFillet (6.12.13) Sharp edges of a 3D solid or surface. Creates a variable fillet between adjacent faces sharing a sharp edge.  dmChamfer (6.12.4) Sharp edges of a 3D solid or surface Creates a constraint symmetrical chamfer between adjacent faces sharing a sharp edge. ===ERROR WITH DOWNLOADED IMAGE=== dmChamfer (6.12.4) Advanced Mode Sharp edges of a 3D solid or surface Creates a constraint asymmetrical chamfer. ===ERROR WITH DOWNLOADED IMAGE=== Creates a constraint angular chamfer. ===ERROR WITH DOWNLOADED IMAGE=== Creates a variable symmetrical chamfer. ===ERROR WITH DOWNLOADED IMAGE=== Creates a variable asymmetrical chamfer. ===ERROR WITH DOWNLOADED IMAGE=== Creates a variable angular chamfer.  Erase (6.13.8) Removes a solid or a surface. Whole 3D solids and surfaces. Deletes entities. When the faces of a solid entity are deleted, the adjacent faces are extended to fill any gaps. When the faces of a surface entity are deleted, the gap is filled only if the faces form a fillet. Free edges of a surface (a surface edge is called "free" if it has only one

Tutorial: 3D Direct Modeling Basic Commands Click here (1.18.27) to watch

Selection Preview

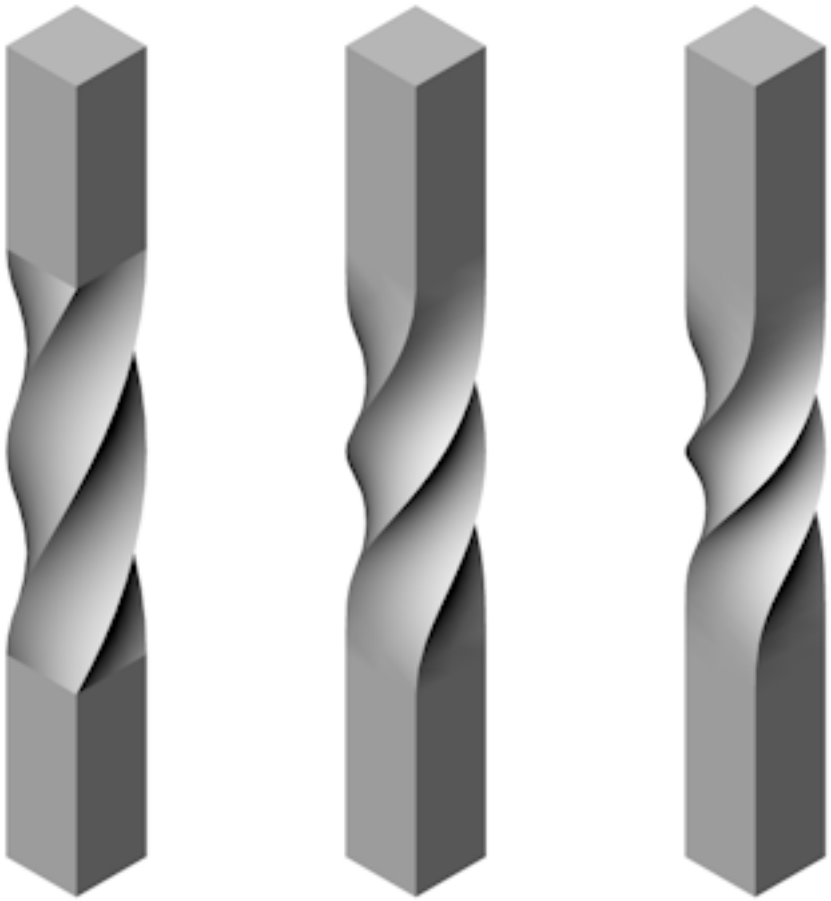
When the Quad cursor menu (1.15.5) is active, the SELECTIONPREVIEW (1.17.10) system variable is unused unless a command prompts you to select an entity (see Selection Settings (1.32.4)).

Select geometry

- Hit the TAB key to select obscured geometry.
- The SELECTIONMODES (1.17.10) system variable controls which subentities highlight: edges, faces, and/or detected boundaries.
- Hit the Enter key or right-click to conclude the selection procedure, if you enter a direct modeling command in the command line (6.9.25) or selected it from a menu or toolbar.
- Click the mouse to confirm the selection of geometry to execute the command if you launch a command from the Quad cursor menu (1.15.5).
- Window selection (1.32.7): to select the faces or edges of 3D solids and surfaces, press the CTRL key to cycle the options. An icon next to the cursor indicates what will be selected.
- The dmSelect (6.12.28) command allows you to select edges and faces based on their geometrical and topological properties:
  - Edges of a particular length.
  - Edges that form a concave/convex network.
  - Edge loops on the border of a set of connected faces.
  - Faces of a particular area.
  - Smoothly connected faces (G1 - tangent faces, or G2 - curvature continuity). (1.770 on the next page) G0: No continuity (left), G1: Tangent Faces (middle), and G2: Curvature continuity (right)
  - Fillets of a radius.
  - Cylindrical protrusions of a radius.
  - Protrusion or depression features; pockets, extrusions, or ribs.

The value of a particular length, area, or radius can be taken from a selected edge/face.

Figure 1.770



To control dimensions

A dynamic dimension displays with the dmPushPull (6.12.25) command. Make sure the Quad (1.15.5) and Dynamic Dimensions (1.21.9) are switched ON.

1. Hover the cursor over the face you want to move. The face highlights.
2. Choose **Push/Pull** (===ERROR WITH DOWNLOADED IMAGE===) from the **Direct Modeling** command group of the Quad cursor menu (1.15.5). The selected face moves with the cursor and a dynamic dimension field displays the relative distance. ===ERROR WITH DOWNLOADED IMAGE===
3. (Option) repeatedly hit the TAB key to see the distance with respect to an internal face, parallel to the selected face (left) or the bottom face (right). Press and hold the SHIFT key and hit the TAB key to reverse the display order of reference faces. ===ERROR WITH DOWNLOADED IMAGE=== ===ERROR WITH DOWNLOADED IMAGE===
4. Type a value in the dynamic dimension field, then hit Enter.

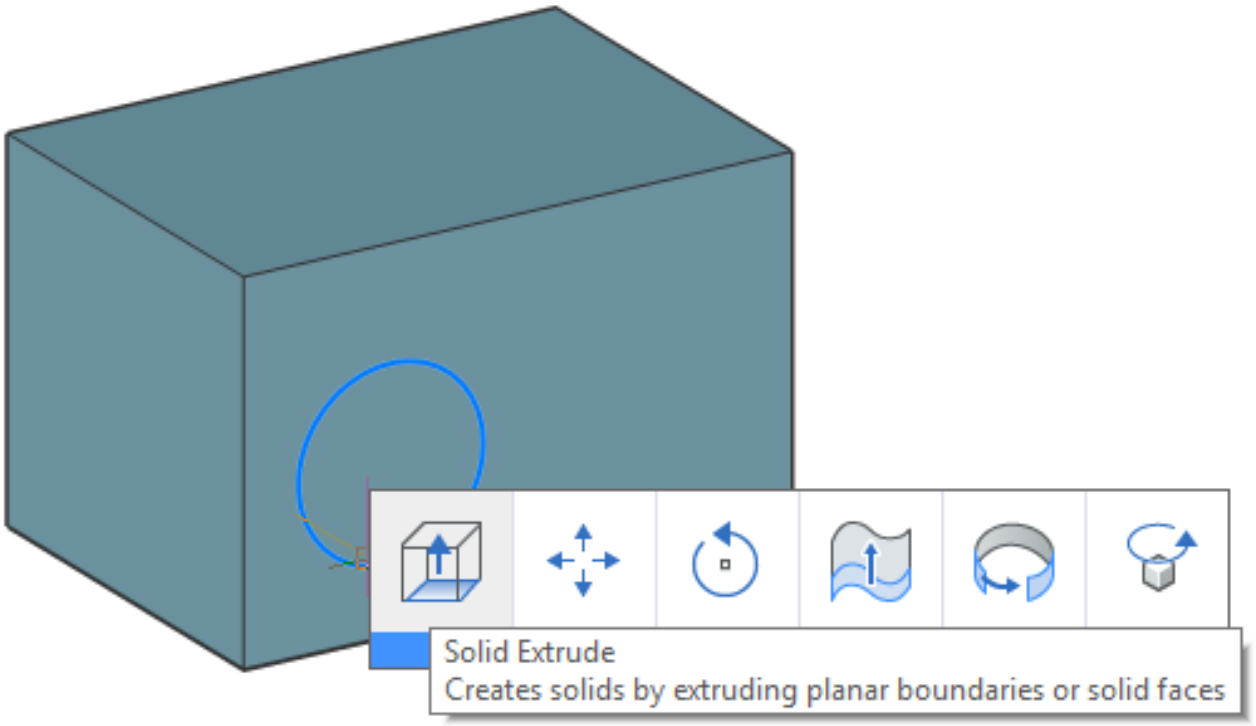
Making holes

Use the SUBTRACT (6.27.58) command. If you push-pull a closed 2D entity that lies on a face of a solid, a hole is created when you push the 2D entity through the solid.

To make a (circular) hole through a solid

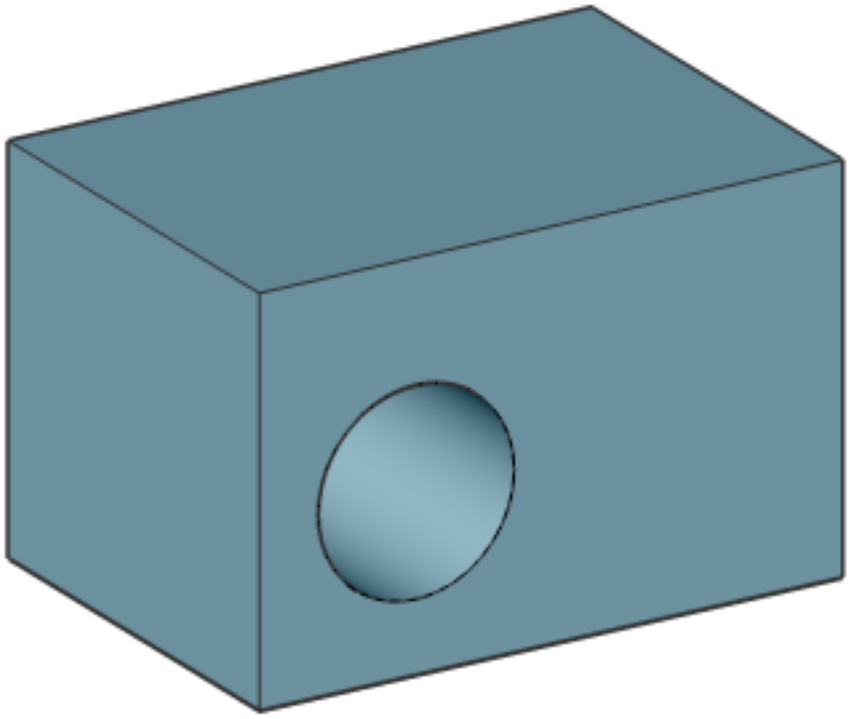
1. Make sure Dynamic UCS (1.21.21) is active.
2. Launch the Circle (1.25.14) command.
3. Move the cursor to the face you want to create to hole on. The UCS automatically aligns to the face the cursor is on.
4. Draw a circle on the face of the solid.

Figure 1.771



5. Hover over the circle, then choose **Extrude** (===ERROR WITH DOWNLOADED IMAGE===) from the **Model** command group of the Quad cursor menu (1.15.5). (1.771)
6. Do one of the following:
   - Type a distance in the dynamic field to define the depth of the hole.
   - Push the circle through the solid to create a through-hole.(1.772 on the next page)
7. (option) Choose **Push/Pull** (===ERROR WITH DOWNLOADED IMAGE===) from the **Model** command group of the Quad cursor menu (1.15.5) to modify the radius of the hole.
8. (option) Use the dmDistance3d (6.12.10) command to apply a distance constraint between the side faces of the solids and the center of the cylindrical surface of the hole to control the position of the hole.
9. (option) Use the dmRadius3d (6.12.22) command to control the radius of the hole.

Figure 1.772



To make a hole in a surface

1. Create a 2D closed entity, e.g. an ellipse. (1.773 on the following page)
2. Hover over the 2D entity.
3. Choose **Extrude** (===ERROR WITH DOWNLOADED IMAGE===) in the **Model** command group of the Quad cursor menu (1.15.5).
4. Extrude the 2D entity in the direction of the surface. (1.774 on page 899)
5. Hit the CTRL key twice to select the **Subtract** option of the DmExtrude (6.12.14) command. (1.775 on page 900)
6. Click the mouse to create the hole.

Figure 1.773

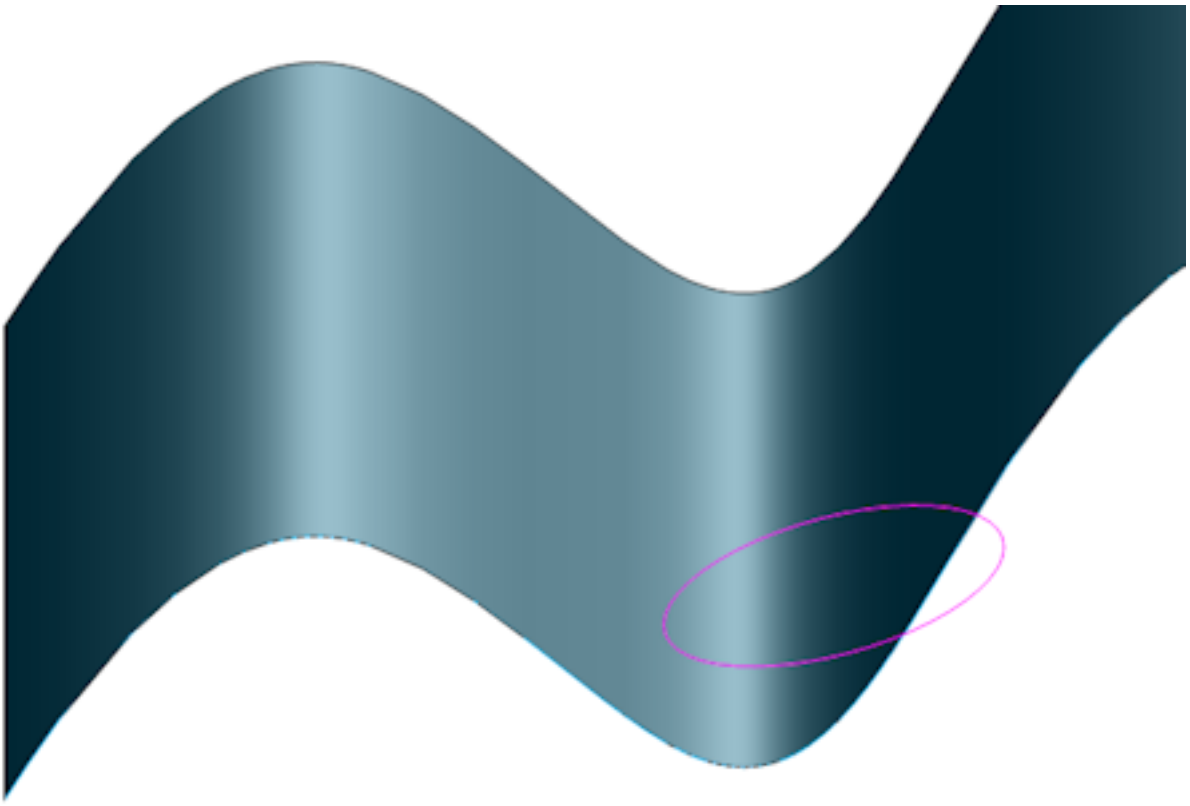


Figure 1.774

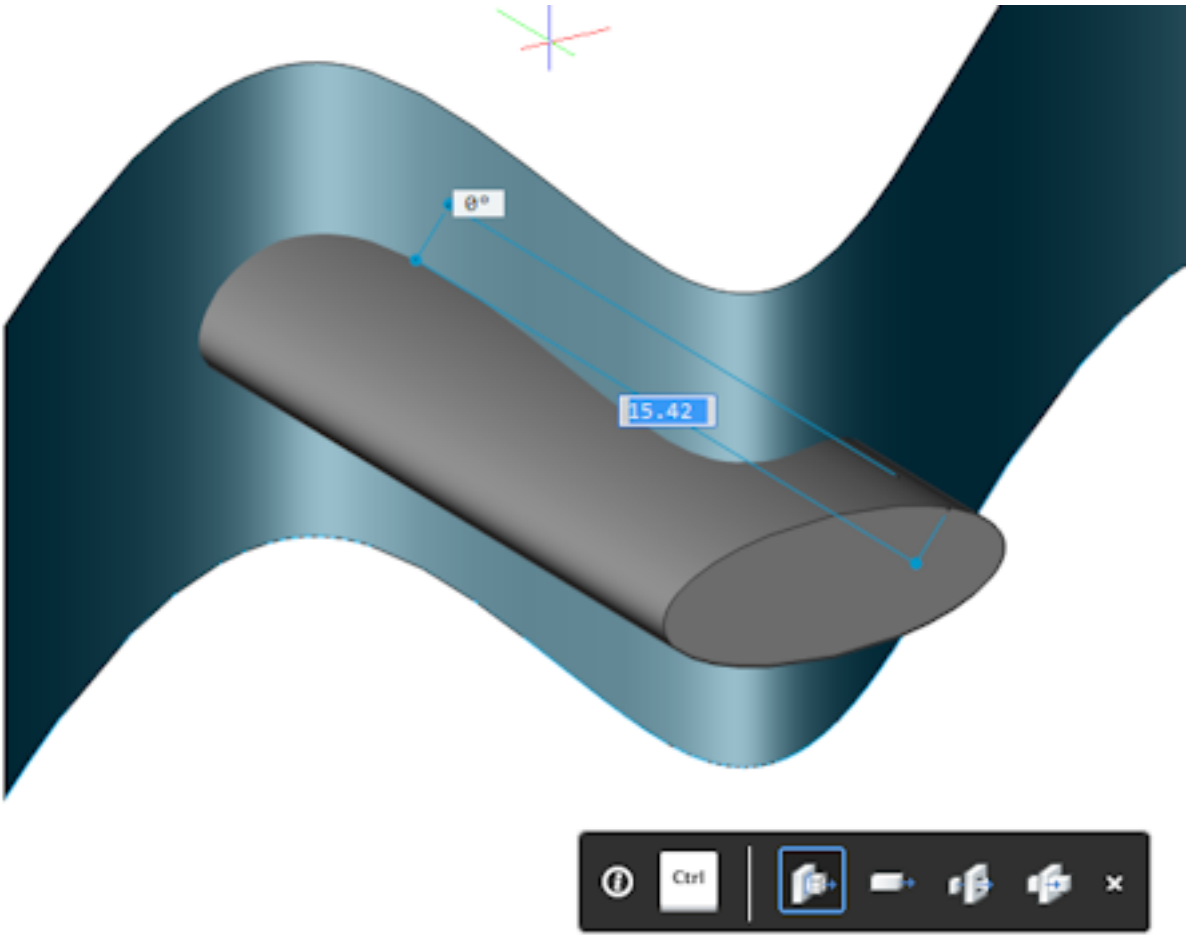

Figure 1.775

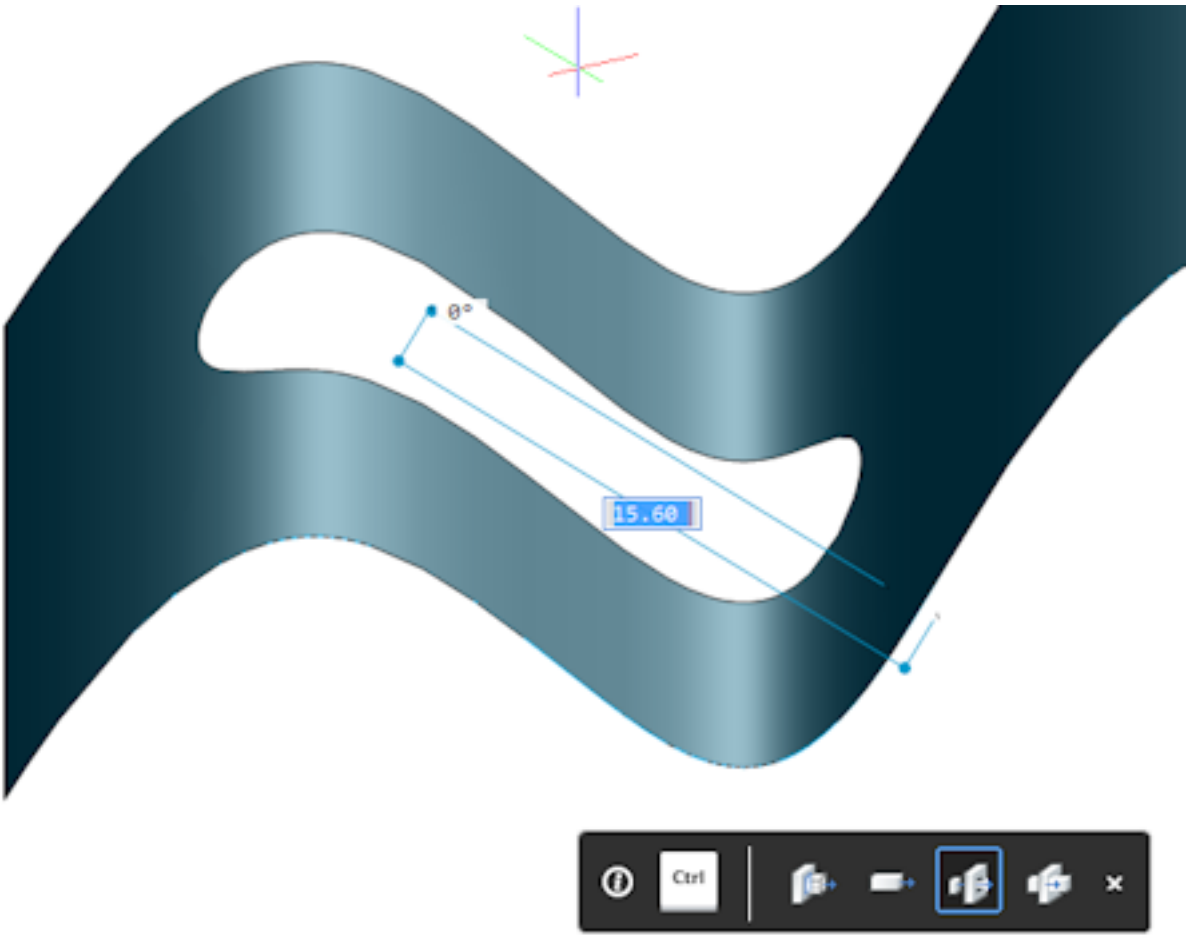


Deleting features

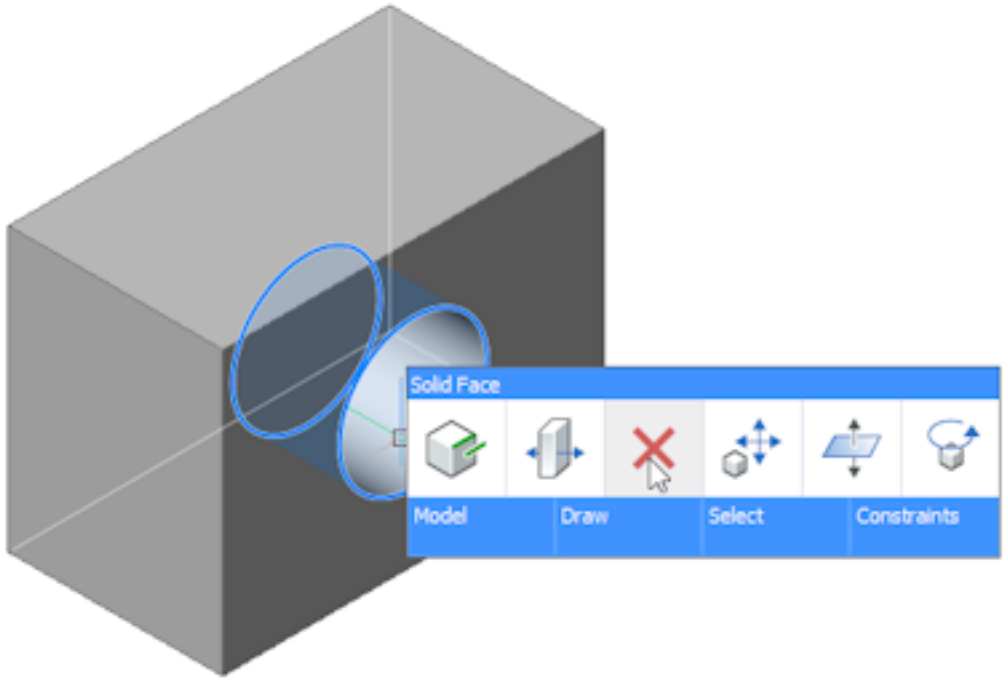
To delete a hole, you must delete all the internal faces and/or surfaces of the hole.

To delete a circular hole

1. Hover over the cylindrical surface of the hole.
2. Choose **Delete** (✕) in the **Model** command group of the Quad cursor menu (1.15.5).

(1.776 on the next page)

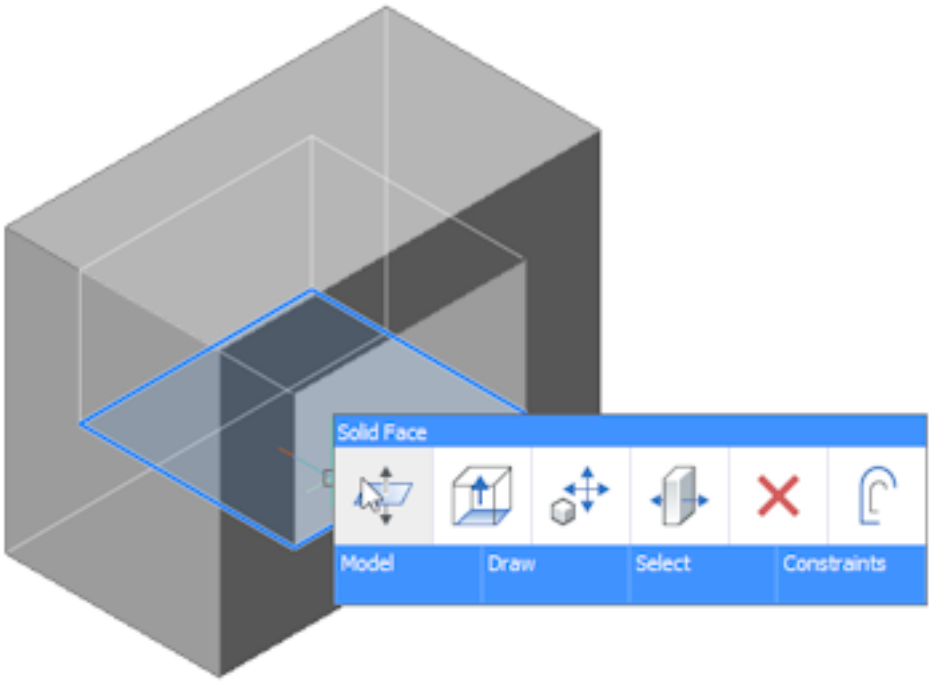
Figure 1.776



To delete a rectangular hole

1. Hover over one of the visible internal faces of the hole. The face highlights.
2. Choose **Push/Pull** (===ERROR WITH DOWNLOADED IMAGE===) from the **Model** command group of the Quad cursor menu (1.15.5) (1.777 on the facing page)
3. Drag the selected face to close the hole.

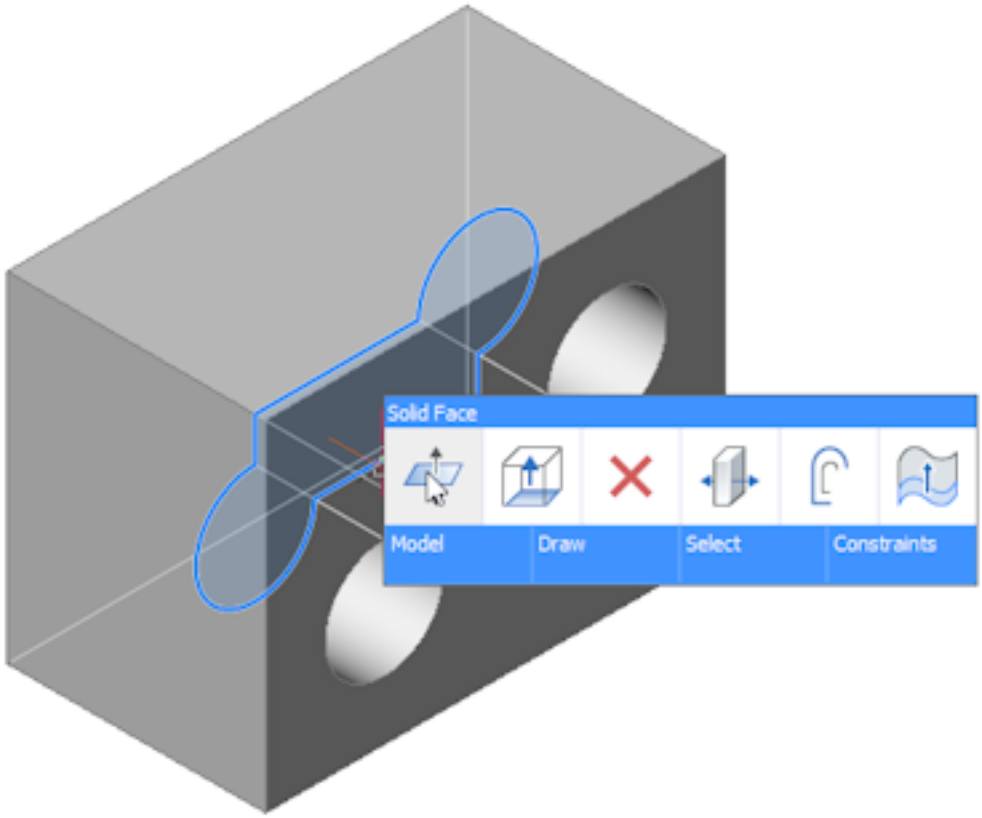
Figure 1.777



To delete a niche or recess

1. Hover over the back (bottom) face of the recess. If the face is obscured in the current view, hit the TAB key until the face highlights.
2. Choose**Push/Pull** (===ERROR WITH DOWNLOADED IMAGE===) in the **Model** command group of the Quad cursor menu (1.15.5). (1.778 on the next page)
3. Drag the face to close the gap.

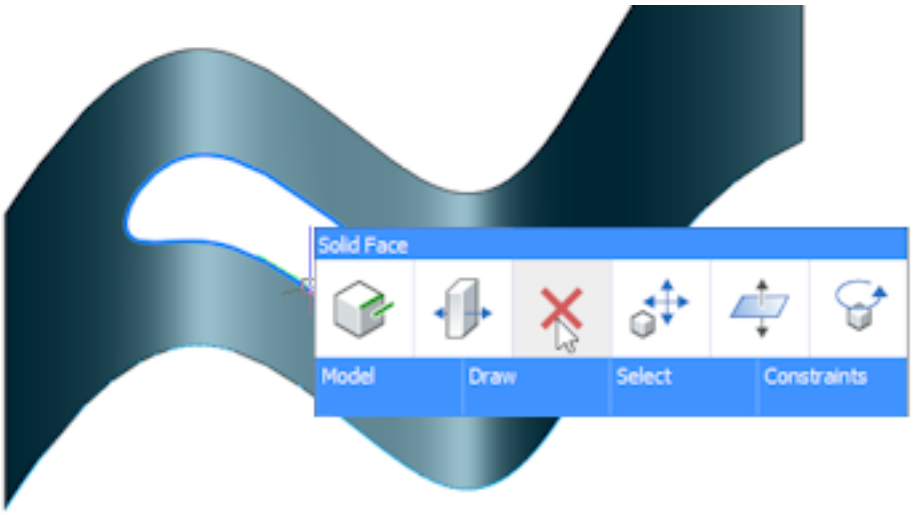
Figure 1.778



To delete a hole in a surface

1. Hover over the edge of the opening. The edge highlights.
2. Choose Erase (6.13.8) (✕) from the **Model** command group of the Quad cursor menu (1.15.5). (1.779 on the facing page)

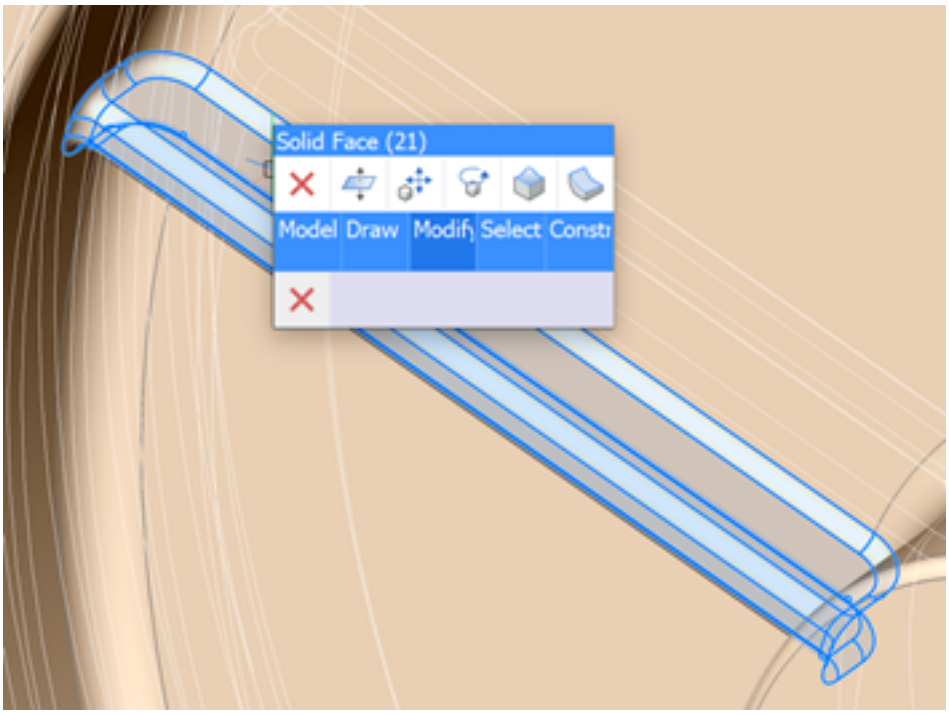
Figure 1.779



To delete a depression (hole or pocket) or a protrusion feature (extrusion or rib)

1. Select one or more faces of the feature you want to delete.
2. Click the **Protrusion** (===ERROR WITH DOWNLOADED IMAGE===) or **Depression** (===ERROR WITH DOWNLOADED IMAGE===) tool button in the **Select** panel of the **Solid** ribbon tab or from the **Select** command group of the Quad (1.15.5).
3. Click the **Erase** ( ) tool button. (1.780 on the next page)

Figure 1.780



Removing edges between coplanar faces

When two or more faces are made coplanar, e.g. with the DmPushPull (2.5.11) command, it might be necessary to remove the shared edges.

(1.783 on page 909) Two depressed faces	(1.784 on page 909) Two depressed faces moved to the top face, to create three coplanar faces.

1. Select the three faces.
2. Choose **Delete** (✕) from the **Model** command group in the Quad (1.15.5). (1.781 on the facing page) The shared edges are deleted and the three selected faces are unified. (1.782 on the next page)

Figure 1.781

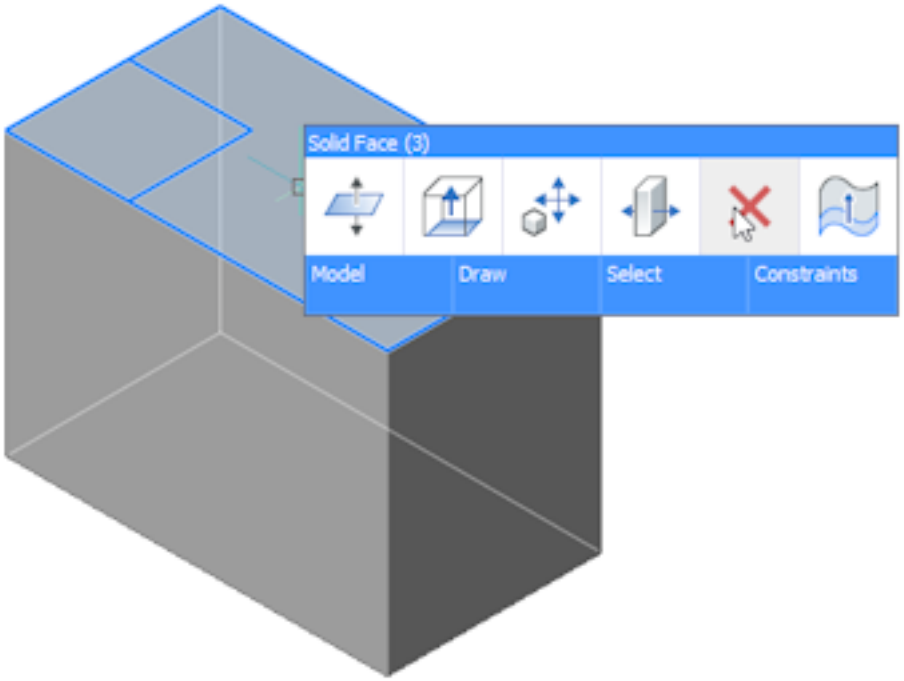


Figure 1.782

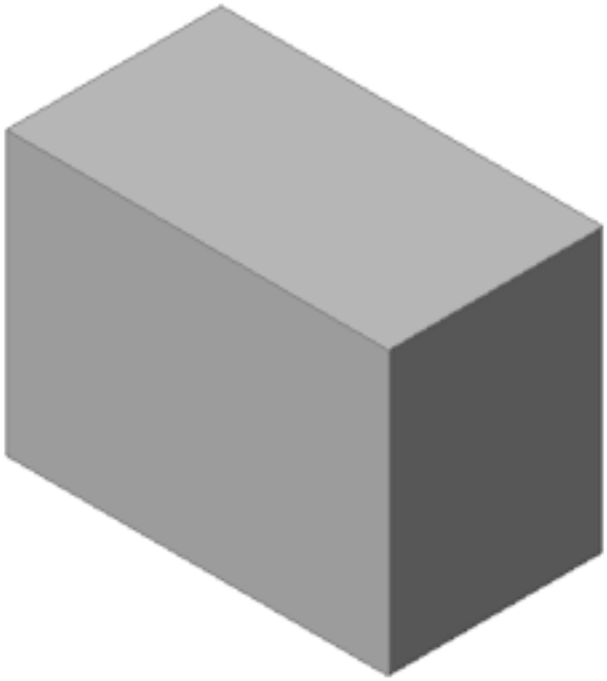

Copying a Feature

The dmCopyFaces (6.12.12) command allows you to copy one or more features from a 3D solid (depressions - holes, grooves, and pockets - or protrusions - extrusions and ribs), to a new location on the same or a different 3D solid.

To copy a feature:

1. Select all faces of the entire feature(s) (see Select Geometry (1.26.2)).
2. Make sure dynamic UCS (1.21.21) is enabled. **Note** Bricsys recommends that you always enable DUCS with the Direct Modeling toolset.
3. Click the **Copy Faces** (===ERROR WITH DOWNLOADED IMAGE===) tool button:
   - on the ribbon: **Solid | Edit | Copy Faces**.
   - on the **Direct Modeling** toolbar.
   - in the menu bar: **Model | Direct Modeling | Copy Faces You are prompted:** Enter base point:
4. Specify the base point. **You are prompted:** Select an insertion point or [Rotate/mUltiple/MOde]:
5. (Optional):
   - Use the **Rotate** option to rotate the faces around the Z axis of the UCS.
   - Use the **Multiple** option to insert the multiple copies of a feature.
6. Specify the insertion point. The feature is copied from the base point to the insertion point with dynamic UCS.

(1.785 on page 910) Select the faces of the entire feature	(1.786 on page 910) Specify base point
(1.787 on page 910) Specify the insertion point	(1.788 on page 911) The feature is copied

Deformable modeling

===ERROR WITH DOWNLOADED IMAGE=== Use the tools on the **Deform** toolbar, to deform a set of adjacent faces on a 3D solid or a surface, to create complex aesthetic shapes. The faces are always deformed if:

- The external boundary (edges, which are adjacent to only one of the selected faces) remain unchanged.
- The internal boundaries (edges, which are adjacent to two of the selected faces) is deformed together with the faces.
- The initial continuity between deformed faces (G1 – tangent faces, or G2 – curvature continuity) is kept when deformed.

For a twist deformation, it is possible to specify the continuity between the deformed and the fixed portion of the entities. Deformation can be defined in several ways:

- Twist the whole entity or a portion.
- Move a point on a face in any direction in 3D space.
- Move or rotate one or more edges.
- Replace an edge with a given 3D curve.

1.26.3 Design intent recognition

Direct modeling operations allow to change geometry of 3D solid models easily: when a single face of a solid is modified with a particular operation other faces are modified accordingly in order to keep design intent of the model and its topological and geometrical validity. For example, consider a model with a number of holes of the same radius. When the radius of a cylindrical face is modified with a push/pull operation or by changing the value of a radial constraint other faces that share the same diameter are recognized by BricsCAD and modified automatically to keep the radii synchronized. (1.789) Apart from the recognition of equal radii, BricsCAD automatically recognizes other geometrical relations between surfaces of a solid and preserves them during direct modeling operations. To define the design intent recognition, click the buttons on the **Design Intent** toolbar. A pressed button indicates the feature is selected. An unpressed button indicates the feature is not active. (1.790)

- tangent surfaces (planes, cylinders and cones) ( )
- coincident planes ( )
- parallel planes ( )
- perpendicular planes ( )
- cylinders perpendicular to planes ( )
- coaxial surfaces (cylinders and cones) ( )
- surfaces of equal radius (cylinders and spheres) ( )
- vertices between 4 or more faces ( )
- edges between coincident faces ( )
- switch off/on all ( )

The design intent options can also be set by editing the DMRECOGNIZE system variable in the Settings dialog (1.17.10). Click the **Options** tool button ( ) on the **3D Constraints** toolbar to set the **Automatic 3D geometry constraints recognition**. The state of tool buttons on the **Design Intent** toolbar (pressed or unpressed) is adjusted accordingly. (1.791 on the facing page)

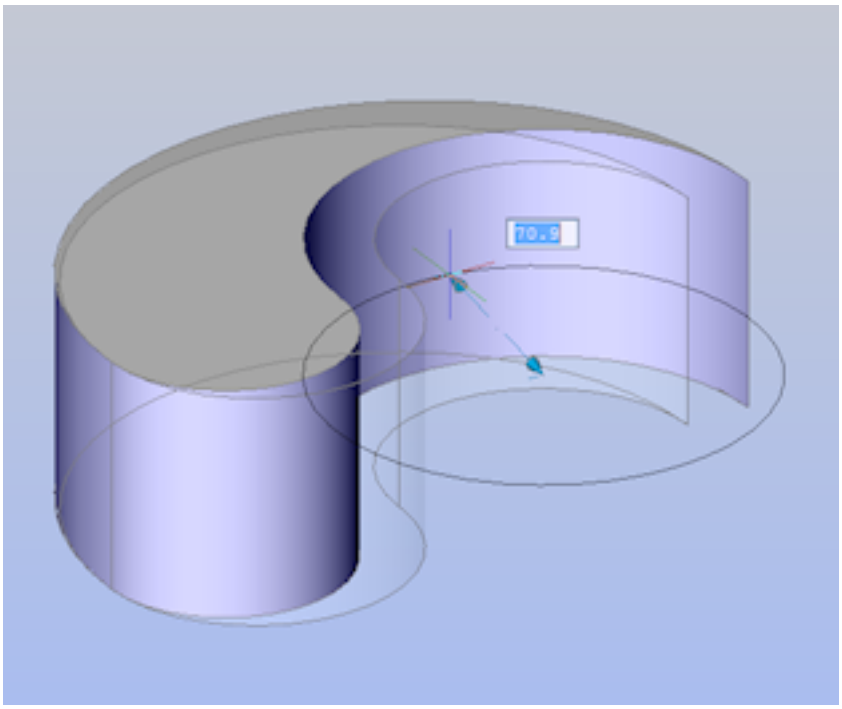
Figure 1.792



NOTE 3D Constraints (1.27.3) which are explicitly defined by the user are taken into account when solid model is being modified with direct modeling commands. These constraints have a higher priority than automatically recognized ones and allow the user to better control the behavior of solid model modifications.

The following examples show the difference in the behavior whether automatic 3D geometry constraints are recognized or not. (1.792) (1.793 on the following page) tangent surfaces recognized ( ) tangent surfaces not recognized ( ) (1.794 on the next page) (1.795 on page 915) coincident planes recognized ( ) coincident planes not recognized ( ) (1.796 on page 915) (1.797 on page 916) parallel planes recognized ( ) parallel planes not recognized ( ) (1.798 on page 916) (1.799 on page 916) perpendicular planes recognized ( ) perpendicular planes not recognized ( ) (1.800 on page 917) (1.801 on page 917) perpendicular cylinders recognized ( ) perpendicular cylinders not recognized ( ) (1.802 on page 918) (1.803 on page 918) coaxial surfaces recognized ( ) coaxial surfaces not recognized ( ) (1.804 on page 919) (1.805 on page 919) equal radius recognized ( ) equal radius not recognized ( )

1.26.4 Working with sections

Commands: SECTION (6.27.11), SECTIONPLANE (6.27.18), LIVESECTION (6.20.43), SECTIONPLANESETTINGS (6.27.12), SECTIONPLANETOBLOCK (6.27.13). The **Section** command creates section planes of 3D solids; the results are region entities. The **SectionPlane** command creates a section entity that creates sections of 3D solids, surfaces, and meshes. The **LiveSection** command toggles the **Live Section** property of a section plane. The **SectionPlaneSettings** command defines the properties of a section plane entity in the Drawing Explorer (1.19.2) - **Section Planes** dialog. The **SectionPlaneToBlock** command saves the selected section plane to a 2D cross section / elevation block or a 3D cutaway section block.

NOTE	The BimSection (6.7.54) command creates **BIM section** entities, which are SectionPlane entities with extended properties, such as type (plan, section, elevation)and scale.

To launch the Sectionplane command

Do one of the following:

- Click the **Section Plane** tool button () on the **Sections** toolbar.
- Choose **Sections > Section Plane** in the **Model** menu.
- Type **sectionplane** in the command bar.

You are prompted: Specify start point or [select Face/Draw/Orthographic]:

Align a section plane to a face

1. Launch SectionPlane (6.27.18) command.
2. Choose **Select Face** in the prompt menu or type **F** in the command bar. **You are prompted:** Select entity:
3. Select the face of a solid you want to align the section plane to.

(1.814 on page 933)	(1.815 on page 933)	(1.816 on page 934)
Solid	Select face	Section plane aligned to face

   The section plane is aligned to the selected face. The **Clip Display** property of the section entity is switched on automatically.
4. (option) Edit the properties of the section plane.

To create a vertical section plane

1. Make sure the WCS is the current coordinate system.
2. Launch SectionPlane (6.27.18) command.
3. Specify two points. The section plane is created through these points and perpendicular to the XY-plane of the current coordinate system. The part of the solid at the right hand side of the section plane is cut away. The **Clip Display** property of the section entity is switched on automatically.

(1.817 on page 934)	(1.818 on page 934)
Specify two points	Vertical section plane

4. (option) Edit the properties of the section plane.

To create a horizontal section plane

1. Choose **Front** in the **Look From** widget.
2. Align the UCS (1.21.21) to the front view: Type **ucs** at the command prompt, choose the **View** option in the prompt menu or type **V** in the command bar. If UCSORTH0 (1.17.10) = ON, the UCS (1.21.21) is aligned with the view automatically.
3. Launch SectionPlane (6.27.18) command.
4. Specify two points. The section plane is created through these points and perpendicular to the XY-plane of the current coordinate system. The part of the solid at the right hand side of the section plane is cut away. The **Clip Display** property of the section entity is switched on automatically.

(1.819 on page 935) Specify two points	(1.820 on page 935) The part of the solid at the right hand side of the section plane is cut away.	(1.821 on page 935) Horizontal section plane

5. (option) Edit the properties of the section plane.

To create a vertical jogged section plane

1. Make sure the WCS is the current coordinate system.
2. Launch SectionPlane (6.27.18) command.
3. Choose **Draw** in the prompt menu or type **D** in the command bar. **You are prompted:** Specify start point:
4. Specify the first point (1). **You are prompted:** Specify next point:
5. Specify the second point (2): **You are prompted:** Specify next point or ENTER to finish:
6. Specify the other points (3 - 6), the right click or press Enter to stop. **You are prompted:** Specify the direction of the section entity:
7. Click a point (7) to specify the direction of the section entity. The part of the solid opposite to the direction of the section entity is cut away. The **Clip Display** property of the section entity is switched on automatically.

(1.822 on page 936) Specify points	(1.823 on page 936) The part of the solid opposite to the direction of the section entity is cut away.	(1.824 on page 936) Vertical jogged section plane

8. (option) Edit the properties of the section plane.

To create a horizontal jogged section plane

1. Choose **Front** in the **Look From** toolbar.
2. Align the UCS (1.21.21) to the front view: Type **ucs** at the command prompt, choose the **View** option in the prompt menu or type **V** in the command bar. If UCSORTH0 (1.17.10) = ON, the UCS (1.21.21) is aligned with the view automatically.

3. Launch SectionPlane (6.27.18) command.
4. Choose **Draw** in the prompt menu or type **D** in the command bar. **You are prompted:** Specify start point:
5. Specify the first point (1). **You are prompted:** Specify next point:
6. Specify the second point (2). **You are prompted:** Specify next point or ENTER to finish:
7. Specify the other points (3 - 6) , the right click or press Enter to stop. **You are prompted:** Specify the direction of the section entity:
8. Click a point (7) to specify the direction of the section entity. The part of the solid opposite to the direction of the section entity is cut away. The **Clip Display** property of the section entity is switched on automatically. The section plane gets the **Boundary** state.

(1.825 on page 937) Specify points	(1.826 on page 937) The part of the solid opposite to the direction of the section entity is cut away.	(1.827 on page 937) Horizontal jogged section plane

9. (option) Edit the properties of the section plane.

To create an orthographic section plane

1. Make sure the WCS is the current coordinate system.
2. Launch SectionPlane (6.27.18) command.
3. Choose **Orthographic** in the prompt menu or type **O** in the command bar. **You are prompted:** Align section to [Front/bAck/Top/Bottom/Left/Right] <Top>:
4. Pick the orthographic section orientation of your choice in the prompt menu or type the corresponding option in the command bar. Orthographic section planes are created through the center of the solid, parallel to the XY-plane (Top and Bottom), YZ-plane (Left and Right) or XZ-plane (Front and Back) of the current coordinate system. The **Clip Display** property of the section entity is switched on automatically.

(1.828 on page 938) Top	(1.829 on page 938) Front	(1.830 on page 938) Right

5. (option) Edit the properties of the section plane.

To open the Drawing Explorer - Section Planes dialog

Do one of the following:

- Choose **Drawing Explorer > Section Planes** in the **Tools** menu.
- Choose **Sections > Section Plane Settings...** in the **Model** menu.
- Type **sectionplanesettings** in the command bar, then press Enter.

Editing the properties of a section plane

Double click the section entity in the model to toggle its **Clip Display** property.

To edit the properties of a section plane in the Drawing Explorer

1. Open the Drawing Explorer (1.19.2) - **Section Planes** dialog. (1.806 on the facing page)
2. (option) Click the **Section Plane Name** field, then click again to type a new name.
3. (option) Click the **Live Section** check box of a section plane to toggle the **Live Section** property of the section plane.
4. If necessary, click the **Regen** tool button ( ) in the **Details** toolbar to update the display.

Figure 1.806

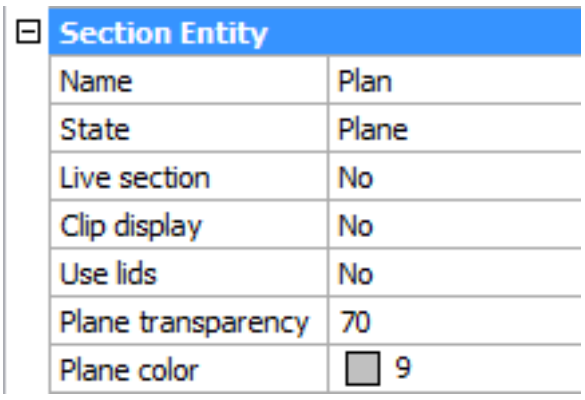
5. (option) Click the **State** field of a section plane to choose a different state for the section plane.
6. (option) click the **Plane Transparency** field of a section plane to change the transparency of the section plane entity in the drawing. 0 = Opaque, 100 = Transparent (invisible).
7. (option) Click the **Plane Color** field, then choose a new color in the Select Color (1.25.5) dialog.

To edit the properties of a section plane in the properties bar: Select the section entity in the drawing. (1.807)

- **Name**: allows to rename the section entity.
- **State**: click, then select **Plane**, **Boundary** or **Volume**.
- **Live Section**: click, then select **Yes** or **No**.
- **Clip display**: click, then select **Yes** or **No**.
- **Use lids**: click, then select **Yes** or **No**.
- **Plane transparency**: allows to define the transparency of the section plane.
- **Plane color**: allows to define the color of the section plane.

Figure 1.807



Difference between Live Section and Clip Display

In both statuses all drawing content is sectioned and clipped-away parts are no longer displayed. **Live** status: entities in a drawing are temporarily modified, e.g. clipped solids are replaced by temporary solids with a different shape. **Clip Display** status: the display of entities is clipped. As in the AutoCAD **3DCLIP** command, entities are not replaced by temporary versions. Different from the **Live** status, the **Clip Display** status allows to continue using all modeling and editing operations on all drawing content. While the **3DCLIP** command allows to clip the display by a **Front** and a **Back** plane, it is not very useful because these planes must be reset whenever the view direction changes. Using a Section entity to control which part of a model is displayed, makes it easy to store and repeat display states. Besides the **Plane** state, which typically clips a model in two halves, also the **Boundary** and **Volume** state of section entity can be used. As opposed to the **Live** status, the Clip Display status can be set for multiple section entities simultaneously. Clipped solids can optionally be closed by setting the **Use Lids** option. Although it has been made possible to snap to the geometry of these lids, they are not actually added to the drawing. If enabled, the hatch pattern defined in the **2dSection Intersection Fill** settings of the section entity displays on top of the lids. To set the **Live Section** property of a section plane:

- Use the **LiveSection** command.
- Set the **Live Section** field in the Properties bar
- Use the **Drawing Explorer - Section Planes** dialog. (1.808 on the following page)

(1.831 on page 939) Cut-away Geometry ON	(1.832 on page 939) Cut-away Geometry OFF

To modify the size and position of a section plane

1. Select the section plane entity in the drawing. Depending on the current state of the section plane entity a number of grips display.
2. (option) Switch on the **Clip Display** property of the section plane to see the result of the modifications dynamically.
3. (option) To grip edit a **Plane** state section plane entity: (1.809 on the next page) Four grips display.
   - 1 () = origin point: moves the position of the section plane in the XY-plane.
   - 2 () = through point: redefines the through point of the section plane. The section plane is rotated around the origin point (1).
   - 3 () = midpoint: moves the section plane parallel in a direction perpendicular to the section plane.
   - 4 (): click to flip the view direction of the section plane.
4. (option) To grip edit a **Boundary** state section plane entity: (1.810 on page 929) Ten grips display.
   - 1 () = origin point: moves the position of the section plane in the XY-plane.
   - 2 () = through point: redefines the through point of the section plane. The section plane boundary is stretched and rotated around the origin point (1).
   - 3 (): stretches the section plane boundary parallel.
   - 4 (): modifies the shape of the section plane boundary.
   - 5 (): click to flip the view direction of the section plane.
5. (option) To grip edit a **Volume** state section plane entity: (1.811 on page 929) Twelve grips display.
   - 1 () = origin point: moves the position of the section plane in the XY-plane.
   - 2 () = through point: redefines the through point of the section plane. The section plane volume is stretched and rotated around the origin point (1).
   - 3 () :stretches the section plane volume parallel.
   - 4 (): modifies the shape of the section plane volume.
   - 5 (): modifies the height of the section plane volume.
   - Polar Tracking (1.21.18) must be on to move grips 5. (1.812 on page 930)
   - 6 (): click to flip the view direction of the section plane.

To save a section

SectionPlaneToBlock (6.27.13) command allows you to:

- Insert a section in the drawing as a 2D (1.26.4) section / elevation block or a 3D cutaway (1.26.4) block.
- Replace a section block (1.26.4) (e.g. when the section entity has been modified).
- Save (1.26.4) a section to a new drawing.

To launch SectionPlaneToBlock command

Do one of the following:

- Click the **Section Plane to Block** tool button ( ) on the **Sections** toolbar.
- Choose **Section Plane to Block** in the **Model > Sections** menu.
- Type **sectionplanetoblock** in the command bar, then press Enter

The **Create Section/Elevation** dialog box displays: (1.813 on the next page)

To insert a section as a 2D block

1. (option) Adjust the 2D Section / Elevation (6.27.12) settings of the section plane entity.
2. Launch SectionPlaneToBlock (6.27.13) command.
3. Set the **Destination** to **Insert new block**.
4. Under **Source Geometry**, do one of the following:
   - Choose **Include all entities** to include all 3D solids in the drawing.
   - Choose **Select entities**, then click the **Select** button ( ) to select 3D solids.
5. Under **Section plane**, click the **Select** button ( ), then select a section plane entity in the drawing.
6. Set the **Section type** to **2D cross section/elevation**.
7. Adjust the **Insert** options (see Insert a block (1.30.5)).
8. Click the **OK** button. The **Create Section/Elevation** dialog closes. The block is attached to the cursor. Follow the instructions in the command bar to place the block in the drawing.

To insert a section as a 3D block

1. (option) Adjust the 3D cutaway section (6.27.12) settings of the section plane entity.
2. Launch SectionPlaneToBlock (6.27.13) command.
3. Set the **Destination** to **Insert new block**.
4. Under **Source Geometry**, do one of the following:
   - Choose **Include all entities** to include all 3D solids in the drawing.
   - Choose **Select entities**, then click the **Select** button ( ) to select 3D solids.
5. Under **Section plane**, click the **Select** button ( ), then select a section plane entity in the drawing.
6. Set the **Section type** to **3D cutaway section**.
7. Adjust the **Insert** options (see Insert a block (1.30.5)).
8. Click the **OK** button. The **Create Section/Elevation** dialog closes. The block is attached to the cursor. Follow the instructions in the command bar to place the block in the drawing.

To replace an existing block

1. Launch SectionPlaneToBlock (6.27.13) command.
2. Set the **Destination** to **Replace existing block**.
3. Click the **Select** button ( ), then select the block to be replaced in the drawing.
4. Under **Source Geometry**, do one of the following:
   - Choose **Include all entities** to include all 3D solids in the drawing.
   - Choose **Select entities**, then click the **Select** button ( ) to select 3D solids.
5. Under **Section plane**, click the **Select** button ( ), then select a section plane entity in the drawing.
6. Under **Section type**, do one of the following:
   - Choose **2D cross section/elevation** , to replace the block by a 2D section / elevation block.
   - Choose **3D cutaway section,** to replace the block by a 3D cutaway section block.
7. Click the **OK** button. The selected block is replaced.

Figure 1.814

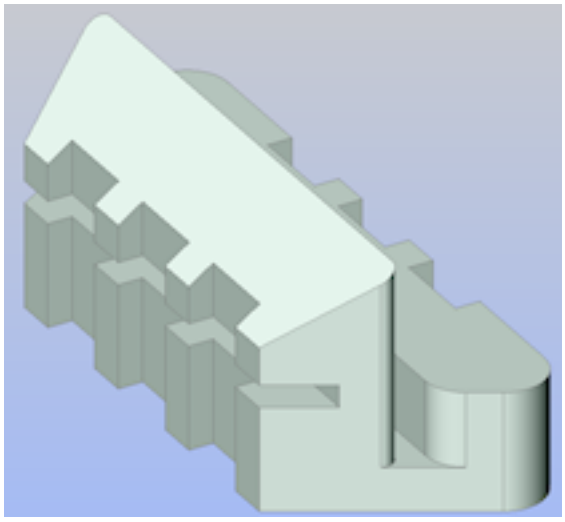

Figure 1.815

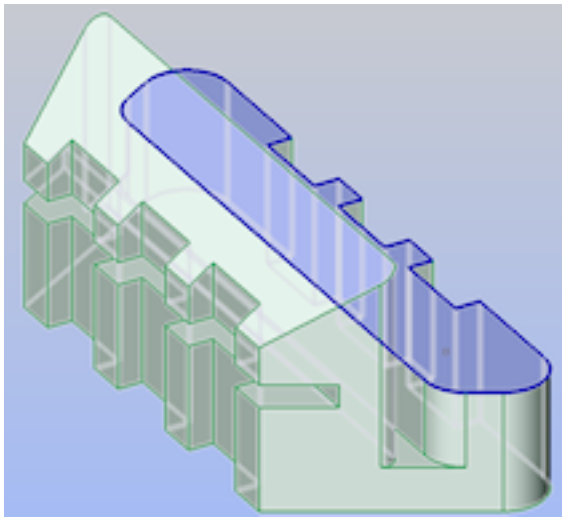

To export a section to a file

1. Launch SectionPlaneToBlock (6.27.13) command.
2. Set the **Destination** to **Export to file**.
3. Click the **Browse** button (...), then do the following in the **Select export file** dialog box:
   - Select a folder.
   - Type a name in the **File name** field.
   - Click the **Save** button.
4. Under **Source Geometry**, do one of the following:
   - Choose **Include all entities** to include all 3D solids in the drawing.
   - Choose **Select entities**, then click the **Select** button ( ) to select 3D solids.
5. Under **Section plane**, click the **Select** button ( ), then select a section plane entity in the drawing.
6. Under **Section type**, do one of the following:
   - Choose **2D cross section/elevation** , to replace the block by a 2D section / elevation block.
   - Choose **3D cutaway section** . to replace the block by a 3D cutaway section block.
7. Click the **OK** button. A section is saved to a drawing.

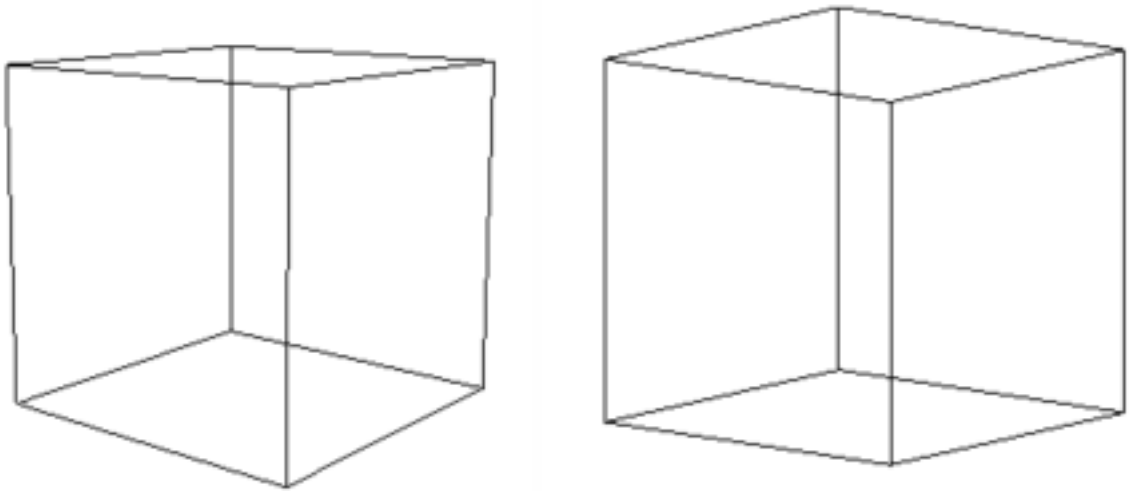
1.26.5 Navigate in 3D

As you navigate around and through your 3D model, the location of the model in space remain constant. It's your current view (viewpoint), of the model that's changing. You can see the current view properties in the Properties panel when no objects are selected. The Camera (X,Y,Z) represents your location as you view the model. Pretend you're viewing it through a camera lens. The Target (X,Y,Z) is where the camera lens is pointed. As you navigate around the model, the Camera and Target coordinates update accordingly. Those coordinates are read-only in the Properties Panel. There are other View properties that you can edit. Perspective is the most important controls to be aware of for navigation purposes. (1.833) You can set Perspective to On or Off for the current view. When set to On, the view displays in visual perspective mode (left). When set to Off, it displays in parallel perspective mode (right). (1.834 on the next page)

Figure 1.834



Mouse and Keyboard Navigation Options

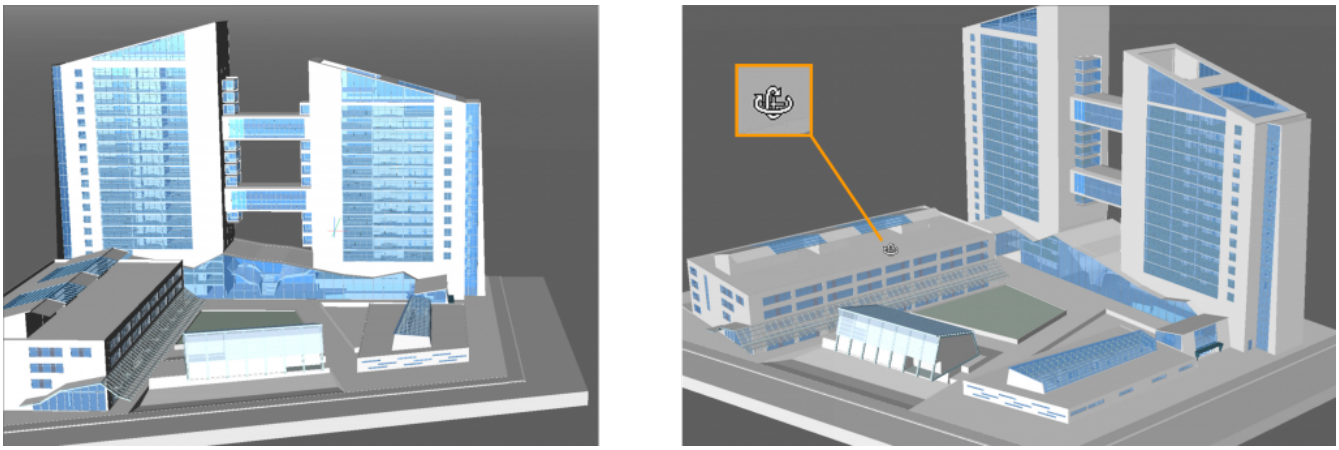
One of the easiest and most common methods for navigating around a 3D model is with the mouse and keyboard. Simply press the Shift key and middle mouse button as you move the mouse to orbit the model. The cursor changes to an orbit icon indicating you're in orbit mode. (1.835) There are many other mouse and keyboard navigation methods that you're probably familiar with from your 2D CAD experience. Most of those methods are also useful for 3D modeling. Below are a few of my favorites.

- Zoom in/out – Roll the mouse wheel. You can zoom all the way into a model and walk around inside it when in perspective mode (1.23.15). In isometric mode you can only zoom in very close, but not go inside.
- Zoom Extents – Double-click on the mouse wheel.
- Pan – Press the mouse wheel or middle mouse button.

Refer to the Help system for a comprehensive list of view manipulation controls using the mouse and keyboard (1.23.6).

Tutorial: How to setup the 3DConnexion 3D mouse in BricsCAD Click here (1.18.35) to watch

Figure 1.835



LookFrom Navigation Tool

The LookFrom tool is displayed in the upper right corner of the Drawing area. It's comparable to the ViewCube in AutoCAD. Click on different places on the LookFrom tool to display the view from standard viewpoints. By default, it includes Top, Left, Right, Front, Back, Top Back Left, Top Back Right, Top Front Left, and Top Front Right. As you pass the cursor over a viewpoint, the relevant icon appears at the center and a tooltip displays below. You can press the Ctrl key to access similar options for Bottom viewpoints. (1.836) A right-click menu offers access to additional controls and settings. To learn more refer to BricsCAD Online Help (1.23.7). (1.837 on the facing page)

1.26.6 Create a TIN Surface

Command: Tin (6.29.14), TinAssignImage (6.29.15), TinProject (6.29.21) **Overview:** In BricsCAD, topographical surfaces are created using the **TIN Surface** (triangulated irregular network) tool.

- Points contain x, y coordinates, and z values. All points are used to make a connection with the two nearest neighbors to create triangles. The surface triangulation is based on the Delaunay algorithm, which ensures that no point is inside the circumcircle of any triangle.
- Breaklines represent linear infrastructure features like curbs, retaining walls, etc. These lines also define the edges of triangles. Break lines can be created from linear entities such as line, polyline, arc, circle.
- Boundaries are the features to define bounded 3D surfaces. The surface boundaries can be created with closed polylines. Defining outer boundaries on a large 3D surface improves the performance of a TIN Surface plan.

Lesson objectives: After completing this lesson, you will be able to:

- Create TIN Surfaces from a selection set of points and polylines.
- Importing points file, such as survey points data obtained from a surveyor. These points can be used to create a topographical surface.
- Creating a topographical surface by placing Points in the drawing area set by elevation.
- Add the linear entities as breaklines or points to the TIN Surface.
- Create a TIN Surface from a point cloud.
- Create toposurface from Civil 3D surface.
- Assign an image to a TIN Surface.
- Project entities to a TIN Surface.

About Tin Surfaces Creating a TIN Surface is a process that needs to be followed to map a particular area in detail. On BIM models, these topographic surfaces are used to represent the site. The topographical surface can be generated based on drawing entities, data imported from a comma-delimited file format (CSV) or text file format (TXT), and points placed at different elevations, created from Civil 3D surface.  For more information about this command, visit the Command Reference article Tin (6.29.14).

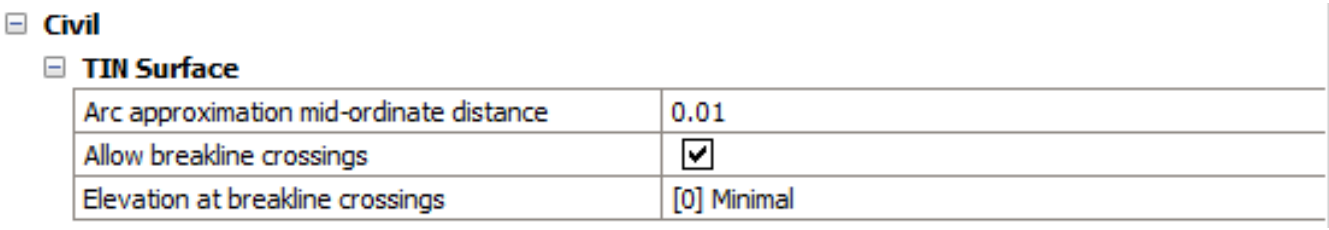
Setting the TIN Surface preferences

1. Open the Settings dialog.
2. Under **Civil** options, expand the **TIN Surface** settings category.

(1.838) (1.931 on page 1025)

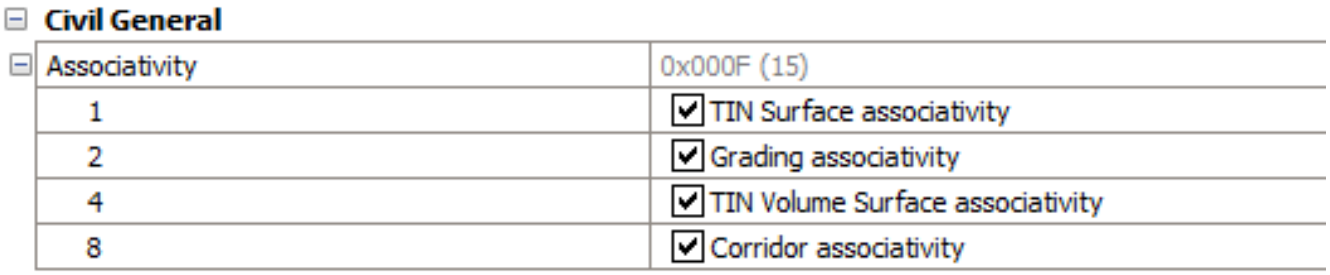
Arc approximation mid-ordinate distance	Mid-ordinate distance is the maximal distance between arc and chord (straight) segment which is used for arc approximation. Defines how many points along the curve you want to add. When you have polylines with curves, this parameter allows you to tessellate the arcs in the polyline. The default value of this parameter is variable in Bricsys predefined templates. For instance, the distance value is set to **0.01** in **BIM-m**, **1** in **BIM-cm**, **10** in **BIM-mm**, and **0.4** in **BIM imperial** templates.

Figure 1.838



Allow breakline crossings	Defines if crossing breaklines are allowed. By default, it is set to "On". If breakline crossings are allowed, intersections between breakline segments are calculated and added as points to the TIN Surface.
Elevation at breakline crossings	Defines how elevation at crossing breaklines should be determined. There are three options (e.g., minimal, maximal, and average) for defining breaklines elevation at the intersection.
Associativity	Enable/disable Grading, Surface and Corridor associativities. By default, the system variable is set to 15. • 0: Neither **Tin Surface**, **Grading nor Corridor** associativity is enabled. • 1:Enables Tin Surface associativity. • 2: Enables **Grading** associativity. • 3: Both **Tin Surface** and **Grading** associativities are enabled. • 4: Enables **TIN Volume Surface** associativity. • 5: Both **Tin Surface** and **TIN Volume Surface** associativities are enabled. • 6: Both **Grading** and **TIN Volume Surface** associativities are enabled. • 7: **Tin Surface**, **Grading** and **TIN Volume Surface** associativities are enabled. • 8: Enables **Corridor** associativity. • 9: Both **Tin Surface** and **Corridor** associativities are enabled. • 10: Both **Grading** and **Corridor** associativities are enabled. • 11: **Tin Surface**, **Grading** and **Corridor** associativities are enabled. • 12: Both **TIN Volume Surface** and **Corridor** associativities are enabled. • 13: **TIN Surface**, **TIN Volume Surface** and **Corridor** associativities are enabled. • 14: **Grading**, **TIN Volume Surface** and **Corridor** associativities are enabled. • 15: All **TIN Surface**, **Grading**, **TIN Volume Surface** and **Corridor** associativities are enabled.

Figure 1.839



Displaying the properties of a TIN Surface

Select the TIN Surface. The properties of the TIN Surface display in the **Properties** panel: (1.840 on page 948)

Data	Add extra data to your TIN Surface: • Name: Name the TIN Surface. • Description: Description of the TIN Surface.
TIN Visibility	Controls the visibility of the following properties: • **Boundary line**: Represents the toposurface boundary lines. • **Points**: Represents the toposurface points. • **Triangles**: Represents how the elevation points are connected to each other. It follows the Delaunay triangulation method where breaklines are not included in densification. • **Contours**: Represents the joining of points of equal elevation within a line. To turn one of the properties on/off, click their field in the Properties bar, then press the arrow button and choose On/Off in the context menu.
TIN Contours	Controls the contour lines settings. • **Major contours interval:** Sets the major contour interval. • **Minor contours interval**: Sets the minor contours interval. • **Major contours color**: Defines the color of the major contour. • **Minor contours color**: Defines the color of the minor contour.

TIN Statistics	Demonstrates the statistical information about the TIN Surface. • **The number of points**: Demonstrates the number of points that define the TIN Surface. • **The number of triangles**: Demonstrates the number of non-overlapping triangles in the TIN Surface. • **Minimum elevation**: Demonstrates the minimum elevation value found in the TIN Surface. • **Maximum elevation**: Demonstrates the maximum elevation value found in the TIN Surface. • **2D area**: Demonstrates the 2D area that is calculated from the flat TIN Surface. • **3D area**: Demonstrates the 3D area that is calculated from the TIN Surface.

Procedure: Creating a TIN Surface from a selection set of Points and Polylines

1. Open the drawing file that contains a set of points and polylines. (1.841 on the following page)
2. Launch the TIN (6.29.14) command. **You are prompted:** Select entities to create TIN surface or [Import from file/place Points/create from Faces/Create from civil3d surface/cLip polygon/selection options (?)]:
3. Select the entities in the drawing area to create a toposurface. **(Optional)** prompt menu can be used to select all entities in the drawing area. (1.842 on page 951) **Note:** The commandline depicts how many entities are included in the set, e.g. Entities in set: 2044.
4. Press Enter. The toposurface is created from selected entities. Points are added to the surface as points, 3D polylines are added to the surface as breaklines. (1.843 on page 951)

Figure 1.841

Figure 1.842

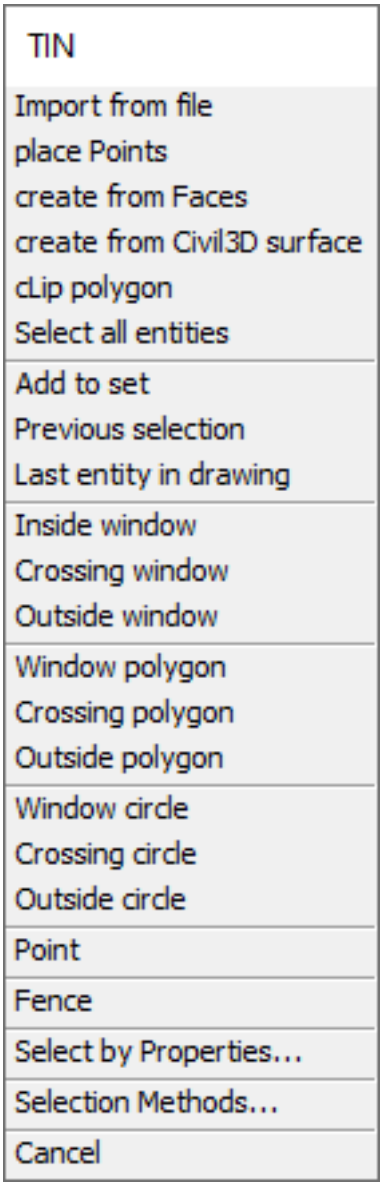

Figure 1.843

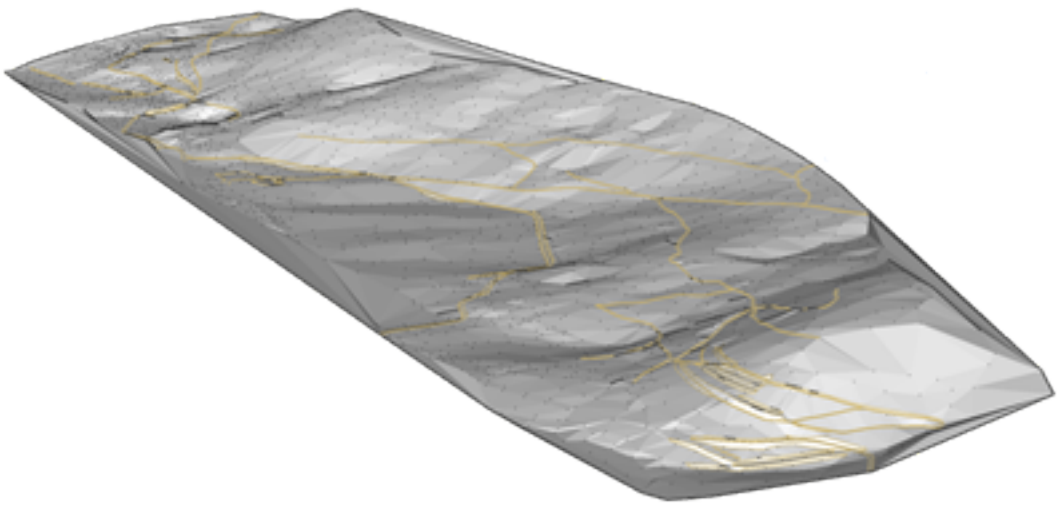
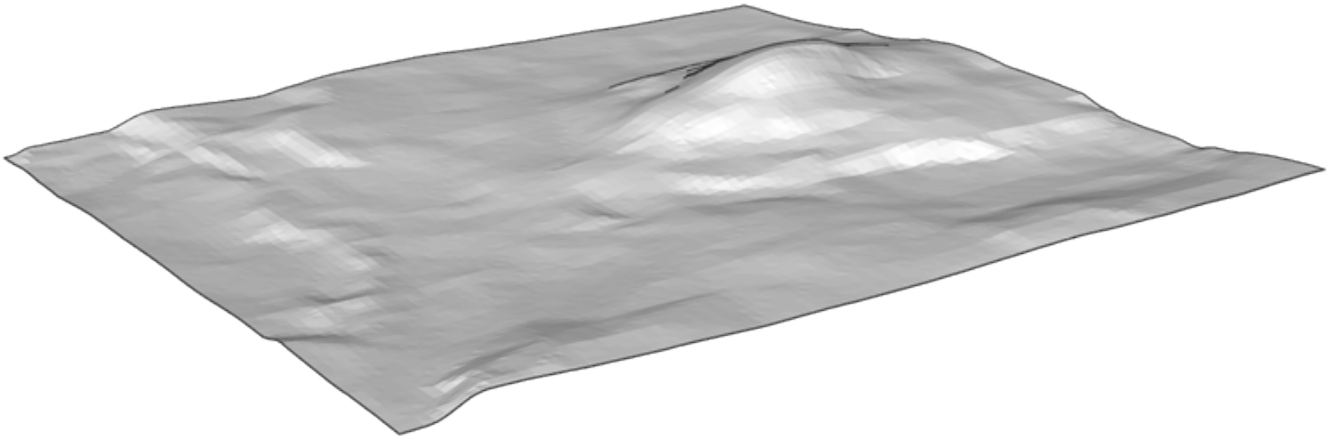


Procedure: Creating a TIN Surface from an imported Points file

1. Launch the TIN (6.29.14) command. **You are prompted:** Select entities to create TIN surface or [Import from file/place Points/create from Faces/Create from civil3d surface/cLip polygon/selection options (?)]:
2. Launch the **TIN** command in the command line. **Or** select Create TIN Surface in the Model tab from the Quad. **You are prompted:** Select entities to create TIN Surface or [Import from file/Place points]
2. Select the **Import from file** option in the prompt menu. **Or** type "I" in the command line.
3. Choose the point data file you want to open (.txt-file). **Or** you can choose multiple files to import all at once.
4. Click Open to import the points. The toposurface is imported from an existing survey points file. (1.844) **Note:** If the toposurface is not shown in the current viewport, use the **Zoom Extents** option to display it to the extents of entities.

Figure 1.844



Procedure: Creating a TIN Surface of a selected area using Clip polygon

1. Open the drawing file that contains closed polyline. (1.845 on the following page)
2. Launch the TIN (6.29.14) command. **You are prompted:** Select entities to create TIN surface or [Import from file/place Points/create from Faces/Create from civil3d surface/cLip polygon/selection options (?)]:
3. Select the **cLip polygon** (X) option in the prompt menu. **Or** type "L" in the command line.
4. **You are prompted:** Select clip polygon:
5. **You are prompted:** Remove crossed breaklines if any [Yes/No]: **(if the surface we are going to make contains breaklines, we define what should happen to the breaklines crossing the clipped polygon. Type "Y" to create TIN Surface without crossed breaklines or "N" to create TIN Surface including crossed breaklines)**
6. **You are prompted:** Select entities to create TIN Surface or [Import from file/Create from Faces/Create from civil 3d surface/]: (1.846 on the next page) Select any of the options (Select entities in the drawing, Import from file, create from faces, create from Civil 3D Surface) and proceed as described in the previous sections. TIN Surface is created only in the area defined by the CLIP polygon. With this functionality, we can significantly improve the performance of the TIN Surface created from large point files.

Figure 1.845

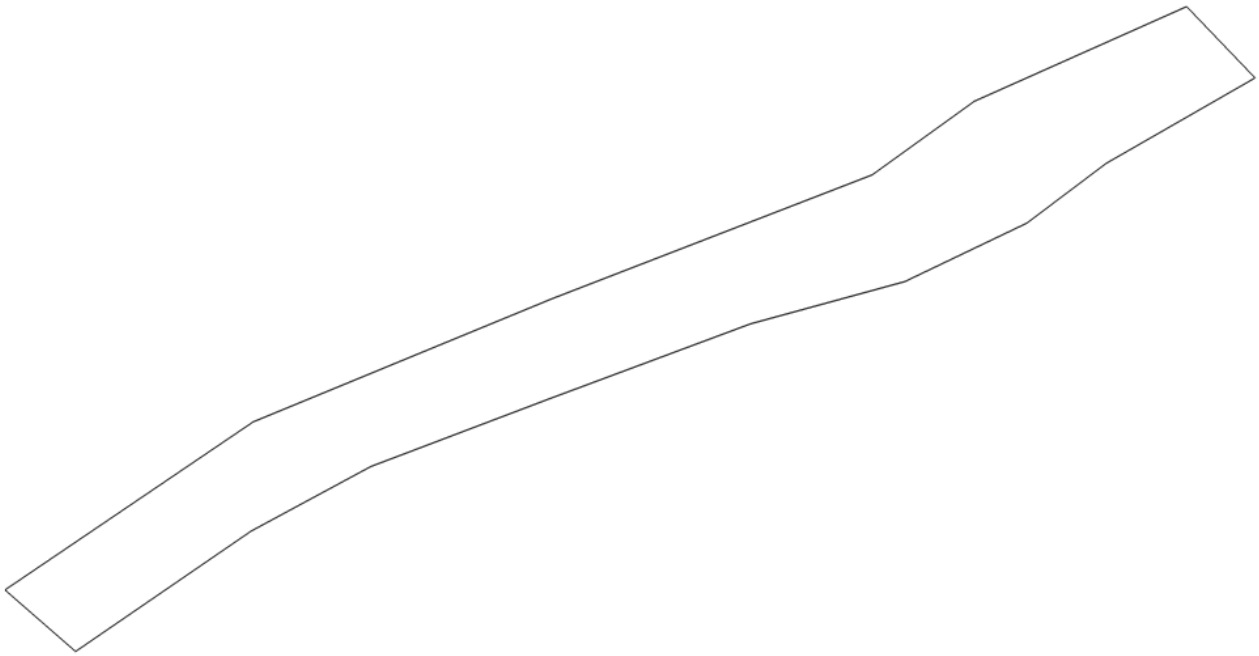


Figure 1.846

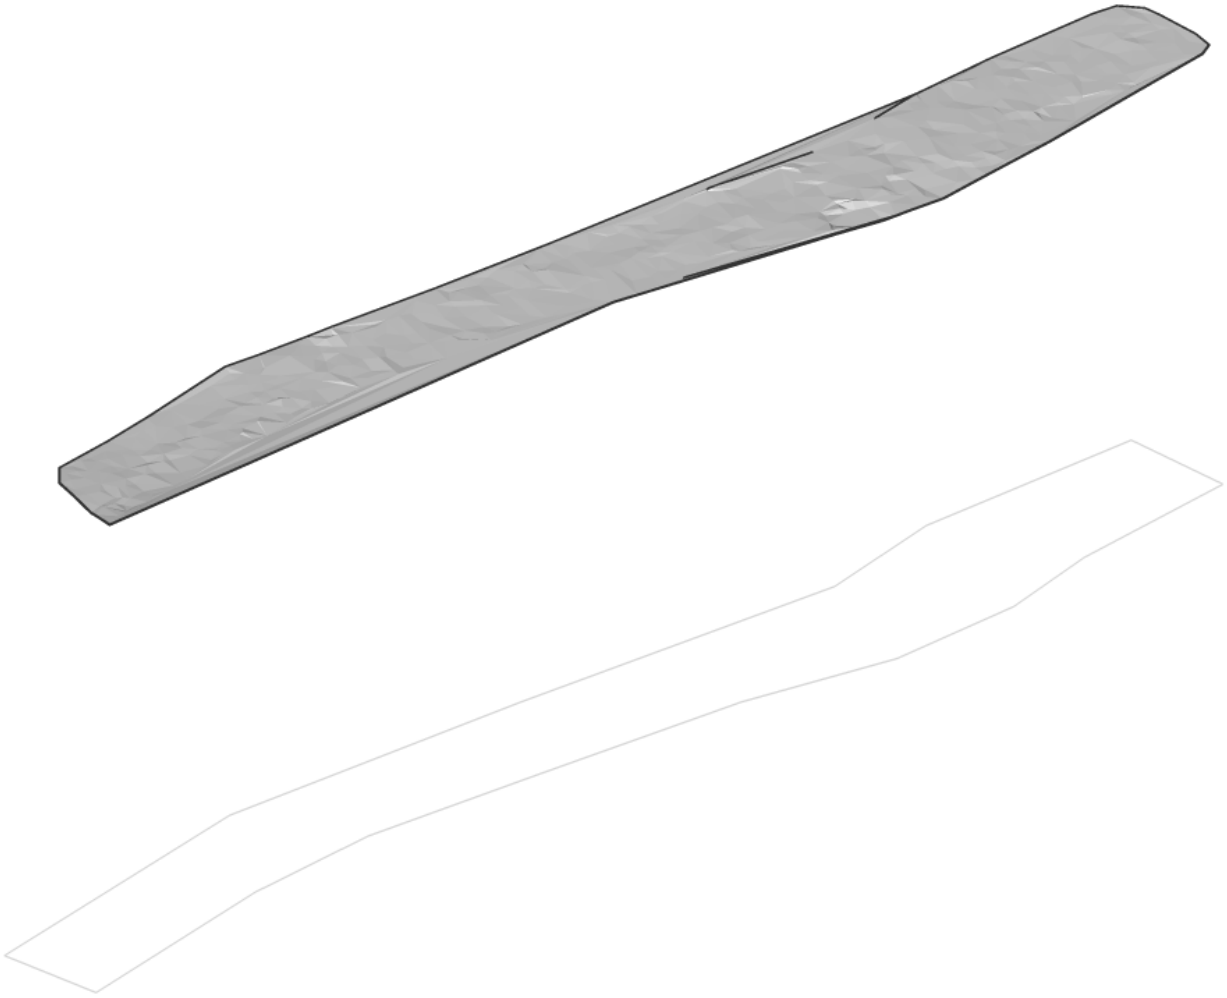

Procedure: Creating a TIN Surface by placing points

1. Open a new drawing. **Note:** The new drawing is created from the default template as defined by the BASEFILE system variable. The default template can be set in the Start tab (1.6.1).
2. Launch the TIN (6.29.14) command. **You are prompted:** Select entities to create TIN surface or [Import from file/place Points/create from Faces/Create from civil3d surface/cLip polygon/selection options (?)]:
3. Select the **Place points** option in the prompt menu. **Or** type "P" in the command line. **You are prompted:** Pick point
4. Pick a point where you want to start creating a TIN Surface. **You are prompted:** Enter elevation <0.000>
5. Specify the elevation value of each those points, and press Enter to accept. **Note:** At least three points are needed to create a TIN Surface.

Procedure: Creating a TIN Surface from Faces

1. Open the drawing file that contains 3D Faces. (1.847 on the following page)
2. Launch the TIN (6.29.14) command. **You are prompted:** Select entities to create TIN surface or [Import from file/place Points/create from Faces/Create from civil3d surface/cLip polygon/selection options (?)]:
3. Select the **Create from Faces** (X) option in the prompt menu. **Or** type "F" in the command line. **You are prompted:** Select 3D Faces: **(Select 3D faces in the drawing)**
4. Press Enter. **You are prompted:** Add 3D Faces as breaklines [Yes/No]: **(type "Y" to add edges of 3D faces as breaklines or "N" to create TIN Surface only with points of 3D Faces)** (1.848 on the next page)

Figure 1.847

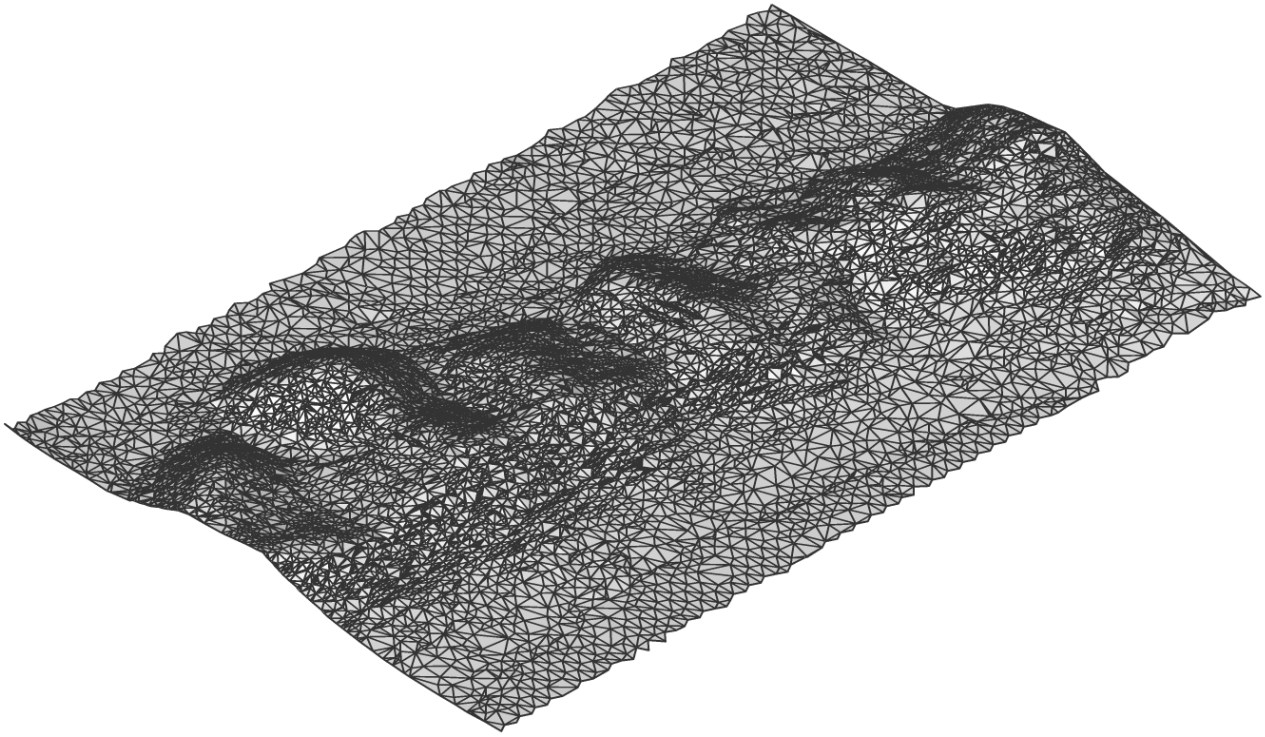

Figure 1.848

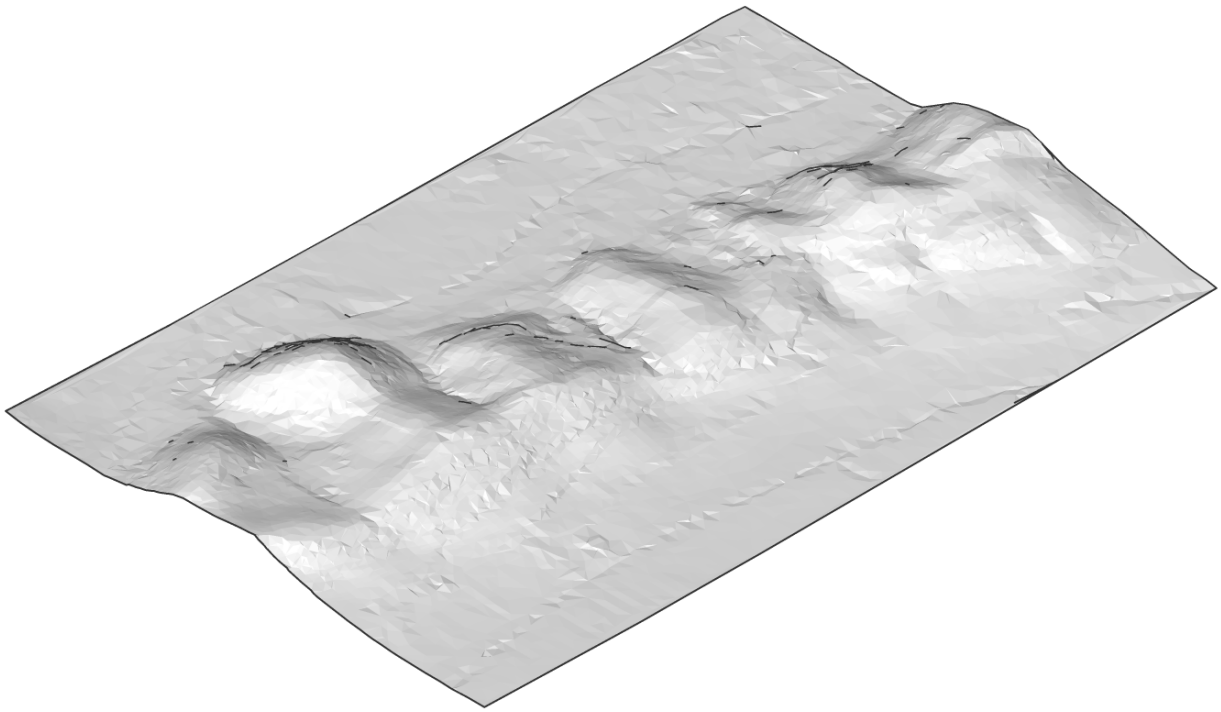

Procedure: Creating a TIN Surface from a Point cloud

1. Open the drawing file that contains a Point cloud. (1.849 on the following page)
2. Launch the TIN (6.29.14) command. **You are prompted:** Select entities to create TIN surface or [Import from file/place Points/create from Faces/Create from civil3d surface/cLip polygon/selection options (?)]:
3. Select the Point cloud in the drawing area to create a toposurface. **(Optional)** prompt menu can be used to select all entities in the drawing area.
4. Press Enter. The toposurface is created from the Point cloud. (1.850 on the next page)

Figure 1.849

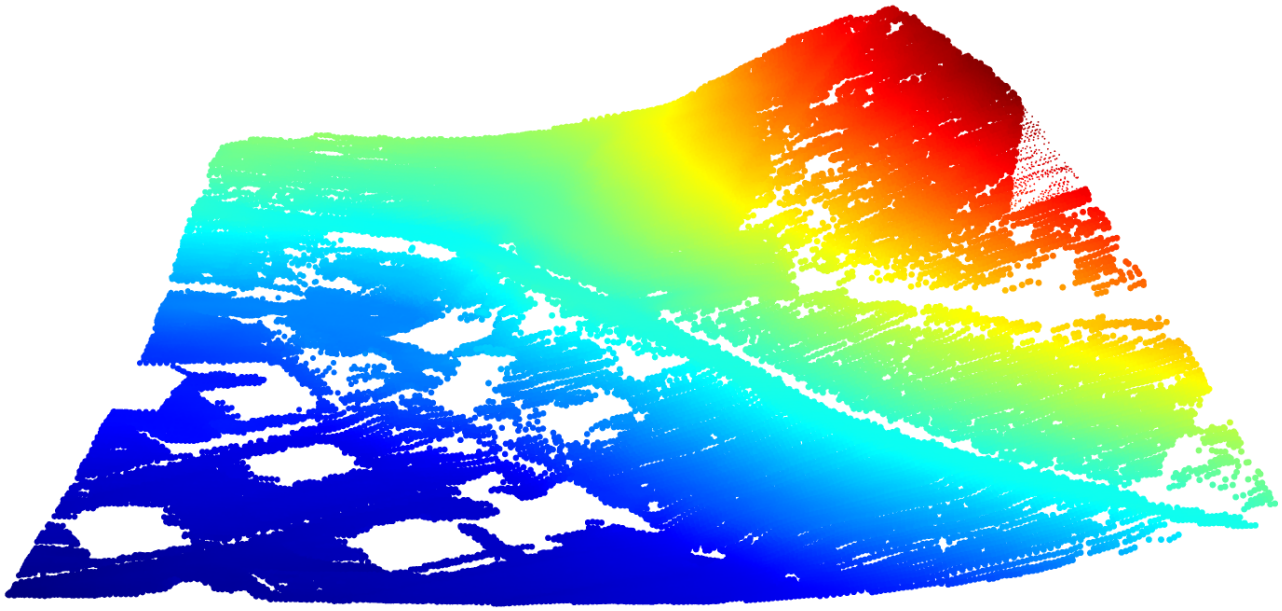

Figure 1.850

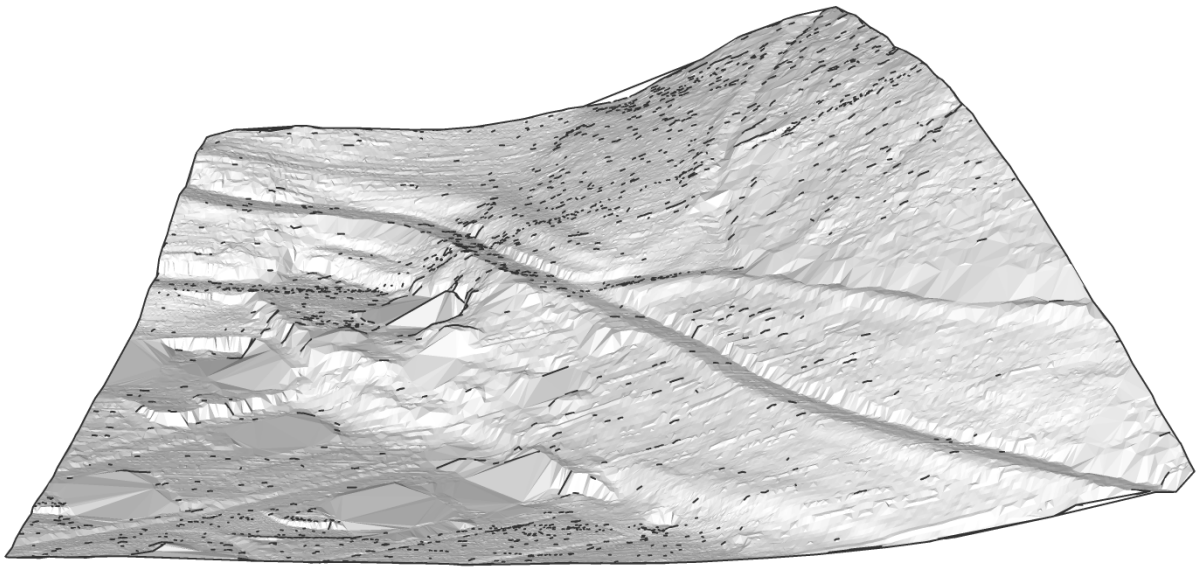
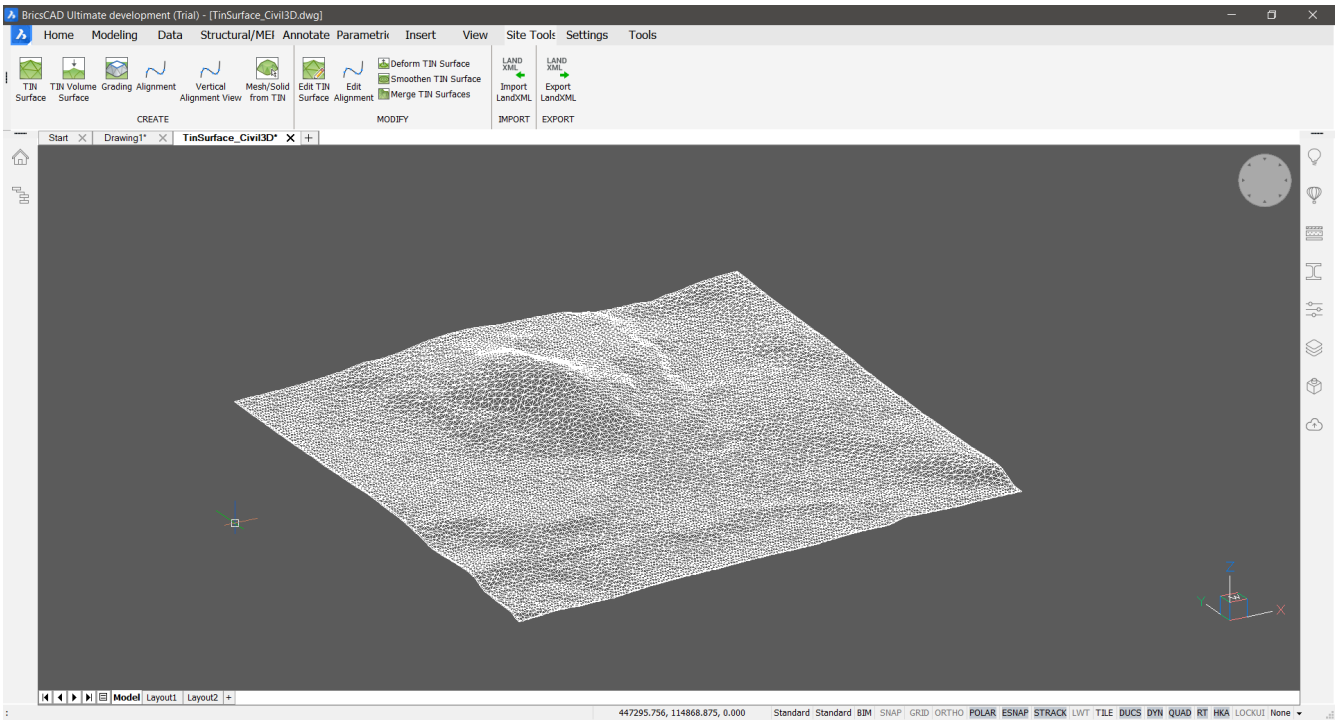


Procedure: Creating a TIN surface from a Civil 3D surface

1. Open a drawing with a Civil 3D surface
2. Launch the TIN (6.29.14) command. **You are prompted:** Select entities to create TIN surface or [Import from file/place Points/create from Faces/Create from civil3d surface/cLip polygon/selection options (?)]:
3. Select **Create from civil 3D surface** Or type in "C" in the commandline. **You are prompted:** Select a Civil 3D surface.
4. Select the Civil 3D surface. A TIN Surface is created. (1.851 on the following page)

Figure 1.851



About Tin Assign Image

The TinAssignImage command drapes a selected raster image onto a TIN Surface. The raster image can be attached to the drawing by using the ImageAttach command. This command also enables to use the position file with geocoding information, which specifies the size, location and rotation of the image file. This way you can make sure that a certain surface gets the image that is correct for its location.  For more information about this command, visit the Command Reference article TinAssignImage (6.29.15).

Assigning an image to TIN surface

1. Open the drawing file that contains a TIN Surface and an image.
2. Launch the TINAssignImage (6.29.15) command. **You are prompted:** Select TIN Surface: **(select TIN Surface) (1.852 on the next page)**

3. **You are prompted:** Select raster image: **(select orthophoto image)** (1.853 on the facing page) **Note:** If the image is not shown on the TIN Surface, change Visual Style to Realistic or BIM and set TIN Surface triangles to **ON**.

Figure 1.852

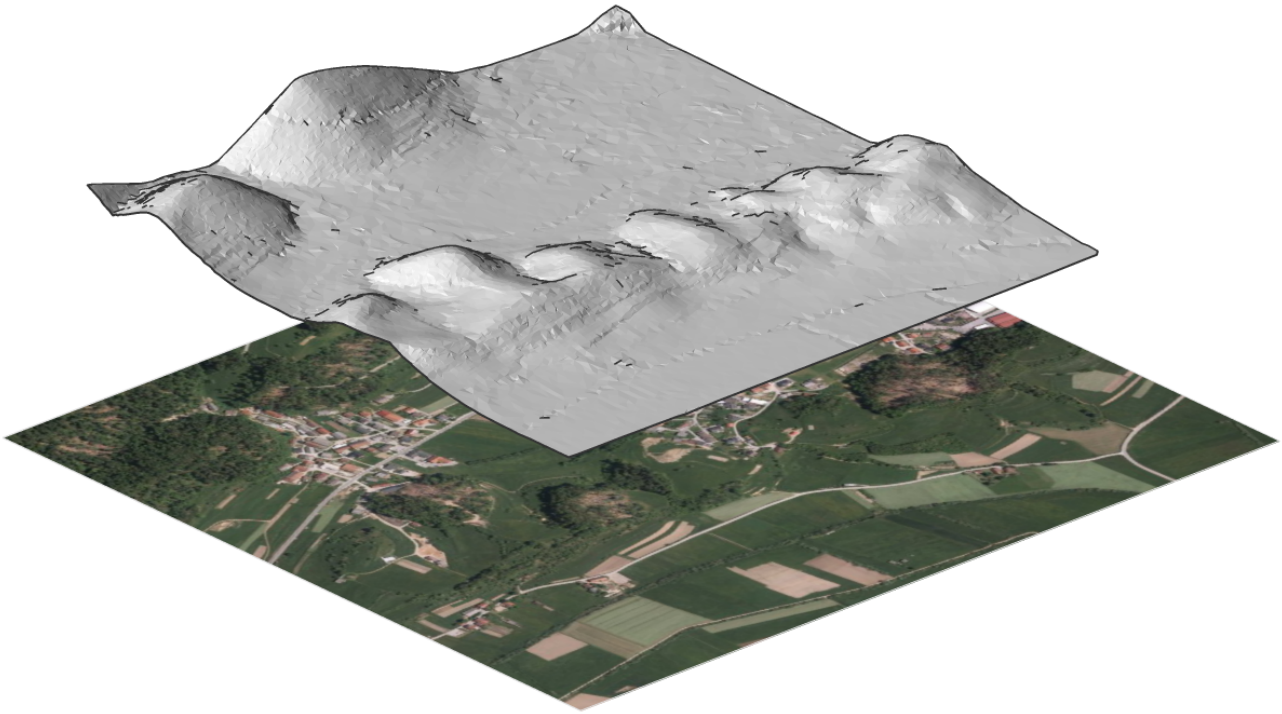


Figure 1.853

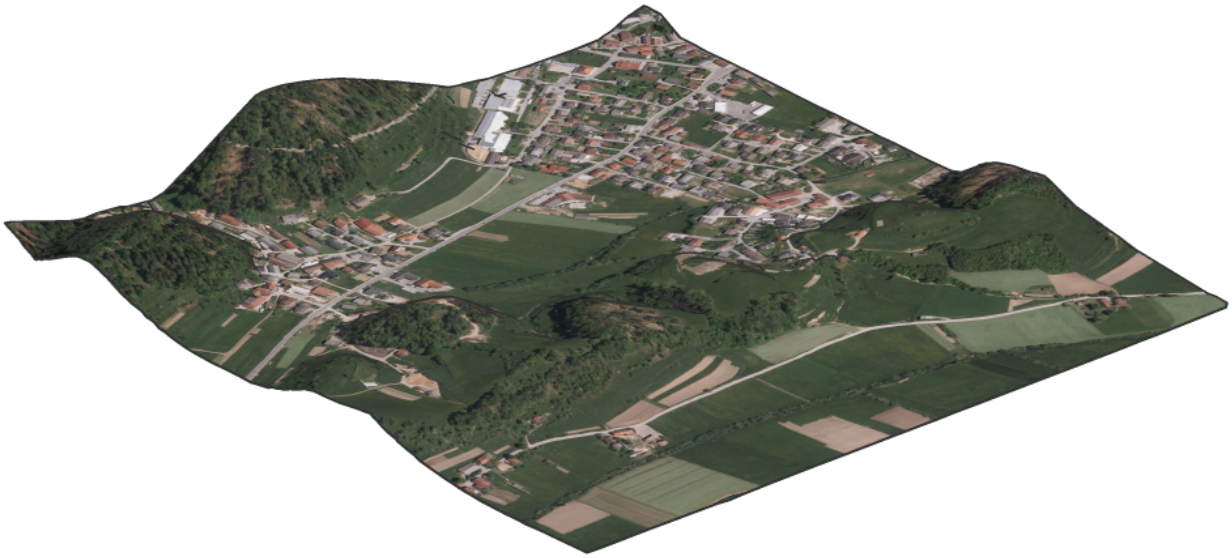

About Tin Project

The TinProject command is used to project point entities (Point, Block, Text) or linear entities (Line, Polyline, Circle) to a TIN Surface.  For more information about this command, visit the Command Reference article TinProject (6.29.21).

Projecting entities to TIN Surface

1. Open the drawing file that contains TIN Surface and entities (Points, Blocks, Text, Lines, Polylines, Circles...). (1.854 on the next page)
2. Launch the TinProject (6.29.21) command. **You are prompted:** Select TIN Surface: **(select TIN Surface)**
3. **You are prompted:** Select entities to project: **(select entities under the TIN Surface)**
4. **You are prompted:** Erase selected entities [Yes/No]: **(type "Y" to erase original entities or "N" to keep the entities in the drawing)** (1.855 on the facing page)

Figure 1.854

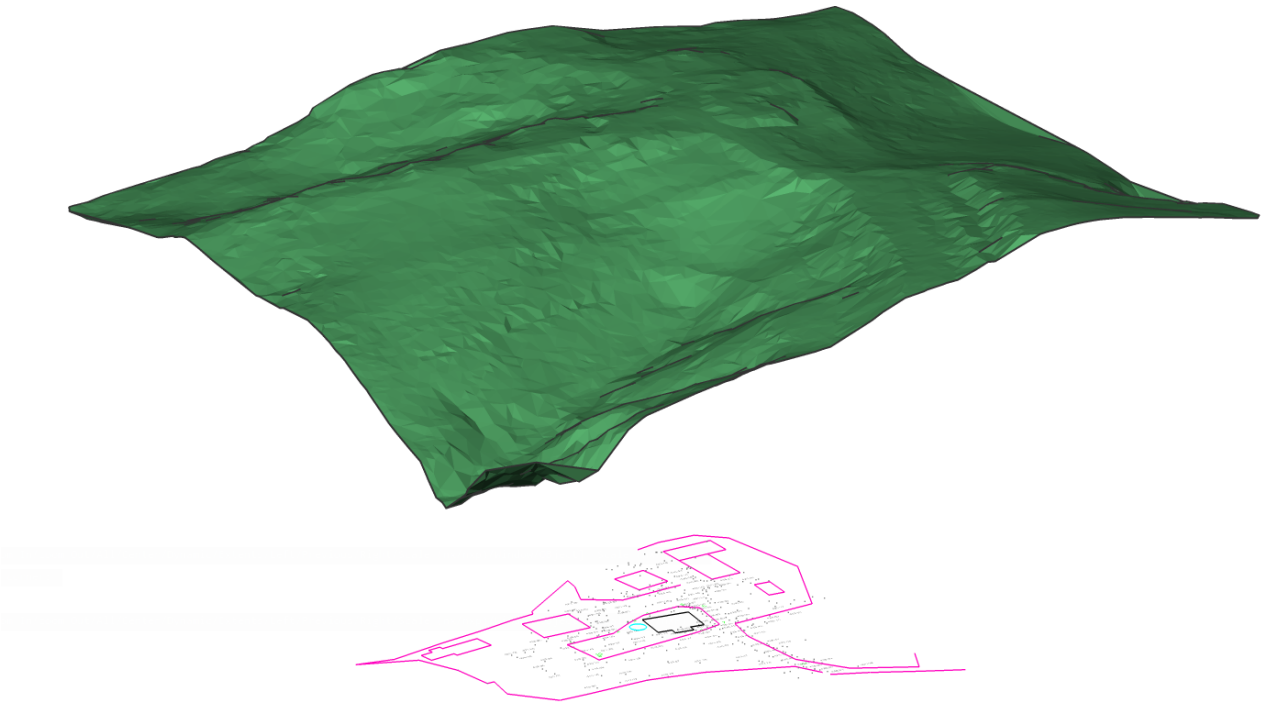

Figure 1.855

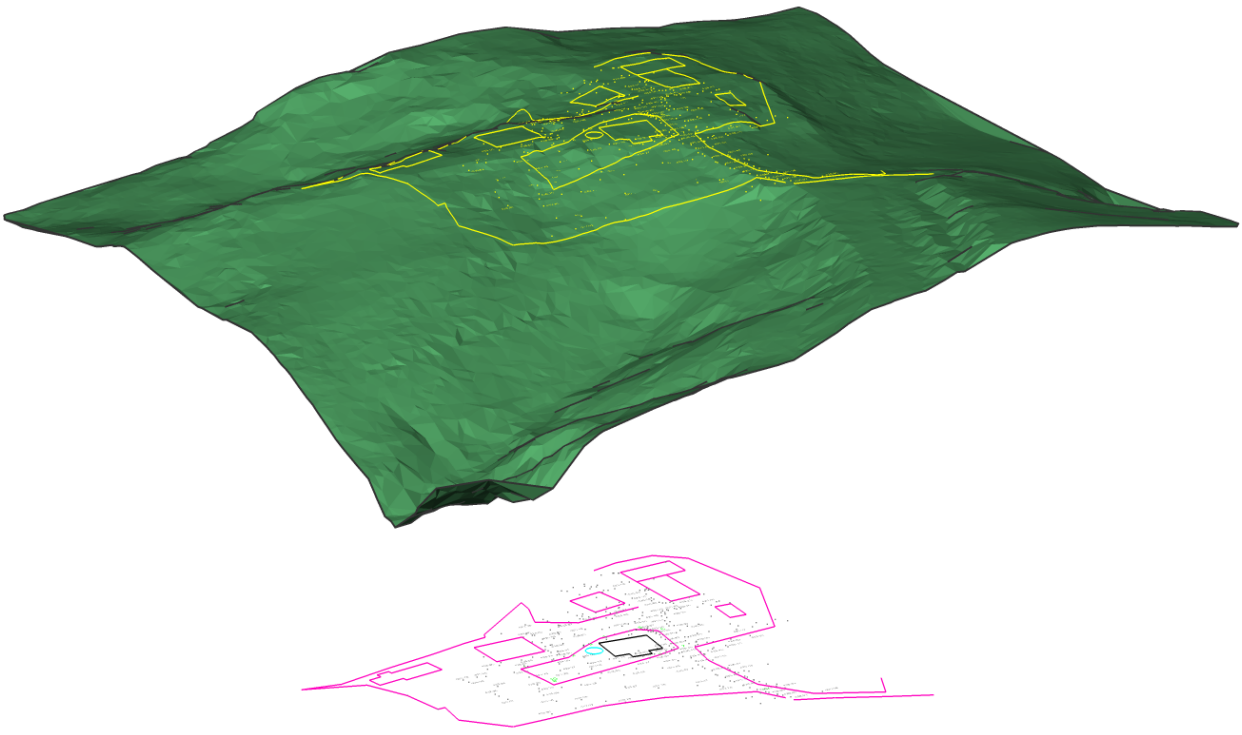

1.26.7 Working with Gradings

Command: Grading (6.15.25), GradingBalance (6.15.1) **Overview:** In BricsCAD, graded surfaces are created using the **Create Grading** tool.

- Graded surfaces can be created from an existing surface.
- Defining a graded area can be accomplished using a polyline as an entity.
- Two projection methods namely 'Slope to surface' and 'Offset to slope' are supported. Slope to surface needs an input entity (e.g. polyline, line, arc, circle), surface, and slope to grade the surface. Offset to slope needs an input entity, offset, and slope.
- The graded surfaces are not editable with the **TinEdit** command.

Lesson objectives: After completing this lesson, you will be able to:

- Grading surfaces.
- Grading 3D Alignments
- Balance Gradings

Tutorial: How to create a Grading Click here (2.4.19) to watch

About Grading

Grading is a set of processes to maintain a base level for construction works or TIN surface designing by defining a slope or adjusting the offset of a grading. For instance, creating; parking areas, recreation reserves or road and railway designs.  For more information about this command, visit the Command Reference article Grading (6.15.25).

Procedure: Grading a surface to create a pond

1. Open a drawing that has a topographical surface (1). (1.856 on the next page)
2. Launch the Grading (6.15.25) command in the command line. **Or** select Create Grading tool in the Model tab from the Quad. **You are prompted:** Select entity: **(Select the entity (2) that defines the footprint area of your pond.)**
3. **You are prompted:** Select target surface or [slope/Offset]: **(Optional)** without selecting any target surface, click the slope/Offset option in the prompt menu or type 'O' in the command line to follow the offset-projection method. **Note:** The offset-slope projection method requires input entity, offset, and slope.
4. Select the target surface (3) to create a graded area. (1.857 on the facing page)
5. Define the slope of the grading. **Note:** Grading is attached to the input entity and it is connected with the target surface. Moving the mouse in/out dynamically increase/decrease the slope of the grading. If **Dynamic dimension (DYN)** is On, change the slope in the highlighted cell (4), and press Enter. (1.858 on page 966)
6. Press **Enter** to accept the slope of the grading.

Figure 1.856

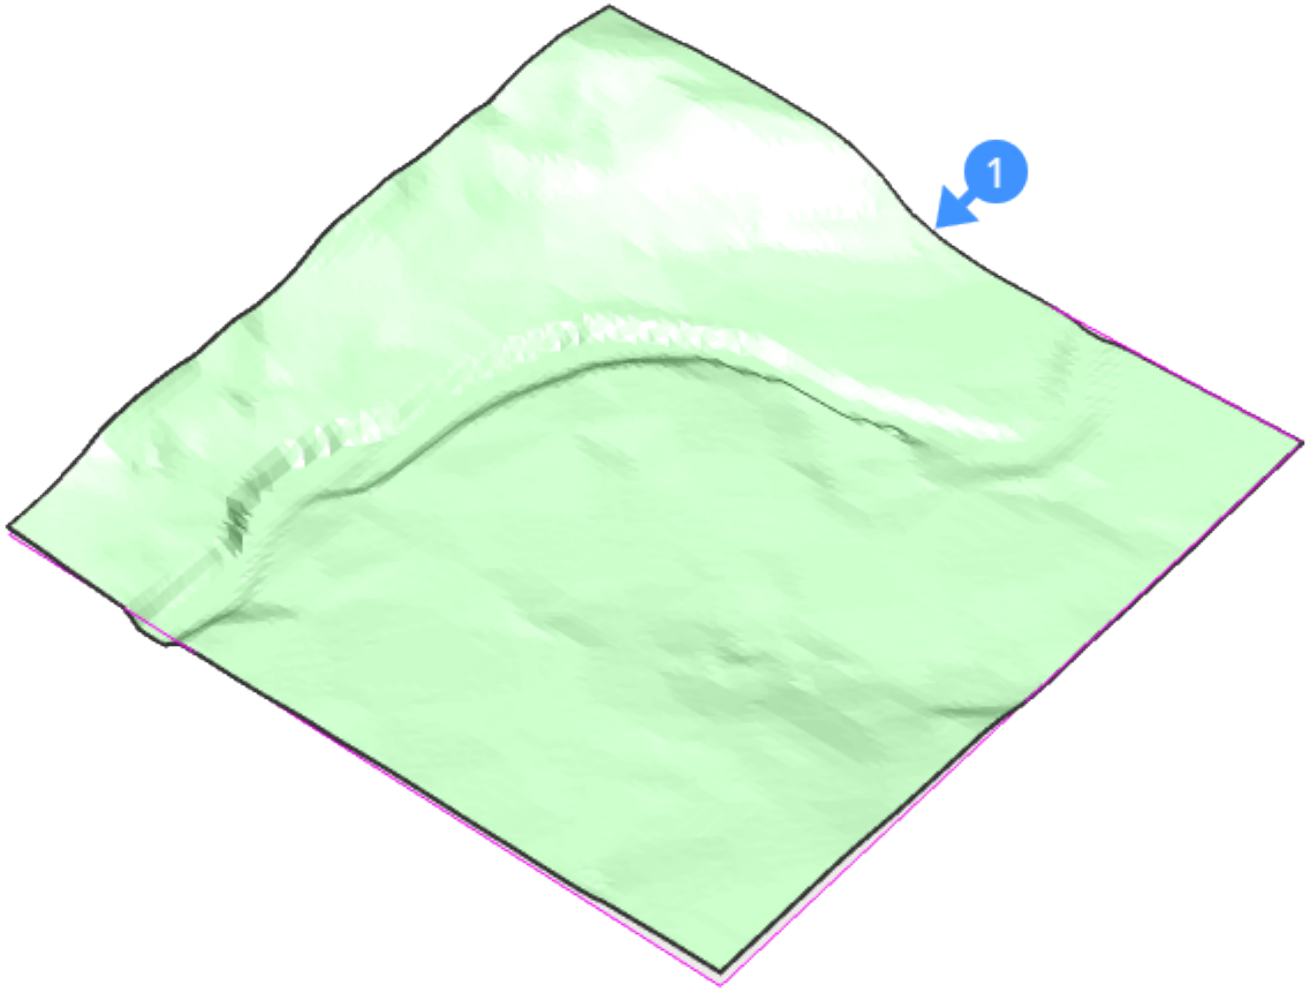

Figure 1.857

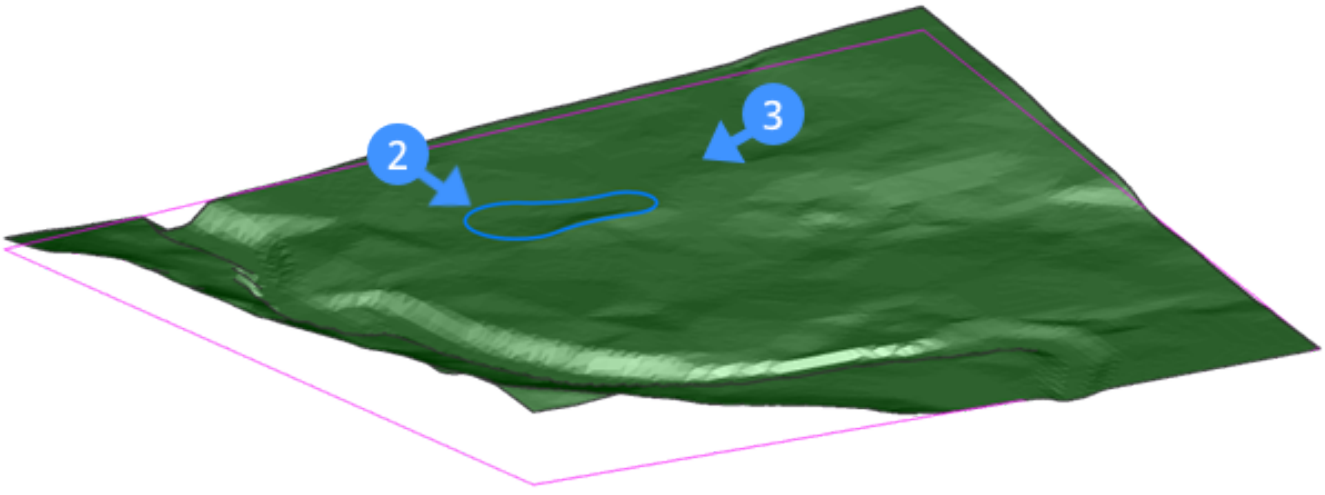

Figure 1.858

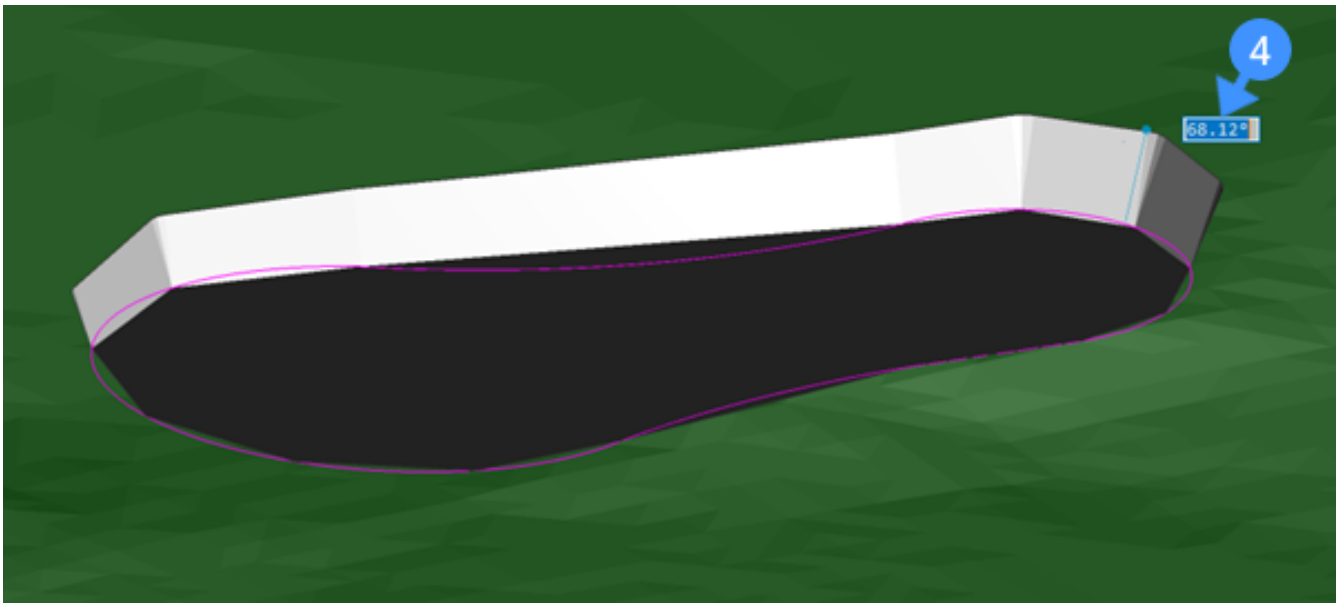

Displaying the properties of a graded surface

1. Select the graded surface. The properties of this Grading is displayed in the **Properties Panel**. (1.859 on the facing page)

Grading type	Demonstrates which projection method is used to grade the surface e.g. Slope to surface or Offset-slope.
Target surface	Displays the handle number of the target surface.
Cut slope	Displays the cut slope.
Fill slope	Displays the fill slope.
Side	Controls on which side of input entity grading is drawn. Left or right. To change the side of the grading, click its field, press the arrow button and choose the side in the context menu.
Infill	The internal area of entities is filled if this option is turned on. Valid for closed entities only (circle, closed polyline).
Boundary	Controls the boundary of the grading. To turn the boundary on/off, click its field, and press the arrow button and choose On/Off in the context menu. When the grading boundary is turned on, that boundary is added as a 'hide' boundary to the target surface.
Fill volume	Displays the fill volume for a body/shape limited with the target surface and graded surface.
Cut volume	Displays the cut volume for a body/shape limited with the target surface and graded surface.
Net volume	Displays the net volume for a body/shape limited with the target surface and graded surface. Note that only 'Slope to surface' grading type is valid.

The following images show when the grading boundary of the pond is off (5) and on (6). Based on the grading boundary, the net volume for the body of the pond is calculated and can be found in the properties panel (7). (1.860 on page 968) (1.861 on page 968) (1.862 on page 968)

Procedure: Grading a surface to create a platform

1. Open a drawing that has a topographical surface (8). (1.863 on the following page)
2. Launch the Grading (6.15.25) command in the command line. **Or** select Create Grading tool in the Model tab from the Quad. **You are prompted:** Select entity:
   (Select the entity (9) that defines the footprint area of your platform.)
3. **You are prompted:** Select target surface or [slope/Offset]: **(Select the target surface (10) to create a graded area.) (1.864 on the next page) Optional** without selecting any target surface, click the slope/Offset option in the prompt menu or type 'O' in the command line to follow the offset-projection method. **Note:** The offset-slope projection method requires input entity, offset, and slope.
4. Define the slope of the grading.
   (1.865 on page 972)

Figure 1.863

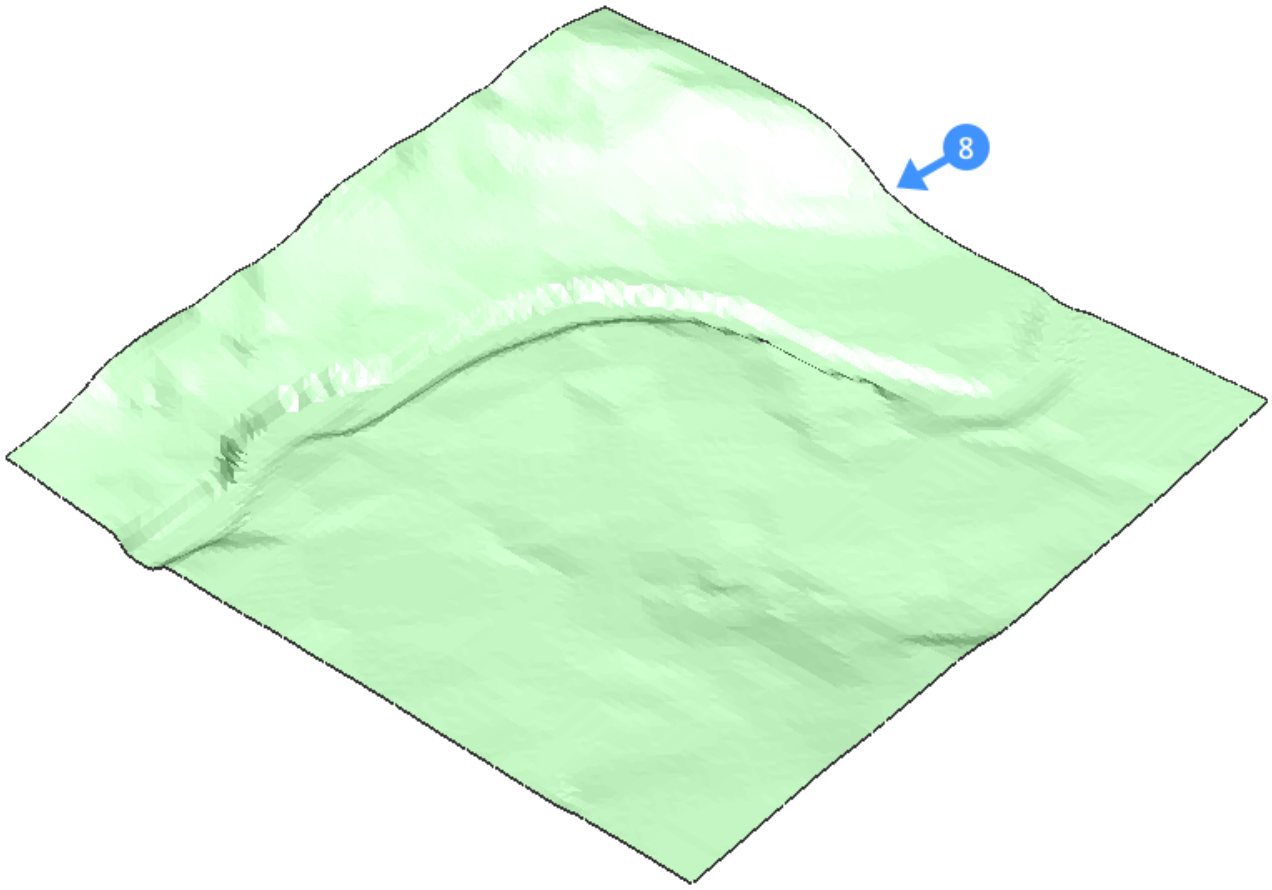

Figure 1.864

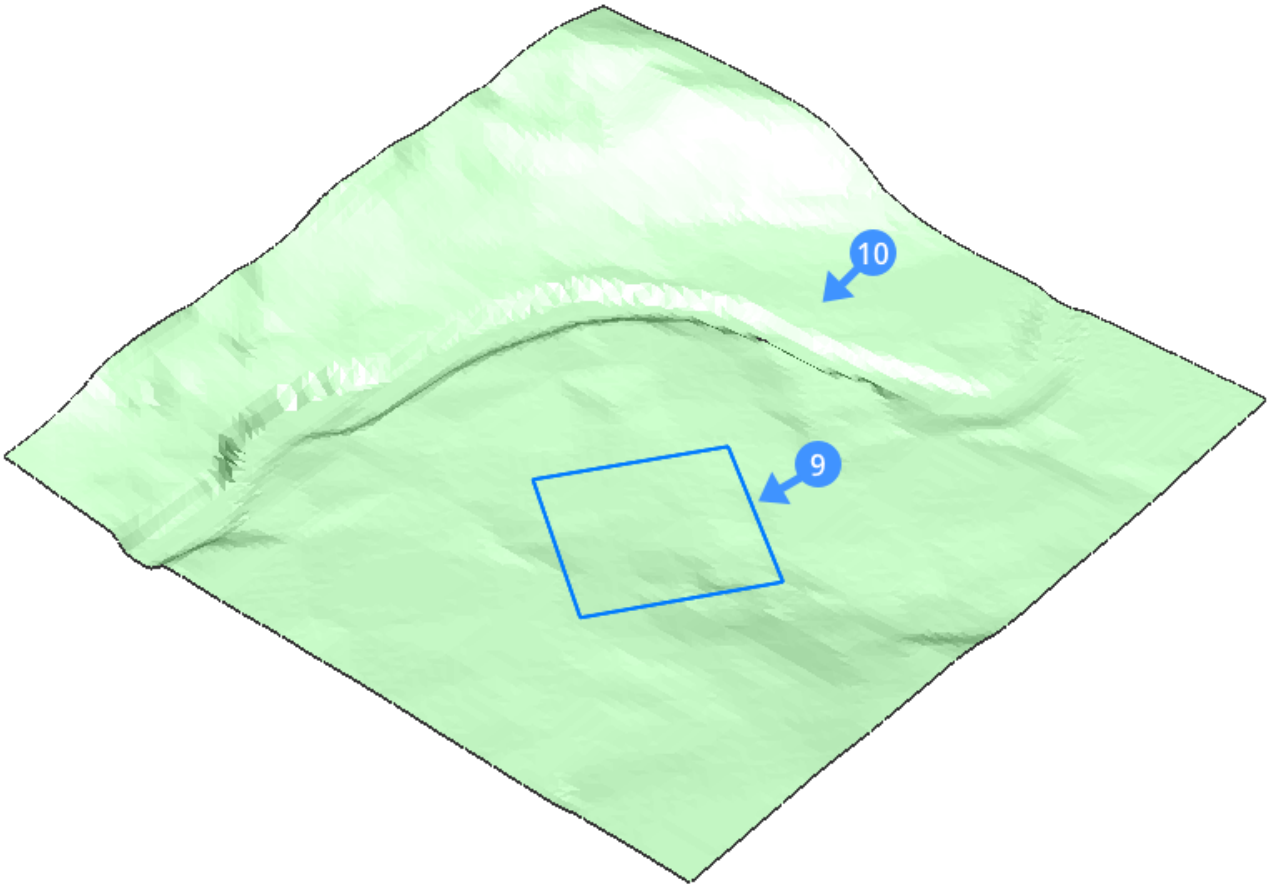

Note: Grading is attached to the input entity and it is connected with the target surface. Moving the mouse in/out dynamically increase/decrease the slope of the grading. If **Dynamic dimension (DYN)** is On, change the slope in the highlighted cell (11), and press Enter.

5. Press **Enter** to accept the slope of the grading. **Note**: You can easily move the platform that you created. Do this by using the manipulator on the entity from which you created the platform. You can move both horizontally and vertically. (1.866 on page 973) The grading will automatically be adapted to its surroundings. (1.867 on page 974)

Figure 1.865

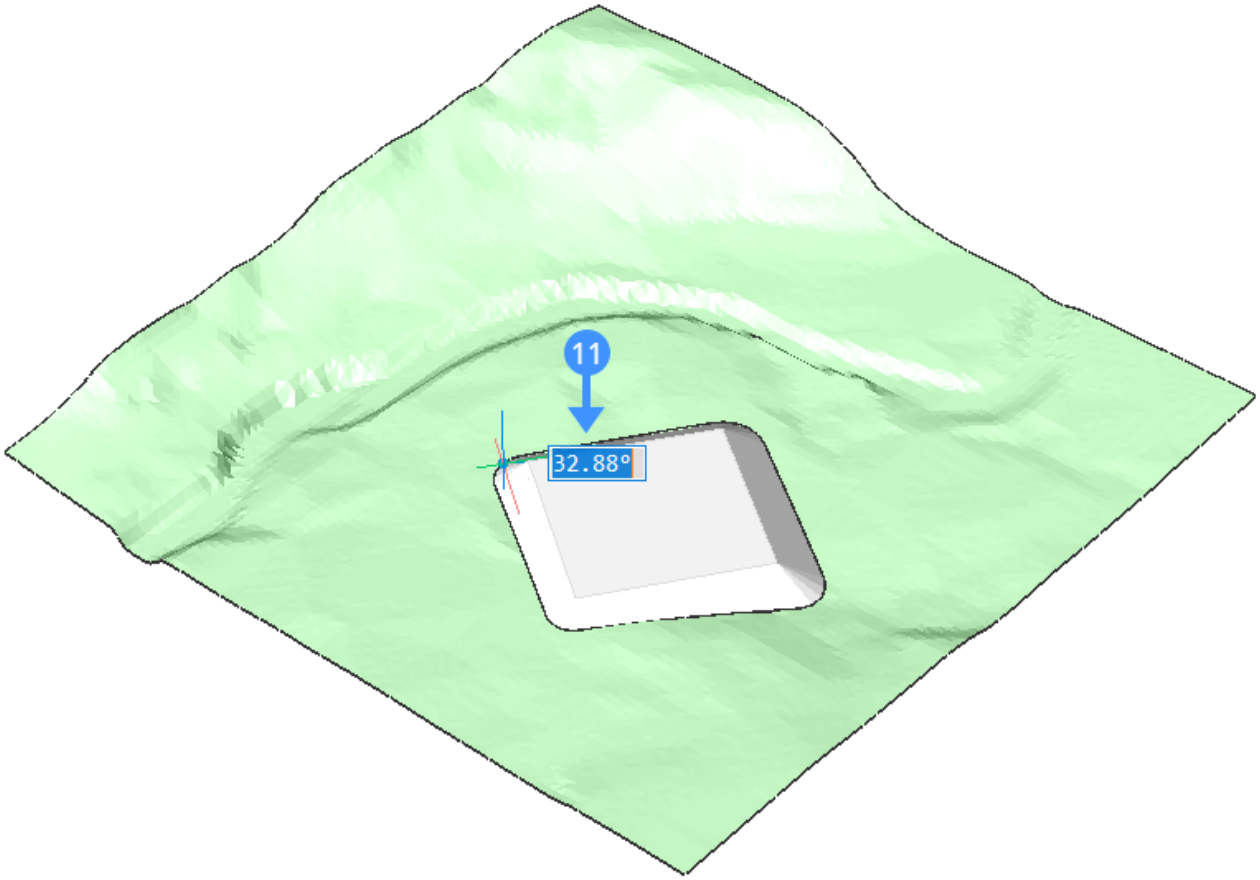

Figure 1.866

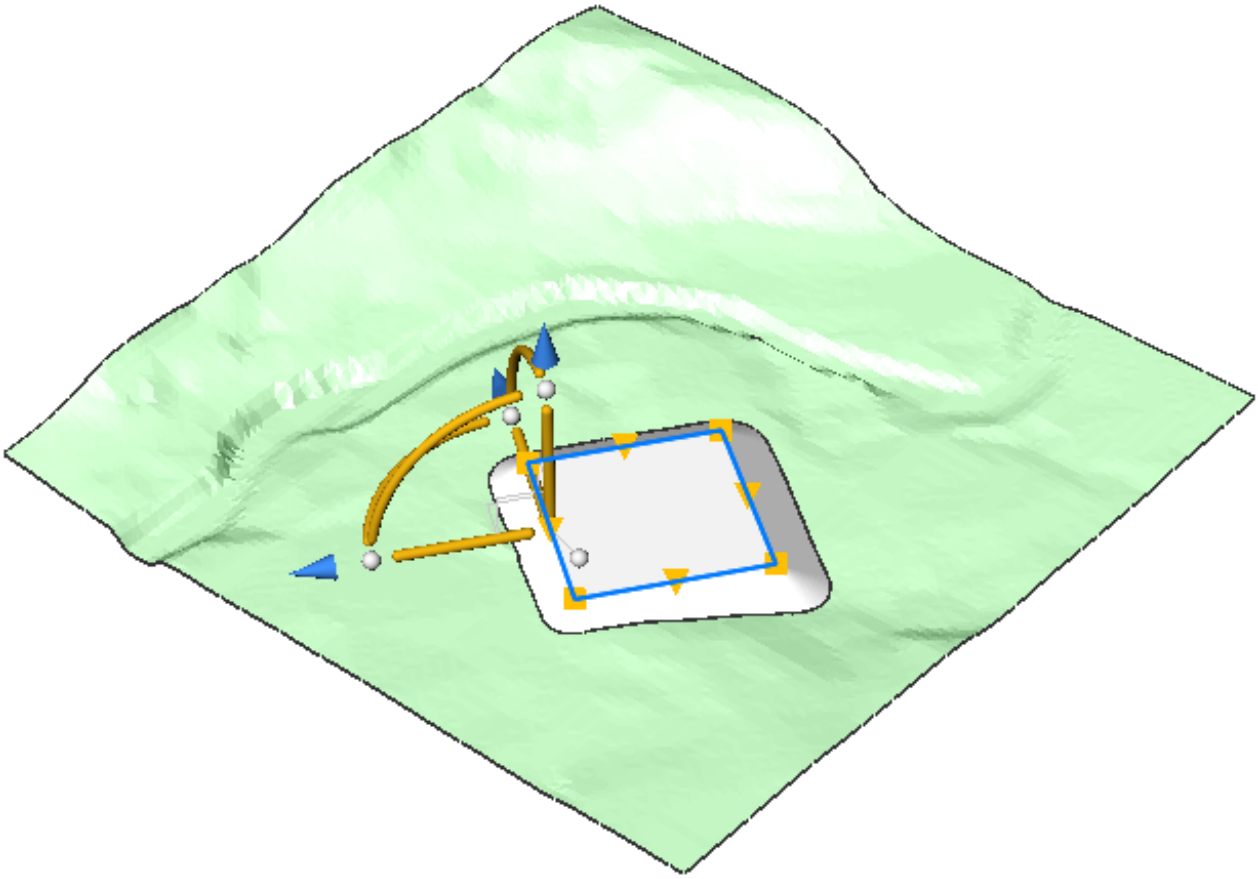

Figure 1.867

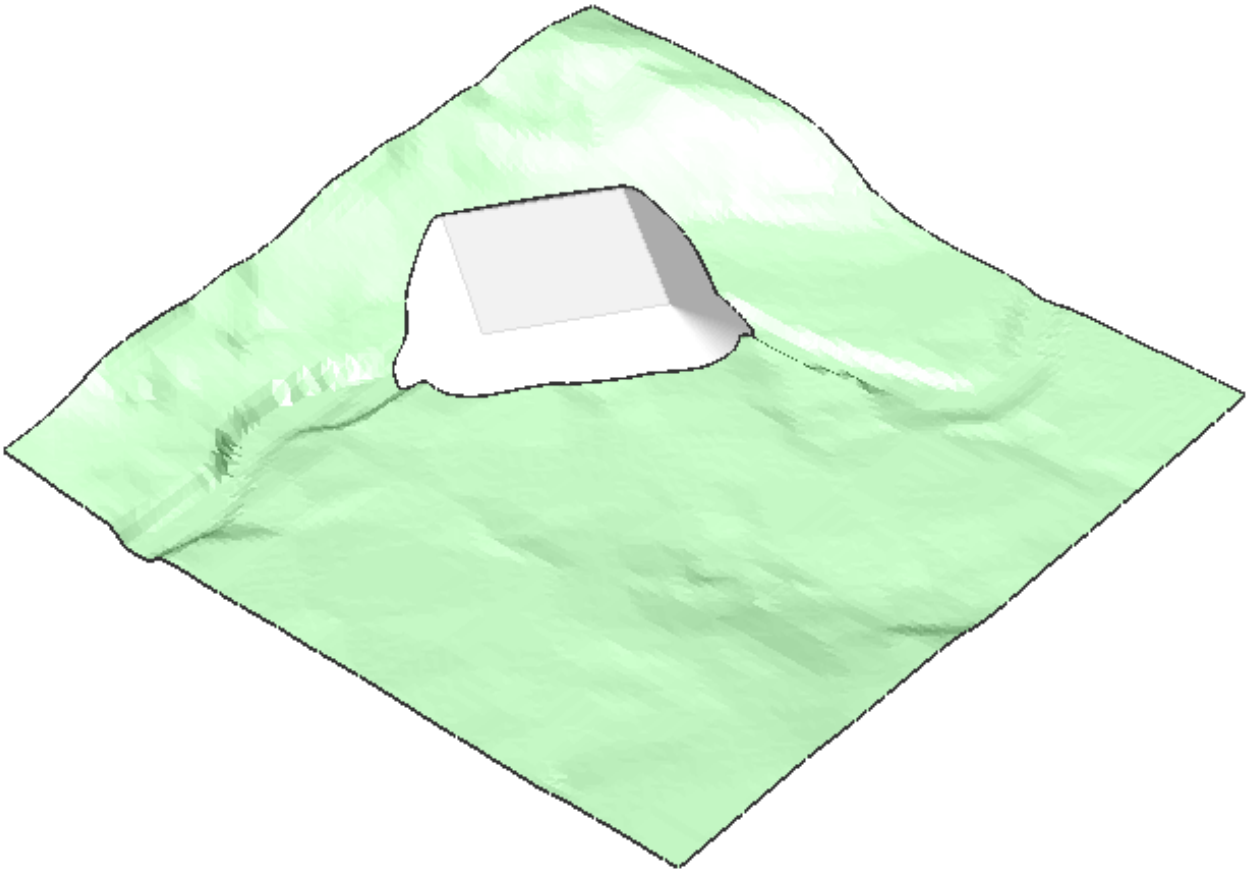

About Balance Grading Volumes

The GradingBalance command allows you to balance cut and fill volumes within the specified tolerance. This is achieved by raising/lowering the elevation of the grading input entity and the result is grading that has a net volume around zero, depending on the set tolerance.  For more information about this command, visit the Command Reference article GradingBalance (6.15.1).

Procedure: Adjusting the elevation of a grading to balance cut and fill volumes

1. Open a drawing that contains a TIN Surface and a Grading representing building pad. (1.868 on the next page)
2. Launch the GradingBalance command in the command line. **Or** select Balance Grading Volumes tool in the Model tab from the Quad. **You are prompted:** Select Grading entities: **(Select the grading)** The command allows you to select multiple gradings at once.
3. **You are prompted:** Enter tolerance in percent (1-100): **(1 means that the difference between the cut and fill volume will be less than one percent and 100 means that the difference between the cut and fill volume will be less than 100 percent)** (1.869 on the following page)

In the **Properties Panel** in the Grading statistic section, we can see that the cut and fill volumes are now balanced. (1.870 on the next page) **Note:** Balance Grading Volumes command works only on gradings that has Boundary set to **OFF**. (1.871 on page 977)

1.26.8 TIN Surface Edit

Command: TINEdit (6.29.19) **Overview:** In BricsCAD, points, breaklines, and boundaries on a triangulated irregular network (TIN) surface can be added or removed using the TINEdit command. The following entities represent features on a TIN surface.

- Points contain x, y coordinates, and z values. All points are used to make a connection with the two nearest neighbors to create triangles. The surface triangulation is based on the Delaunay algorithm, which ensures that no point is inside the circumcircle of any triangle.
- Breaklines represent linear infrastructure features like curbs, retaining walls, etc. These lines also define the edges of triangles. Breaklines can be created from linear entities such as line, polyline, arc, circle.
- Boundaries are the features to define bounded 3D surfaces. The surface boundaries can be created with closed polylines. Defining outer boundaries on a large 3D surface improves the performance of a TIN Surface plan.

Lesson objectives: After completing this lesson, you will be able to:

- Add new points on a TIN Surface.
- Add breaklines on a TIN Surface.
- Add boundaries on a TIN Surface.

Tutorial: How to edit a TIN Surface Click here (**??**) to watch

About

The **TIN edit** command adds or removes points, breaklines, boundaries from an existing TIN Surface.  For more information about this command, visit the Command Reference article TINEdit (6.29.19).

Procedure: Adding points to a Toposurface

1. Open a TIN Surface with surface points.

(1.872)

2. Select the TIN Surface, and click the Add to TIN Surface tool in the BIM Toolbar. **Or** launch the **TINEdit** command in the command line **You are prompted:** Pick points to add to the TIN surface or [Add Points/Add Breaklines/Add bOundaries/Remove Points/Remove Breaklines/Remove bOundaries]:

3. Click on the area to add points to the surface. **You are prompted:** Enter elevation <*value>: ***value= is calculated as an interpolated elevation for selected point inside triangle (2, 3,4). Note:** "Enter elevation" displays in the command line when the Entity Snap Tracking (ESNAP) mode is off. If ESNAP is On you can check the elevation of a point in the cursor coordinate. (1.873 on the facing page)

Figure 1.872

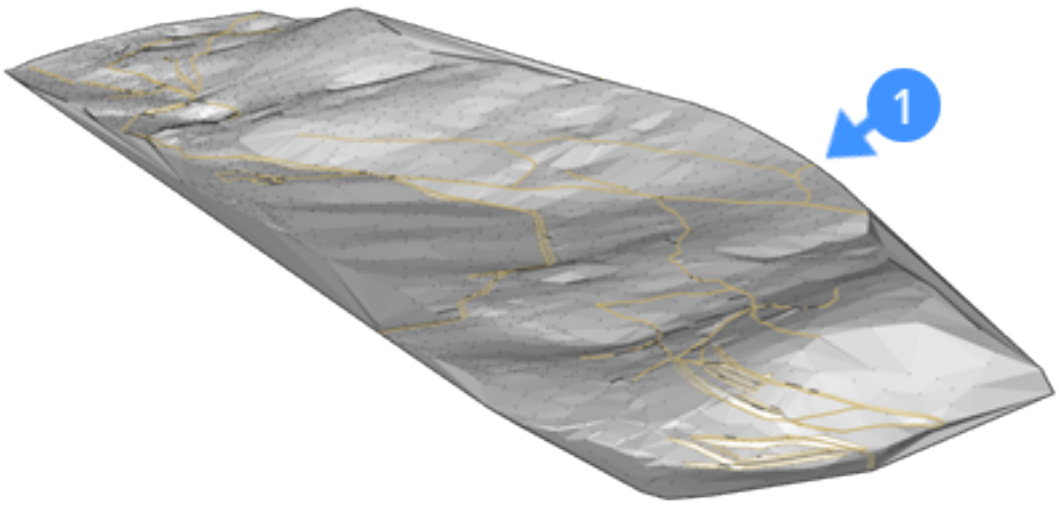

Figure 1.873

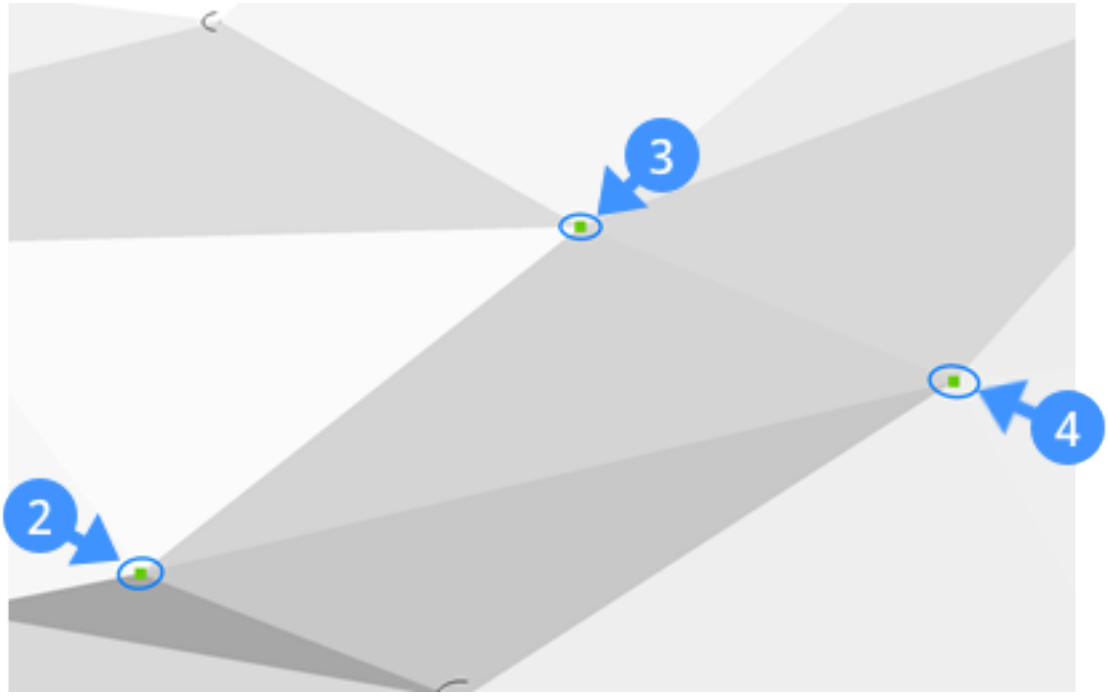
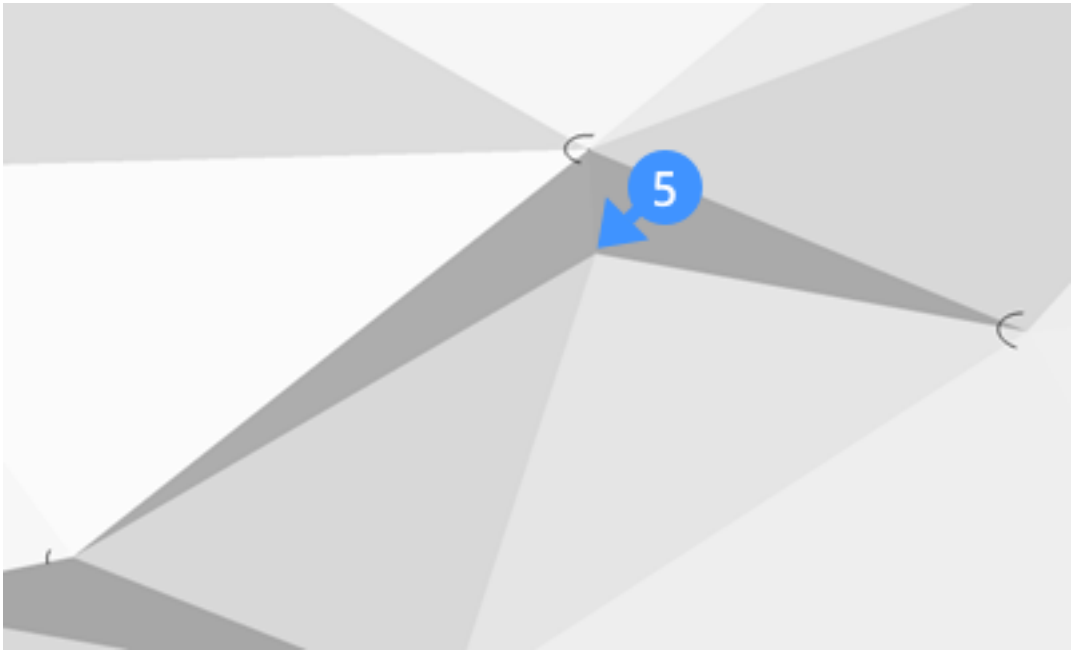


4. To specify the elevation of the newly added point, type an elevation value in the command line, and press Enter. **You are prompted:** Pick point Keep on adding points on the surface, or press Enter to exit the command. The new surface point (5) is added from entities, such as polyline vertices. (1.874 on the next page)

Figure 1.874



Procedure: Adding breaklines to a Toposurface

1. Open a TIN Surface. (1.875)
2. Select the TIN Surface, and click the Add to TIN Surface tool in the BIM Toolbar. **Or** launch the **TINEdit** command in the command line. **You are prompted:** Pick points to add to the TIN surface or [Add Points/Add Breaklines/Add bOundaries/Remove Points/Remove Breaklines/Remove bOundaries]:
3. Select the Add Breaklines option or type AB in the command line. **You are prompted:** Select entities **(1.876 on the next page) Figure 1, the retaining wall breaklines before adding breaklines to the surface (7).**
4. Select the breaklines you want to modify the surface according to the edges of these linear features, and press Enter. **Note:** If the breakline is moved, the surface will be updated automatically. (1.877 on the facing page) **Figure 2, the retaining wall breaklines after adding breaklines to the surface (8).** The TIN Surface is modified according to the edge of retaining wall breaklines.

Figure 1.875

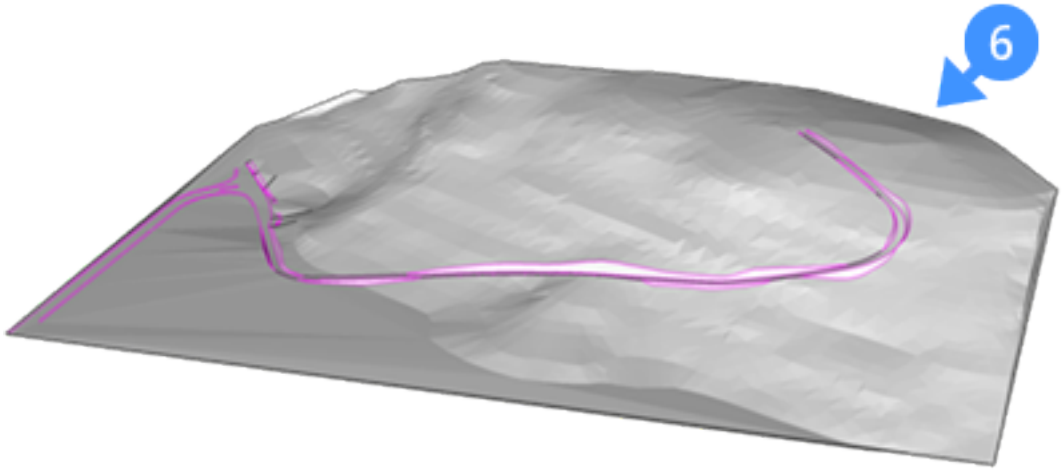


Figure 1.876

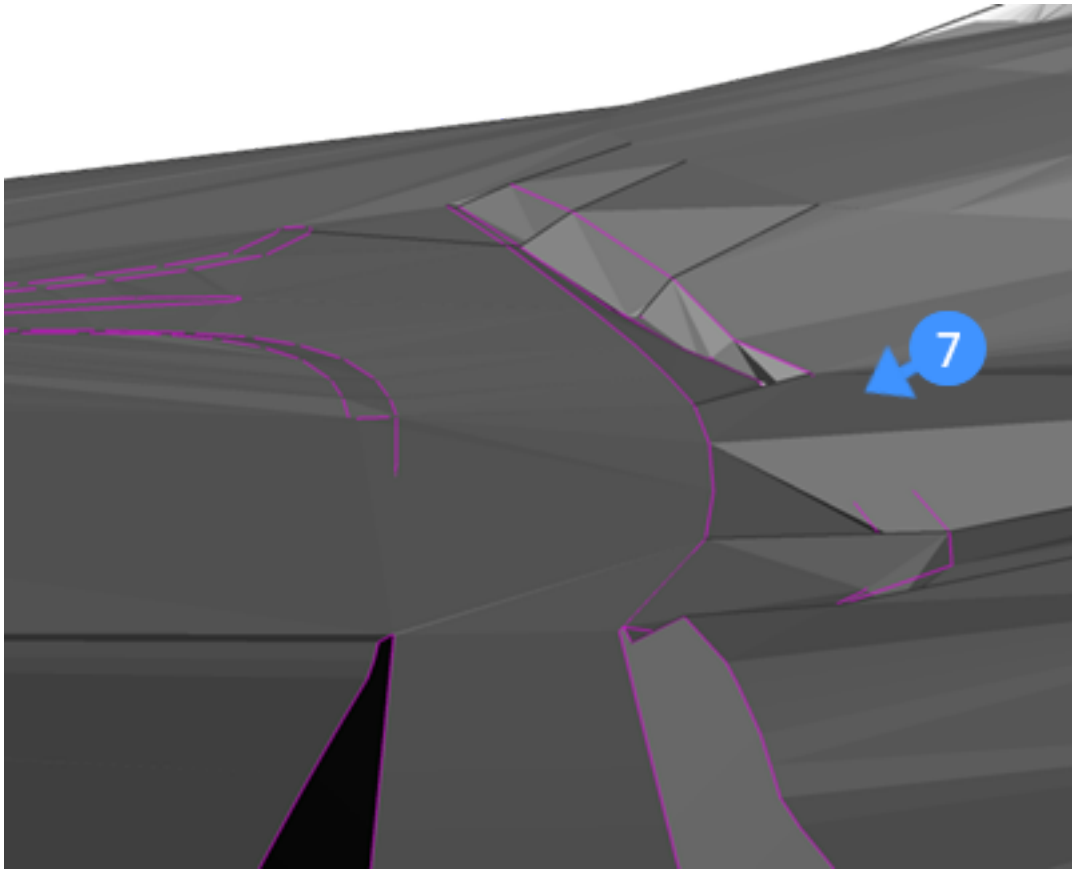

Figure 1.877

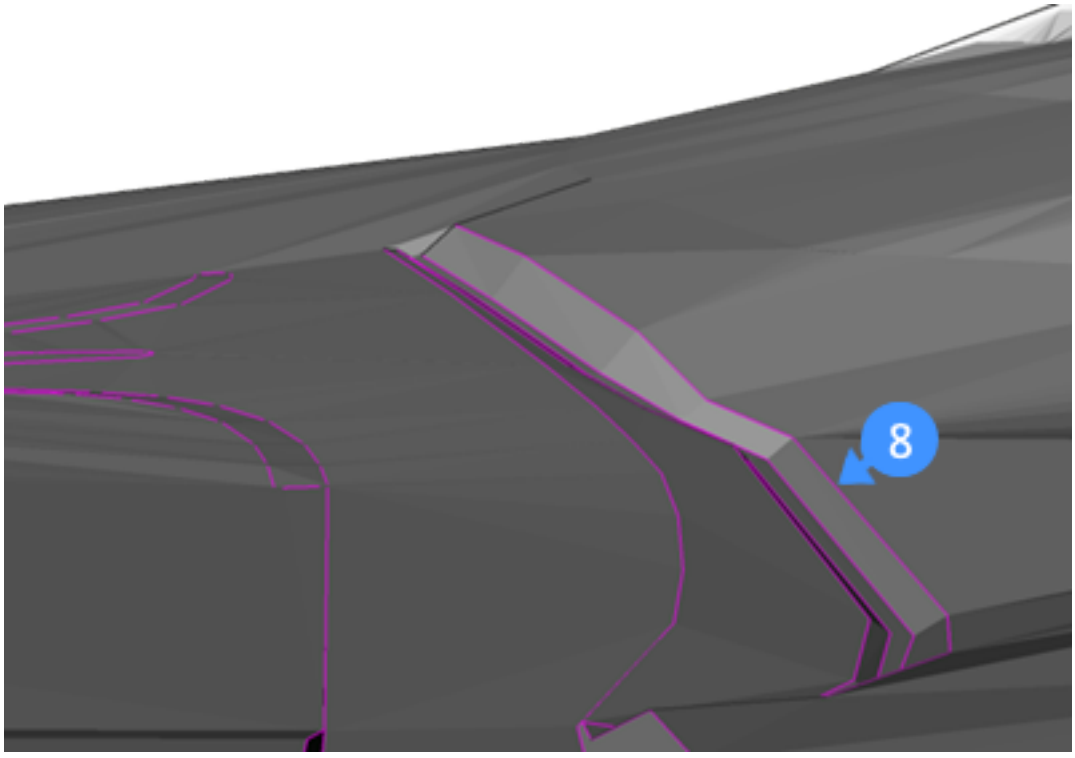

Procedure: Adding boundaries to a Toposurface

1. Open a TIN Surface you want to create a surface boundary. (9) (1.878)
2. Create a closed boundary on the location you want to clip the surface. **Note:** Make sure that Entity Snap Tracking (ESNAP) is active. (1.879 on the facing page)
3. Select the TIN Surface, and click the Add to Tin Surface tool in the BIM Toolbar. **Or** launch the TINEdit command in the command line **You are prompted:** Pick points to add to the TIN Surface or [Add Points/Add Breaklines/Add bOundaries/Remove Points/Remove Breaklines/Remove bOundaries]:
4. Select the Add Boundaries option or type AO in the command line. **You are prompted:** Select entities for boundary of type: [Outer/Show/Hide] <Outer>:
5. Click on the closed boundary to use in the surface boundary definition, and press Enter. By default, the outer option is selected, which allows creating an outer surface boundary (11). (1.880 on the next page) **Optional** Select the bounding entity (12)(e.g. polyline) to resize the surface boundary. Moving the grip (13) of the entity changes the surface dynamically (14). (1.881 on page 984)

Figure 1.878

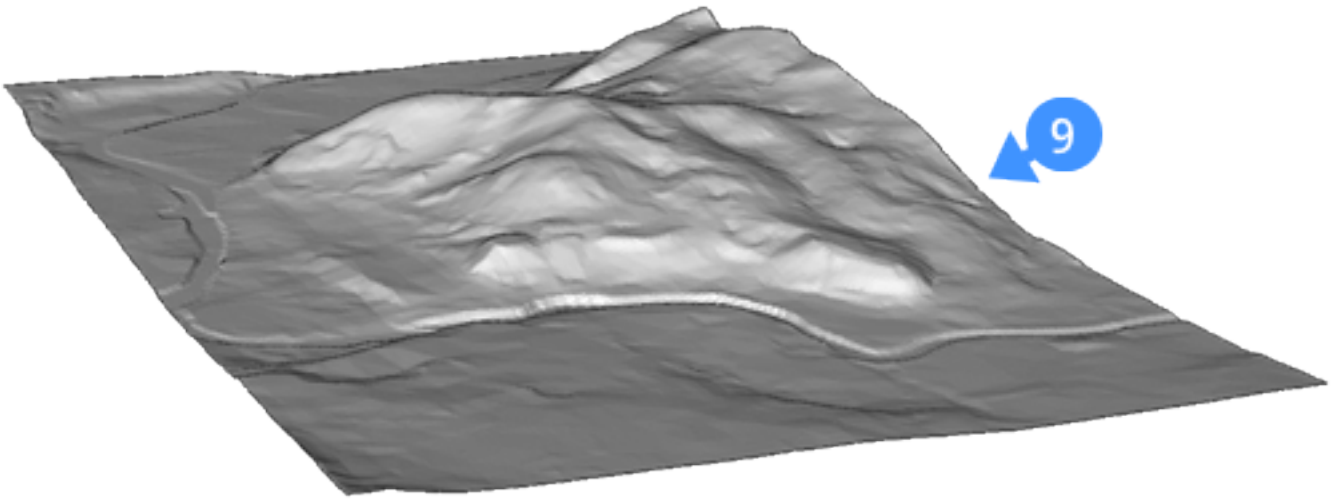

Figure 1.879

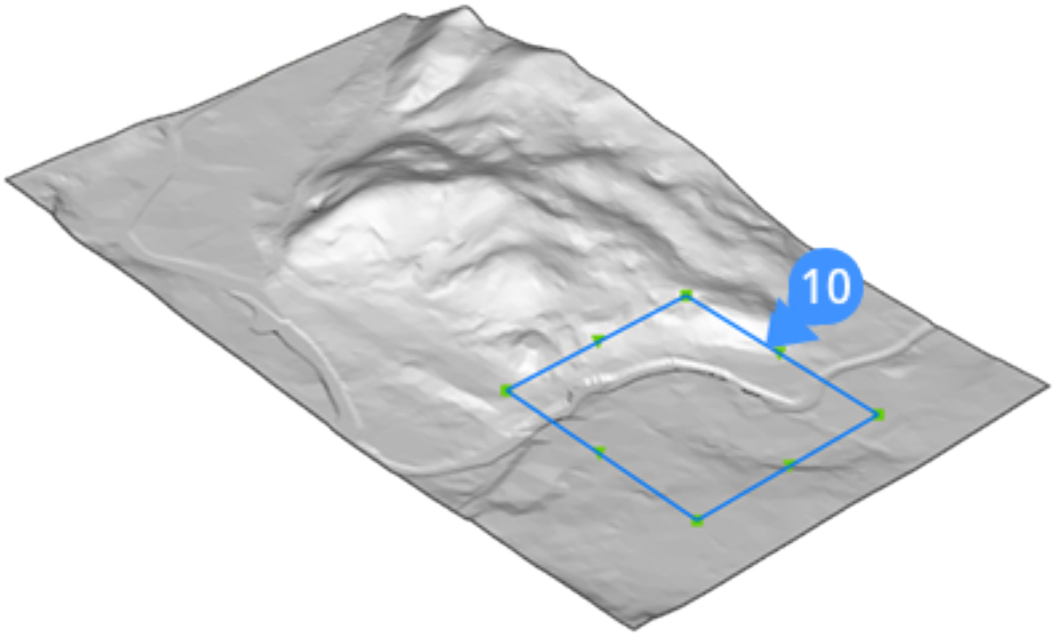

Figure 1.880

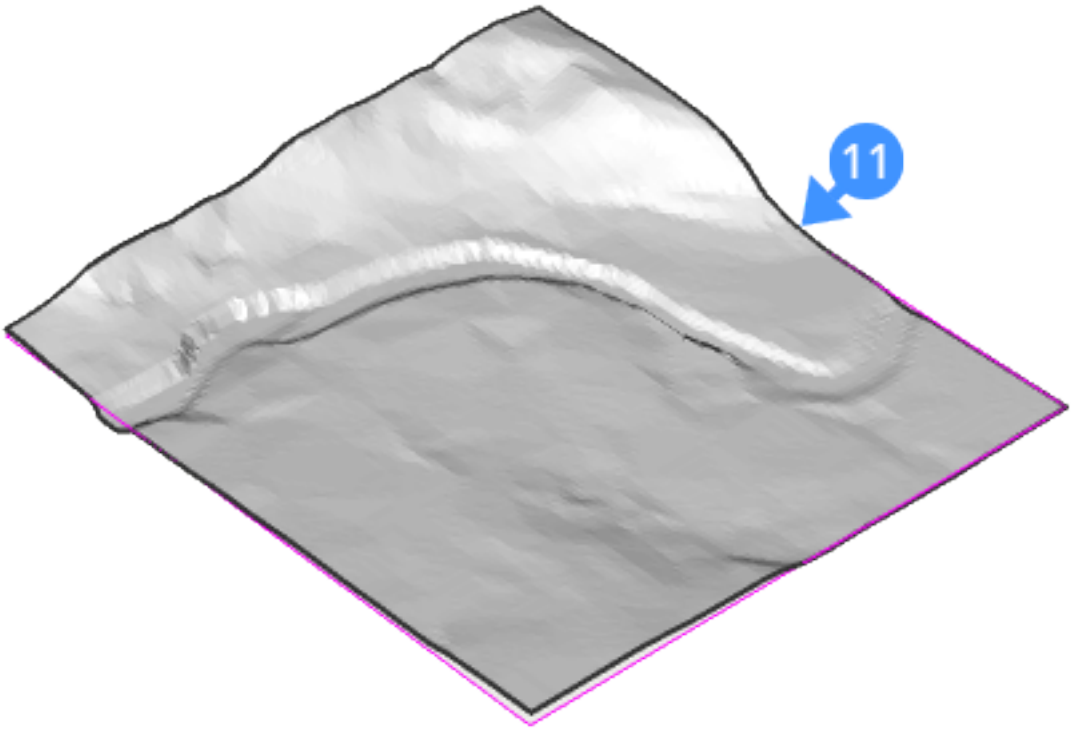

Optional Select the hide option to exclude a part of the surface from the TIN when calculating the total area.
Optional Select the show option to reveal the hidden surface in the TIN. (1.882 on the next page) The hidden part according to the closed boundary (15) is shown, the surface of the hidden part revealed (16) using the show option.

Figure 1.881

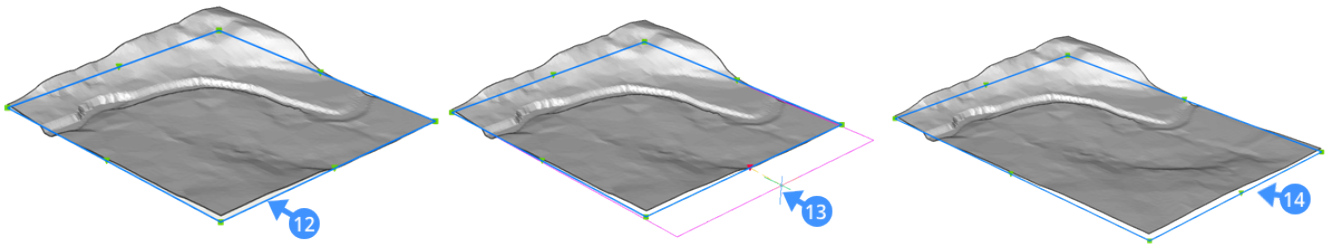

Figure 1.882

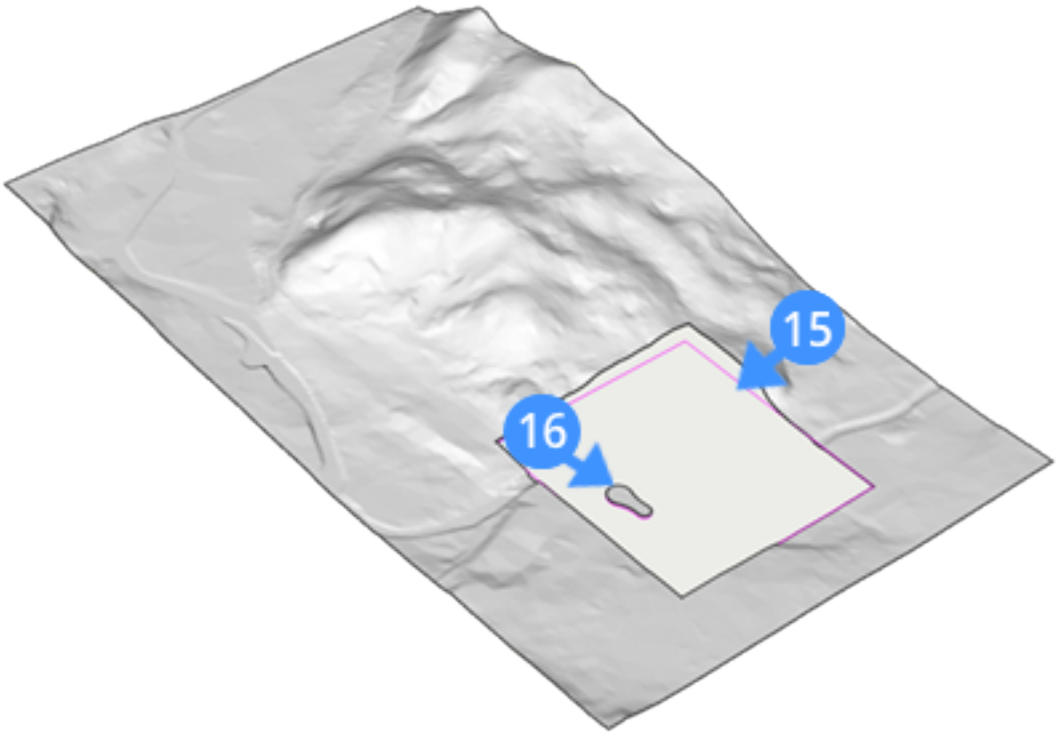

1.26.9 TIN Surface Direct Modeling

Command: TinExtract (6.29.18), TinMerge (6.29.22), TinModify (6.29.23) **About:** In BricsCAD, topographical surfaces created as a TIN Surface, can be adjusted using different tools. **Lesson objectives:** After completing this lesson, you will be able to:

- Creating meshes, solids, borders, faces and points from TIN Surfaces.
- Merge TIN Surface
- Deforming TIN Surfaces
- Smoothen TIN Surfaces

About TIN Extract

The TINExtract command is used to generate a solid, mesh, border, faces and points from a TIN surface. You can exchange these entities in other applications, to further analyze the surfaces. The solids or meshes can be created in different ways: as a vertical offset of the TIN Surface, as a model between two TIN Surfaces or as a model between a fixed elevation plane and the TIN Surface.  For more information about this command, visit the Command Reference article TinExtract (6.29.18).

Procedure: Creating a solid from a TIN surface using option Elevation

1. Select a TIN Surface and type **TINExtract** in the commandline. **You are prompted:** Extract [Mesh/Solid/Points/Faces/Co <Mesh>: (1.902 on page 1002)
2. Choose the desired extraction. Type in **S** of Solid and press Enter. **You are prompted:** Enter vertical offset or select [between Surfaces/Elevation] <1>:
3. Choose the elevation height and press Enter. **You are prompted:** 1 entities extracted. (1.884 on the next page)

Figure 1.883

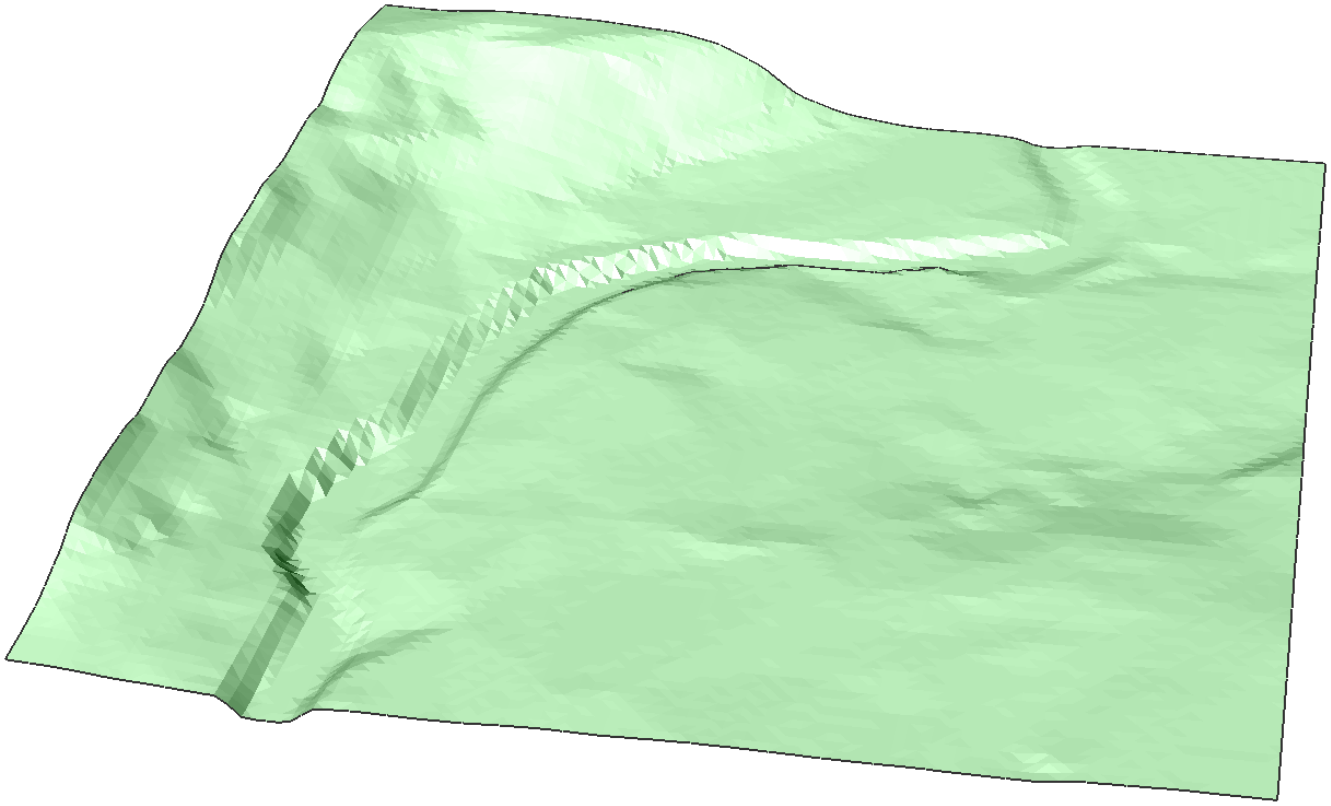

Figure 1.884

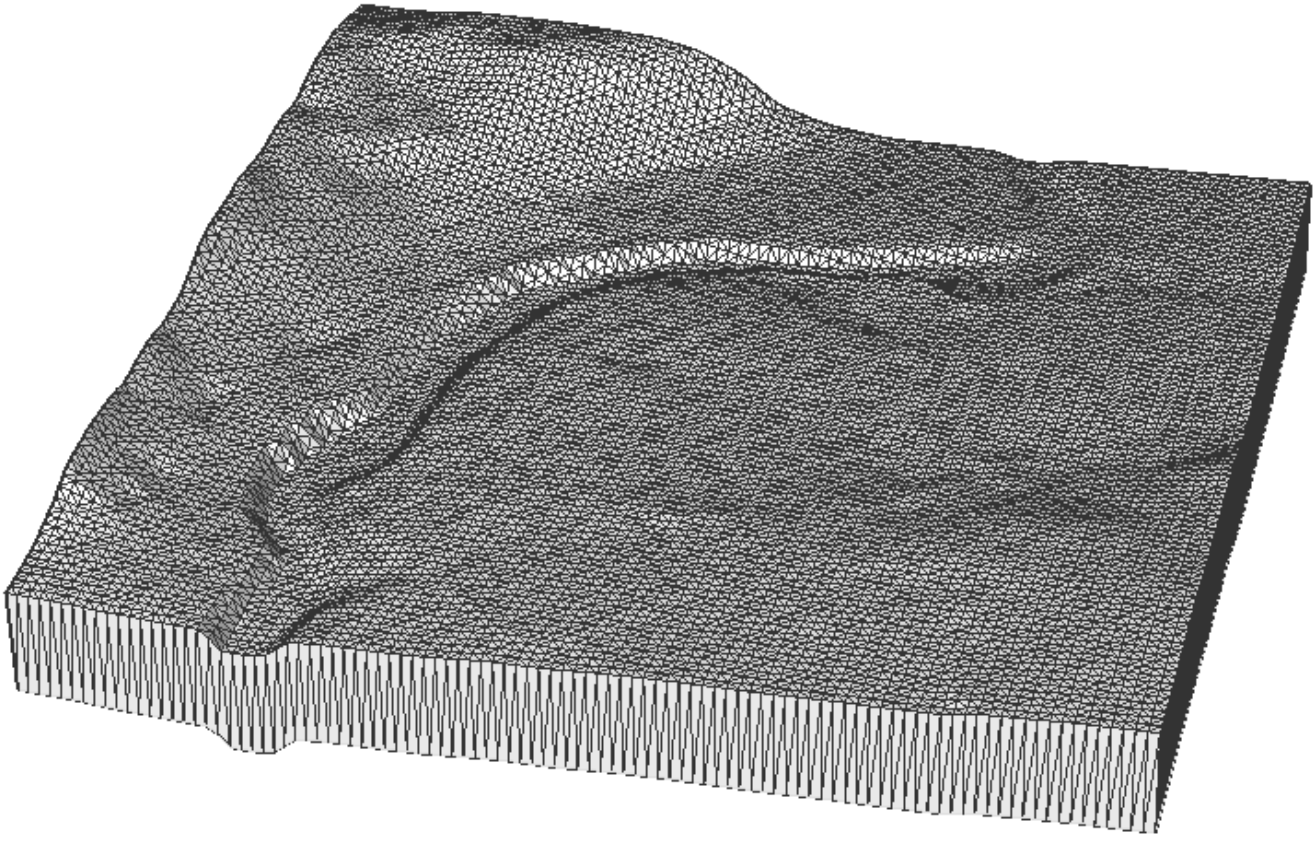
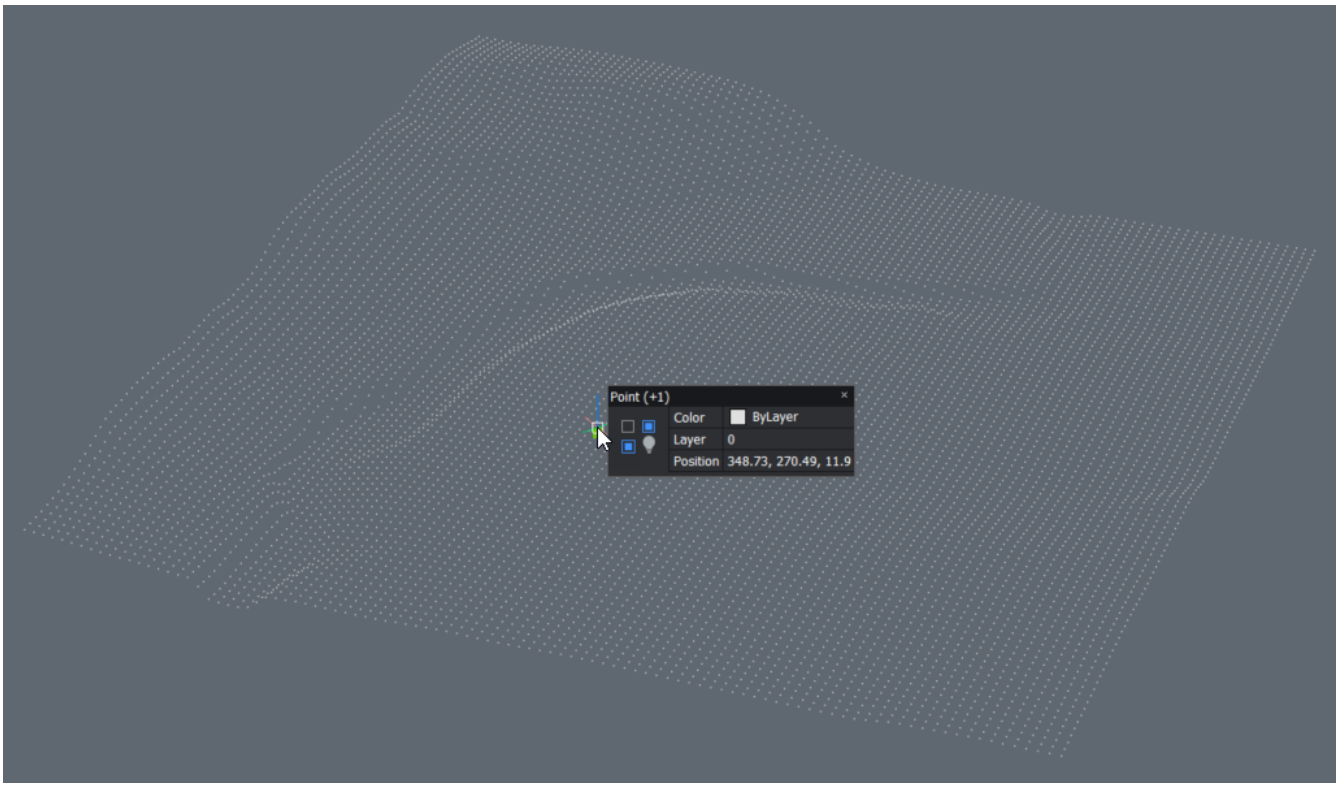


Procedure: Creating Points from a TIN surface

1. Select a TIN Surface and type **TINExtract** in the commandline. **You are prompted:** Extract [Mesh/Solid/Points/Faces/Co
<Mesh>:
2. Choose the desired extraction. Type in **P** for Points and press Enter. **You are prompted:** 10000 entities extracted. (1.885 on the facing page)

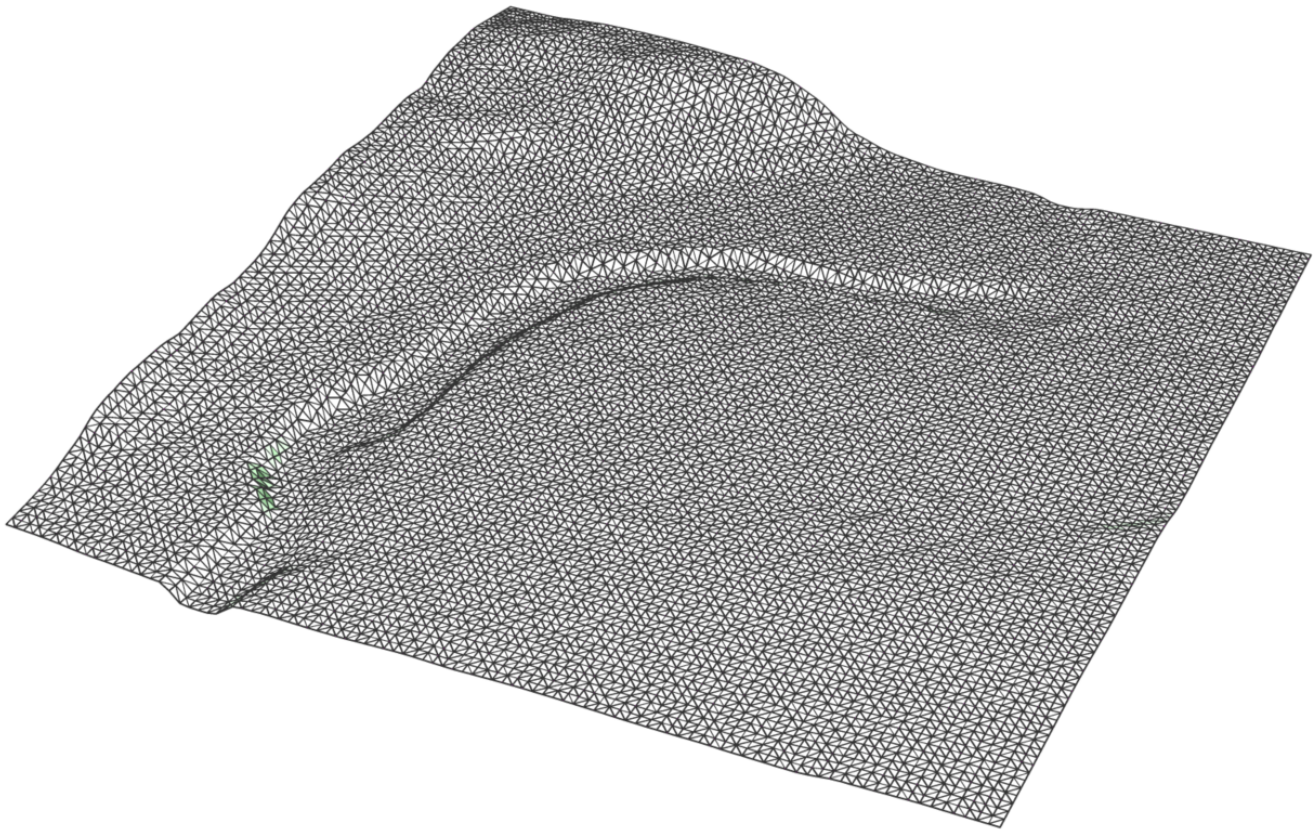
Figure 1.885



Procedure: Creating Faces from a TIN surface

1. Select a TIN Surface and type **TINExtract** in the commandline. **You are prompted:** Extract [Mesh/Solid/Points/Faces/Co <Mesh>:
2. Choose the desired extraction. Type in **F** for Faces and press Enter. **You are prompted:** 19602 entities extracted. (1.886 on the next page)

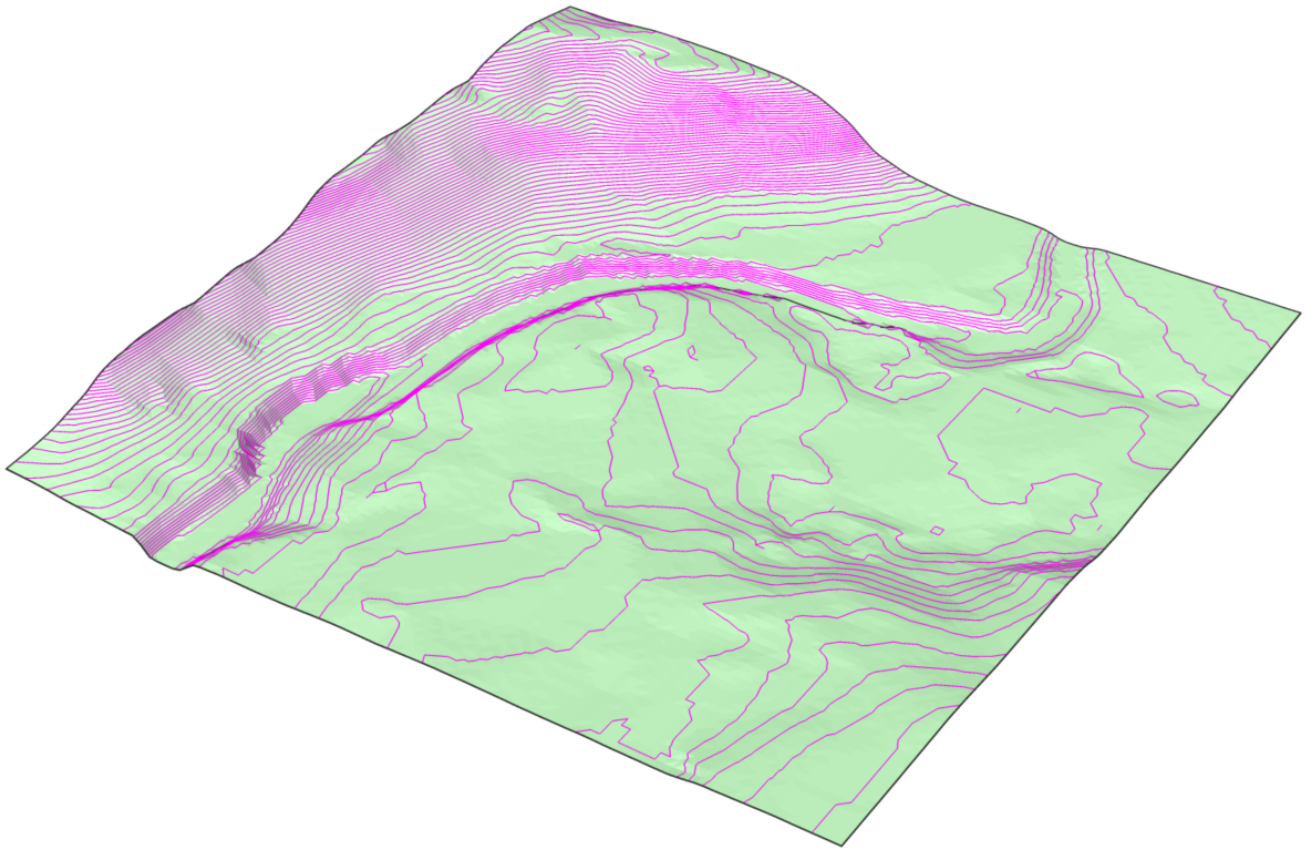
Figure 1.886



Procedure: Creating a Contours from a TIN surface

1. Select a TIN Surface and type **TINExtract** in the commandline. **You are prompted:** Extract [Mesh/Solid/Points/Faces/Co <Mesh>:
2. Choose the desired extraction. Type in **C** for Contours and press Enter. **You are prompted:** Enter contour elevation or [Minor/maJor/All] <0>:
3. Type in **A** for All and press Enter. **You are prompted:** 107 entities extracted. (1.887 on the facing page)

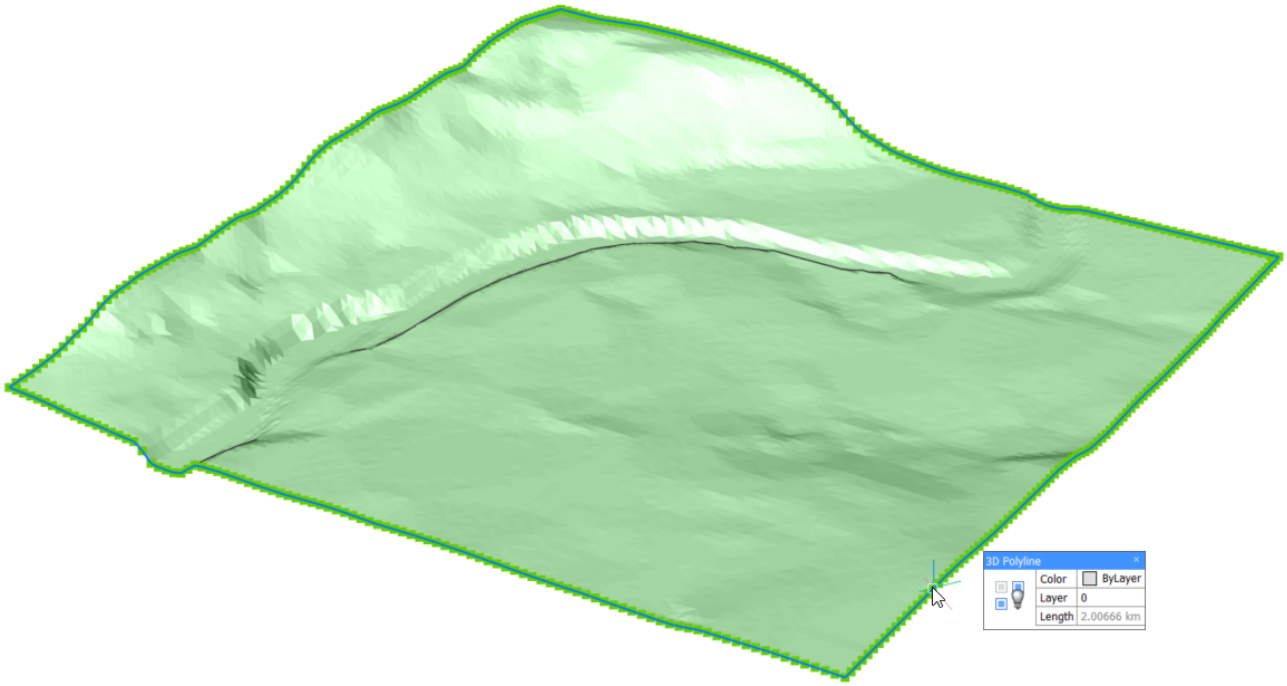
Figure 1.887



Procedure: Creating a Border from a TIN surface

1. Select a TIN Surface and type **TINExtract** in the commandline. **You are prompted:** Extract [Mesh/Solid/Points/Faces/Co
<Mesh>:
2. Choose the desired extraction. Type in **B** for Border and press Enter. **You are prompted:** 1 entities extracted.
(1.888 on the next page)

Figure 1.888



About TIN Merge

Different TIN Surfaces can be merged into one by using the TINMerge command. A merge is executed between a base surface and one or more surfaces to merge with. For more information about this command, visit the Command Reference article TinMerge (6.29.22).

Merging TIN Surfaces

1. Type TINMerge in the command bar. **You are prompted:** Select base TIN surface (1.889 on the facing page)
2. Choose a base surface. In this example, we choose the green surface as the base surface. **You are prompted:** Select TIN surfaces to merge:
3. Choose one or more TIN Surfaces to merge with the base surface. Press enter when done. In this example, we choose the red and the blue TIN Surface. **You are prompted:** Remove merged TIN surfaces [Yes/No] <No>:
4. Choose to keep or delete the original surfaces. **Note:** Selecting a different baseline, results in a different merge. It is important to remember that the surface to merge replaces the part of the base surface that it covers. (1.890 on the next page) (1.891 on page 994) **The first example shows the merge of the green surface as the base surface and the blue and red surface. The second surface shows the merge of the blue surface as the base surface and the green surface. The third surface shows the merge of the red surface as the base surface and the green surface.**

Figure 1.889

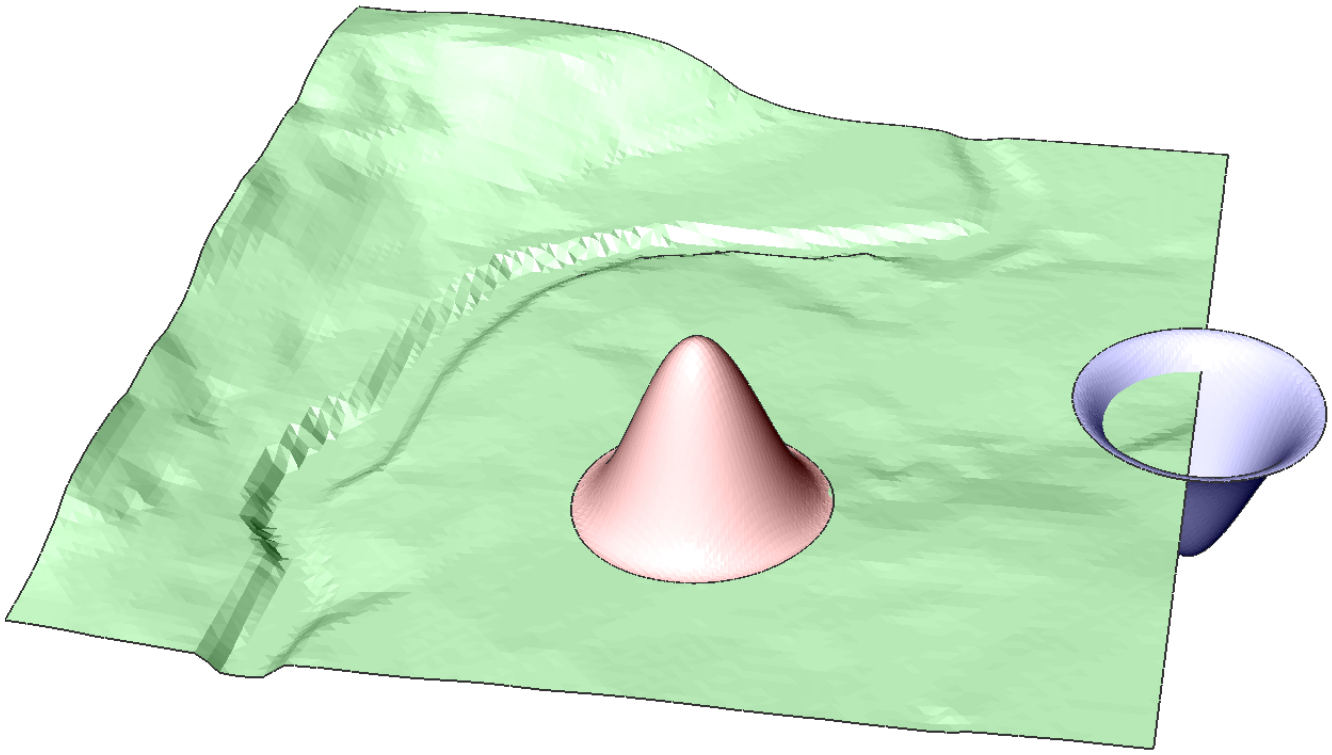


Figure 1.890

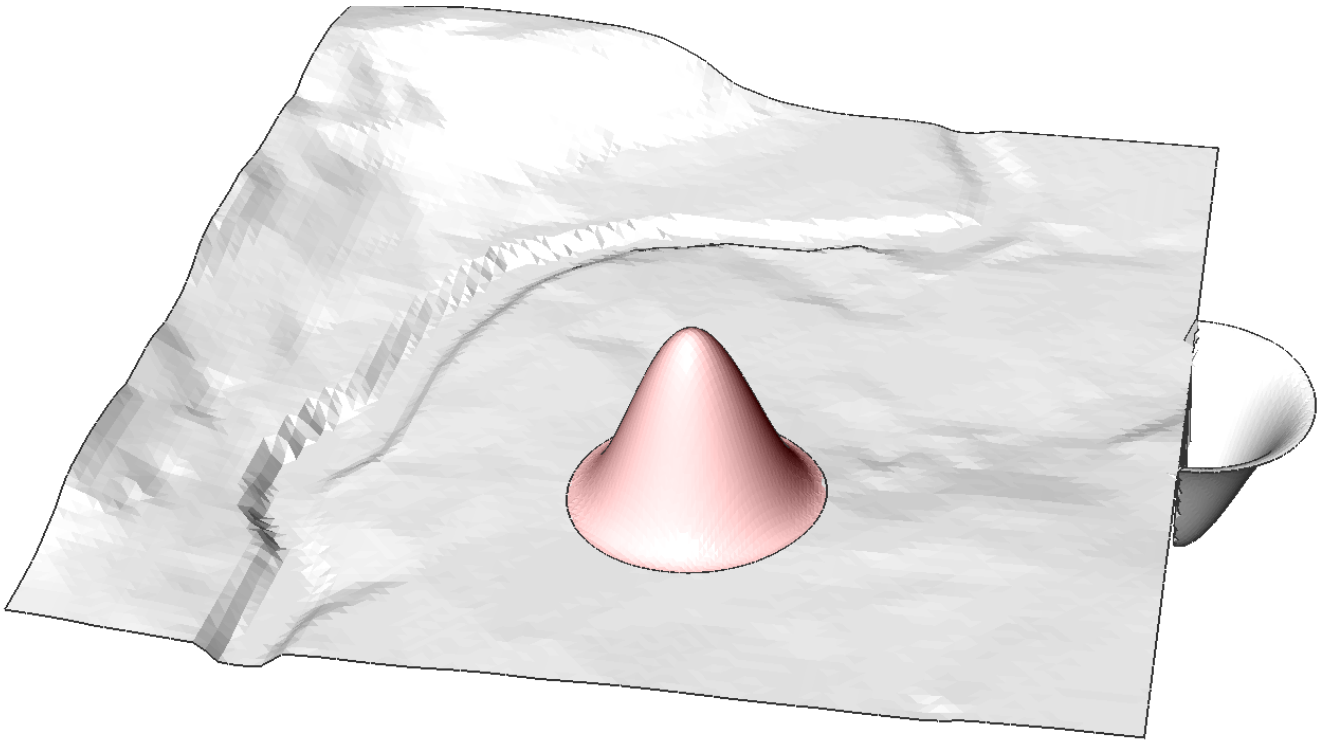

Figure 1.891

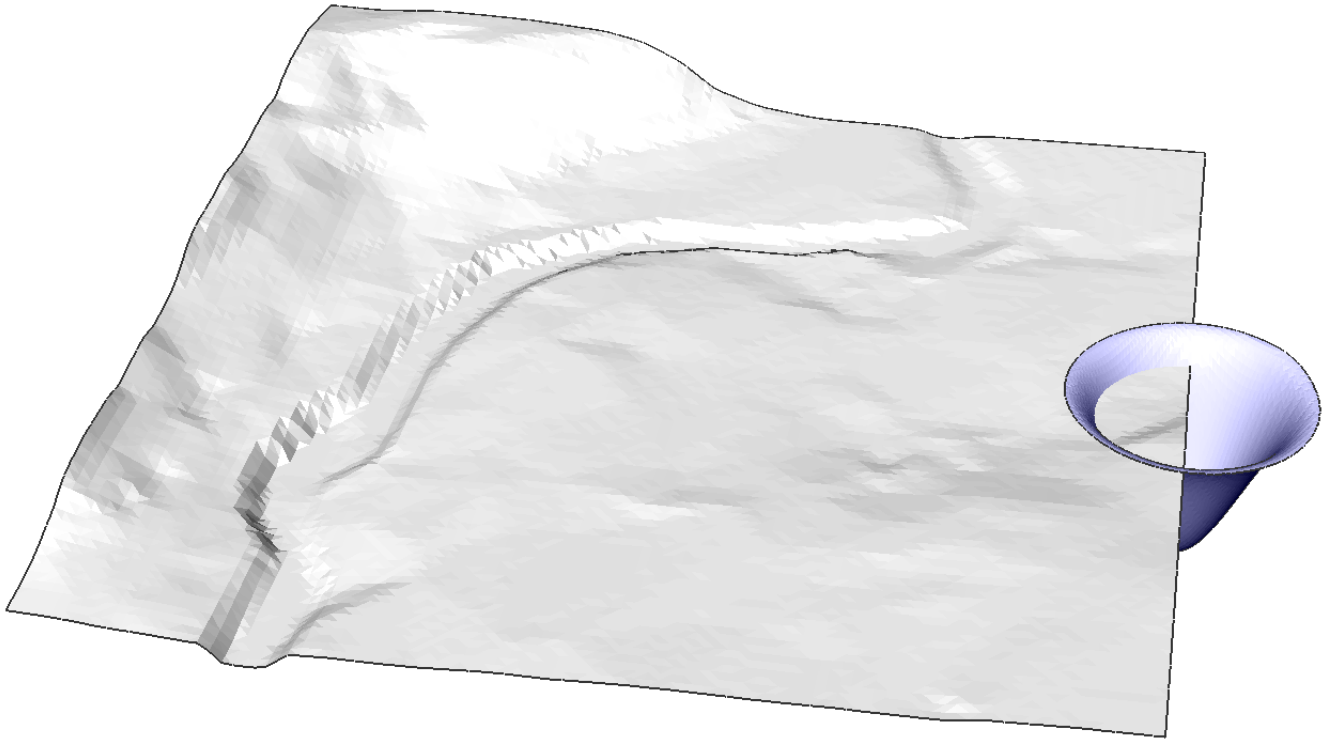

About TIN Modify

A TIN Surface can be modified by deforming or smoothening the surface. By deforming the surface, the TIN Surface is adjusted following the contours of an area defined by the user. By smoothening the surface, a selected area is leveled which is done by interpolation of this predefined area.  For more information about this command, visit the Command Reference article TinModify (6.29.23).

Procedure: Adding deformations on a TIN Surface using Radius

1. Select a TIN Surface and type TINModify in the command bar. **You are prompted:** Select modification method [Deform/Smoothen] <Deform>: (1.902 on page 1002)
2. Choose the desired modification. Type D to choose deformation. **You are prompted:** Enter radius or [specify Contour/select Entity/draw Polygon] <10>:
3. Choose a deformation radius. **You are prompted:** Specify location to deform or enter radius:
4. Click on the area to apply the deformation. **You are prompted:** Set elevation or select deformation method [Cosine/Sine] <Sine>:
5. Choose the elevation height. **You are prompted:** Modify existing or [create New/Existing] <Existing>:
6. Choose whether you want to add the adjustment as a new element or as a modification of the existing TIN Surface. (1.893 on the facing page) **Note:** By adding the modification as a new element, the structure of the original TIN Surface isn't modified but added as a new TIN surface. (1.894 on page 996)
7. Click on other areas to add new deformation or press Enter to end the command.

Figure 1.892

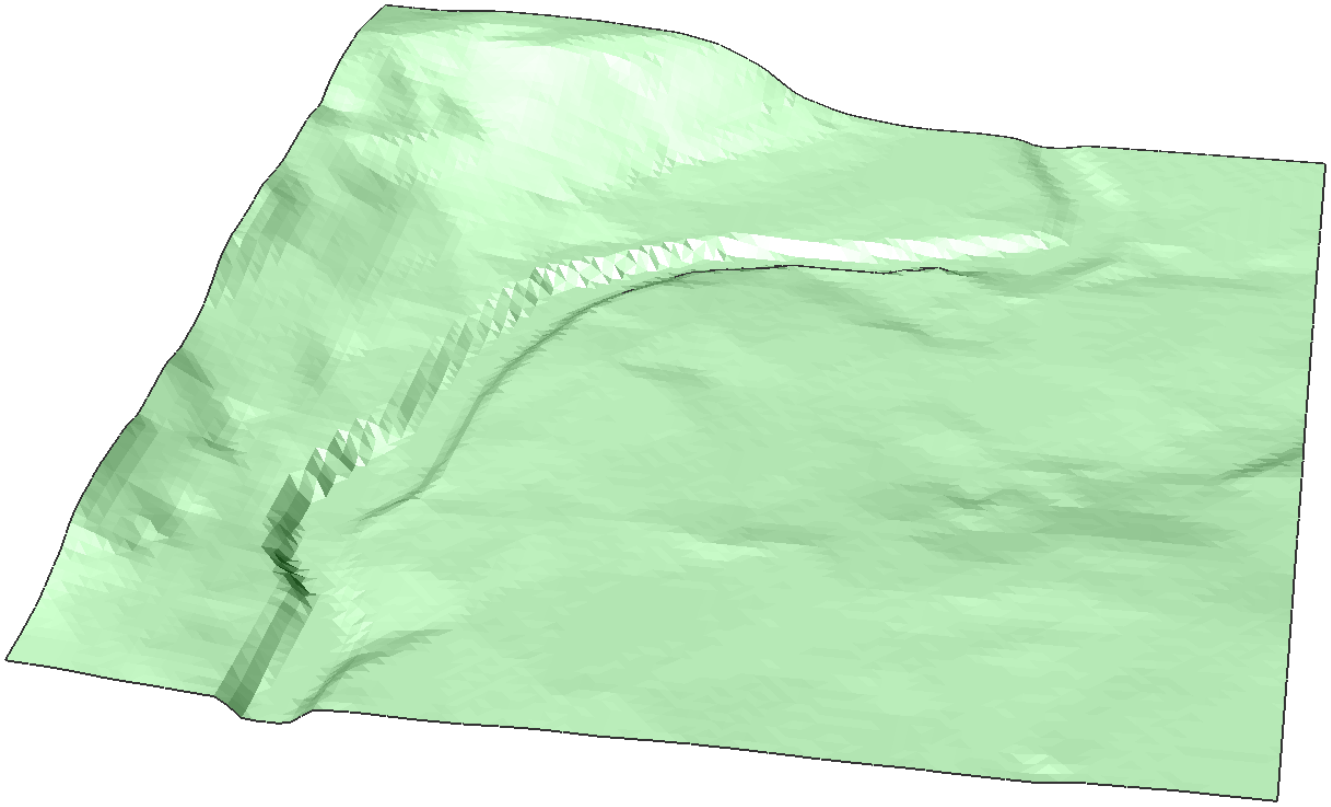

Figure 1.893

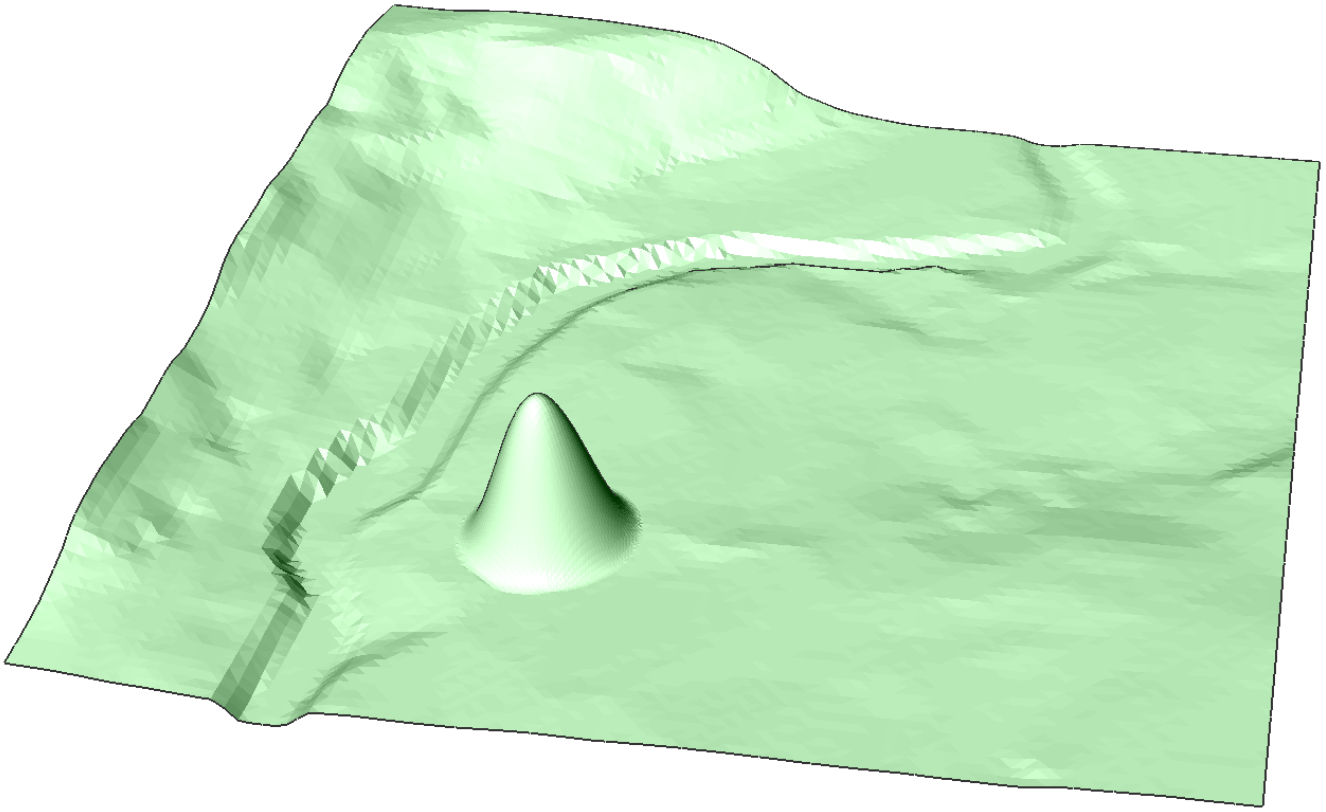

Figure 1.894

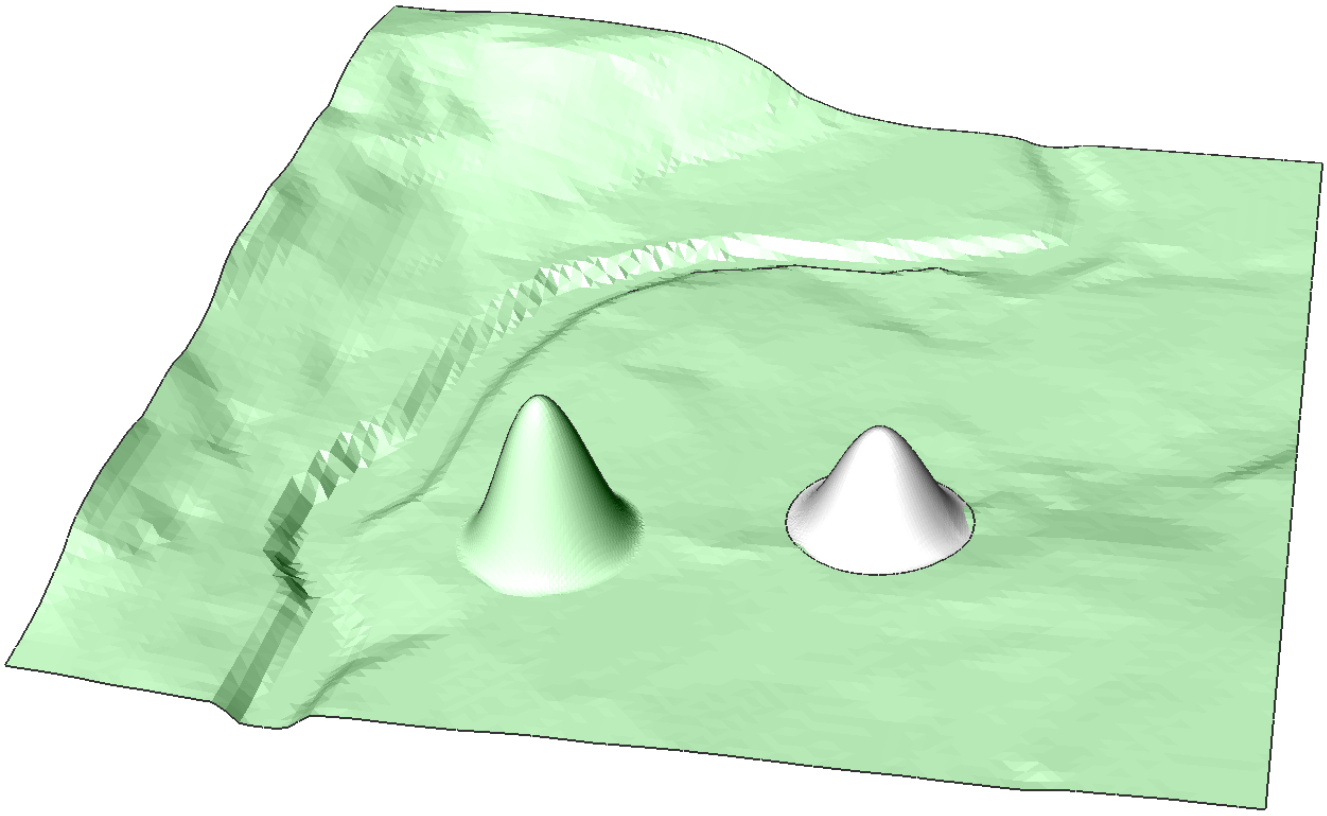

Procedure: Adding deformations on a TIN Surface using specify Contour

1. Select a TIN Surface and type TINModify in the command bar. **You are prompted:** Select modification method [Deform/Smoothen] <Deform>:
2. Choose the desired modification. Type D to choose deformation. **You are prompted:** Enter radius or [specify Contour/select Entity/draw Polygon] <10>:
3. Type C and hit Enter to choose to **specify Contour**. **You are prompted:** Specify contour location:
4. Pick a contour on the TIN Surface. **You are prompted:** Modify existing or [create New/Existing] <Existing>: (1.895 on the facing page)
5. Choose whether you want to add the adjustment as a new element or as a modification of the existing TIN Surface. Type N to create a new element for the adjustment.
6. Click on other contours to add new deformation or press Enter to end the command.
7. You have now created a new element on your TIN Surface. You can change its properties as you like. For example: change the color of the element. (1.896 on the next page)

Figure 1.895

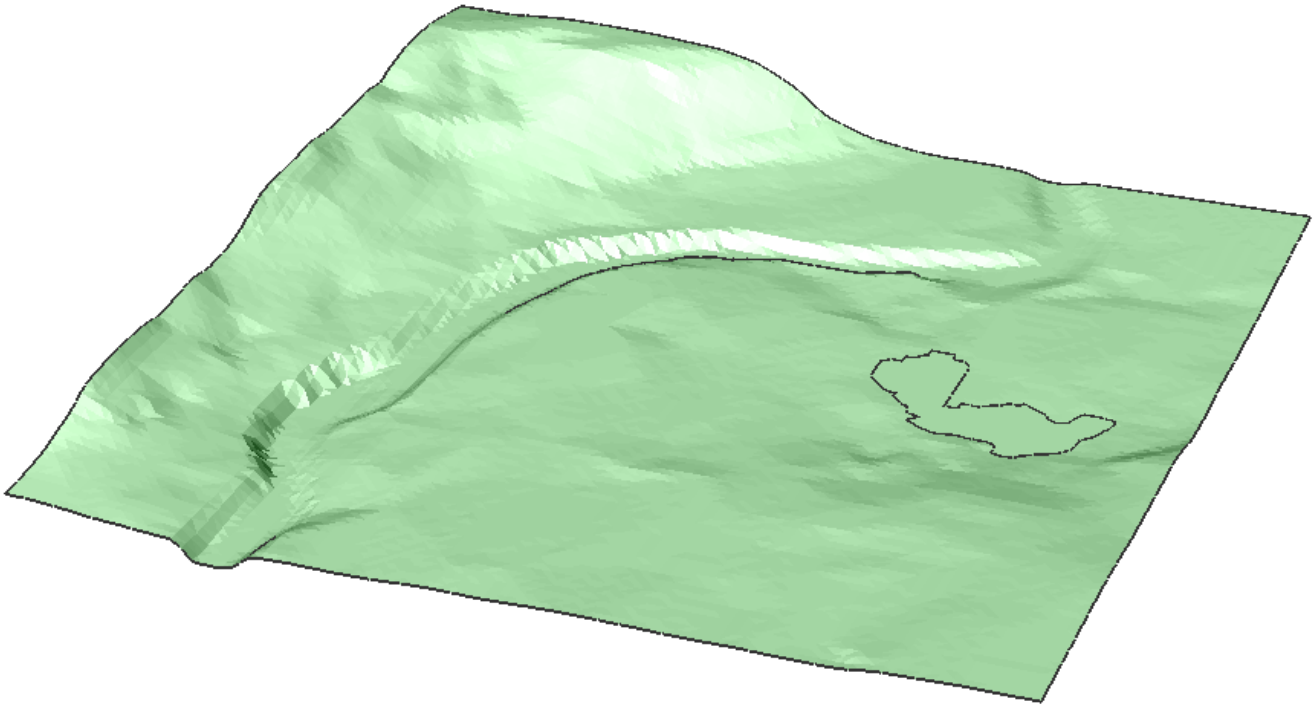

Figure 1.896

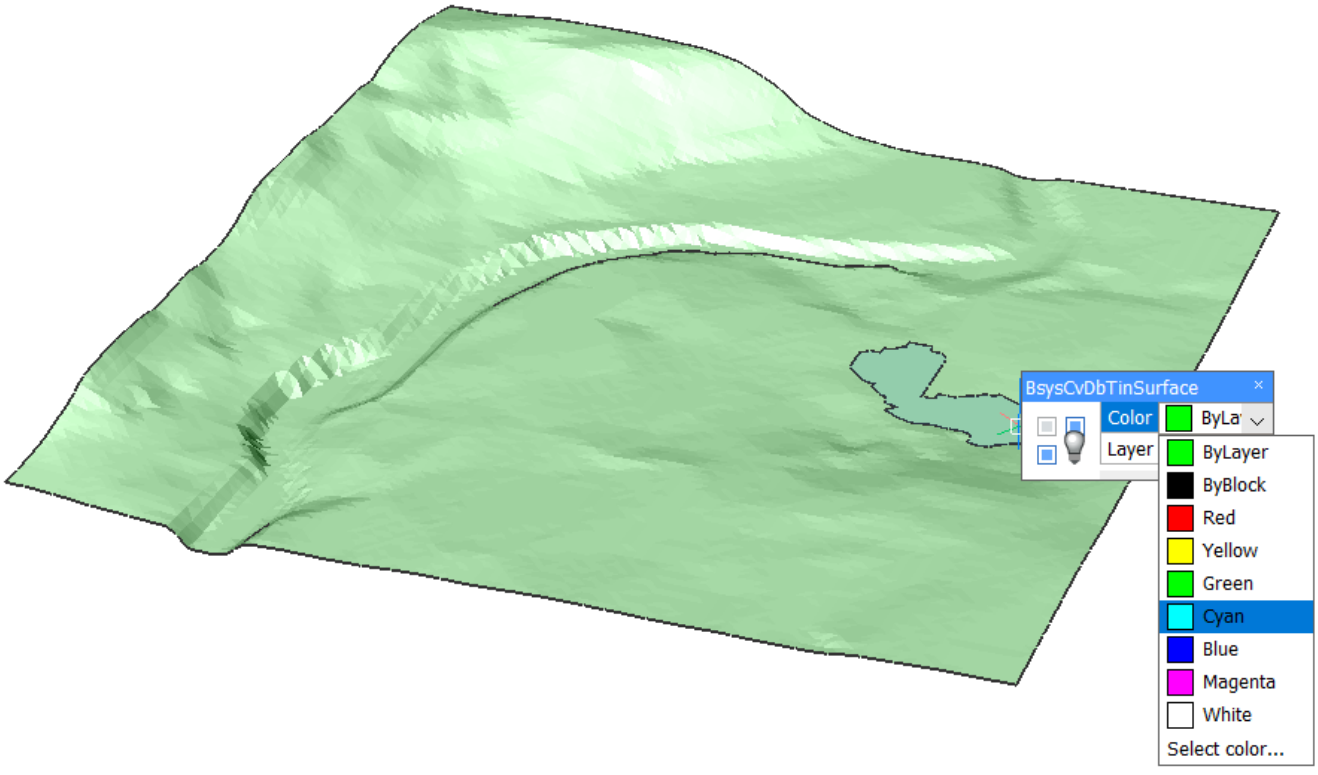

Procedure: Adding deformations on a TIN Surface using select Entity

1. Select a TIN Surface and type TINModify in the command bar. **You are prompted:** Select modification method [Deform/Smoothen] <Deform>:
2. Choose the desired modification. Type D to choose deformation. **You are prompted:** Enter radius or [specify Contour/select Entity/draw Polygon] <10>:
3. Type E and hit enter to choose **Select Entity**. **You are prompted:** Select closed entity:
4. Select a closed entity (e.g. Polyline). **You are prompted:** Enter offset distance:
5. Choose an offset distance. **You are prompted:** Specify location to deform: (1.897)
6. Click on the area to apply the deformation. **You are prompted:** Set elevation: (1.898 on the next page)
7. Choose the elevation height. **You are prompted:** Modify existing or [create New/Existing] <Existing>:(1.899 on the facing page)
8. Choose whether you want to add the adjustment as a new element or as a modification of the existing TIN Surface. Type **N** to create a New element for your adjustment. **You are prompted:** Specify location to deform:
9. Click on other areas to add new deformation or press Enter to end the command. You have now added a deformation using select entity.

Figure 1.897

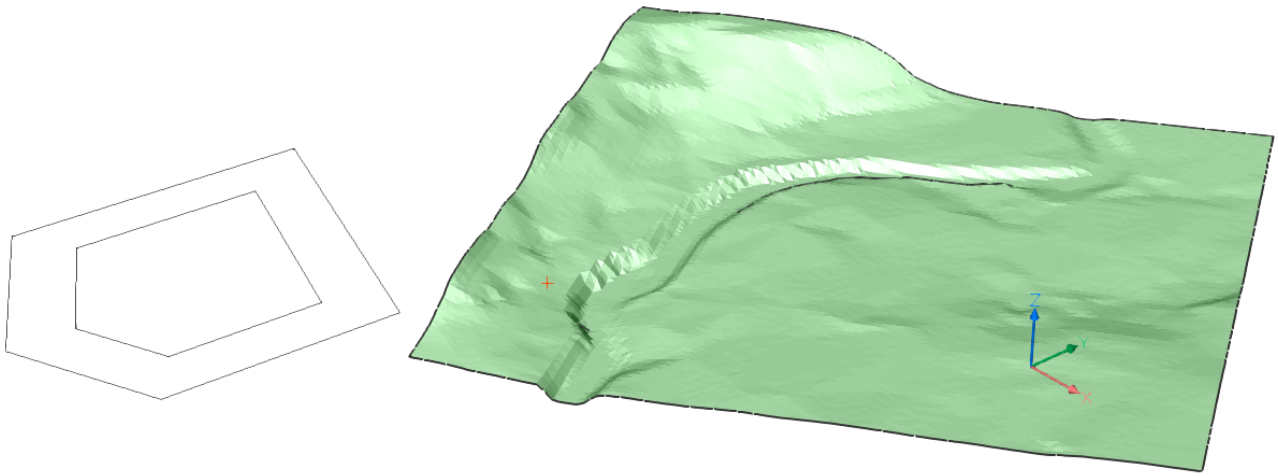

Figure 1.898

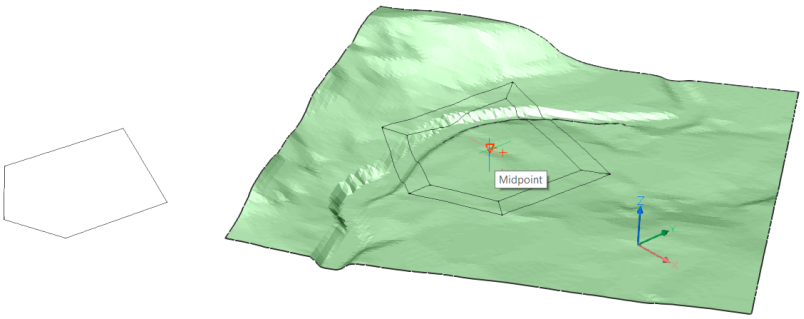

Figure 1.899

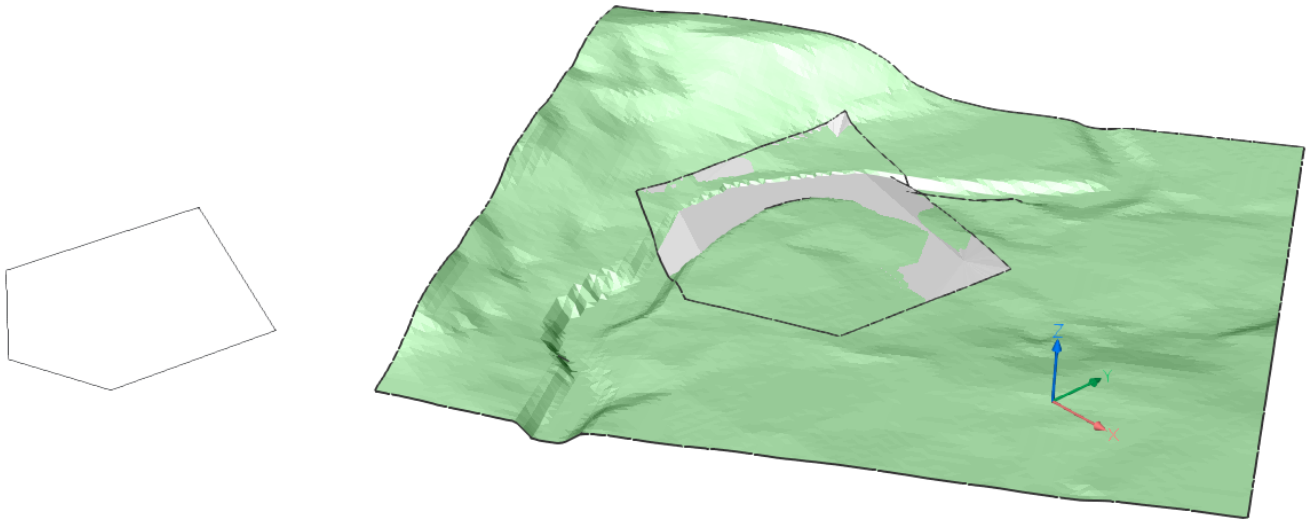

Procedure: Adding deformations on a TIN Surface using draw Polygon

1. Select a TIN Surface and type TINModify in the command bar. **You are prompted:** Select modification method [Deform/Smoothen] <Deform>:
2. Choose the desired modification. Type D to choose deformation. **You are prompted:** Enter radius or [specify Contour/select Entity/draw Polygon] <10>:
3. Type P and hit enter to choose to **draw Polygon**. **You are prompted:** Pick point [close] <close>:
4. Draw a polygon, hit enter to close the polygon. **You are prompted:** Enter offset distance:
5. Choose an offset distance. **You are prompted:** Specify location to deform: (1.900)
6. Click on the area to apply the deformation. **You are prompted:** Set elevation:
7. Choose the elevation height. **You are prompted:** Modify existing or [create New/Existing] <Existing>: (1.901 on the facing page)
8. Choose whether you want to add the adjustment as a new element or as a modification of the existing TIN Surface. Type N to create a new element for your adjustment. **You are prompted:** Specify location to deform:
9. Click on other areas to add new deformation or press Enter to end the command. You have now added a deformation using draw polygon.

Figure 1.900

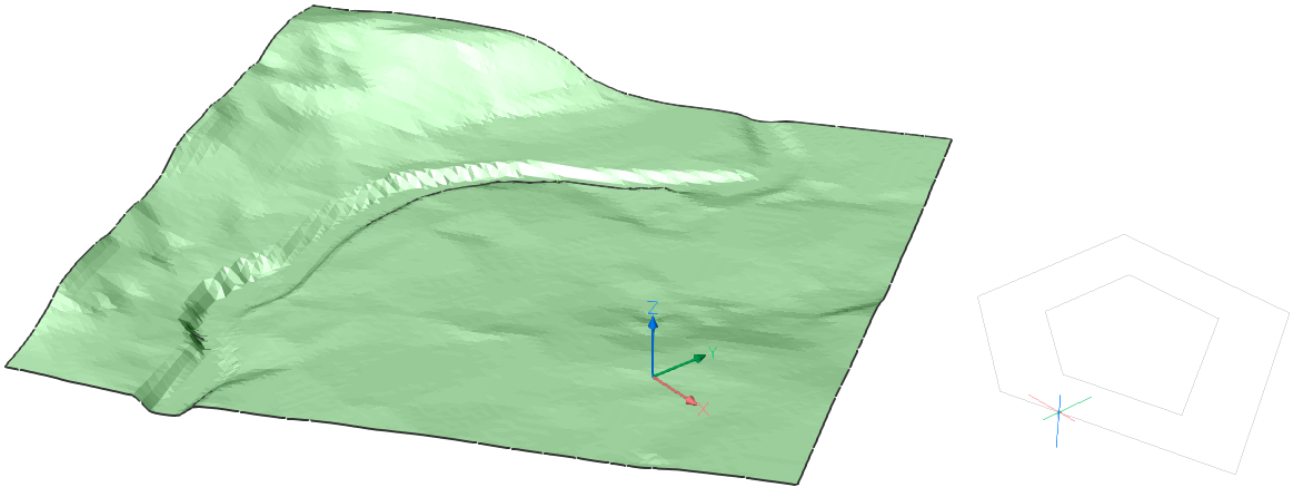

Figure 1.901

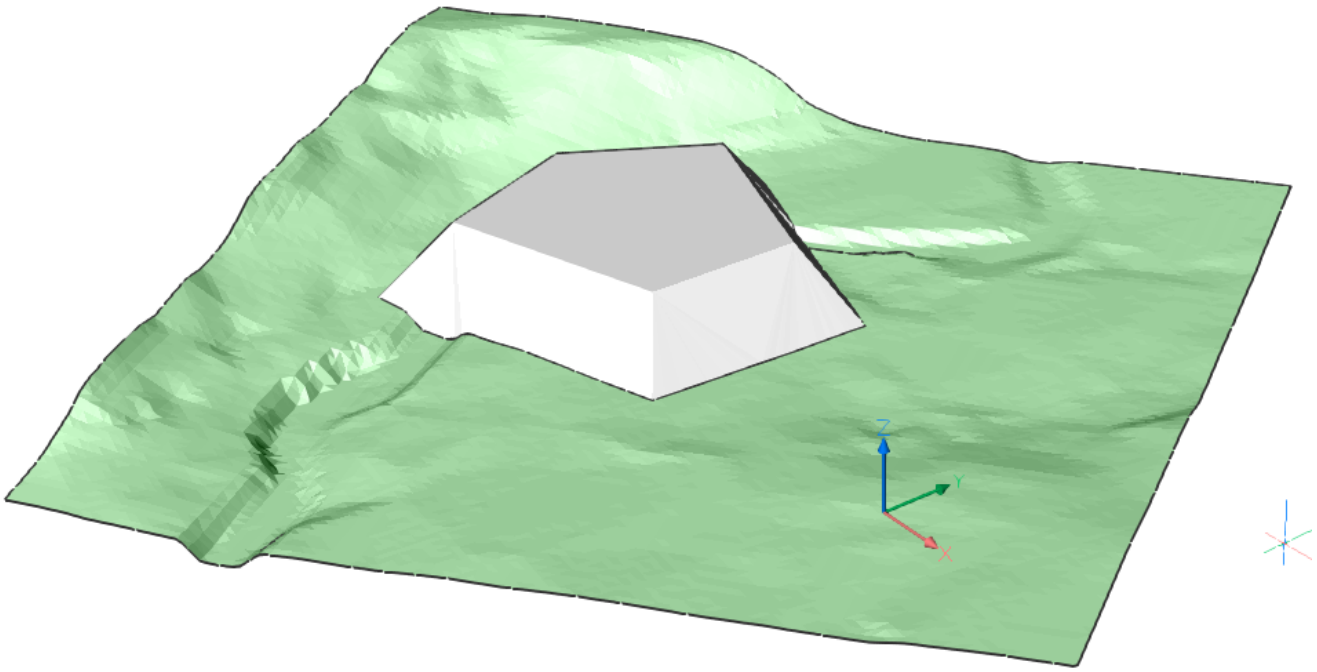

Procedure: Smoothening a TIN Surface

1. Select a TIN Surface and type TINModify in the command bar. **You are prompted:** Select modification method [Deform/Smoothen] <Deform>: (1.902 on the next page)
2. Choose the desired modification. Press S to choose Smoothen. **You are prompted:** Enter radius or [select Entity/draw Polygon] <10>:
3. Choose a radius. **You are prompted:** Specify location to deform or enter radius: **Note:** The procedure for **select Entity** or **draw Polygon** is analog to Adding deformations using select Entity (1.26.9) and Adding deformations using draw Polygon (1.26.9) starting from step 3.
4. A preview of the intervention is shown. (1.903 on the following page)
5. Click to execute the command. (1.904 on page 1003)
6. Click on other areas to smoothen or press Enter to end the command. (1.905 on page 1003)

1.26.10 Create and edit Alignments

Command: Alignment (6.4.5), AlignmentEdit (6.4.8), AlignmentView (6.4.9) **About:** In BricsCAD, alignments are created using the Alignment tool. Alignment is the route of the linear objects, defined as a combination of lines and curves that are viewed as one object. **Lesson objectives:** After completing this lesson, you will be able to:

- Create a horizontal alignment
- Create a vertical alignment
- Create a 3D alignment
- Create alignment from Civil 3D alignment
- Edit an alignment
- Create a vertical alignment view

About Alignment

Alignment is a reference system used to position linear objects, like roads, railways, pipe networks, streets, retaining walls and bridges, in space. An alignment is represented with horizontal, vertical 2D curves, resulting in 3D alignment.  For more information about this command, visit the Command Reference article Alignment (6.4.5). **Horizontal alignment** Horizontal alignment is a 2D curve that is needed to precisely position linear objects in a horizontal direction. It becomes defined by the Points of Intersection (PI). Horizontal alignment is the horizontal trace on your TIN Surface which is used to generate the height profile and vertical alignment. A single horizontal alignment can have multiple vertical alignments. The horizontal alignment will appear under the surface. (1.906 on the next page) **Vertical alignment** A vertical alignment is needed to precisely define a linear object in the vertical sense. The horizontal path defined by the horizontal alignment corresponds with a vertical profile of the TIN Surface. By defining Points of Vertical Intersection (PVI) on these vertical profiles of the target surfaces, the new 2D curve defines the vertical alignment. (1.907 on the facing page) **3D alignment** A 3D Alignment is a 3D polygonal curve defined by the horizontal and vertical alignment. (1.908 on page 1006)

Figure 1.906

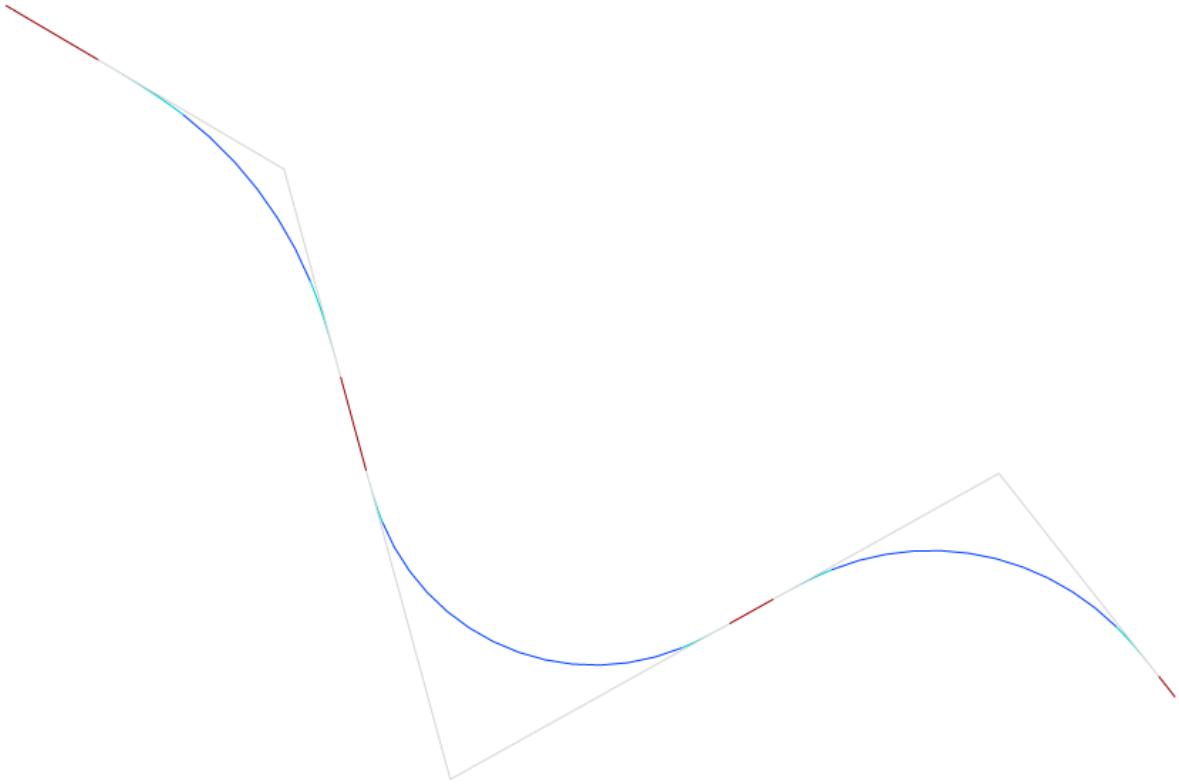

Figure 1.907

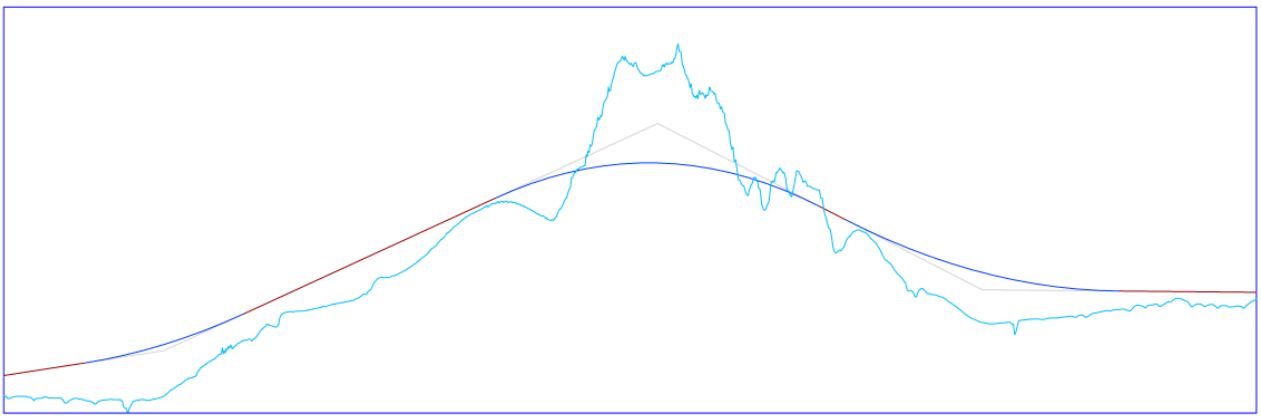

Figure 1.908

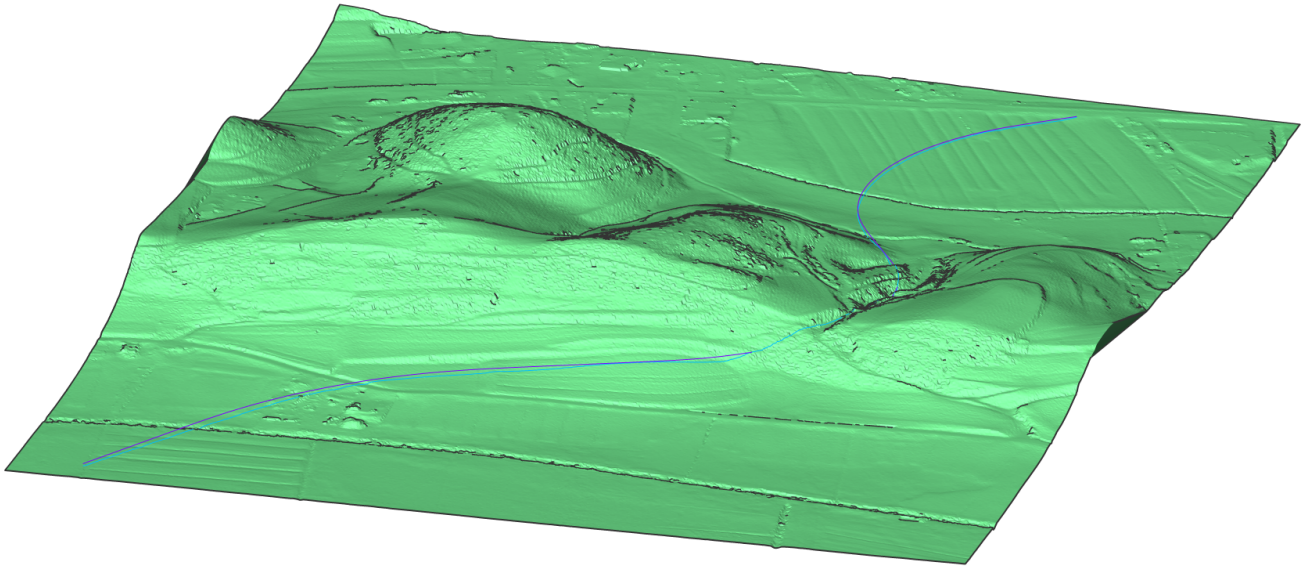
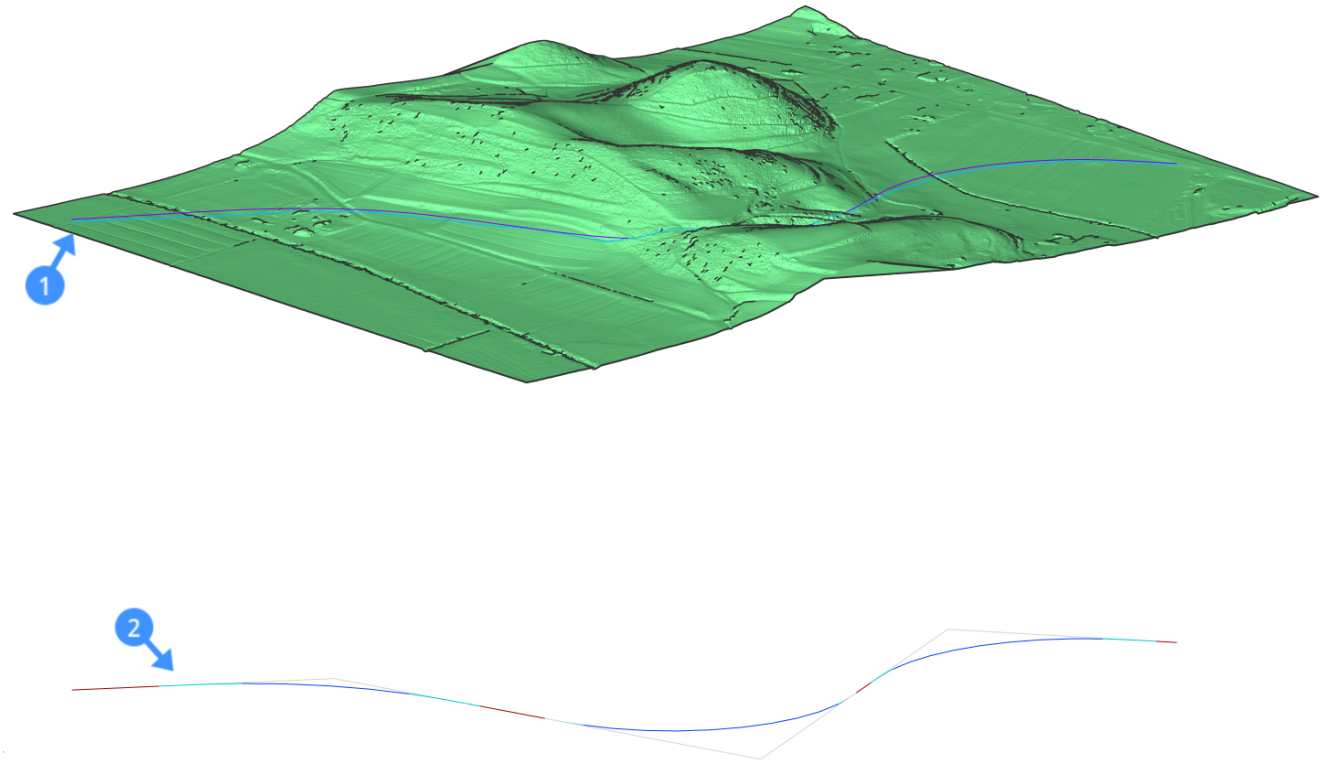


Procedure: Creating an Alignment

1. Open the drawing file that contains a TIN Surface.
2. Launch the **Alignment** command in the command line **Or** select Alignment in the Model tab from the Quad. **You are prompted:** Create [Horizontal/Vertical/3D/create from Civil 3d alignment] <Horizontal>: **(press enter or type "H" for horizontal alignment)**
3. **You are prompted:** Select TIN surface or [pick Pi point]: **(select the TIN Surface in the drawing)**
4. **You are prompted:** Pick horizontal alignment PI point [Undo]: **(pick the horizontal alignment PI points on your surface. Press enter when done.)** Your horizontal alignment (1) and 3D alignments (2) are now generated. (1.909 on the facing page)

Note: Three alignments are shown. The horizontal alignment on plane 0,0, light blue 3D alignment shows the projection of horizontal alignment on TIN Surface and the purple 3D alignment shows the design alignment that is automatically generated.

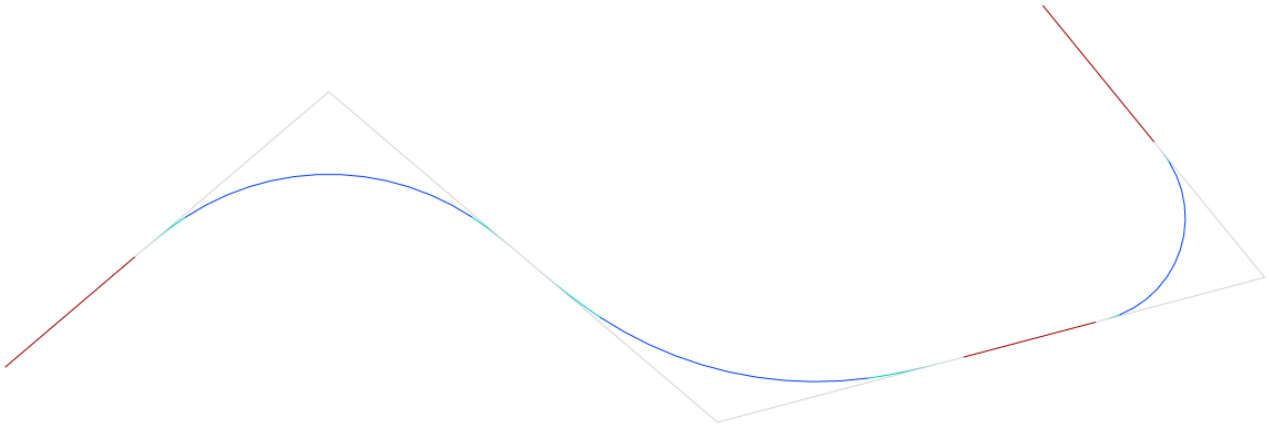
Figure 1.909



Procedure: Creating a Horizontal Alignment without 3D alignments

1. Open an empty drawing and launch the **Alignment** command in the command line **Or** select Alignment in the Model tab from the Quad. **You are prompted:** Create [Horizontal/Vertical/3D/create from Civil 3d alignment] <Horizontal>: **(press enter or type "H" for horizontal alignment)**
2. **You are prompted:** Select TIN surface or [pick Pi point]: **(type "P" to select pick Pi point)**
3. **You are prompted:** Pick horizontal alignment PI point [Undo]: **(pick the horizontal alignment PI points on your surface. Press enter when done.)** Your horizontal alignment is now generated. (1.910)

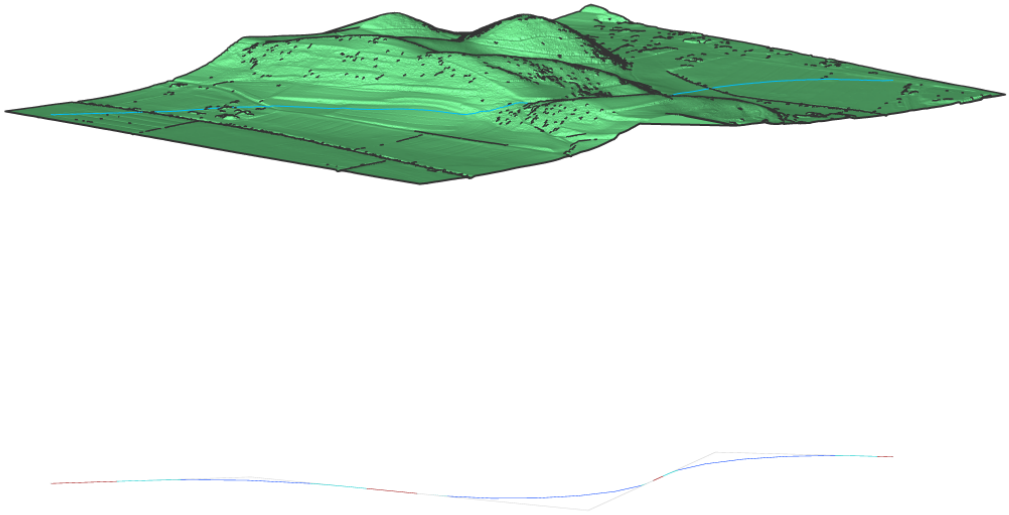
Figure 1.910



Procedure: Creating a Vertical Alignment

1. Open the drawing file that contains a TIN Surface, Horizontal Alignment and Vertical Alignment View. (1.911 on the facing page)
2. Launch the **Alignment** command in the command line **Or** select Alignment in the Model tab from the Quad. **You are prompted:** Create [Horizontal/Vertical/3D/create from Civil 3d alignment] <Horizontal>: **(press enter or type "V" for vertical alignment)**
3. **You are prompted:** Select vertical alignment View: **(select vertical alignment view in the drawing)** (1.912 on the next page)
4. **You are prompted:** Pick vertical alignment PVI point [Undo/Automatic 3d alignment]: **(pick the vertical alignment PVI points. Press enter when done. If you want to go one step back, use Undo. Automatic 3d alignment option generate design vertical alignment automatically).** Your design vertical alignment is now generated. (1.913 on page 1010)

Figure 1.911



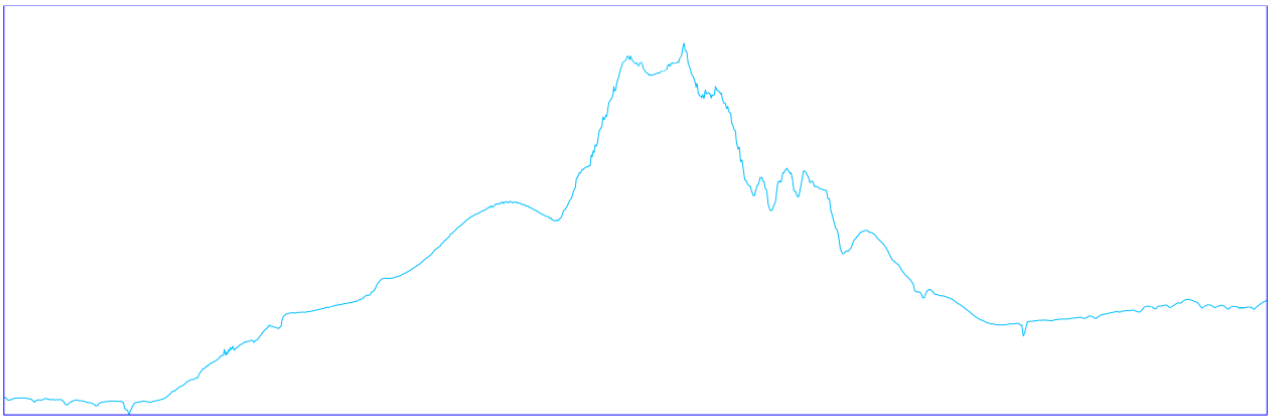


Figure 1.912

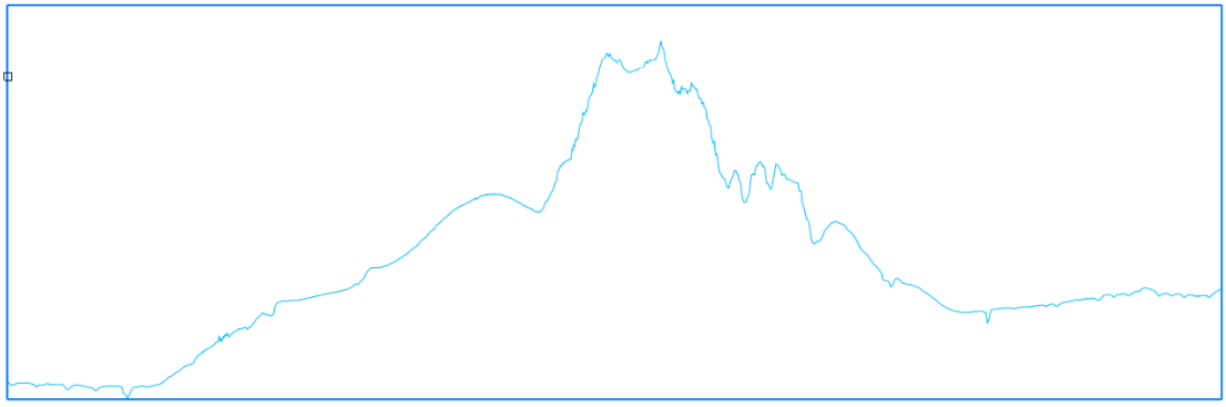

Figure 1.913

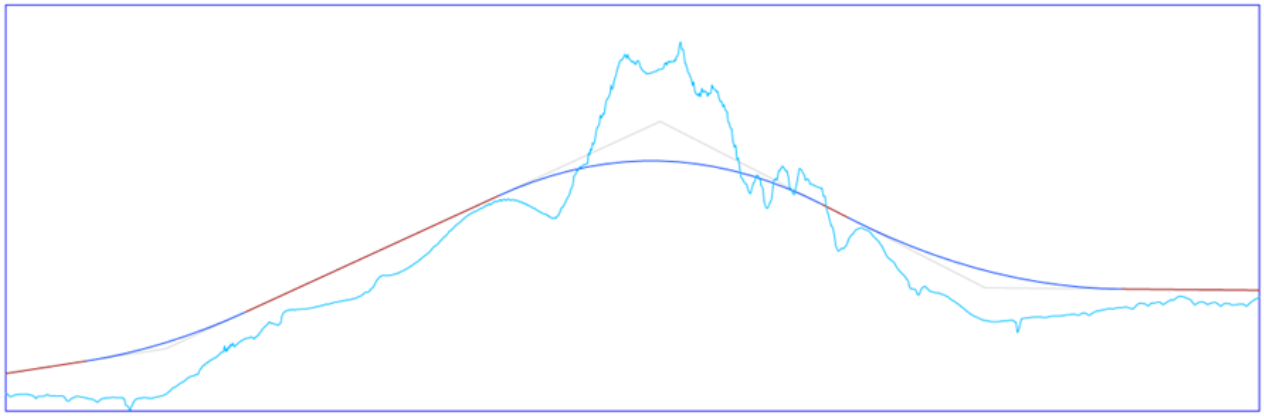

Procedure: Creating an Alignment from Civil 3D drawing

1. Open the drawing file from Civil 3D that contains a Civil 3D Alignment. (1.914 on the next page)
2. Launch the **Alignment** command in the command line **Or** select Alignment in the Model tab from the Quad. **You are prompted:** Create [Horizontal/Vertical/3D/create from Civil 3d alignment] <Horizontal>: **(type "C" for create from Civil 3d alignment)**
3. **You are prompted:** Select Civil 3D alignments or profiles: **(select the alignment in the drawing and press enter.)** Civil 3D alignment is converted to BricsCAD Alignment. (1.915 on page 1012)

About AlignmentEdit

After creating an alignment, you can continue a horizontal or vertical alignment, add or delete PV/PVI points or change the TIN Surface using the command **AlignmentEdit**. The 3D alignment will be updated automatically.

 For more information about this command, visit the Command Reference article AlignmentEdit (6.4.8).

Procedure: Continuing a horizontal alignment with AlignmentEdit

1. Draw a horizontal alignment following the steps from the procedure: Creating an alignment.
2. Type **AlignmentEdit** in the command bar.
   You are prompted: Select horizontal or vertical alignment
3. Select the horizontal alignment you want to edit.
   You are prompted: Pick a point to continue alignment or [Add Pi/Remove Pi/change Tin surface] (1.917 on the facing page)
4. Select points on your surface to continue your existing alignment. (1.918 on the next page)
5. Press enter when finished. You have now continued your horizontal alignment. The 3D alignment will be updated automatically. (1.919 on page 1016)

Figure 1.917

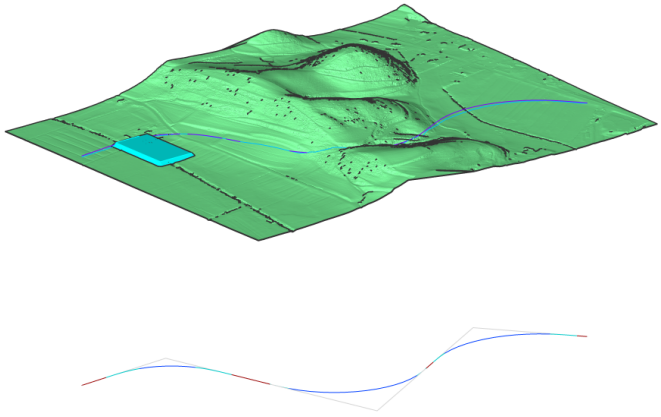
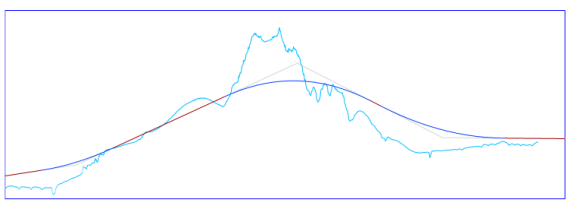
Procedure: Adding additional TIN Surface to Vertical alignment view

1. Open the drawing file that contains a TIN Surface, Alignments, Vertical Alignment View and grading. (1.924)

2. Launch the **AlignmentEdit** command in the command line **You are prompted:** Select horizontal or vertical alignment**: (select vertical alignment from the vertical alignment view)** (1.925 on the following page)

Figure 1.924





3. **You are prompted:** Pick point to continue vertical alignment or [Add Pvi/Remove Pvi/ change Tin surface]: **(type "T" to select change tin surface).**
4. **You are prompted:** Select TIN surface to add: **(select grading)** **(1.926 on the next page)** In the vertical alignment view, you can see an additional light blue line representing the grading object. (1.927 on the facing page)

Figure 1.925

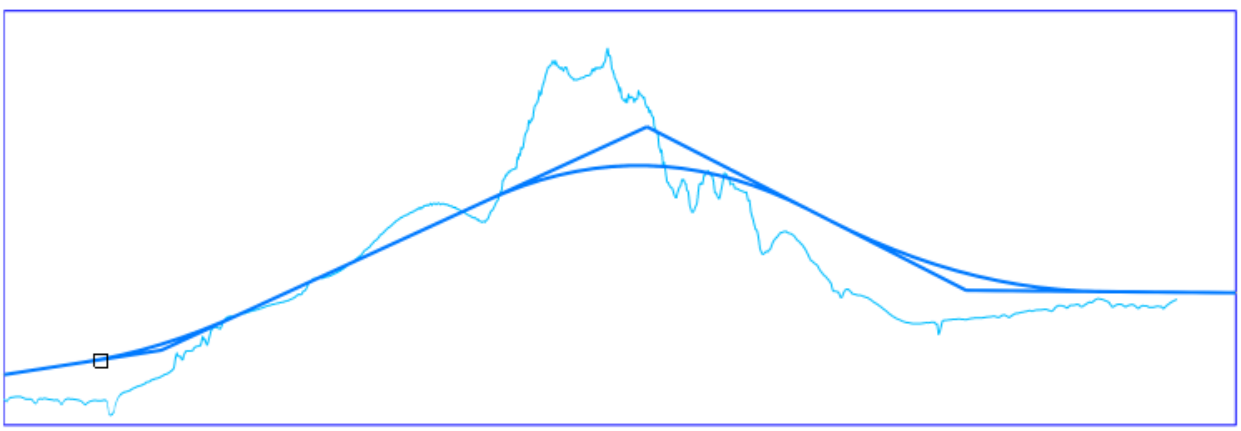


Figure 1.926

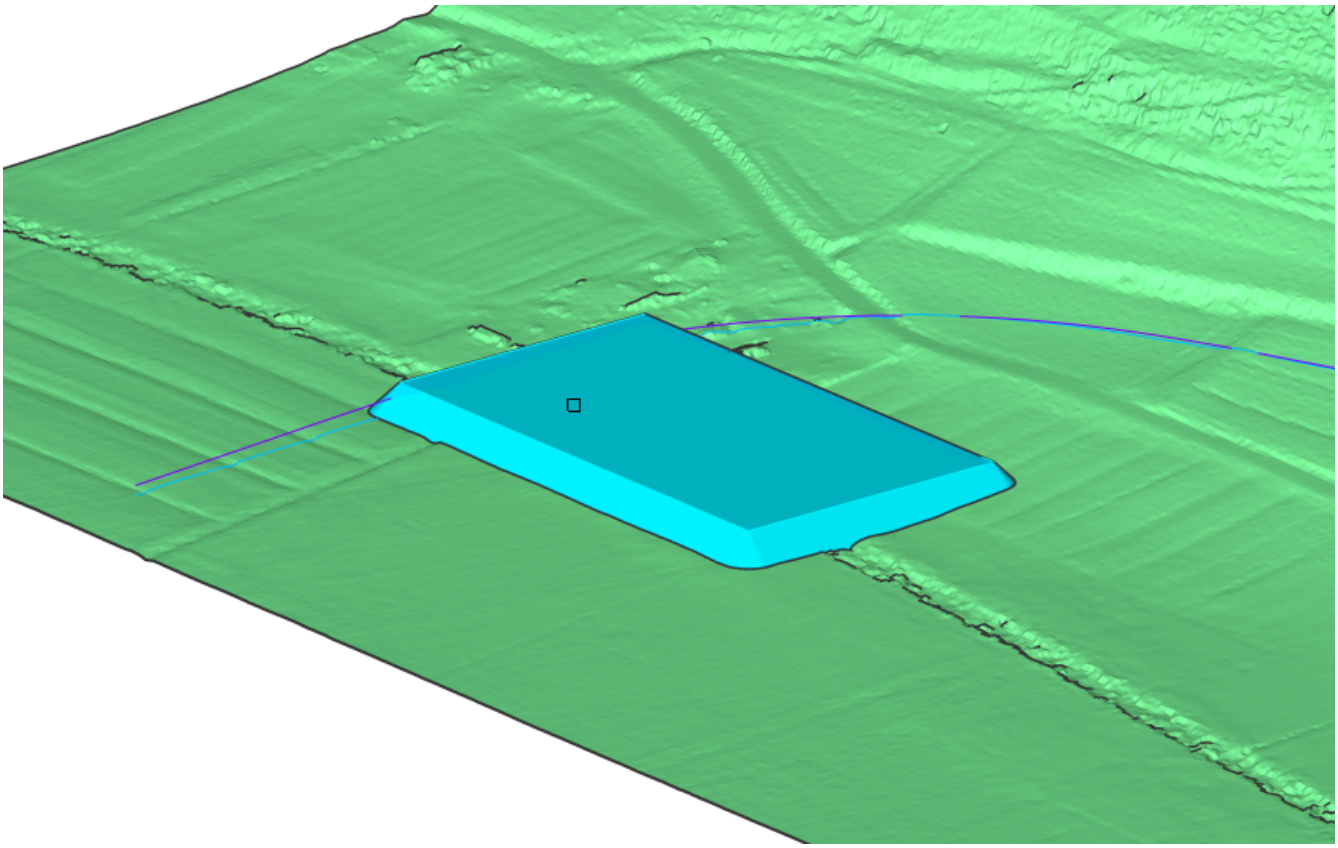

Figure 1.927

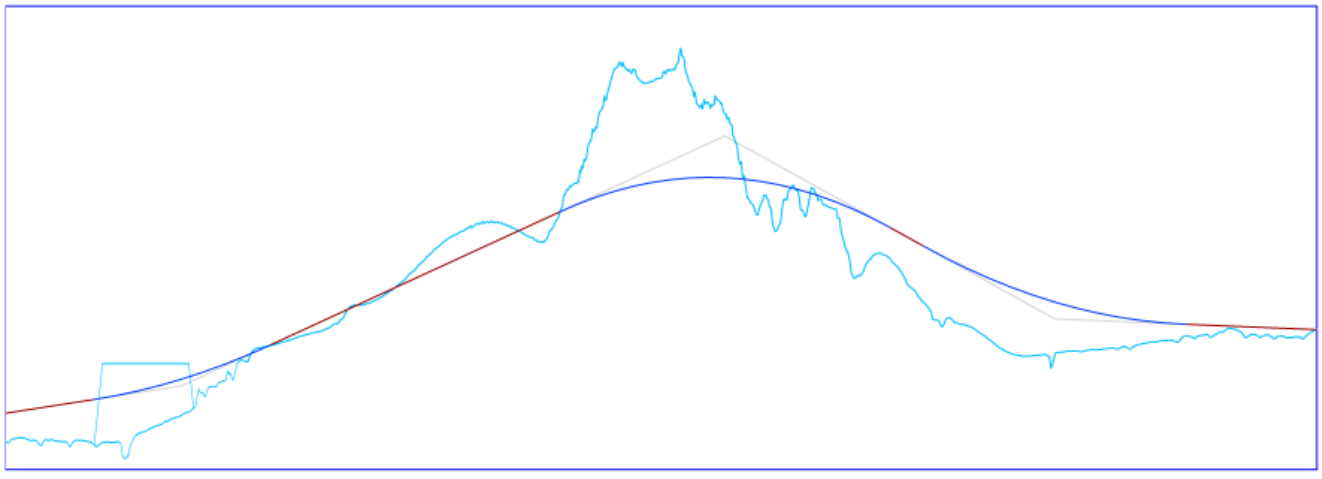

About Vertical Alignment View

The horizontal alignment creates a vertical section of the target surface. This 2D curve can be displayed in a separate viewport inside your model space using the command **Alignmentview**.  For more information about this command, visit the Command Reference article Alignmentview (6.4.9).

Procedure: Creating a Vertical Alignment View

1. Open the drawing file that contains a TIN Surface, Horizontal Alignment and 3D Alignments. (1.928 on the next page)
2. Launch the **AlignmentView** command in the command line **Or** select Vertical Alignment View command from the Civil panel of the ribbon. **You are prompted:** Select horizontal or 3d alignment: **(select horizontal or 3d alignment in the drawing)**
3. **You are prompted:** Pick origin point for vertical alignment view: **(pick a point as origin for the vertical alignment view) Your vertical alignment view is now generated.** (1.929 on the facing page)

Note: Two vertical alignments are shown. Light blue represents terrain line from the TIN Surface and another is design vertical alignment. The design vertical alignment has straight gradients and vertical curves and is created automatically based on the accuracy factor. You can change the accuracy factor from 1 to 100. When you choose 1 the accuracy will be the lowest. (1.930 on page 1024)

1.26.11 Analyzing TIN Surfaces

Command: TinVolume (6.29.24), TinWaterDrop (6.29.25) **About:** In BricsCAD, topographical surfaces created as a TIN Surface, can be analyzed using different tools. **Lesson objectives:** After completing this lesson, you will be able to:

- Create TIN Volumes to calculate and divide fill/cut volumes inside bounding area
- Create TIN Volumes to visualize the mass distribution
- Create Water drop paths

About TIN Volume

A TIN volume surface provides an exact difference between the base and comparison surfaces. Therefore, the Z-value of any point in the volume surface is precisely the difference between the Z of the comparison surface at that point and the base surface at that point. A TIN Volume Surface is drawn as a custom entity with additional fill/cut volume properties.  You can use TIN Volume to calculate or analyze earthworks:

- Calculate fill/cut volumes inside bounding area
- Draw zero contours which divide fill and cut areas
- Visualize the mass distribution

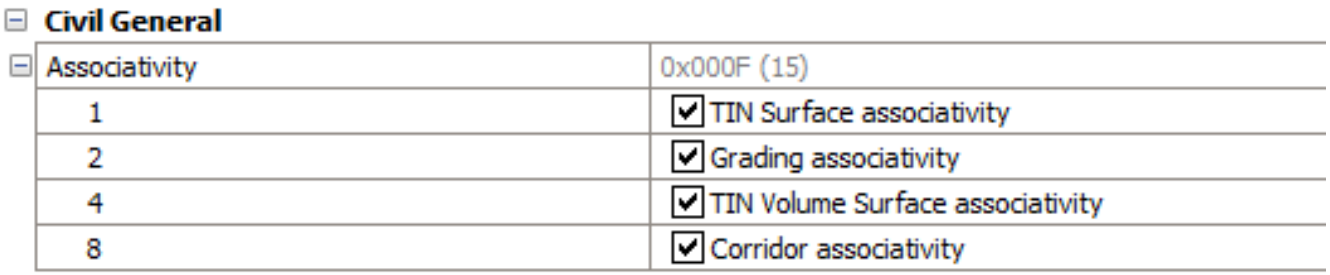
For more information about this command, visit the Command Reference article TinVolume (6.29.24).

Procedure: Creating a TIN Volume

In the following procedures, a TIN Volume is created. Choose whether the volume is associative or not. If associativity is turned on: TIN Volume Surface is automatically updated if base or comparison surfaces are changed. To disable or enable the associativity, follow these steps:

1. Type **Settings** in the commandline and hit Enter.
2. Go to Civil > Civil General > Associativity.
3. Check or uncheck **TIN Volume Surface Associativity**. (1.931)

Figure 1.931



Creating a TIN Volume using a comparison TIN Surface

1. Type TINVolume in the commandline. **You are prompted:** Select base TIN surface:
2. Choose a base surface. In this example, we choose the green TIN surface as the base surface. **You are prompted:** Select comparison TIN surface or [Elevation]: (1.932 on the next page)
3. Choose a comparison surface. In this example, we choose the red grading as the comparison surface **You are prompted:** Select bounding area.
4. Select a bounding area as the area to apply the operation **Or** press Enter. The outer boundary of the surface will be used as a boundary.
5. The TIN Volume appears under the TIN Surface (1.933 on the facing page)

Figure 1.932

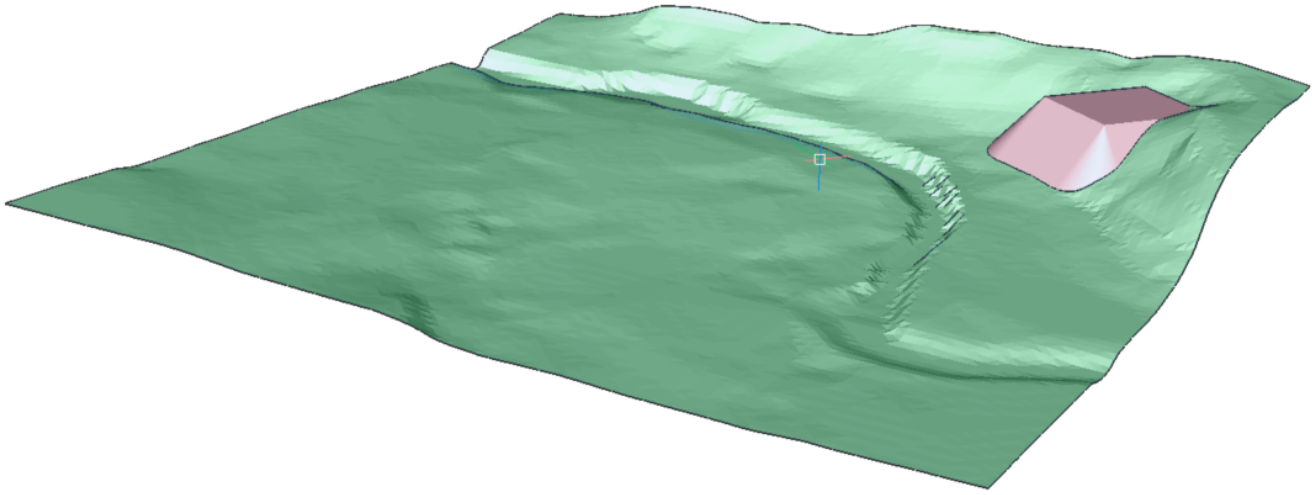


Figure 1.933

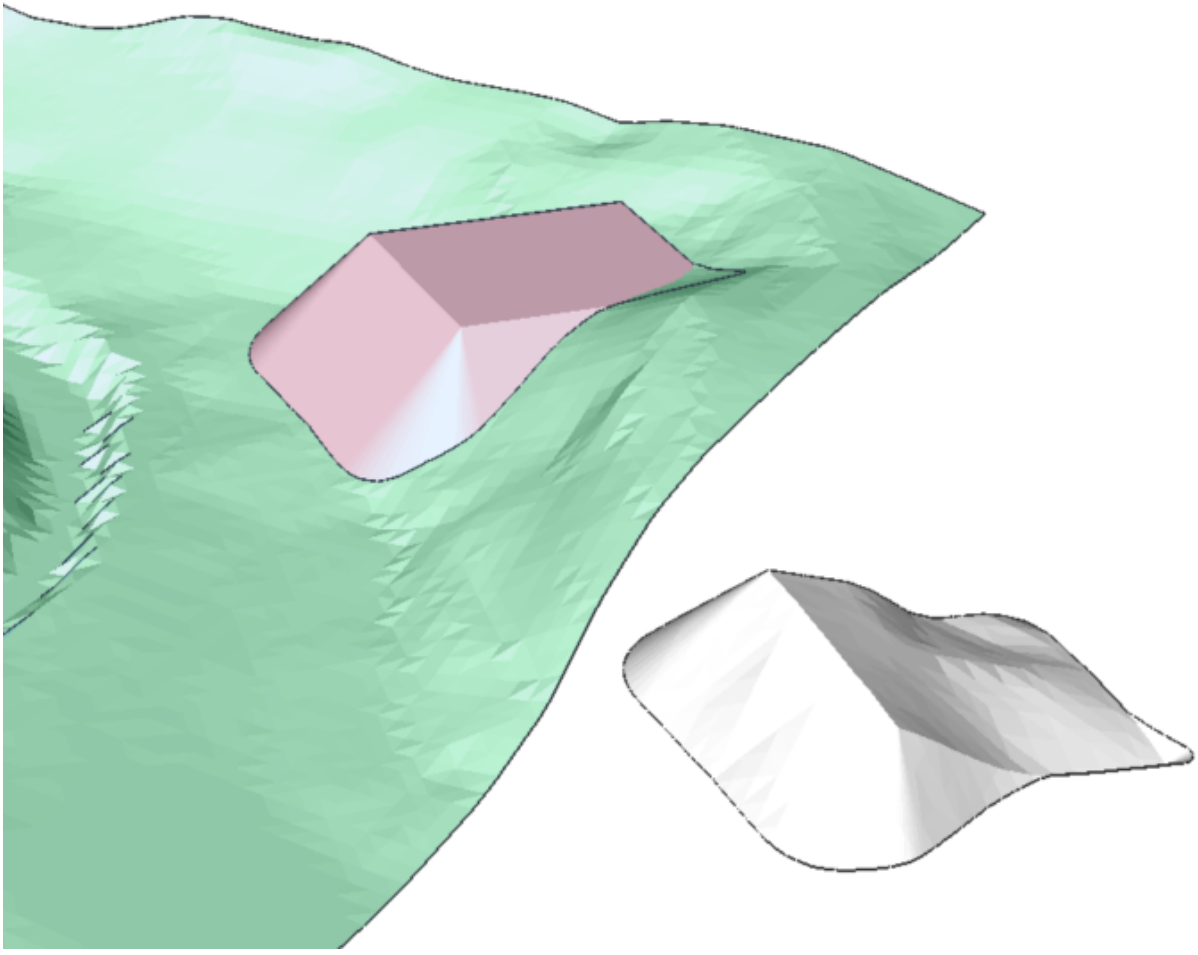
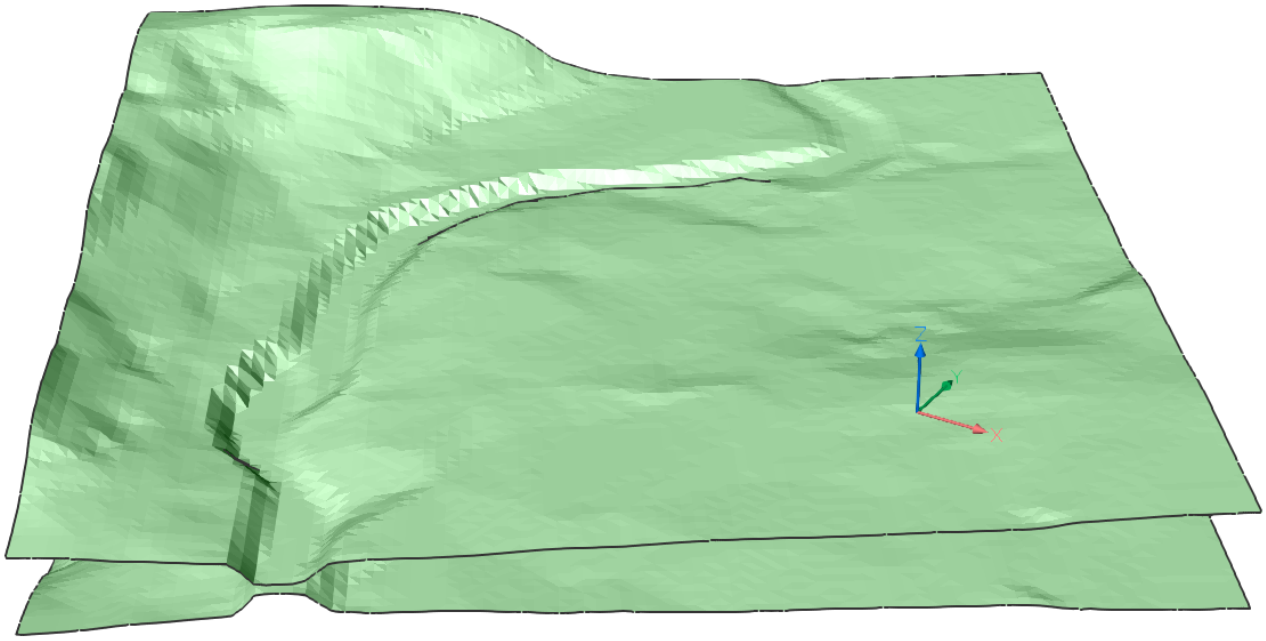


Creating a TIN Volume using Elevation

1. Type TINVolume in the command bar. **You are prompted:** Select base TIN surface:
2. Choose a base surface. **You are prompted:** Select comparison TIN surface or [Elevation]:
3. Type E and hit enter. **You are prompted:** Enter elevation <0>:
4. Choose the elevation height. **You are prompted:** Select bounding area.
5. Select a bounding area as the area to apply the operation **Or** press Enter. The outer boundary of the surface will be used as a boundary. (1.934 on the next page)

Figure 1.934



About TIN Water Drop

The TINWaterDrop command creates water drop paths in real-time by moving the cursor over a TIN Surface. Water path is created as a 3D polyline in the current position if you click the mouse button. For more information about this command, visit the Command Reference article TinWaterDrop (6.29.25).

Procedure: Creating a water drop path

1. Type **TinWaterDrop** in the commandline and hit Enter.
2. Select the TIN surface.
3. Move the cursor over the surface, a line representing the drop path is shown in real-time. **Note:** It would be better if the water drop path is colored so it could be seen more clear. To do so you should change the current layer to another color, eg. red. (1.935 on the following page)
4. Left-click with the mouse to create a 3D polyline of the water drop path. (1.936 on the next page)

1.26.12 Modeling a Corridor

Command: Corridor (6.9.41), CorridorTemplate (6.9.43), CorridorTemplateElement (6.9.44), CorridorEdit (6.9.42), CorridorExtract (6.9.52) **Overview**: In BricsCAD, Corridors that follow a certain 3D alignment are created using the Corridor tool. **Lesson Objectives** After completing this lesson, you will be able to:

- Create a Corridor based on a Corridor Template (closed polylines in 2D) that follow a chosen 3D alignment
- Edit a Corridor horizontally and vertically
- Extract a mesh or a solid from a Corridor

About Corridor

A Corridor is a BricsCAD Civil drawing object used for modeling three-dimensional linear objects such as roads, railway, retaining walls, and bridges. It principally consists of a 3D alignment of the linear object and its typical cross-section – which is called "Corridor Template" in BricsCAD. The **Corridor** command enables you to create a

Corridor ,based on a Corridor Template, that follows a 3D alignment on a certain topographical surface. For more information about this command, visit the Command Reference article Corridor (6.9.41).

About Corridor Template

In BricsCAD, a **Corridor Template** entity represents the framework to append a collection of template element objects. The command enables you to create a corridor template entity and append one or more template elements

to it. For more information about this command, visit the Command Reference article CorridorTemplate (6.9.43).

Procedure: Creating a template of road cross-section with asphalt layer and left and right kerb

1. Open the drawing file that contains a collection of template elements. (1.937)
2. Launch the CorridorTemplate command in the command line. **You are prompted:** Pick point to create corridor template or [Add template element]: **(pick point in the drawing where you want to create corridor template)** (1.938 on the next page)
3. Lunch the CorridorTemplate command in the command line. **You are prompted:** Pick point to create corridor template or [Add template element]: **(type "A")**
4. **You are prompted:** Select corridor template element that you wish to append: **(select template element representing asphalt layer)**
5. **You are prompted:** Select corridor template or template element point: **(select template)** (1.939 on page 1033)
6. Lunch the CorridorTemplate command in the command line. **You are prompted:** Pick point to create corridor template or [Add template element]: **(type "A")**

Figure 1.937

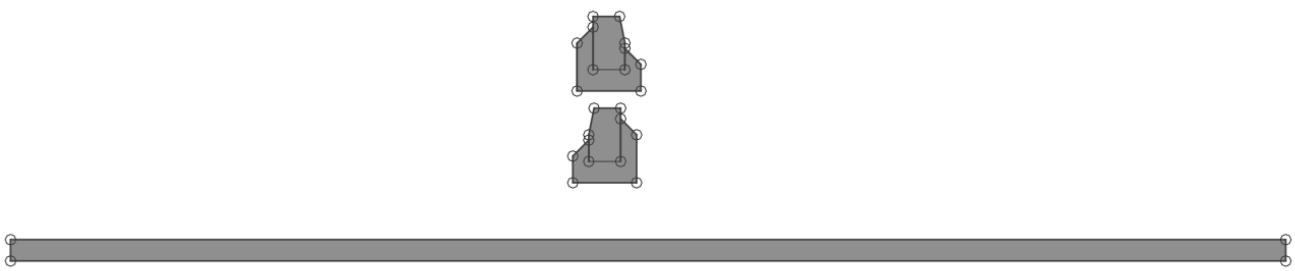

Figure 1.938

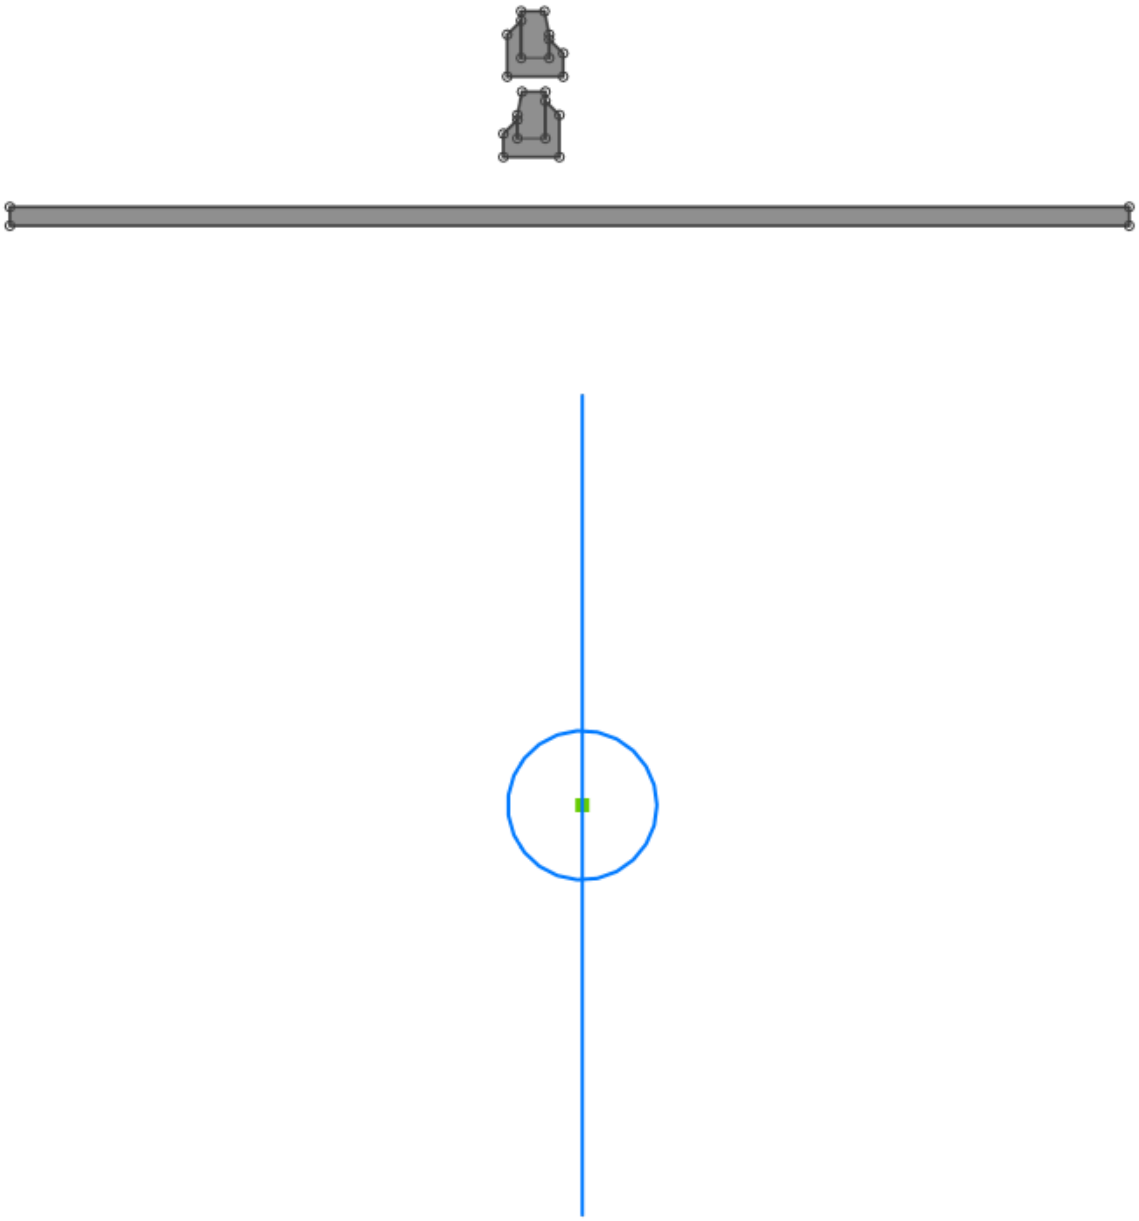

Figure 1.939

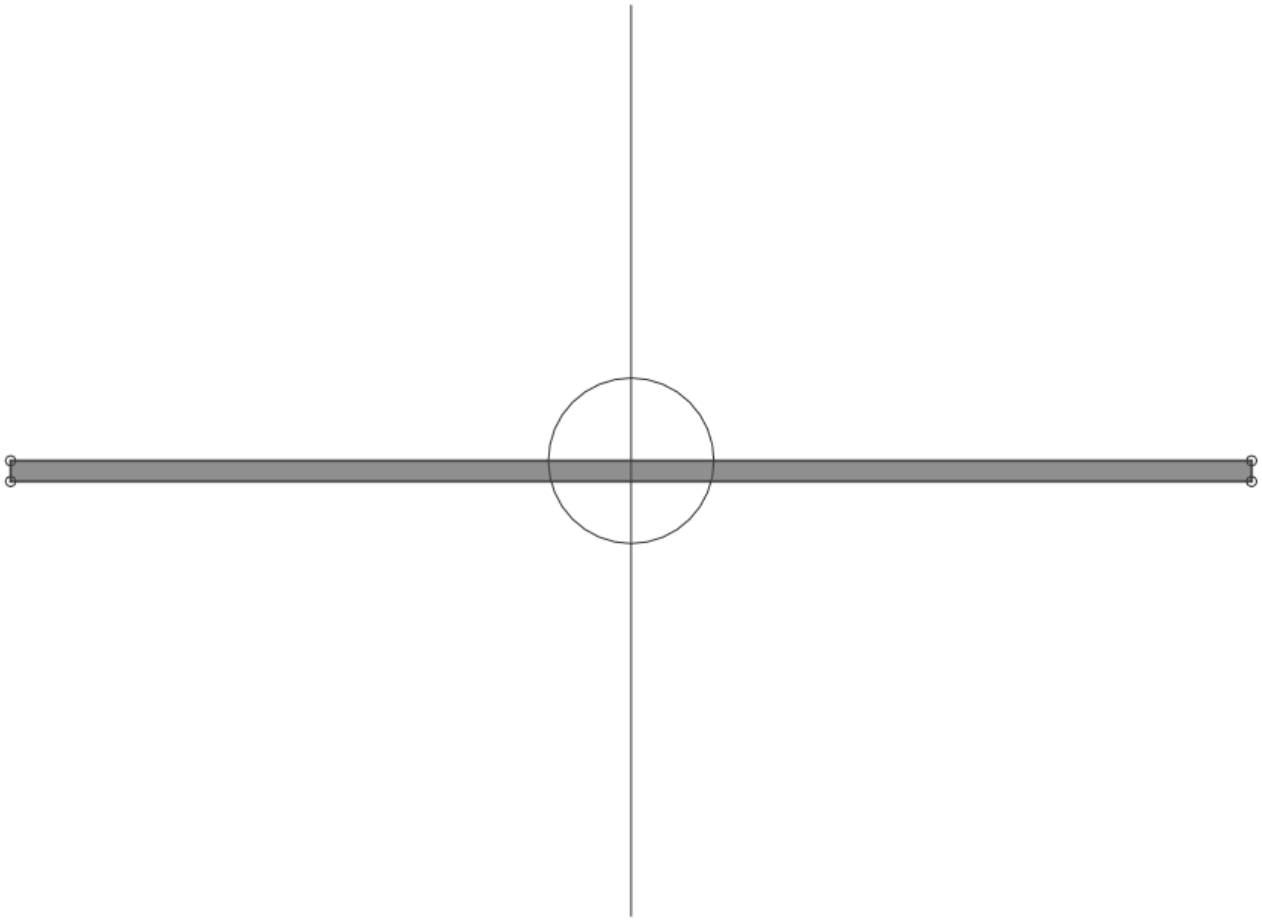

Figure 1.940

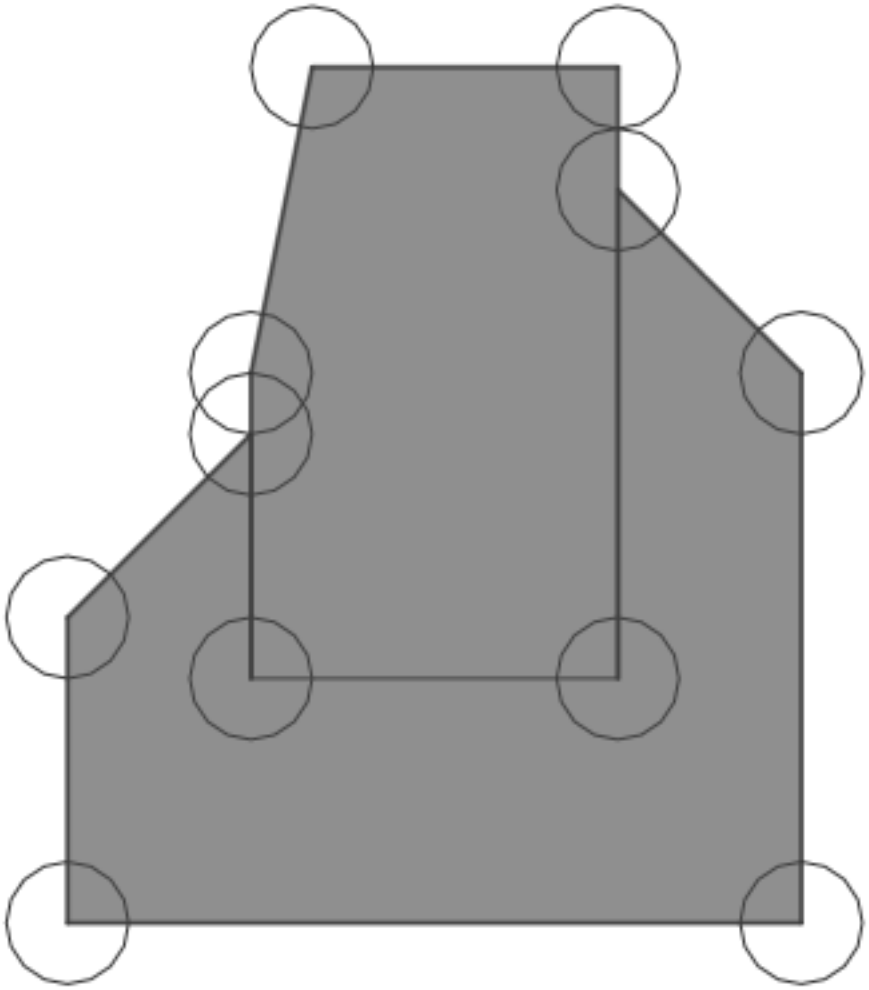

7. **You are prompted: Select corridor template or template element point: (select right top template element point of asphalt layer)** (1.940)
8. **You are prompted:** Select corridor template element that you wish to append: **(select template element representing right kerb)** (1.941 on the facing page) (1.942 on the next page)
9. To add a kerb to the left side, repeat the steps described in points 6, 7, 8. Just remind you to select left kerb and left top point of asphalt layer this time. (1.943 on page 1036)

Figure 1.941

Figure 1.942

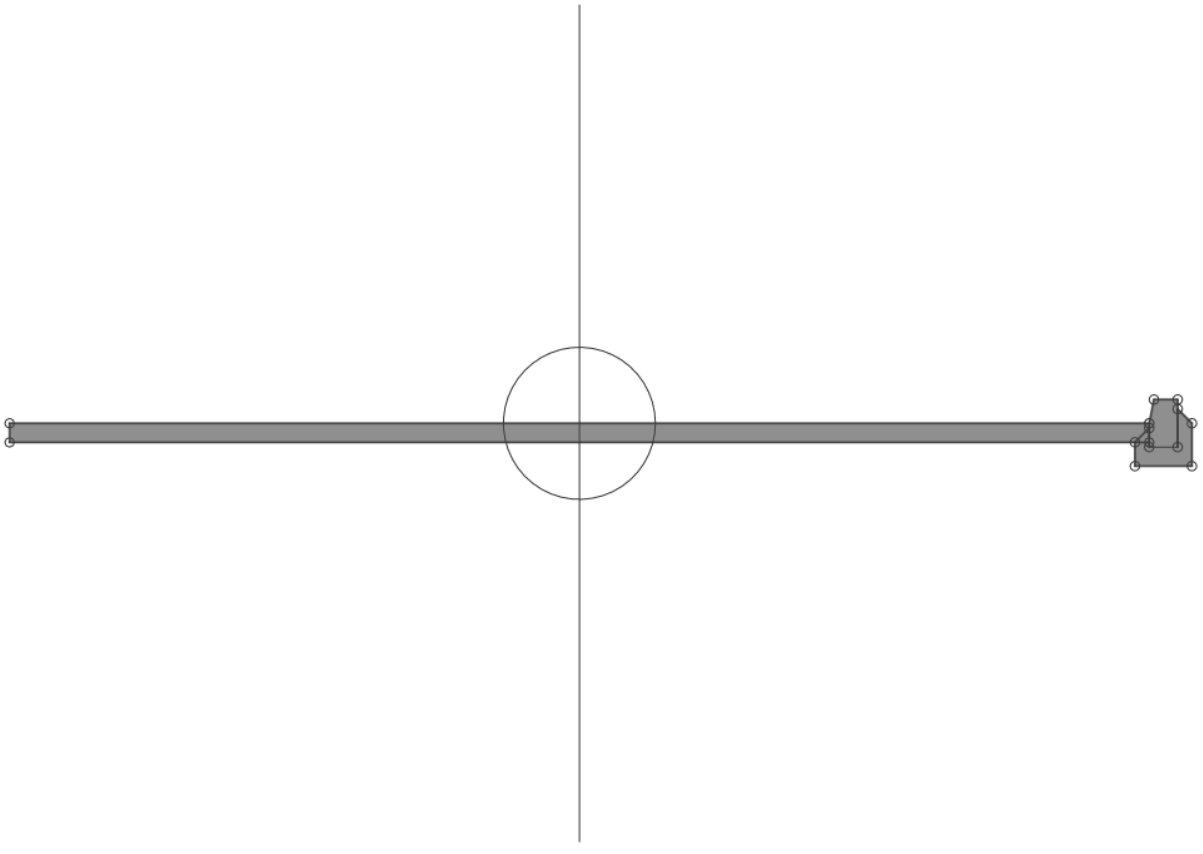

Figure 1.943

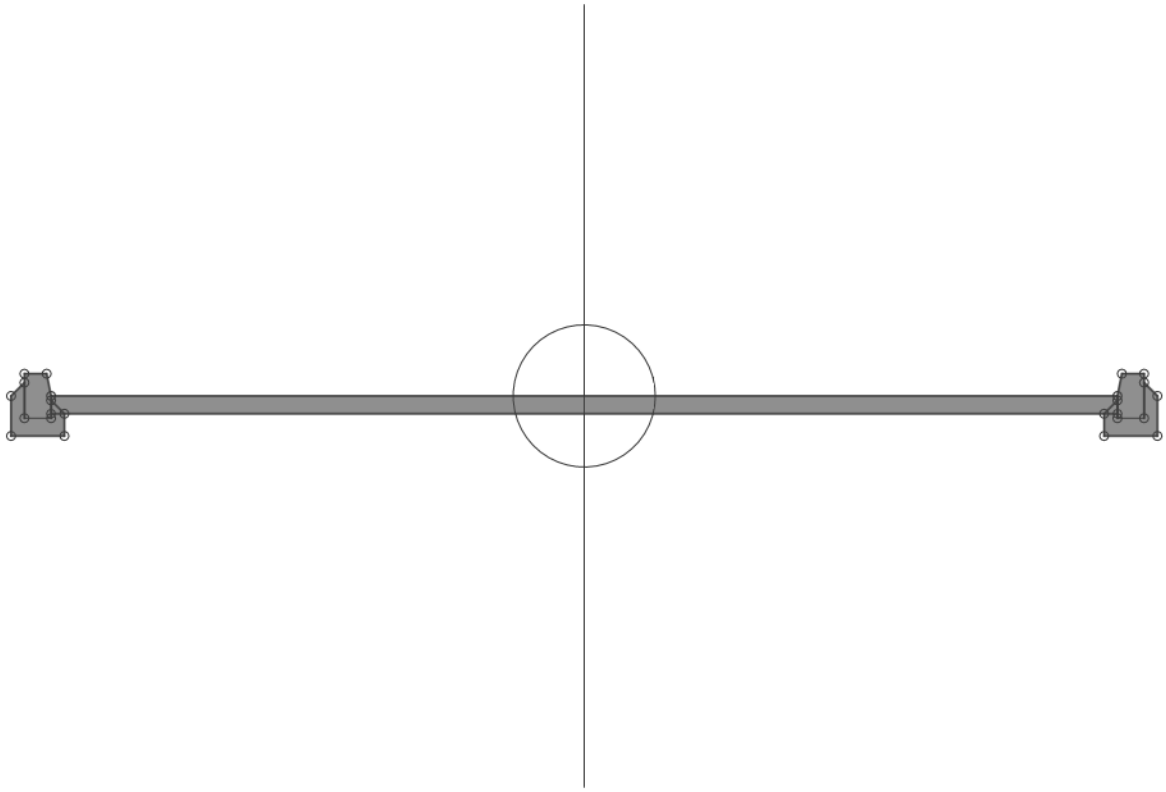

About Corridor Template Element

In BricsCAD, a Corridor Template Element entity defines the geometry of a component used in a corridor section. The Template Element command enables you to create a corridor template element from closed polylines.

For more information about this command, visit the Command Reference article CorridorTemplateElement (6.9.44).

Procedure: Creating a template element of kerb

1. Open the empty drawing.
2. Draw closed polylines representing road kerb (1.944 on the next page)
3. Launch the CorridorTemplateElement command in the command line. **You are prompted:** Select polylines representing the corridor template element: **(select polylines representing kerb)**
4. **You are prompted:** Pick corridor template element base point: **(pick one of the polyline vertex, the base point position can also be changed afterward)** (1.945 on page 1038)

Figure 1.944

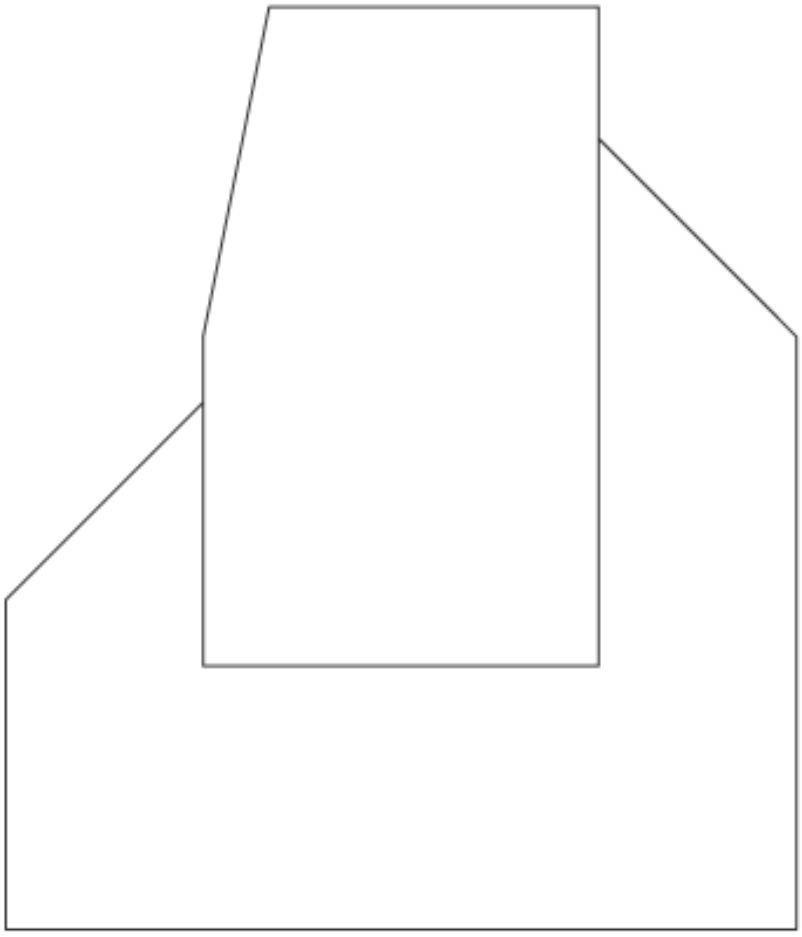

Figure 1.945

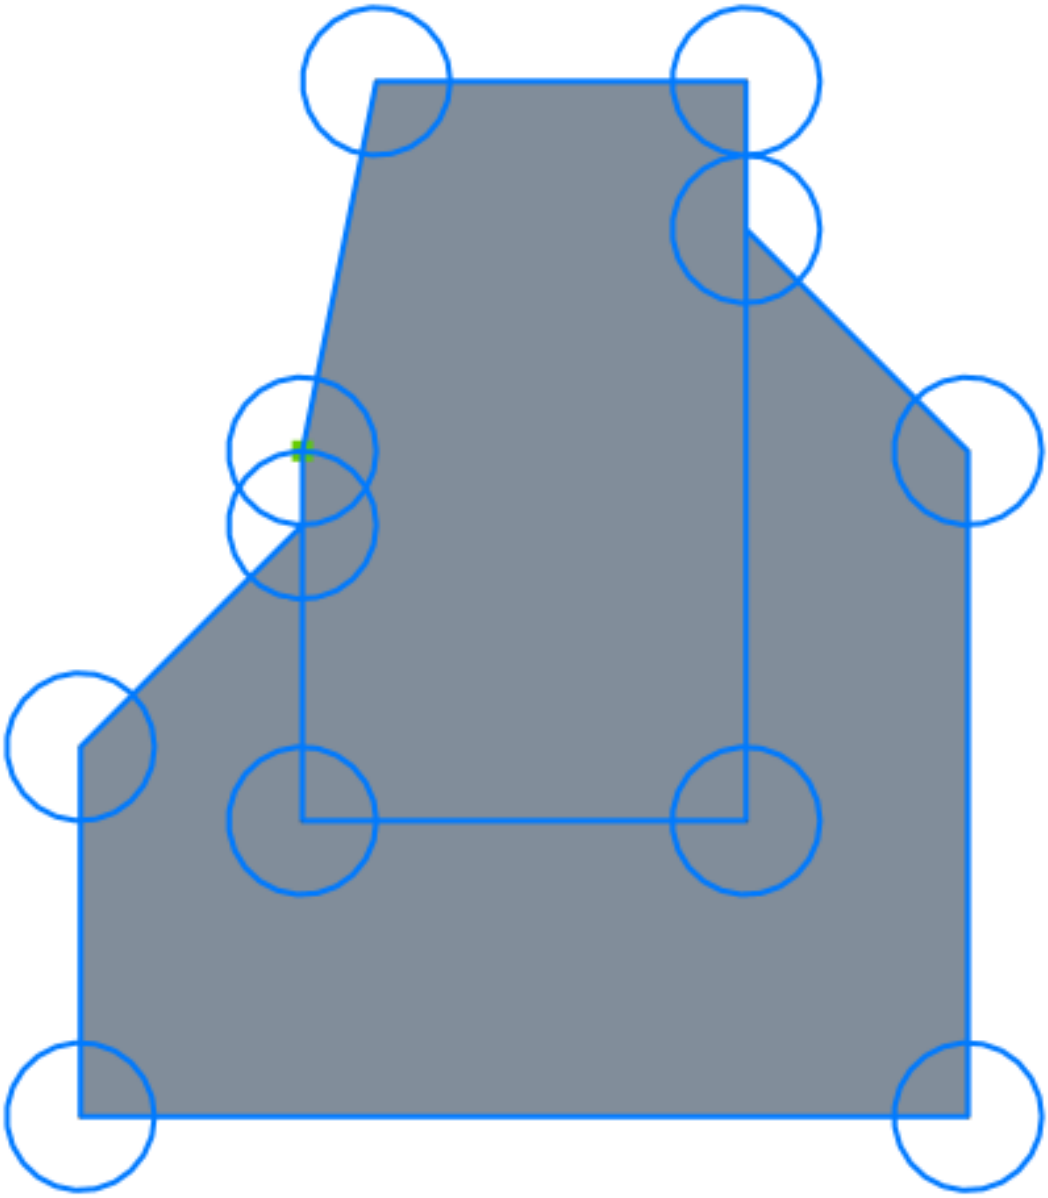

About Corridor Extract

The Corridor Extract command is used to generate meshes, solids, polylines or outer boundaries from an existing Corridor.  For more information about this command, visit the Command Reference article CorridorExtract (6.9.52).

Procedure: Creating a road corridor

1. Open the drawing file that contains the TIN Surface (1), 3D Alignment (2) and Corridor Template (3). (1.946 on the next page)
2. Launch the **Corridor** command in the command line **Or** select Create Corridor in the Model tab from the Quad. **You are prompted:** Select 3d alignment used as a corridor baseline: **(select 3d alignment (2))**
3. **You are prompted:** Select corridor template: **(select corridor template (3))**
4. **You are prompted:** Enter region start station: **(press enter to start from beginning or type any station where you want your corridor to start)**
5. **You are prompted:** Enter region end station: **(press enter to create corridor to the end of selected alignment or type any station where you want your corridor to end) (1.947 on the following page) (1.948 on page 1041) (1.949 on page 1041)**
6.

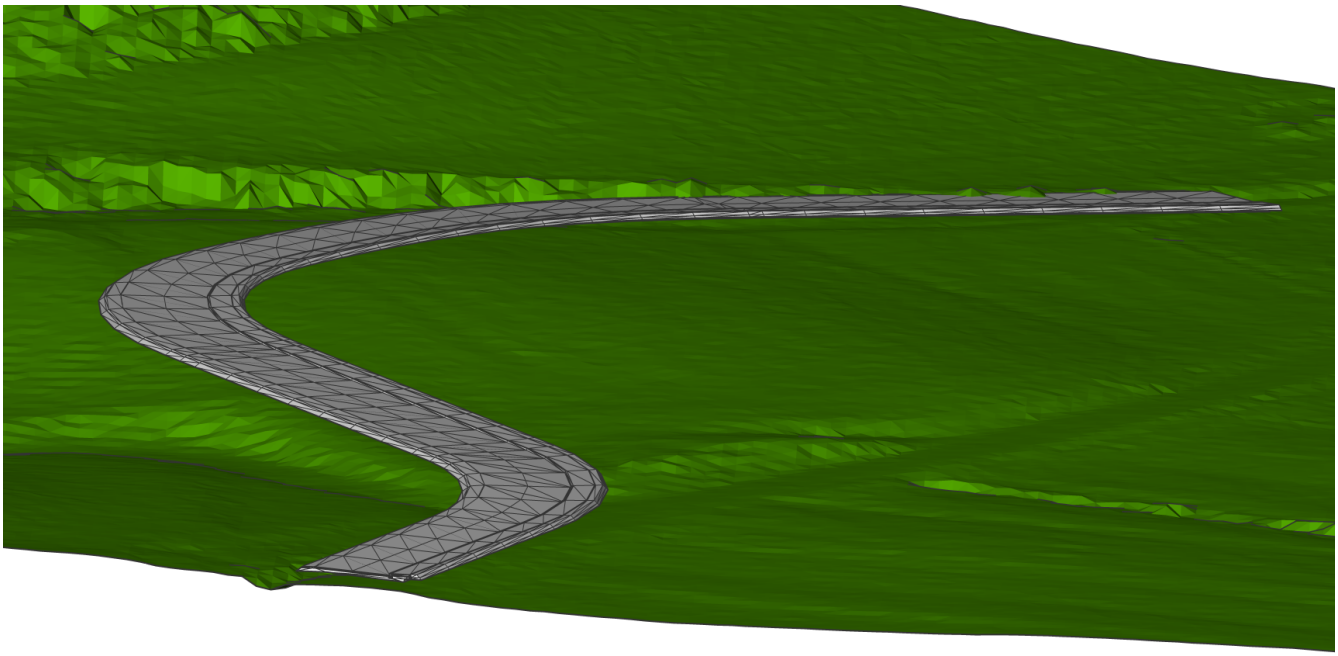

Figure 1.949

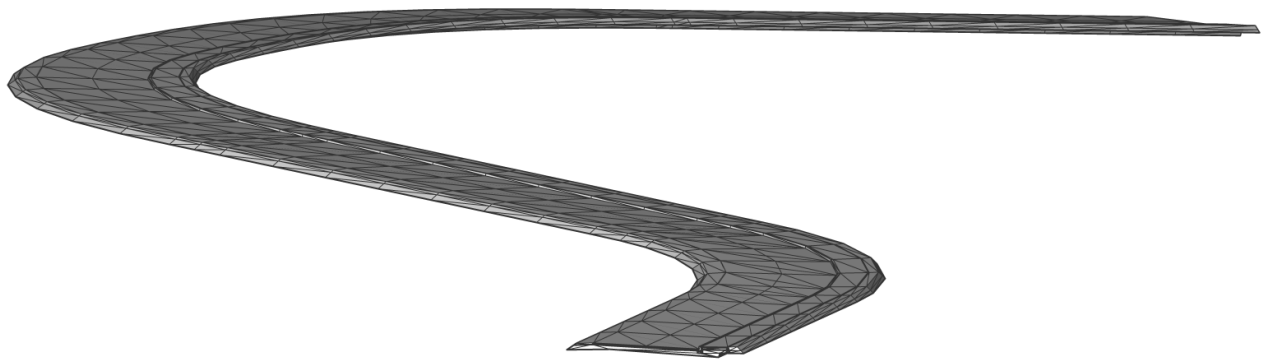

About Corridor Edit

The Corridor Edit command adds or removes regions from an existing Corridor.  For more information about this command, visit the Command Reference article CorridorEdit (6.9.42).

Procedure: Editing a corridor

1. Open the drawing file that contains the corridor you would like to edit.
2. Select the 3D alignment that the corridor has as a reference and move the grip points to edit the corridor horizontally. (1.950)
3. To edit the corridor vertically, select the 3D alignment that the corridor has as a reference and open the Properties Panel. Set the **Update mode** to Manual. Extra grip points will appear. (1.951 on the facing page) (1.952 on the next page)
4. Move these grip points to edit the corridor vertically. (1.953 on page 1044) (1.954 on page 1044)
5. Press Enter and you have finished your edited corridor. (1.955 on page 1044)

1.27 Parametric Modeling

1.27.1 Parametric Modeling Overview

BricsCAD provides a rich toolset to control 2D and 3D geometric models with parameters of different kinds. This includes:

- Global parameters; parameters of 2D/3D dimensional constraints, user-defined parameters, configuration parameters of design table, etc.
- Local parameters; parameters of arrays and constrained entities inside arrays, parameters of inserts of parametric components, etc.

All parameters and their current values are can be found in different sections in the Mechanical Browser (3.3.2). Parameter values can be linked together via expressions. When you change the value of a parameter, the model is updated automatically. This workflow allows you to add parametric behavior to any geometry and explore design variants easily.

NOTE	In BricsCAD there are no parent-child dependencies between geometric elements: for example, if you change a sketch used to create an extruded 3d solid, the solid is not changed accordingly. However, you can create dependencies with parameters and expressions afterward.

Global and local parameters

Commands: -PARAMETERS (6.24.6), MECHANICALBROWSEROPEN (6.8.32), CLEANUNUSEDVARIABLES (6.9.15)
Parameters in BricsCAD can be global or local. Local parameters are attached to a particular entity, an associative array or a mechanical component. Global parameters are not attached to a particular entity, they are subdivided into four groups:

- Parameters of 2D dimensional constraints
- Parameters of 3D dimensional constraints
- User-defined parameters
- Configuration parameters of design tables

To learn how to create 2D dimensional constraints, see Using Dimensional Constraints (1.21.7). To learn how to create 3D dimensional constraints, see 3D Constraints (1.27.3). To create a user-defined parameter, see Creating a New Parameter (1.21.7). To create a configuration parameter for a design table, see Creating a design table to drive Parametric Blocks parameters (1.27.6).

Define an expression for a parameter

You define an expression for any parameter type, global or local. The simplest expression is a number or the name of a global parameter (local parameters cannot be referenced in expressions). A more complex expression can include standard operators and functions (see below). To define an expression for a parameter: in the Mechanical Browser (3.3.2), click on the parameter name and fill out the **Expression** field: ===ERROR WITH DOWNLOADED IMAGE===

NOTE	You can also define an expression for a parameter in the command line using the -PARAMETERS (6.24.6) command.

You can use operators (1.21.7) and functions (1.21.7) to compose an expression.

Defining dependent parameters

In expressions, you can use both: names of global parameters and numbers. This is known as a 'non-constant expression'. If a non-constant expression is set to a parameter, its icon changes from an open padlock () to a closed padlock (), in the Mechanical Browser (3.3.2): ===ERROR WITH DOWNLOADED IMAGE=== This means that the parameter becomes dependent on other (defining) parameters (its value will be automatically recalculated when the value(s) of the defining parameter(s) changes). You can create a chain of parameters, where every element is dependent on the previous one. There is no limit to the length of the chain. However, be careful not to create a loop where the next element in a chain drives one of the previous elements. This might result in an infinite evaluation of expressions. BricsCAD automatically detects such problems and does not accept expressions that lead to a parametric loop.

Parameters of Associative Arrays

Commands: ARRAY (6.4.19), ARRAYRECT (6.4.28), ARRAYPOLAR (6.4.41), ARRAYEDIT (6.4.25). Properties of associative arrays that can be controlled with an expression:

- **Rectangular arrays** :Number of columns, Column spacing, Number of rows, Row spacing, Row elevation increment, Number of levels, Level spacing, and Axis angle.
- **Polar arrays**: Radius, Number of Items, Angle between items, Fill angle, Number of rows, Row spacing, Row elevation increment, Number of Levels, and Level spacing.

To define an expression for any of these properties, select the corresponding array entity, either in the drawing area or in the Mechanical Browser (3.3.2) and enter the expression in the corresponding properties field in the Mechanical Browser (3.3.2) or in the Properties bar (1.15.4). ===ERROR WITH DOWNLOADED IMAGE=== If an associative array contains entities constrained with 2D or 3D dimensional constraints, then parameters of these constraints can also be evaluated with expressions. These nested parameters are listed in the Mechanical Browser (3.3.2). If you select any of them, you can define an expression: ===ERROR WITH DOWNLOADED IMAGE===

Parameters of Mechanical Components

Commands: -BMPARAMETERS (6.8.25), BMUPDATE (6.8.29), The BMUPDATEMODE (1.17.10) system variable controls whether external assembly components are always reloaded or only when modified. If you insert a mechanical component or just a plain .dwg file into a drawing with BMINSERT (6.8.16) command and the insert contains global exposed parameters (1.30.25), these parameters are converted to local parameters. They are associated with the corresponding component insert and are visible in the Mechanical Browser (3.3.2) under the name of this insert. Click the parameter(s) to edit: ===ERROR WITH DOWNLOADED IMAGE===

Design Tables

Commands: DESIGNTABLE (6.10.31), -DESIGNTABLEEDIT (6.10.27) A design table allows you to evaluate several global parameters at once with the value of one configuration parameter. You can create design tables from scratch in BricsCAD or import them from a .csv file (a comma-separated values text file). You can create such files with a spreadsheet software package or a text editor.

Creating a Design Table from a .csv file The expected format of the .csv file is: Configuration_Name,Parameter1, Parameter2, ... , ParameterN Configuration_1,Value1Parameter1,Value1Parameter2,...,Value1ParameterN Configuration_2,Value2Parameter1,Value2Parameter2,...,Value2ParameterN Configuration_3,Value3Parameter1,Value3Parameter2 ... The first row lists the parameter names separated by a comma. The first name must be different from the name of any global parameter in your drawing. It is called the configuration name. No spaces are allowed in the configuration name. Other names in the first row can be identical to the names of a global parameter The next rows list possible values for these parameters as strings or numbers. Example: Size,Length,Width,Height Small,300,200,100 Medium, 450,300,150 Large,600,400,200 Use the DesignTable (6.10.31) command to import a .csv file into BricsCAD. This creates a special global parameter by the name of the first name in the first row of the .csv file ('Size' in the above example). This is called the 'configuration parameter'. It will drive the values of other parameters in the design table. These are called 'configuration-dependent parameters'.

NOTE	BricsCAD does not maintain an association with the .csv file, used to create a design table: if this file is modified then the design table is not updated automatically. Use the -DESIGNTABLEEDIT (6.10.27) command to replace a design table with a new or modified .csv file.

Direct Lookup in a Design Table To evaluate a configuration parameter:

- Select it in the Mechanical Browser (3.3.2) and type the desired value in its **Expression** field.
- Select a value in the drop-down list of the **Value** field:

===ERROR WITH DOWNLOADED IMAGE=== If you change the value of a configuration parameter all configuration-dependent parameters' values change automatically on the corresponding design table. The values of these parameters are taken from the row in the design table. The first element coincides with the current value of the configuration parameter.

Reverse Lookup in a Design Table You can evaluate parameters, that are defined by a configuration parameter with a design table independently. Select the dependent parameter and apply an expression to it.

- If the value of this expression matches one of the values in the corresponding design table, then the configuration parameter and all dependent parameters of the design table will automatically change to the values specified in the corresponding row in the table.
- If several configurations are possible for a particular value of a dependent parameter, BricsCAD selects the one closest to the current values of the other parameters.
- If you enter an expression and the result is not available in the design table or if you enter expressions for two or more design table parameters and the values cannot be found in a single configuration (the values are not found in the same row in the design table), then the values of the configuration parameter are changed to 'Custom' and the values of the other dependent parameters are not changed. This case corresponds to a configuration that does not exist in the design table.

Add a New Configuration to a Design Table You can add any 'Custom' configuration to a design table and assign it a name. To do so, right-click the configuration parameter in the Mechanical Browser (3.3.2) and select **Save current configuration** in the context menu. The configuration will be added to the design tables as Configuration_N'

- Configuration: the name of the configuration parameter
- N: an index number - one more than the current number of configurations in the design table.

If you want to save a configuration in the design table under a different name, launch the -DesignTableEdit (6.10.27) command.

Creating an Empty Design Table If you use the procedure described above, it is possible to start your design with an empty design table and then fill it with the desired values. Use the 'Empty Design Table' tool. You will be asked:

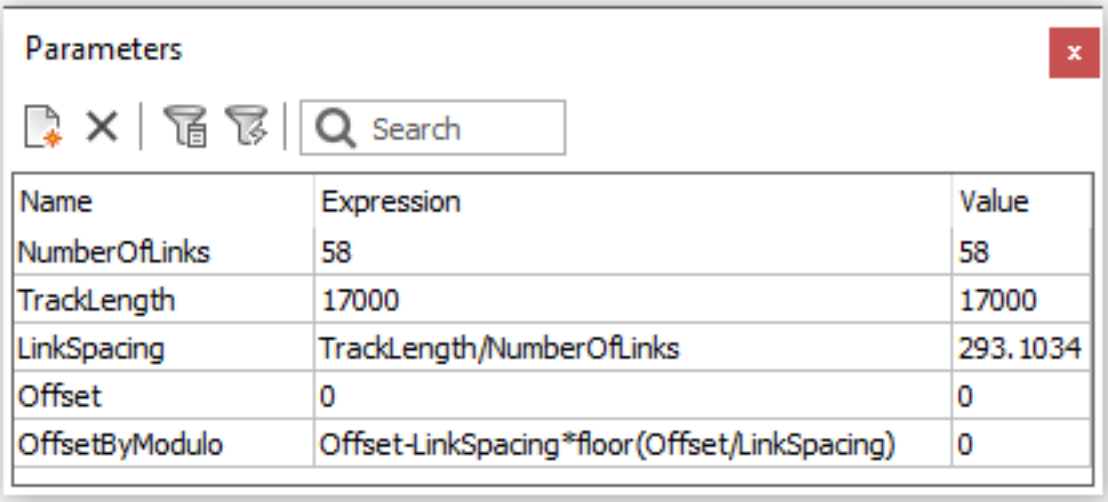
- The name of a new design table
- The name of the corresponding configuration parameter,
- The names of global parameters that will be dependent on this design table.

Using a Parametric Component with Design Tables You can use both configuration parameters and configuration-dependent parameters in assemblies. If you then insert such a component into your drawing, its parameters will include the exposed parameters of design tables. A drop-down list of available values will be available. Both direct and reverse lookup actions are supported for such parameters.

Other Actions with Design Tables The -DESIGNTABLEEDIT (6.10.27) command allows you to:

- Delete a design table.
- Replace a design table.
- Link a new parameter.
- Unlink an existing parameter.
- Add new configurations, remove an existing one
- Export a design table as a .csv file.

Figure 1.962



1.27.2 Parameters Manager

Commands: PARAMETERSPANELOPEN (6.24.10), PARAMETERSPANELCLOSE (6.24.8). The Parameters Manager (a.k.a. Parameters panel) allows you to browse and manage global parameters of your model in tabular form. Every row in this table corresponds to one global parameter, while every column represents a particular property of a parameter - name, expression, value. (1.962) With Parameters Manager you can:

- Create a new parameter
- Delete an existing parameter
- Click a parameter name field and change it
- Click a parameter expression field and change it
- Search a parameter by name
- Sort all parameters by name, expression, and value
- Hide all parameters except those relevant to the selected parameter
- Hide all parameters except those dependent on the selected parameter
- Animate a parameter

To open the Parameters Manager do one of the following:

- Choose **Parameters Manager** in the **Components** menu
- Place the cursor on a toolbar, then right-click and choose **Parameters** in the context menu.
- Call PARAMETERSPANELOPEN command

1.27.3 3D Constraints

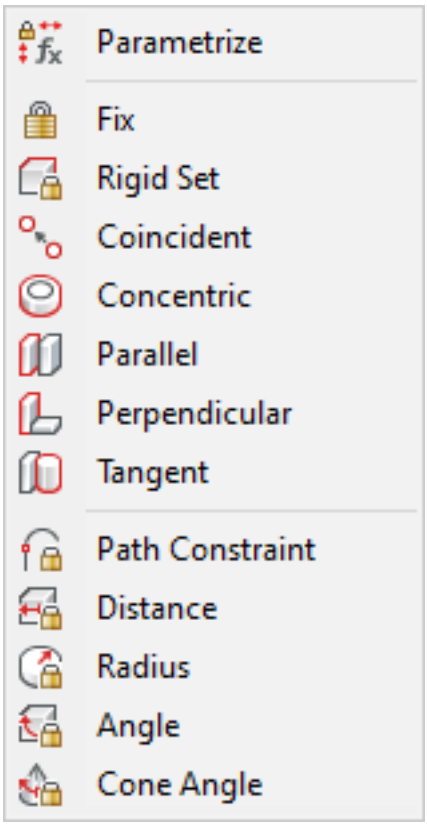
Commands: MechanicalBrowserOpen (6.8.32) , DMUPDATE (6.12.34), DMFIX3D (6.12.15), DMCOINCIDENT3D (6.12.5), DMCONCENTRIC3D (6.12.8), DMPARALLEL3D (6.12.18), DMPERPENDICULAR3D (6.12.20), DMTANGENT3D (6.12.32), DMDISTANCE3D (6.12.10), DMRADIUS3D (6.12.22), DMANGLE3D (6.12.1)

Variational Direct Modeling

Use geometric constraints (aka variational direct modeling) to model parametric solids and surfaces. Define constraints between elements (edges and faces) to modify solid and surface models. As soon as a constraint is added BricsCAD automatically modifies the model and these constraints are updated with subsequent modifications to the model. The key advantage of variational direct modeling is that all constraints are taken into account simultaneously and the model behavior does not depend on the constraint creation order. It allows you to parameterize any feature of the 3D model without the worry of model creation history. Dimensional constraints control the dimensions of the model. When such a constraint is introduced or the value of its parameter is changed BricsCAD automatically updates the solid and surface geometry. For example, the dimensions of a box can be controlled by the parameters of three distance constraints applied to the opposite faces. Constraints can be created using the **3D Constraints** toolbar, the **Parametric/3D Constraints** menu or the **Constraints** command group in the Quad (1.15.5). (1.964 on the next page) BricsCAD provides the following 3D constraints:

- Geometrical constraints: **Fix** (), **Coincident** (), **Concentric** (), **Parallel** (), **Perpendicular** (), **Tangent** (), and **Rigid Set**().
- Dimensional 3D constraints: **Distance** () , **Radius** (), **Angle** (), **Cone Angle** (), **Path Constraint** ().

Figure 1.964



The Mechanical Browser

Use the Mechanical Browser (3.3.2) ( ) to navigate through all the constraints in the model. Select a constraint in the Mechanical Browser, to check and edit its properties (1.27.4). (1.965 on the facing page)

3D Constraints types

The following (sub)entities and items are supported for constraint creation:

- Vertices, edges and faces of 3D solids, surfaces, meshes and regions and surfaces of planar, cylindrical, spherical, toroidal and conical geometry.
- Lines, rays, xlines, circles and arcs.
- Segments and vertices of 3D polylines.
- Arbitrary curves for coincident and path constraints with a point as another argument.
- Planes, axes and origin points of the WCS or a block coordinate system.

3D constraints have a number of properties that allow you to control how BricsCAD treats them in various situations. For full description see the 3D Constraints Properties page (1.27.4).

Geometry-driven Constraints

Dimensional 3D constraints can also be **geometry-driven**. They update the model to accurately reflect the current state of the model. You can not specify their expression. Instead, their value is obtained from the model and can be changed with direct modeling operations and changes to other constraints. Other parameters, including constraints, can depend on the values of geometry-driven constraints. In some circumstances a constraint dependent on geometry-driven constraints can make the model unresolvable. This should be avoided. Turn regular constraints to geometry-driven constraints and vice versa, with the Mechanical Browser (3.3.2), Parameters Manager (1.27.2) or DMCONSTRAINT3D (6.12.6) command. After a regular constraint is turned into a geometry-driven one, its expression will be overwritten with the first modification of the model that affects this constraint.

3D Constraints and Direct Modeling

3D Constraints are taken into account when direct modeling operations are applied. If there is a 3D constraint that fixes the placement of faces or edges this constraint will be preserved during Push/Pull, Move and Rotate operations. A 3D constraint can be temporarily disabled, or erased permanently, with the Mechanical Browser Constraints section. Geometry-driven constraints will update their values when a direct modeling operation is completed. This can lead to additional charges to the model. If some faces or edges disappear, during a direct modeling or in Boolean solid editing operation, 3D constraints applied to such entities are removed. However, if there is an exact correspondence between the initial faces and the faces obtained, 3D constraints are automatically applied to the new entities. Dependent on the value of the DMRECOGNIZE (6.27.28) system variable, BricsCAD will automatically recognize geometrical relations between the surfaces of a solid and will preserve them during direct modeling operations (see Design Intent Recognition (1.26.3)).

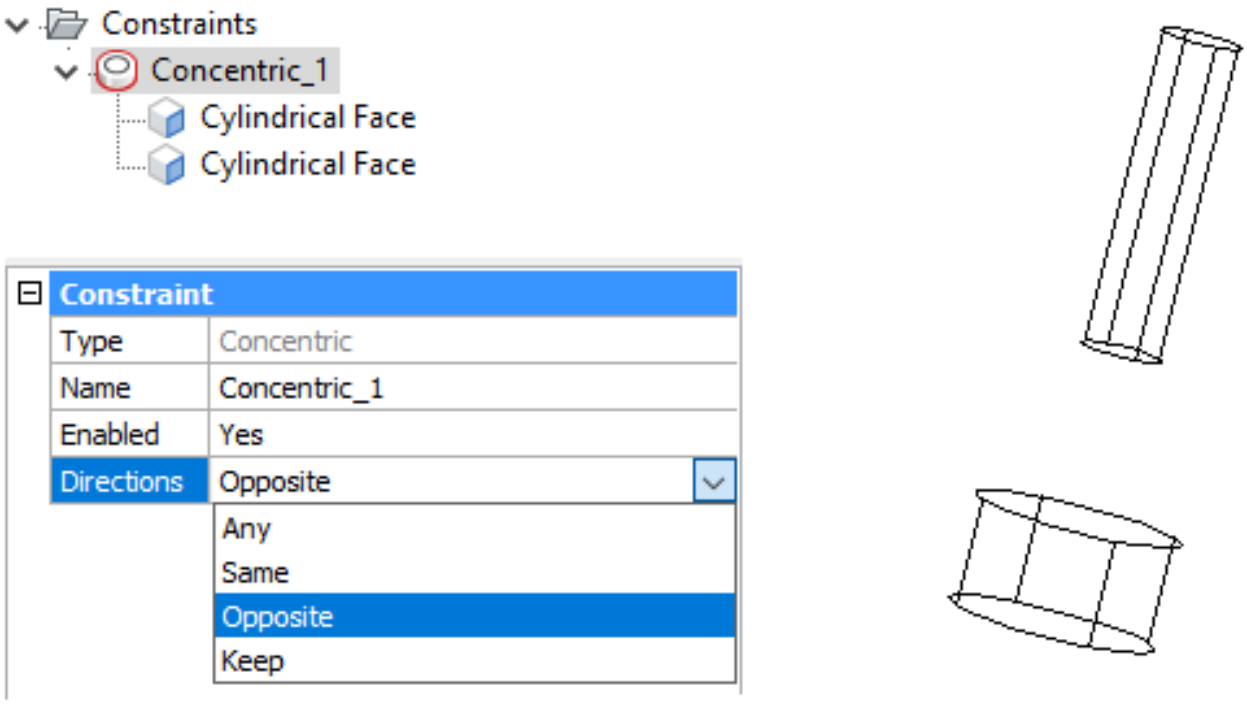
1.27.4 3D Constraints Properties

BricsCAD provides a set of properties for 3D constraints which allow to control mutual placement of the constrained geometrical entities (or constraint arguments) upon 3D constraints recalculation. The properties may be assigned both to a constraint itself (**Directions** property) and/or to the constraints arguments, for each argument separately (**Placement** and **Use as** properties).

"Directions" property

(1.966 on the next page) **Directions** property specifies whether the directions of the constraint arguments are **Same** or **Opposite**. Changing from one to another results flips constrained entities with respect to each other.. Direction has sense for lines, planes, circles, cylinders, cones and torii. It has no sense for points and spheres. Direction of a plane is its normal vector. Direction of a circle is the normal vector of the circle's plane. Direction of a cylinder, cone, or torus is the direction of its axis. The direction of a planar face of a 3D solid is additionally adjusted to be external w.r.t. the 3D solid object. **Any** option means that the directions may change upon direct modelling operations or upon a 3D constraint parameter change. **Keep** option forces BricsCAD to keep the current directions. In other words, this option forces BricsCAD to analyze the mutual location of the arguments prior to 3D constraints solving and use either **Same** or **Opposite** (not both).

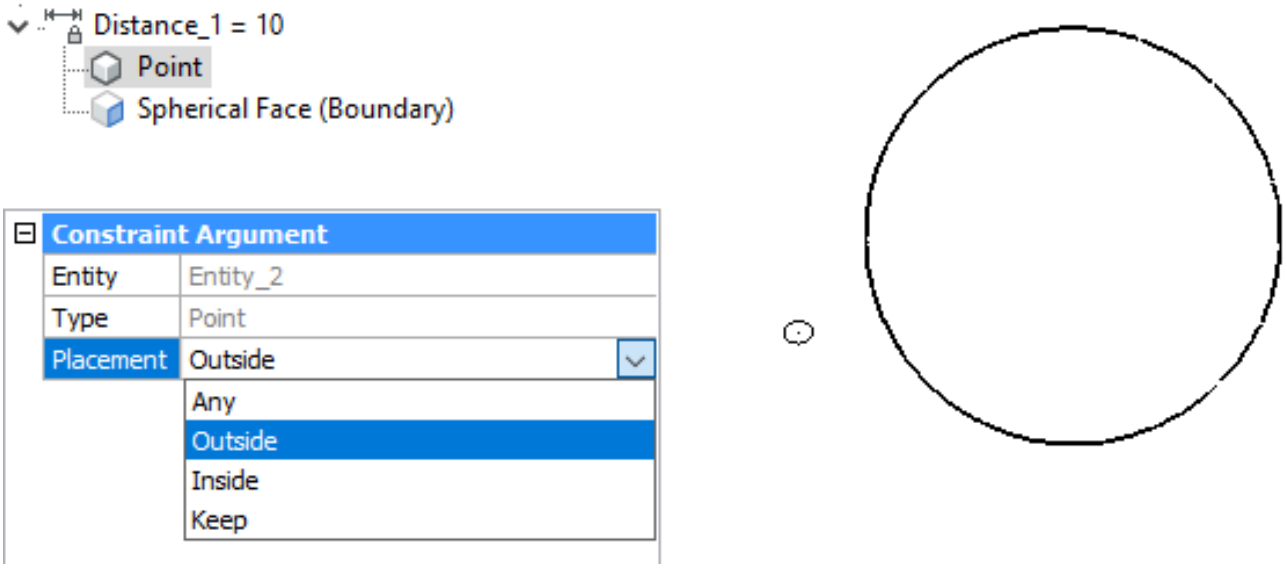
Figure 1.966



"Placement" property

(1.967 on the facing page) **Placement** property specifies how to place an argument with respect to **another** argument of the same constraint. For example, a point in a point-sphere distance may be placed either **Outside** or **Inside** of a sphere. Changing this property for a constraint argument moves the argument to the other side of another argument. The sides are defined for planes, spheres, cylinders, cones, and torii. And not defined for points, lines, and circles. **Any** option means that both **Outside** and **Inside** placement is suitable for user's intentions. **Keep** option forces BricsCAD to keep the current placement of the argument. In other words, this option forces BricsCAD to analyze the mutual location of the arguments prior to 3D constraints solving and use either **Outside** or **Inside** (not both). By default **Keep** option is used.

Figure 1.967



"Use as" property

(1.968) **Use as** property is assigned to the arguments of the **Distance** and **Concentric** constraints. It has sense for circles, spheres, cylinders, cones and torii and defines which geometry is used in a 3D constraint to measure the distance or to made coincident with the other entity. There are four options for the **Use as** property:

- **Boundary** means that the constraint is applied to the boundary of the argument;
- **Axis** is applied to an argument that has axis, namely : circle, cylinder, cone, or torus;
- **Center** is applied to an argument that has central point, namely : circle, sphere, or torus;
- **Vertex** can be applied to the cone vertex only.

Figure 1.968

1.27.5 Suppression Feature

Command: SUPPRESS (6.27.71) A suppression feature temporarily suppresses a set of entities in your drawing. If the condition is equal to zero all entities display, otherwise they are suppressed. (1.973) Suppressed entities are internally placed on a special frozen layer. This allows you to speed up orbit, zoom and pan operations, improves object selection performance and reduces regeneration time for complex drawings. Suppressed entities are also excluded from mass properties calculations (generated drawing views and bill of materials). Use a parametrically-driven expression for the condition parameter of a suppression feature, to create different design variants of your parametric components.

Creating a suppression feature

Execute the SUPPRESS (6.27.71) command.

Managing suppression features in the Mechanical Browser

Select the suppression feature in the Mechanical Browser (3.3.2) panel, then right click to display a context menu. The available options are:

- **Suppress**: Suppresses the entity set.
  - The **Suppressed** icon ( ) indicates the suppressed state.
  - The option now reads **Unsuppress**.
- **Unsuppress**: Unsuppresses the entity set.
  - The **Unuppressed** icon ( ) indicates the unsuppressed state.

        - The option now reads **Unsuppress**.
- **Dissolve**: Deletes the suppression feature.
- **Edit Selection**: Allows to add/remove entities from the selection. All members of the selection highlight.
  - Select entities to add.
  - Shift+Select (hold down the Shift key, then use a selection method) entities to remove.
  - Right click to stop editing.
- **Zoom to**: Zooms onto selected entities. To compose a selection set:
  - Click a suppression feature to select all its members.
  - Expand a suppression feature, then click to select an entity.
  - Ctrl+Click to add/remove entities from the selection.

Select: Selects all members of a suppression feature.

To set a condition for a suppression feature

You can set an expressional condition for a suppression feature: depending on the value of the current expression, the entities will be suppressed or unsuppressed automatically. **In the Mechanical Browser panel:**

1. Select the suppression feature (use "Search" field to search by name).
2. Enter an expression in **Condition** field in the properties grid.

In the Parameters and Constraints panel:

1. Select the parameter with the same name as the suppression feature (use "Search" field to search by name)
2. Enter an expression in the **Expression** column.

1.27.6 Creating a design table to drive Parametric Blocks parameters

Create a design table

First, you must create the design table as a CSV (comma separated) file. You can use a spreadsheet app or a simple text editor. Below are the steps to use Wordpad, but you can use any app that allows you to save it as plain text with a .CSV extension.

1. Open WordPad.
2. Enter the parameter names in the top row, separated by commas. I added a parameter called "Size". It represents the names of the different variations. For example, I might call them Small, Medium, Large, and XLarge. But, I named them according to their size in feet, as is common here in the United States. The Width and Length refer to the dimension constraints that will drive the size (in inches).
3. Add the sizes you want to include with their corresponding Width and Length values. I've only added four sizes, but you can have a long list with any number of size combinations. The image below shows what it looks like in Excel (left) and in WordPad (right). (1.974)
4. Save the file as CSV format. It's plain text separated by commas with a .CSV file extension.

Figure 1.974

	A	B	C
1	Size	Width	Length
2	1x1	12	12
3	2x2	24	24
4	2x4	24	48
5	1x4	12	48

```
Size,Width,Length
1x1,12,12
2x2,24,24
2x4,24,48
1x4,12,48
```

Add the design table to the parametric block

Next, you must associate the design table with the parametric block drawing.

1. In BricsCAD, open **2D Recessed Troffer.dwg**. This is the block definition drawing, not a drawing with the block inserted.
2. Right-click on any UI element and turn on the Mechanical Browser (3.3.2) panel. In the Mechanical Browse (3.3.2), you will see the list of parameters and their values. (1.975 on the facing page)
3. At the Command line, enter DESIGNTABLE (6.10.31) and press enter to accept the default option <From file>
4. Select the .csv file you created. Notice the Size parameter is added to the Mechanical Browser (3.3.2) with the Width and Length parameters grouped under it.
5. Check the Value property for each of the main parameters: Size, Width, and Length. You can select the default values to use when you insert the block. For example, if you most often use 2'x4' fixtures in your designs, set that size as the default. The corresponding Width and Length values will follow. (1.976 on the next page)
6. Check the Exposed property for each of the main parameters: Size, Width, and Length. They should all be set to Auto. I'll explain these settings after we insert the block into a drawing. (1.977 on page 1070)
7. Save the block drawing.

Figure 1.975

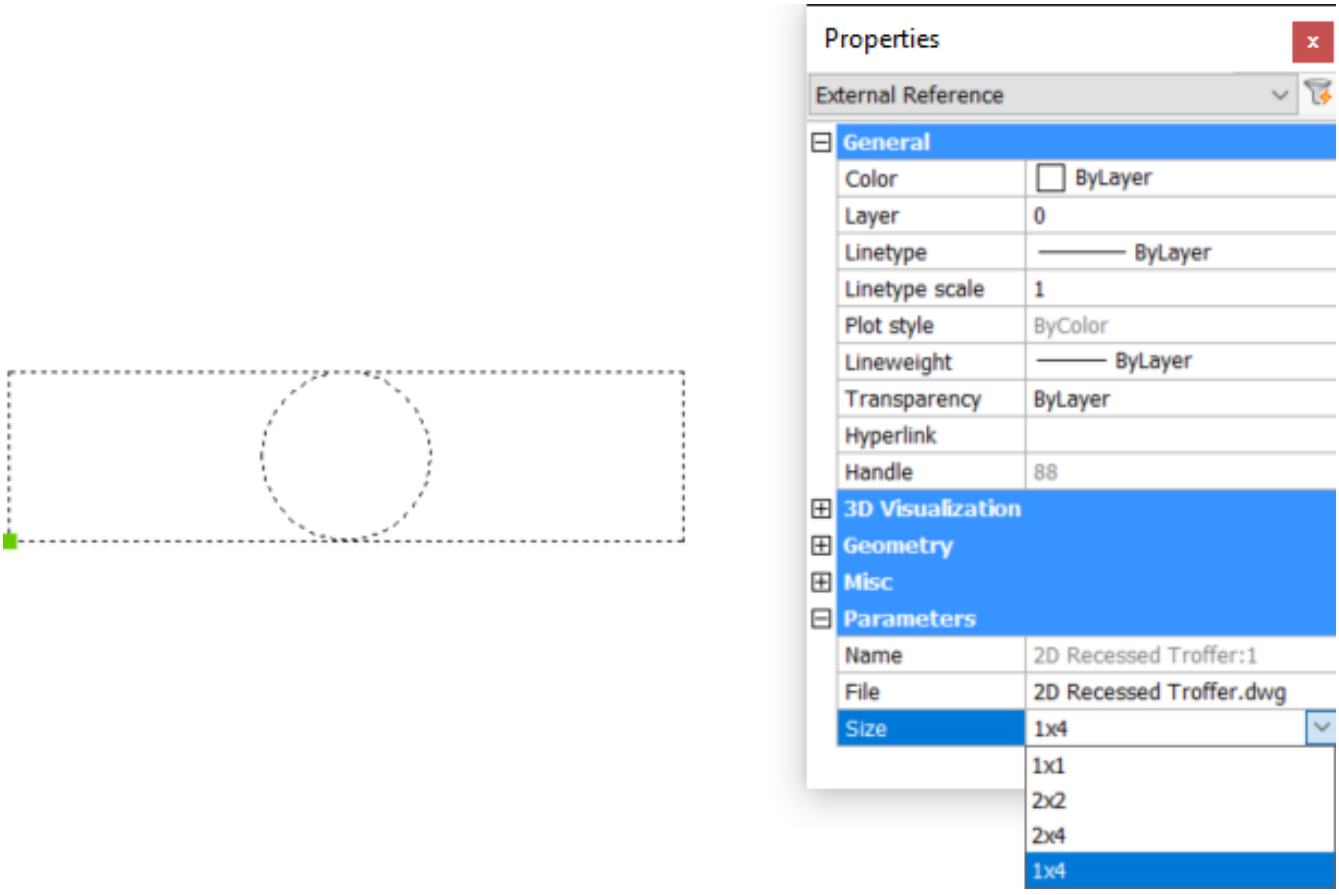
Modify the parametric block instance

Then, you can insert the parametric block into a drawing and test it out.

1. Open the drawing in which you want to insert the light fixture. If a block definition of the same name already exists in the current drawing, you may have to rename or erase/purge the old definition.
2. At the Command line, enter **BMINSERT** and select **2D Recessed Troffer.dwg** to insert it as a block in your current drawing.
3. Select the inserted block.
4. In the **Properties panel**, select a different size under the Parameters pane. Now you can only select from the sized in the design table. This helps ensure accuracy and compliance with standards. (1.978 on the next page)

Figure 1.978



Exposing parameters

When you add the design table to the block, the Exposed property for all three parameters is set to Auto by default. In our example, that means the Size is exposed for modifying the block insertion in the Properties panel but the dependent parameters, Width and Length, are not. You can explicitly set the Exposed property in the block definition to On or Off depending which parameters you want available for modifying the block insertion. Here are a few examples. (1.979 on the facing page)

1.27.7 Parameters and their Properties in Mechanical Browser

All parameters such as; user-defined, 3D constraints, design tables, parameters of parametric components and arrays can be managed via Mechanical Browser (3.3.2). The following context menu items and properties are available:

- Add new parameter: Creates a new parameter, which will control the component (1.30.25).

Context Menu	
Parameter context menu	Right click a component parameter: Main component parameter context menu (left), subcomponents parameter context menu (right): (1.981 on the next page) (1.982 on the facing page) Delete: delete the selected parameter from file. Create design table: creating a design table (1.27.6) to drive parametric block parameters Animate: animate parameter value within some range. Link to parameter: link subcomponent parameter to the main level parameter. Collapse all: collapses the main component and all components and subcomponents. Expand all: expands the main component and all components and subcomponents.

(1.980)

- **Name:** Identifies the parameter. The parameter name can be used in expressions of other parameters in the same **component.** Name cannot begin with a number, it should be alphanumeric without spaces.
- **Expression**: Type a value or an expression.
- **Value:** Displays the current value of the parameter.
- **Description**: Optional description of the parameter.
- **Exposed:** Defines whether the parameter is visible and can be modified when the component is inserted in an assembly. Select the field, then click the down-arrow button and choose an option. A new parameter gets the **Auto** option by default.
  - **Auto** = the parameter is exposed only if it does not depend on other parameters.
  - **ON** = the parameter is always exposed.
  - **OFF** = the parameter is never exposed.
- **Units:** Sets the dimension of the parameter: Linear, 2-dimensional or 3-dimensional. Select the field, then click the down-arrow button and choose an option.

Figure 1.981

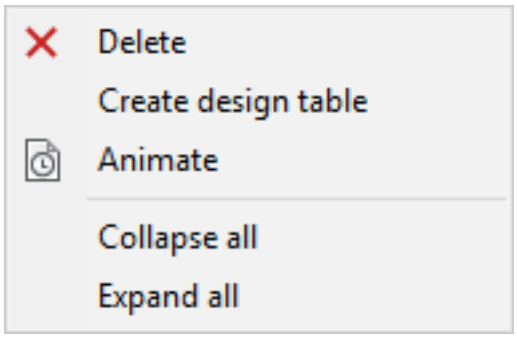

Figure 1.982

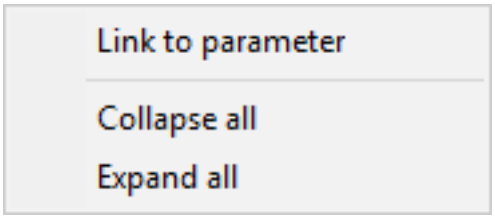

1.28 Point Cloud

1.28.1 Working with Point Clouds (V21)

Commands: **PointCloud, (6.24.31) PointCloudAlign (6.24.67), PointCloudAttach, (6.24.35) -PointCloudAttach (6.24.35), (6.24.36) PointCloudColorMap, (6.24.37) PointCloudCrop, (6.24.41) PointCloudCropSolid, PointCloudDeleteItem (6.24.38), PointCloudDetectFloors, PointCloudExport (6.24.39), PointCloudFitPlanar, PointCloudImport (6.24.40), PointCloudPointSize, (6.24.55) PointCloudPointSize_Minus, (6.24.43) PointCloudPointSize_Plus, (6.24.48) PointCloudPointMax, (6.24.49) PointCloudPreprocess, (6.24.63) -PointCloudPreprocess, PointCloudProjectSection, PointCloudReference (6.24.45), PointCloudShowBubbles, PointCloudUncrop (6.24.46)** Point cloud functionality is significantly faster and more powerful in BricsCAD v21 and is even more powerful with a BIM license.

Pre-processing

The E57 file format is added to the supported files for pre-processing. (1.983 on the facing page) When you attach a point cloud that requires pre-processing, it converts 5 to 8 times faster in BricsCAD v21 than in v20. A progress meter at the bottom of the display shows the conversion progress. (1.984 on the next page)

Figure 1.983

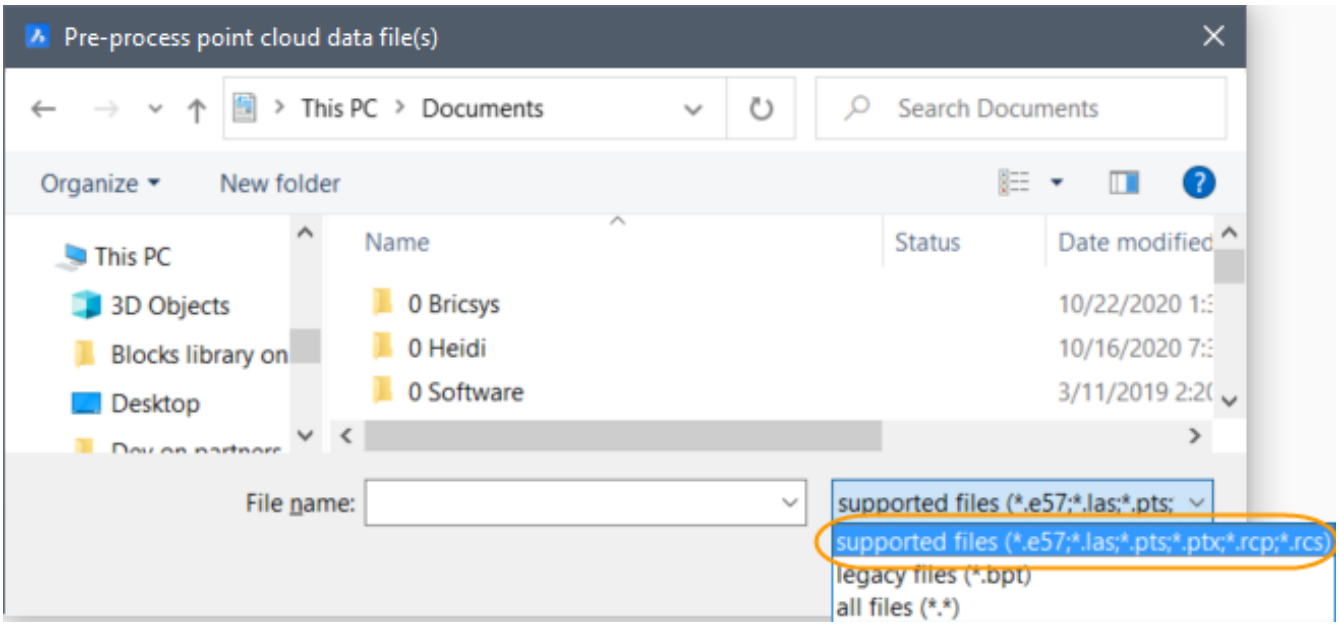

Figure 1.984

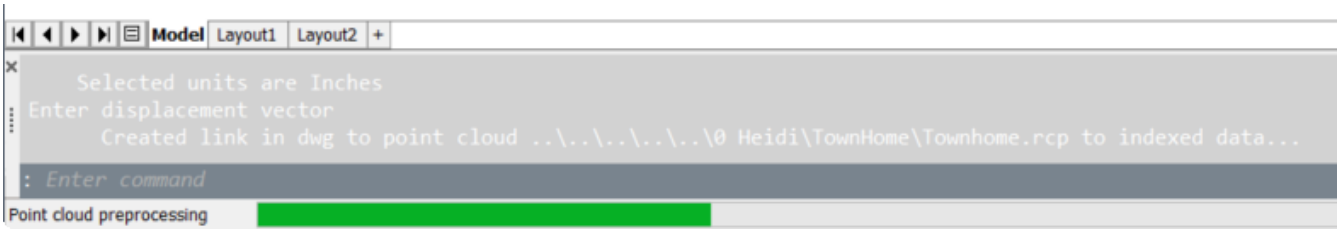
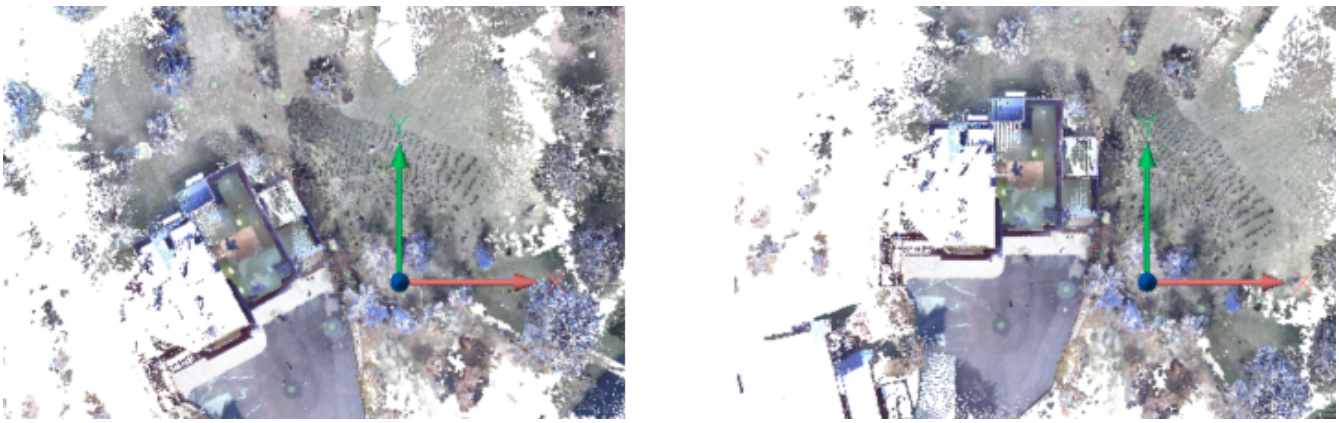


Alignment

The new POINTCLOUDALIGN command automatically rotates a point cloud to optimally align it with the X and Y axis. To determine the best alignment it can analyze the entire point cloud or you can specify the most relevant area. (1.985)

Figure 1.985



Bubble Viewer

The point cloud displays bubbles at all the scan locations. It's at those locations where you will experience the most realistic visual representations. (1.986 on the next page) Double-click one of the bubbles in model space to open the Bubble viewer. You can press the middle mouse button and move the mouse to view the point cloud in any direction from that scan location. (1.987 on the facing page) (1.988 on page 1080) Press the Tab key to cycle between three different visual modes. The first mode displays the points as their actual colors or in greyscale, depending how the data was scanned. (1.989 on page 1080) The second mode displays the points as red, green, or blue according to their normal vectors. The colors correspond to the UCS axes. (1.990 on page 1081) (1.991 on page 1081) The third mode displays the points from light to dark as the distance from the scan location increases. (1.992 on page 1083)

Figure 1.990

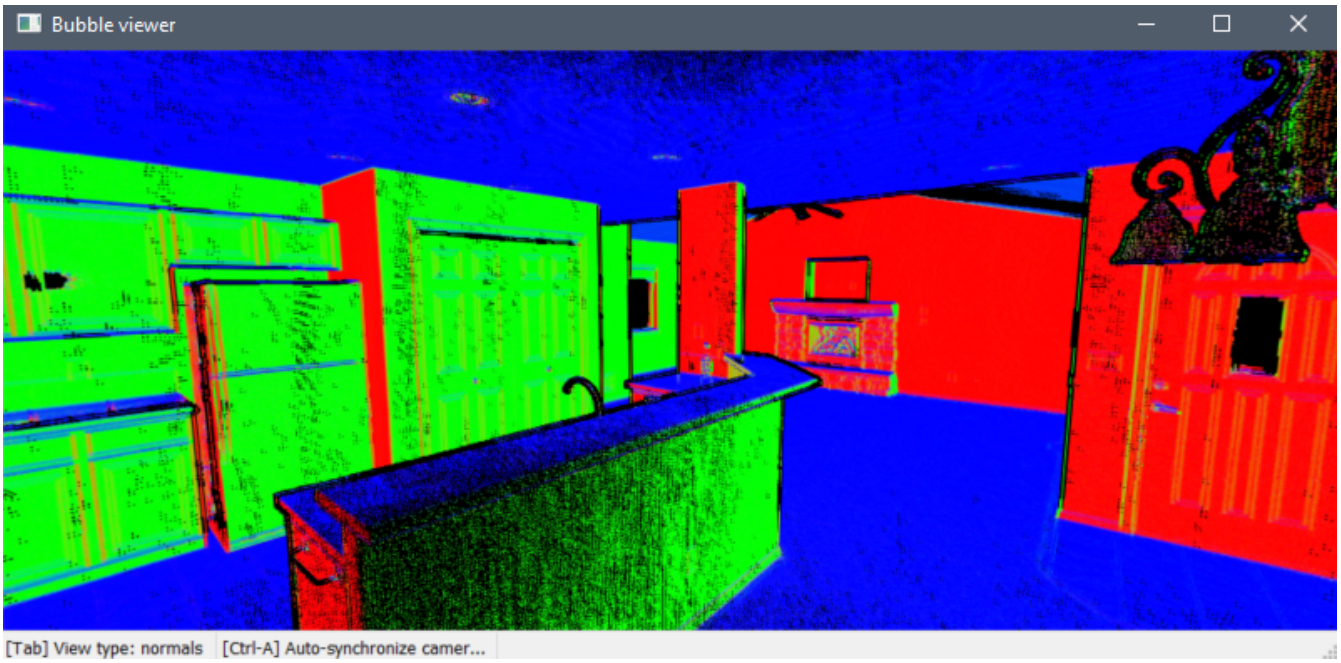

Figure 1.991

You can easily sync the drawing view to match the Bubble viewer by pressing Ctrl A. (1.993 on the facing page)

Figure 1.992

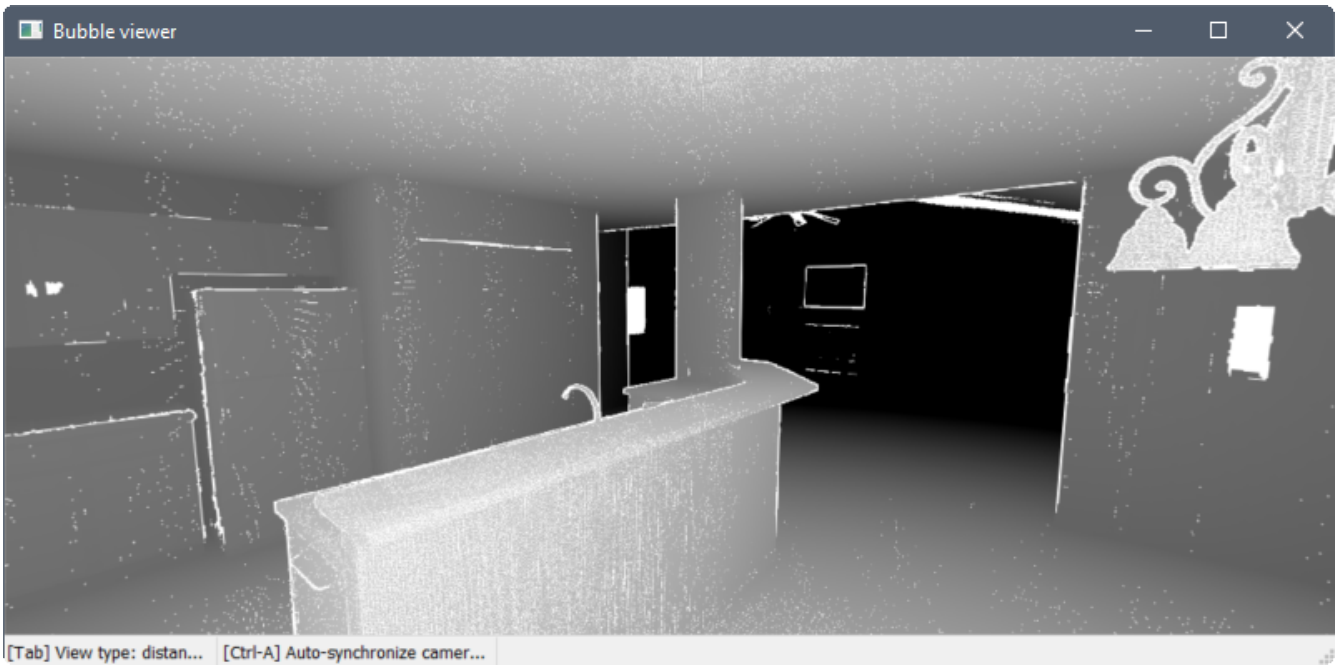

Figure 1.993

Entity snaps

The new Point Cloud Closest Point entity snap significantly improves your ability to select relevant point cloud points. It uses an imaginary cylinder from the current viewpoint toward the cursor. (1.994 on the next page) The radius of the imaginary cylinder is defined by the Entity snap aperture box setting. (1.995 on the facing page) Enable the new Point Cloud Closest Point entity snap along with other 3D entity snaps in the Entity Snap menus, toolbar, and settings. (1.996 on page 1086)

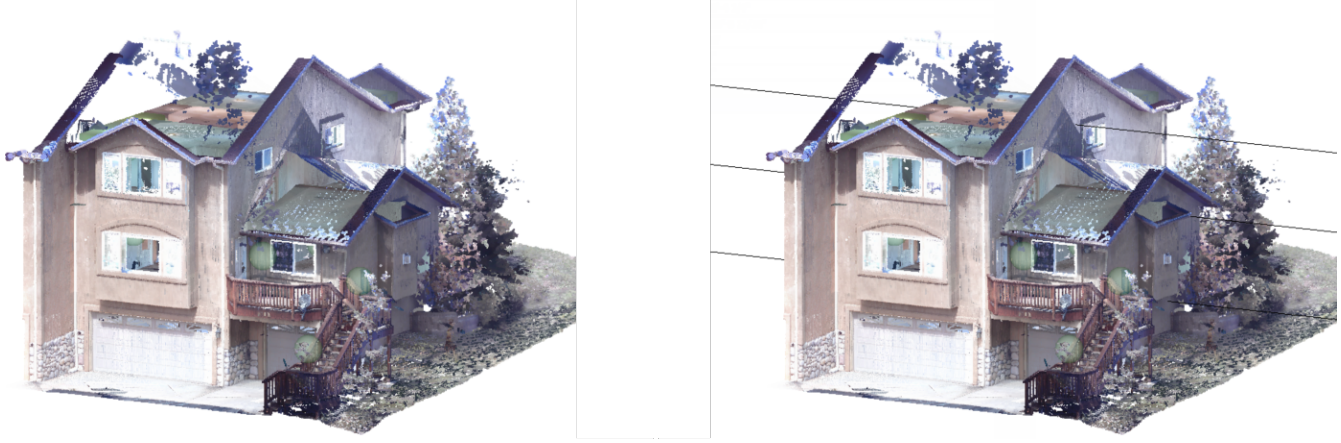
Export

The new POINTCLOUDEXPORT command allows you to export a cropped selection of a point cloud to a .pts file.

Floor Detection

Sectionplanes work on point clouds as well, they can be used to show parts of point clouds. The difference between point cloud crops and sectionplanes is that point cloud crop only clips the point cloud while section planes will clip all geometry in your drawing. The new **POINTCLOUDDETECTFLOORS** command generates volume sections for each floor found in a point cloud representing a building. The detection is based on regions of points with similar Z-coordinates. The generated volume sections can help in navigating point clouds of buildings. (2.927 on page 2523)

Figure 1.997



Planar Fit

The new **POINTCLOUDFITPLANAR** command enables you to create 3d geometry based on the point cloud. It will create a planar surface or solid after a selection of one point in a point cloud. The points that seem to be in a plane are never exactly in one plane, therefore a threshold value is set as a property of the point cloud entity. This also works in bubble view. **In bubble view** If the bubble viewer is open before launching the command, BricsCAD expects you to select in the bubble viewer. The cursor will give you a preview of the direction of the plane. When you click you get a preview in both bubble view and model view. You can toggle between 2 shape representations using the CTRL-key. (2.929 on page 2525) (2.931 on page 2526) **In model space** You can also use this command in the model space when the bubble viewer is not open. BricsCAD will ask you to select a point of the point cloud in model space. Depending on the size of the cropped point cloud, it takes more time but it has 2 advantages by searching multiple scan positions:

- It can create larger surfaces where only parts are visible in each scan position
- It can detect wall and slab thickness since it can take the opposite surface into account.

(2.47 on page 1612) (2.48 on page 1612)

Figure 1.998

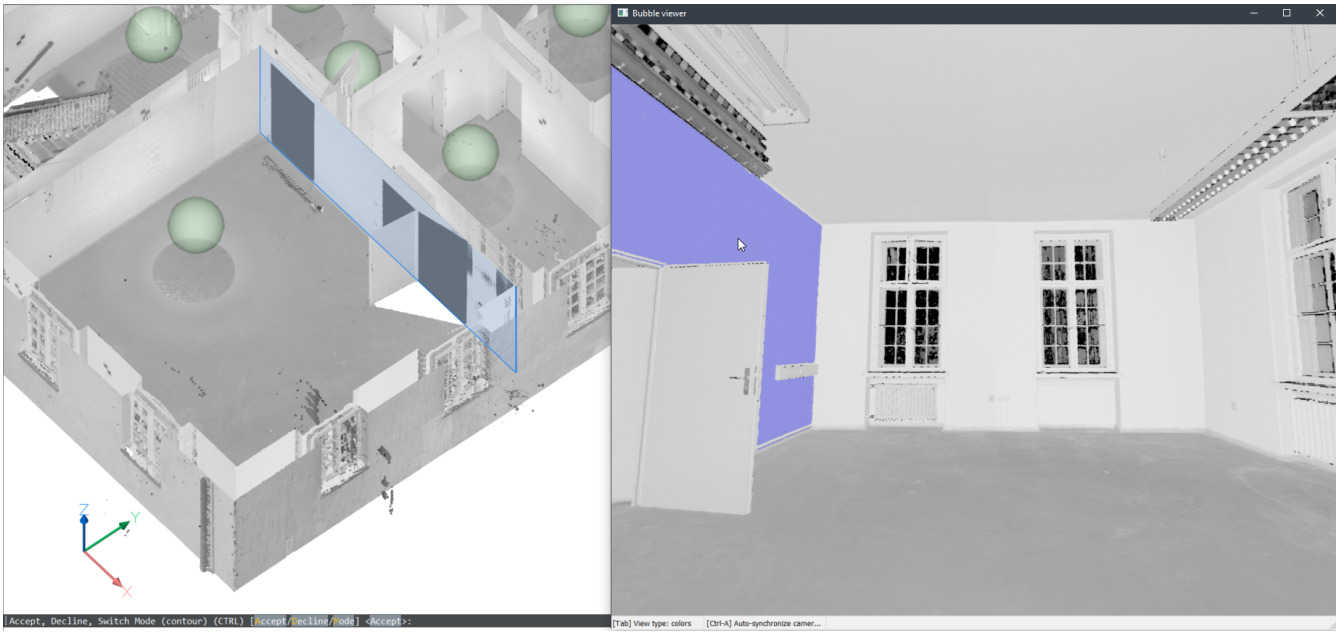


Figure 1.999

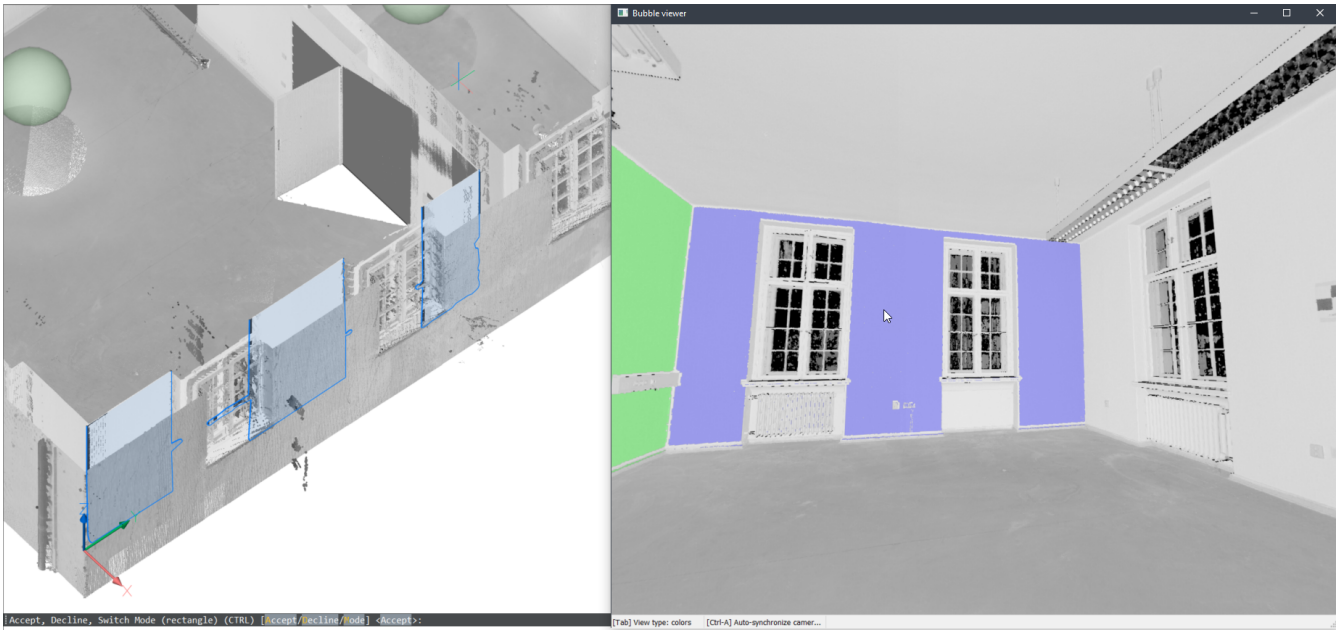

Figure 1.1000

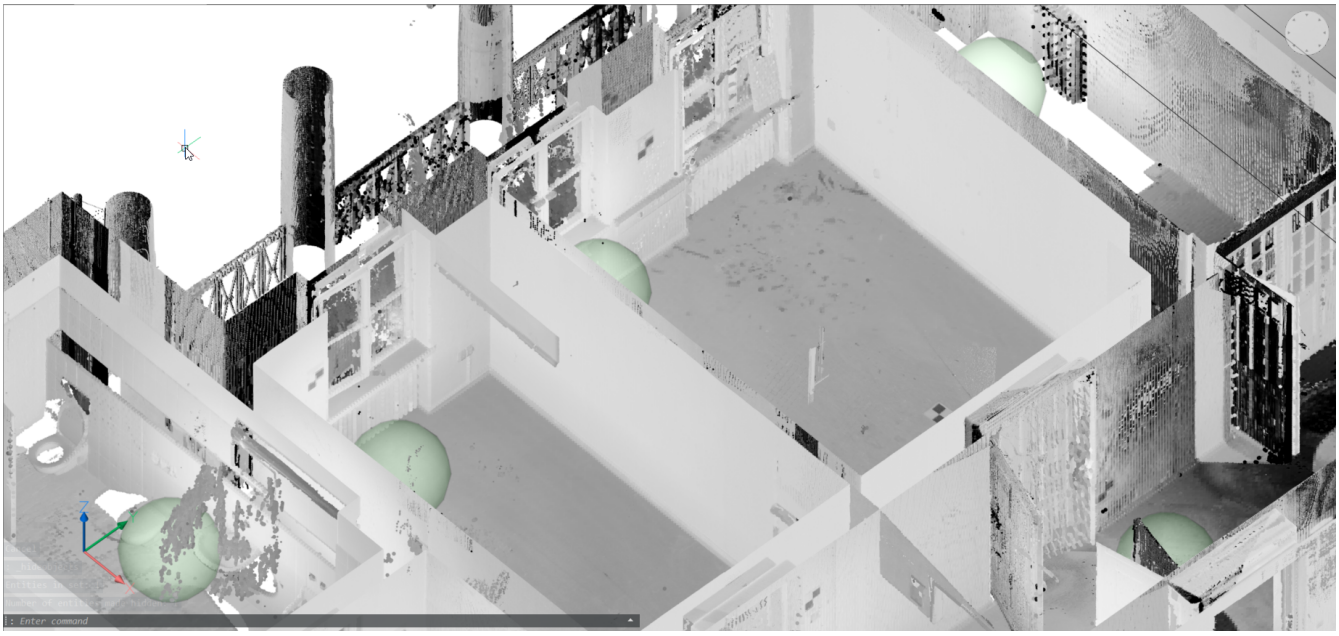

Figure 1.1001

Point cloud projection

The new **POINTCLOUDPROJECTSECTION** command enables you to detect walls from the volume section of a point cloud based on a variety of wall detection options. You can create volume sections automatically for each floor in a building. You can use these sections to generate 2d lines to create a 2d floorplan or a vertical section. This is a background process and multiple sections can be processed in a queue. This way it is possible to run this command in full resolution on all sections. (2.940 on page 2535)

At the same time, a raster image will be generated. In some cases it is not necessary to recreate the existing building. Background images can give so much more context to the design documents. These can be used to verify the created 2d geometry but in high quality scans these images can also be used as graphical material. For example, as a background image for a BIM model in renovation projects where modern intervention are made in historical buildings. (2.942 on page 2537)

1.28.2 Working with point clouds (V20)

Point clouds in BricsCAD has changed significantly in BricsCAD V20 compared to V19: improved data representation and the introduction of a point cloud cache manager.

New improved data representation The internal representation has changed. The output used to be one monolithic binary file with extension .bpt, but is now one project file with extension .vrm accompanied by a folder with the actual point data. This new format has the following advantages:

- It can be displayed faster and more realistically.
- While the old format was up to two times larger on disc than the source data, the new format is up to two times smaller than the source data.
- The data format is fully compatible with the Bricsys Insight VR software.

Point cloud cache manager Before, data needed to be explicitly preprocessed before attaching them to a dwg. Now, this process is simplified by our new point cloud management system.

- A user can directly attach point cloud source data to a dwg.
  - * The cache manager will perform the preprocessing in the background if needed and attach the point cloud to the dwg.
  - * When this data has been processed before (and this thus found in cache), it is directly attached.
- All the cached datasets are centralized in the cache manager, so there is no more need to move around converted datasets. This cache manager also keeps track how much data it contains and warns the user when this is larger than a preset maximum size.

The location and size of the cache folder is set through the PointCloudCacheFolder and PointCloudCacheSize user preferences. For the following example, we used a dataset publicly available on `https://www.navvis.com/m6-pointclouds`. The source file contains 63 million points and takes about 2 minutes to import. (1.1004 on the next page) **Fun tip**: use the NAVIGATE (6.22.1) command to walk inside an imported point cloud. For the example above, the screenshot below shows an impression from inside the point cloud. (1.1005 on the facing page)

Figure 1.1004

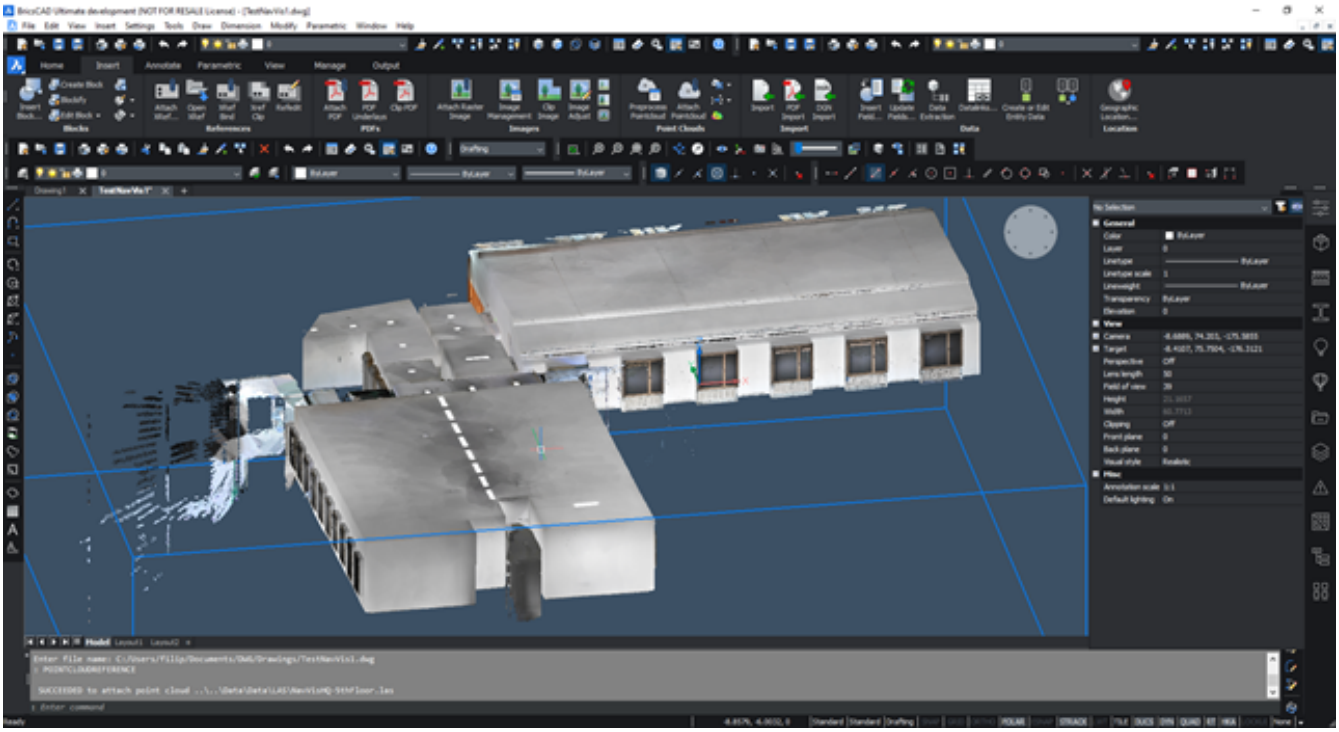

Figure 1.1005

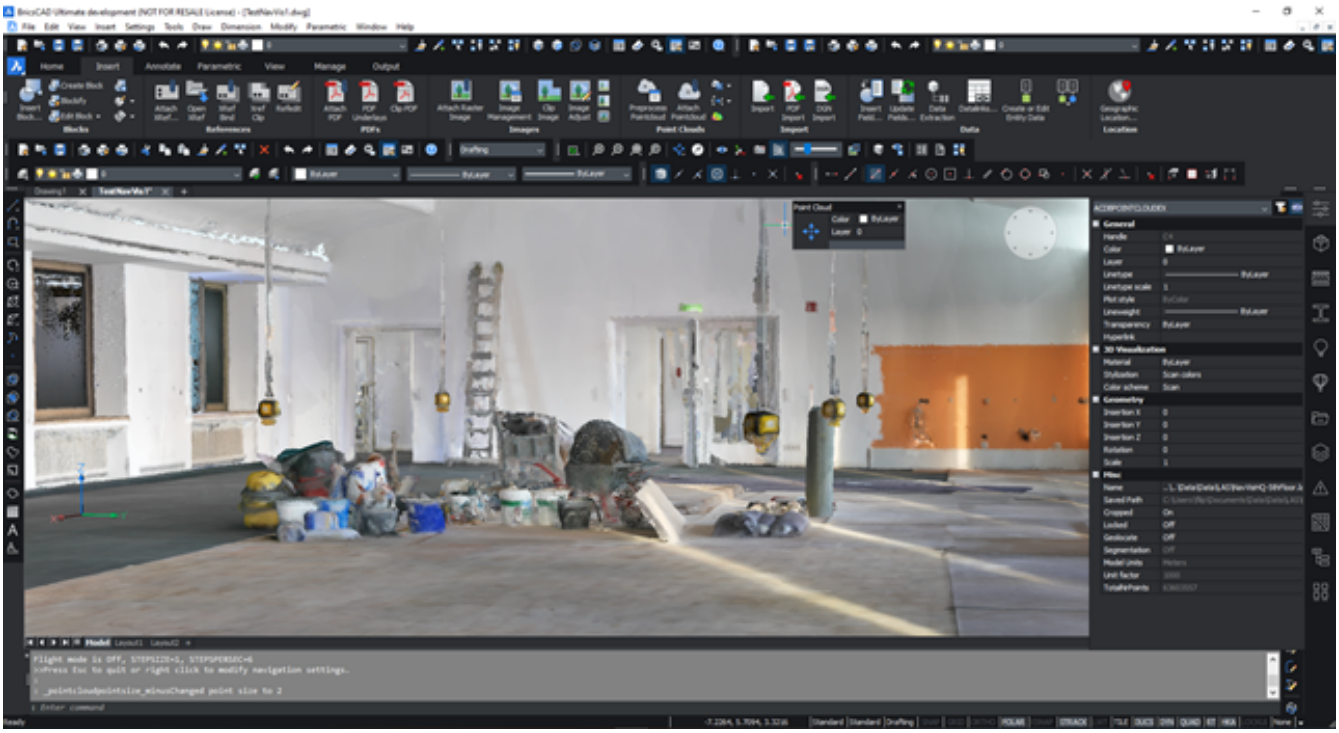


Point cloud user scenarios

To attach a .ptx, .pts, .las or .rcp point cloud file This can now be done directly by attaching such data to the dwg. The preprocessing is executed in a background process and you are notified when it is ready. Then, the point cloud data display after a simple REGEN (6.26.23).

To send a .dwg file with point cloud data attached to another user

- User A creates the dwg and attaches the point cloud data to it. This creates a cache representation on the computer of user A in the point cloud cache folder, e.g. C:\Users\<UserName>\AppData\Roaming\Bricsys\BricsCAD\V2
- When user B wants to work on this dwg, he has to receive both the dwg and the point cloud source data at the same relative path to the dwg as when user A created it.
- When user B then opens the dwg in BricsCAD, the cache will be generated automatically.
- This also applies to a dwg with an rcp attached, as created in AutoCAD.

Attach a point cloud to multiple drawings When you create a new dwg at the same relative path to the point cloud source data and you want to attach these data to the new dwg, the caching recognizes the file location and the data is immediately attached and displayed.

New Point Cloud commands for V20

POINTCLOUDIMPORT (6.24.40): When a point cloud was already preprocessed outside the caching system (like a beta of V20 or the Bricsys VR software Insight), this command lets the user import those data into the cache manager.
POINTCLOUDREFERENCE (6.24.45): opens a dialog to let the user select a dataset from the cache and attach it to a dwg. POINTCLOUDDELETEITEM (6.24.38): opens a dialog to let the user select a dataset from the cache to delete it from disc.

Other new features in V20:

- The POINTCLOUDPREPROCESS command gives balloon progress updates during its computations.
- The POINTCLOUDPREPROCESS command and POINTCLOUDATTACH command now have unattended counterparts, being resp. -POINTCLOUDPREPROCESS and -POINTCLOUDATTACH The result is that the item will prepared in cache AND attached to the current dwg. The user gets to see a notification balloon when the preprocessing is finished. Possibly, a REGEN is needed for now to update the drawing. This also means that the POINTCLOUDPREPROCESS command will no longer be required and probably will disappear.

For legacy reasons, attaching old bpt files will still be supported in V20, but new bpt files can no longer be created. After V20, support for bpt files will be dropped completely. The rest of the functionality remains the same:

- Snapping behavior to point cloud points while editing.
- Sectionplanes (clipping the whole scene including the point cloud) .
- Pointcloudcrop (clipping just the current point cloud object).
- Colormaps: use false colors to highlight differences in intensity or elevation.
- Behavior in drawing explorer (add/modify/remove point cloud definitions).
- Properties panel: when a point cloud is selected, several properties are available for inspection and even direct modification.
- Geometric properties, such as rotation (around the z-axis), scale and insertion X,Y,Z color map to be applied.

1.28.3 Working with Point Clouds (V19)

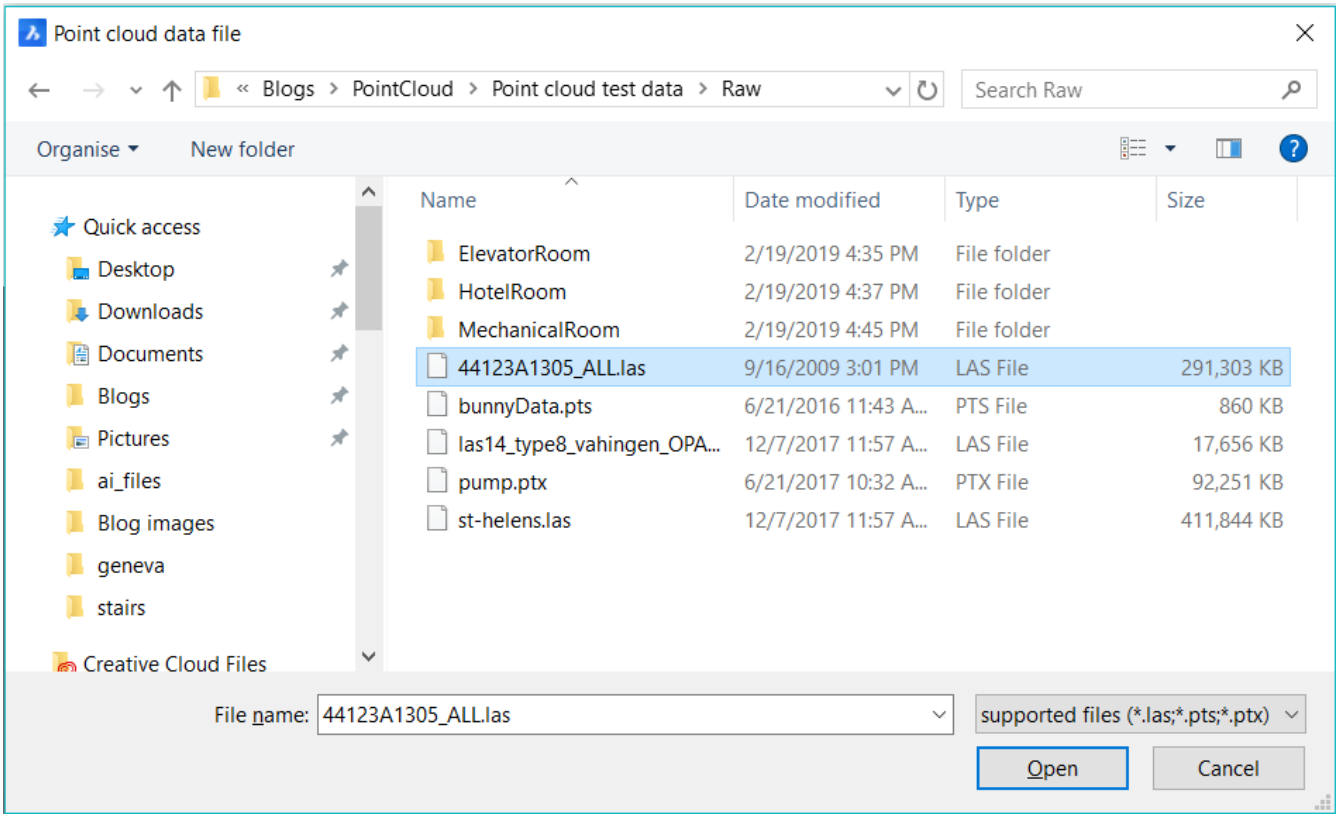
Commands: PointCloud, (6.24.31) PointCloudAttach, (6.24.35) PointCloudBoundary, (6.24.36) PointCloudColorMap, (6.24.37) PointCloudCrop, (6.24.41) PointCloudPointSize, (6.24.55) PointCloudPointSize_Minus, (6.24.43) PointCloudPointSize_Plus, (6.24.48) PointCloudPointMax, (6.24.49) PointCloudPreprocess, (6.24.63) PointCloudUncrop (6.24.46) Overview: In this article, you learn how to use point clouds in BricsCAD.

1. Prepare the data into the right format using preprocessing.
2. Attach the prepared data to a drawing in BricsCAD.
3. Use the drawing with the points, eg as a blueprint to start a drawing.

Preprocessing

File types supported: .las .pts .ptx. To be able to navigate large point cloud datasets quickly, its data must be preprocessed. Use the command POINTCLOUDPREPROCESS (6.24.63). This opens a file dialog that lets you select input point clouds. (1.1006 on the next page) The next step is to select the name of the preprocessed output file. By default, the file dialog suggests the same name of the input file (without numbers before the extension). This name can be modified. The file type is .bpt (Bricsys Point Tree). **For AutoCAD® users:** This is the equivalent of creating a .rcp file in Recap.

Figure 1.1006



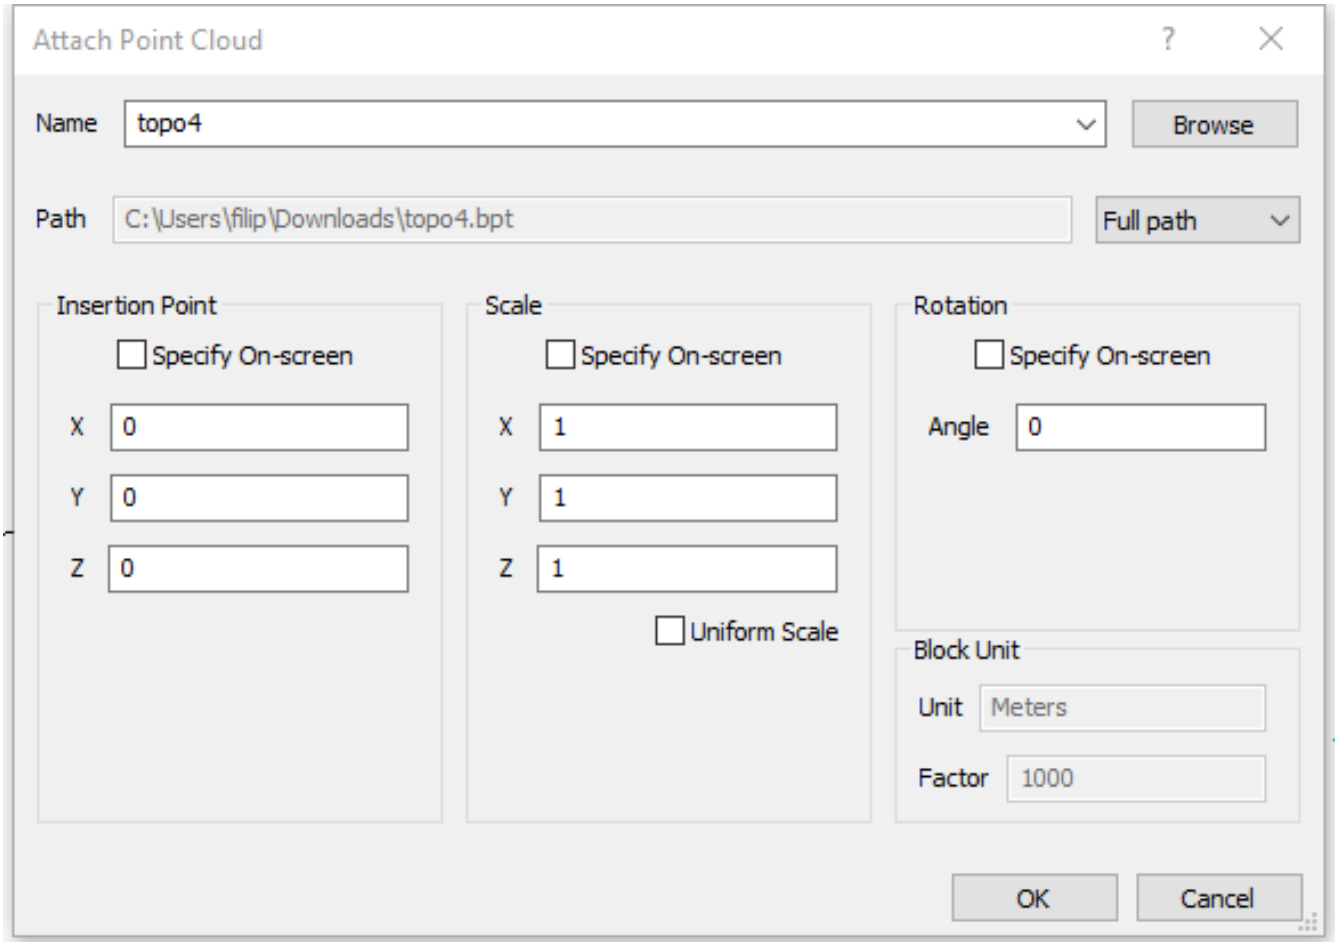
Attach to a drawing

Use the command POINTCLOUDATTACH (6.24.35) to attach the preprocessed .bpt file to the current .dwg file. **Note:** A point cloud can NOT be attached to an empty template. The .dwg has to be saved first. This is because the attached point cloud uses a relative path. When the .bpt to be attached is selected, a dialog appears. This allows the user to specify how to insert the point cloud into the drawing. (1.1007 on the facing page) **Figure 1: point cloud attach dialog. Here the user gets the possibility to choose how the point cloud is to be inserted in the drawing.** Options are:

- Insertion point
- Scale
- Rotation

When the checkbox "specify on screen" is checked, an insertion box will appear to let the user determine translation/rotation/scaling whilst placing the point cloud on the drawing. For the other options, the values in the dialog boxes will be used.

Figure 1.1007



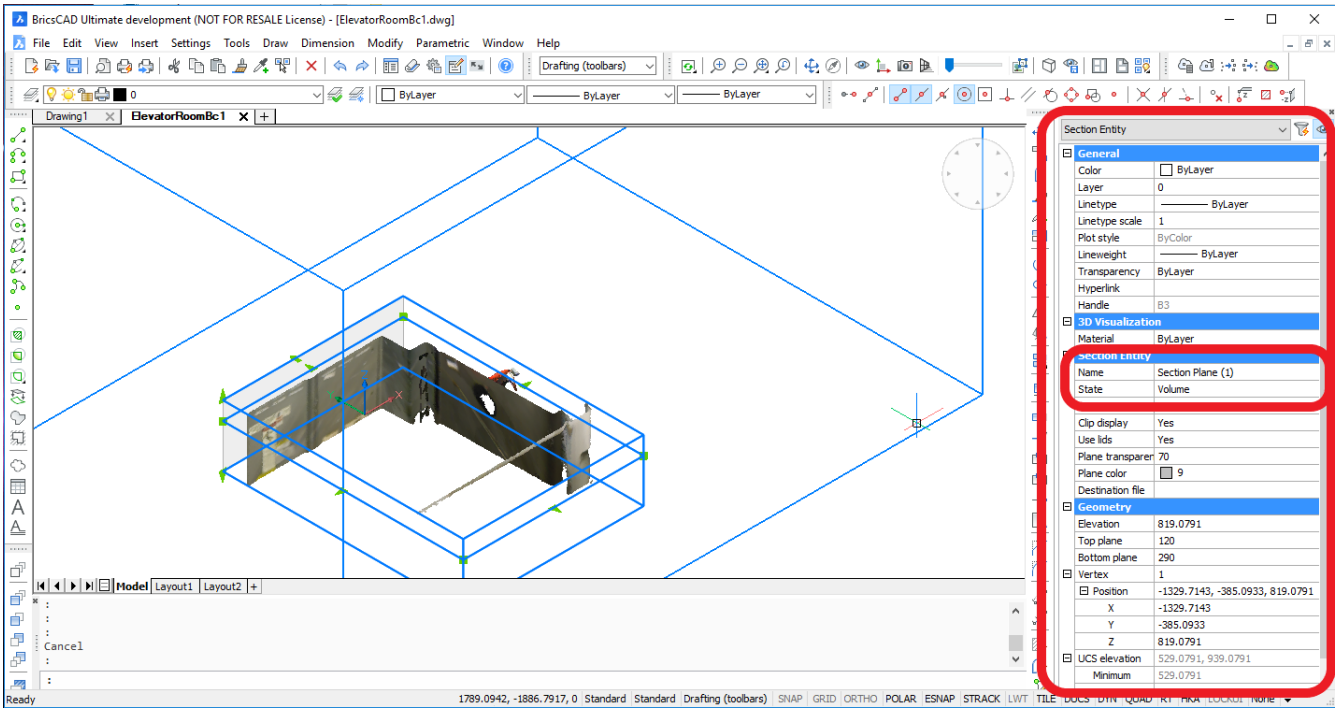
Procedure: Manipulate point cloud in .dwg

Once the point cloud is attached, it can be manipulated like other entities. Moved /rotated/scaled using the Quad. It also responds to section planes. Use the command **SECTIONPLANE** to hide parts outside section planes (Figure 2). **Note:** A section plane has three states:

- Plane: Clip everything away at one side of the plane.
- Boundary: Define an infinite extrusion of the contour drawn on the screen.
- Volume: The same as Boundary, but with a given top and bottom plane.

(1.1008 on the next page) **Figure 2: A point cloud with a section plane (inner blue cuboid). In red: the section plane Properties panel. The section plane state is set to "volume".** Snapping to visible points in the cloud is also possible. Turn on endpoint and/or midpoint, to snap to points on a point cloud.

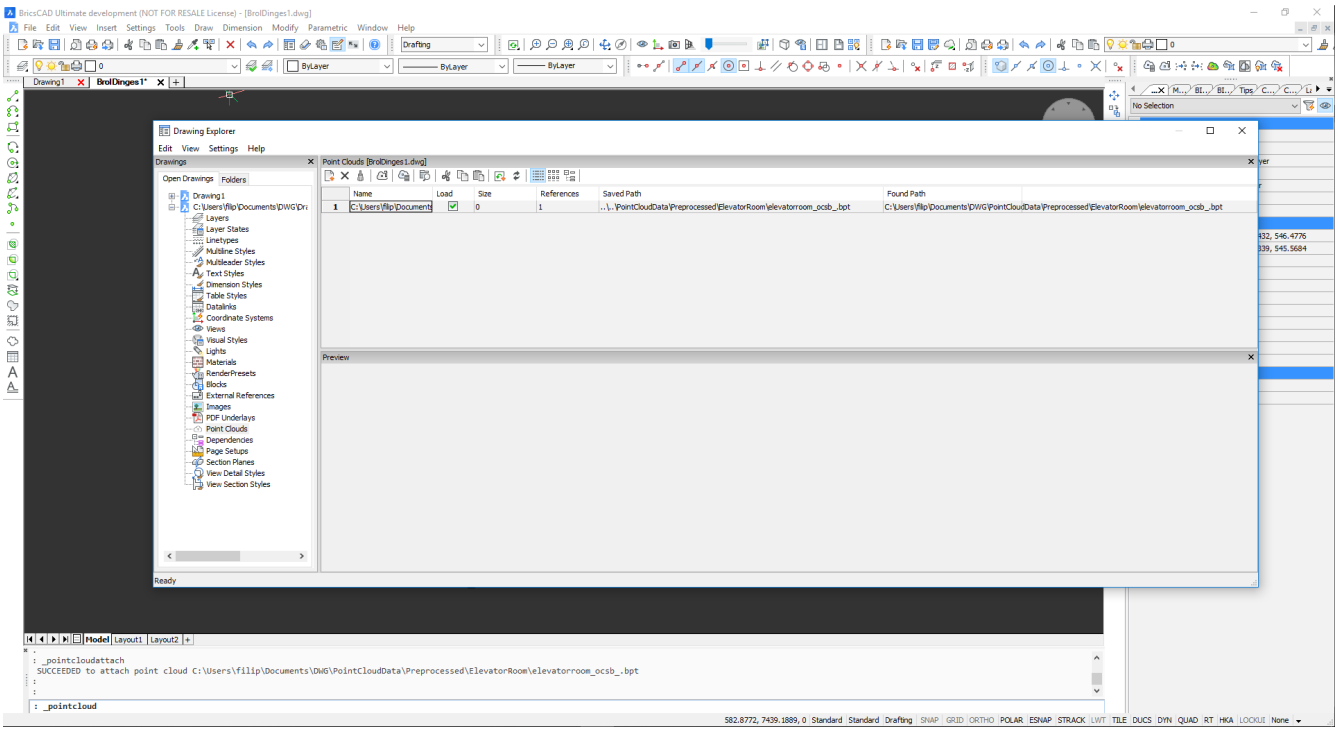
Figure 1.1008



Drawing Explorer

(1.1009 on the facing page) **Figure 3: An example of the Drawing Explorer for point clouds.** The Drawing Explorer also supports point clouds, in particular the definitions of the point clouds attached to a dwg. When receiving a dwg and a point cloud of which the path cannot be referred correctly on your computer, it is possible to adjust the path for the point cloud there. The Drawing Explorer can be found via the GUI menus or via the command PointCloud (6.24.31)

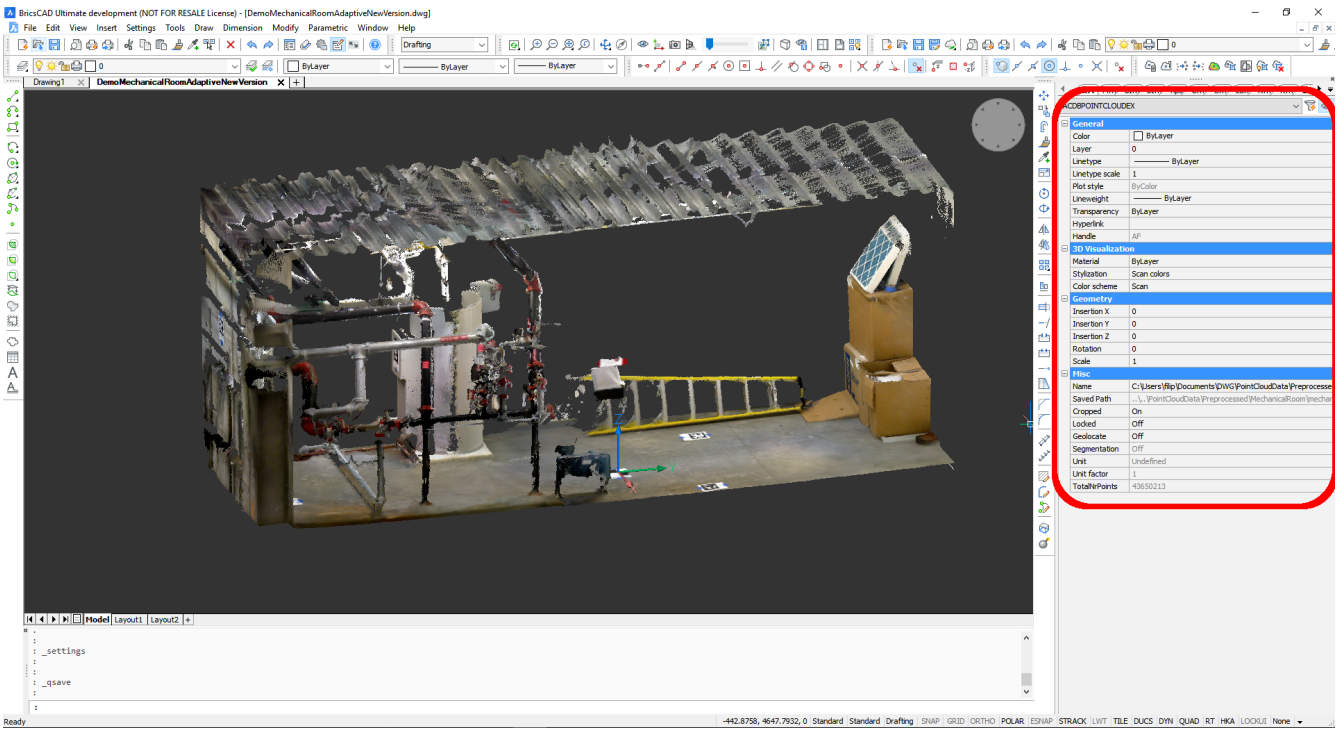
Figure 1.1009



Properties panel

(1.1010 on the next page) **Figure 4: A point cloud in BricsCAD. In red left, the point cloud Properties Panel is shown. This panel appears when the point cloud is selected.** When clicking (and thus selecting) a point cloud, its properties become available in the properties panel. From there, properties like insertion point, rotation, scaling, colormap, ... can also be adjusted.

Figure 1.1010



Other functionalities

- **Colormap** (POINTCLOUDCOLORMAP (6.24.37)): False colors can be assigned to the points corresponding to intensity or elevation. Choose single spectrum colors such as red or blue, or go the whole spectrum.

(1.1011 on the facing page) **Figure 5: some examples of colormaps in function of the point elevation. The left part has colormap "Spectrum"; the middle part colormap "Hydro" and right part has colormap "Earth".**

- **Cropping** (POINTCLOUDCROP (6.24.41)): Crop only the current point cloud, leaving other entities unaffected. A section plane crops everything in the scene.
- **Point Size** (POINTCLOUDPOINTSIZE (6.24.55)): Change display size of points. (Can be useful to make virtually fill in gaps.)
- **Maximum number of points displayed** (POINTCLOUDPOINTMAX (6.24.49)): Change the maximum number of points displayed. Since a computer screen has only a few million pixels, it makes no sense to display billions of points at the same time. This parameter sets the maximum for the number of points to be shown at any given instance on screen. Make no mistake, the actual point cloud can be many times larger than this (easily a few hundred million points and more).
- **Boundary** (POINTCLOUDBOUNDARY (6.24.36)): Show or hide the point cloud bounding box.

(1.1012 on the next page) **Figure 6: point cloud has been sectioned and the left image shows the point cloud with boundary whereas the right image shows the point cloud without boundary.**

Figure 1.1011

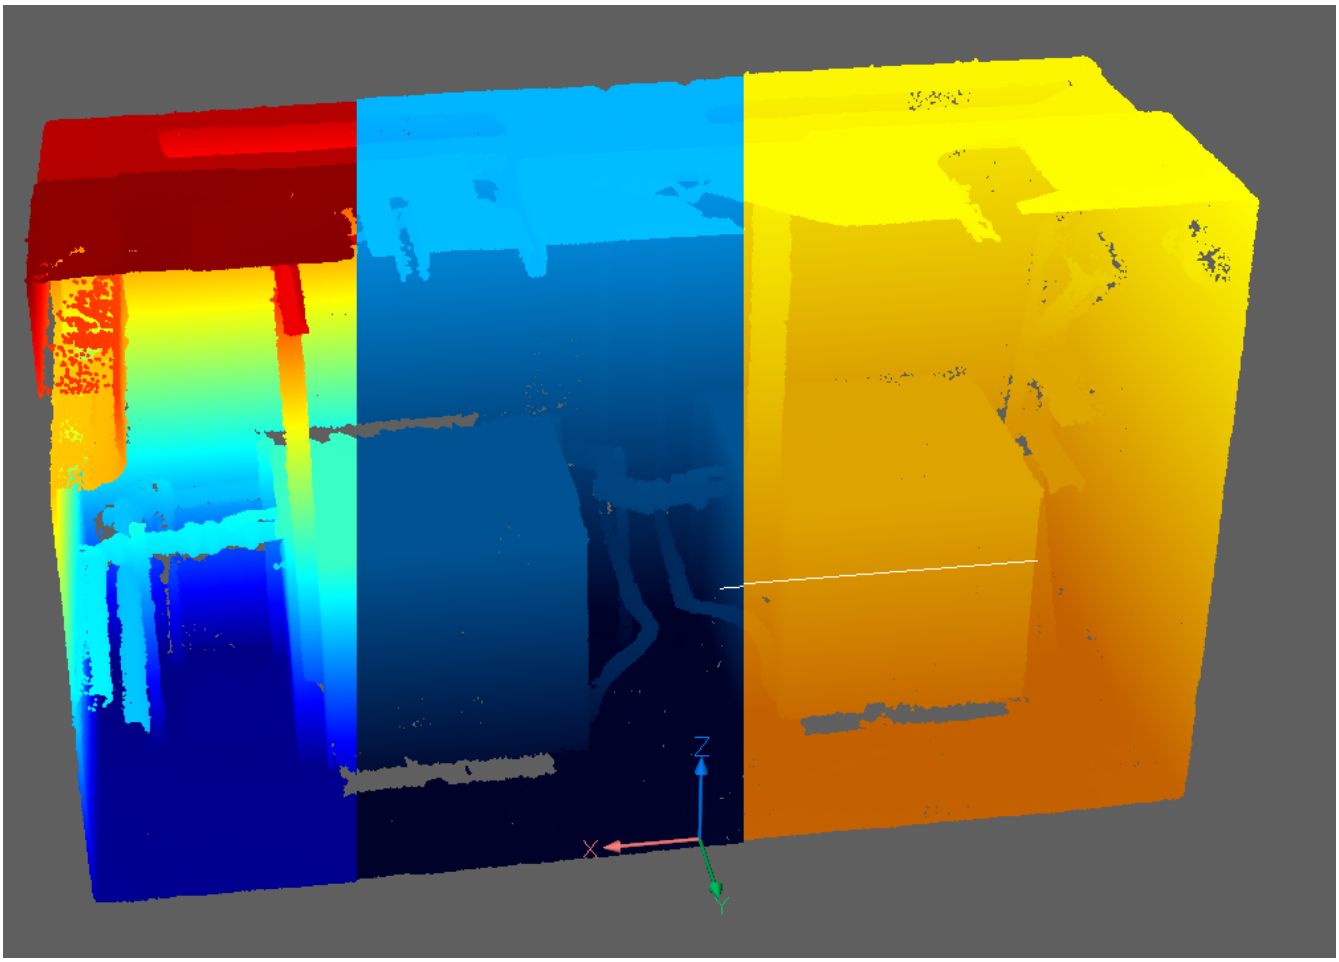


Figure 1.1012

AutoCAD® compatibility

AutoCAD® can open and use the .dwg with the same point cloud, clippings and other entities present in the drawing. When the user also has AutoCAD® and Recap, save the Recap preprocessed, point cloud file in the same location with the same name as our .bpt file. The extension will be different (.rcp). **Note**: This applies to BricsCAD V19 only. Between V19 and V20, there were major disruptive changes in the way point clouds are processed in BricsCAD.

1.29 Annotate

1.29.1 Dimensioning tools overview

All tools to create dimension entities can be found either on the **Dimensions** toolbar or in the **Dimensions** menu.

Toolbar
(1.1013 on the following page)
Menu
(1.1014 on page 1107)

Icon	Tool name	Command	Description
	Linear (1.29.7)	DIMLINEAR (6.11.12)	Creates horizontal or vertical linear dimensions.
	Aligned (1.29.7)	DIMALIGNED (6.11.3)	Creates linear dimensions which are aligned with the dimension points.
	Arc (1.29.7)	DIMARC (6.11.5)	Creates arc length dimensions
	Radius (1.29.9)	DIMRADIUS (6.11.16)	Creates radial dimensions in circles and circular arcs.
	Diameter (1.29.9)	DIMDIAMETER (6.11.9)	Creates diametrical dimensions in circles and circular arcs.
	Angular (1.29.8)	DIMANGULAR (6.11.4)	Creates angular dimensions
	Baseline (1.29.7)	DIMBASELINE (6.11.6)	Creates stacked linear dimensions.
	Continue (1.29.7)	DIMCONTINUE (6.11.8)	Creates a chain of linear dimensions, starting from an existing linear dimension entity.
	Ordinate (1.29.12)	DIMORDINATE (6.11.14)	Creates ordinate dimensions.
	Rotated (1.29.7)	DIMLINEAR (6.11.12)	Creates rotated linear dimensions.
	Make Oblique (1.29.14)	DIMEDIT (6.11.11) + O	Makes the extension lines of the selected dimension(s) oblique.
	Multileader (1.29.13)	MLEADER (6.21.19)	Creates Mleaders (multileaders) using a multileader style.
	Edit Multileader	MLEADEREDIT (6.21.22)	Adds leader lines to and removes leader lines from a multileader entity.
	Multileader add leaders	AIMLEADEREDITADD	Adds leader lines to a multileader.
	Multileader remove leaders	AIMLEADEREDITREMOVE	Removes leader lines from a multileader.
	Tolerance (1.29.15)	TOLERANCE (6.29.26)	Defines the layout of geometric tolerances.
	Center Lines (1.29.9)	DIMCENTER (6.11.7)	Draws center lines in circles and circular arcs.
	Edit Dimension Text (1.29.14)	DIMEDIT (6.11.11)+ E	Defines the dimension text of the selected dimension(s).
	Rotate Dimension Text (1.29.14)	DIMEDIT (6.11.11)+ R	Rotates the dimension text of the selected dimension(s).

	Reposition Dimension Text (1.29.14)	DIMTEDIT (6.11.23)	Lets you reposition the dimension text.
	Restore Text Position (1.29.14)	DIMEDIT (6.11.11)	Undoes the rotation or repositioning of the dimension text of the selected dimension(s).
	Apply Style (1.29.6)	-DIMSTYLE (6.11.21) + A	Applies the current dimension style to the selected dimension(s).
	Save Style (1.29.6)	-DIMSTYLE (6.11.21) + S	Saves the current dimension settings in a new dimension style.
	Restore Style (1.29.6)	-DIMSTYLE (6.11.21)	Sets the current dimension style.
	Dimension Variable Status (1.29.4)	-DIMSTYLE (6.11.21) + ST	Displays the status of the dimension variables in the command bar and the Prompt History window.
	Leader (1.29.11)	DIMLEADER (6.11.13)	Creates a leader with or without text.
	Quick Leader (1.29.11)	QLEADER (6.25.3)	Draws leaders. Lets you specify the properties of the leader through a dialog box and reuse them for a series of leaders.

Figure 1.1013

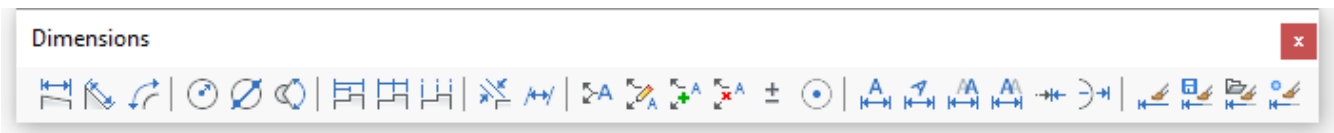

Figure 1.1014

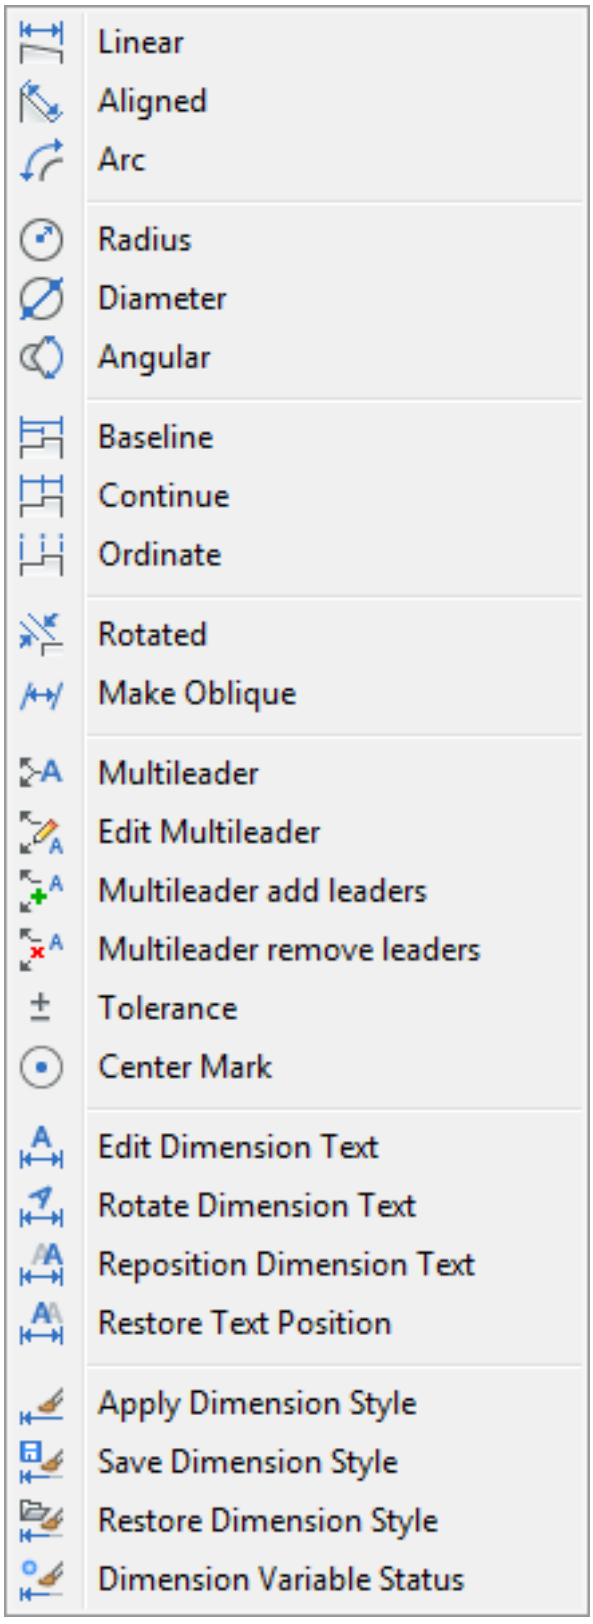

Figure 1.1015

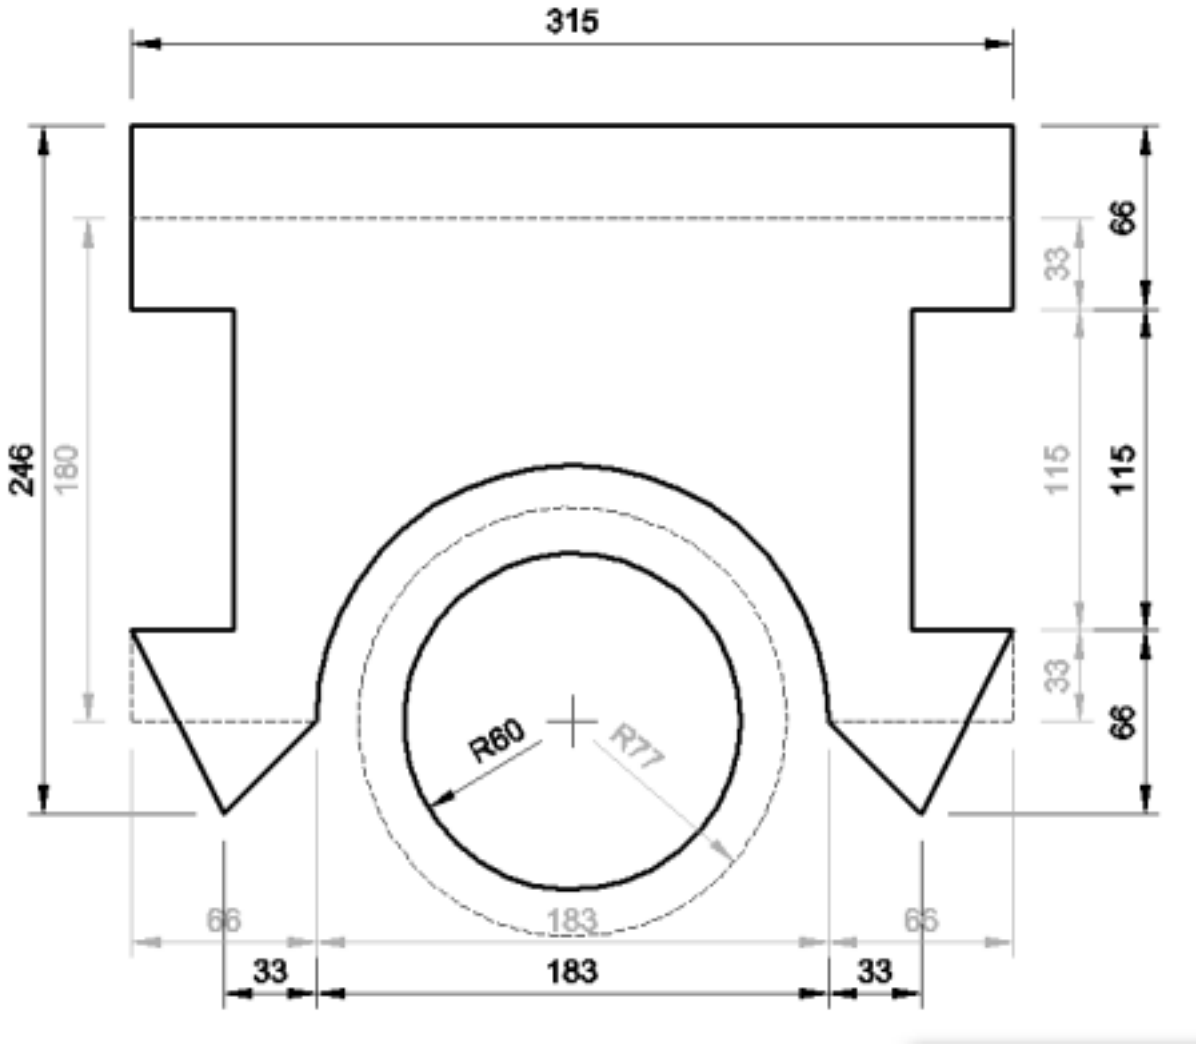


1.29.2 Associative Dimensions

Dimensions created in BricsCAD are associative: if the dimensioned entity is moved or modified, the dimensions will update automatically. The associative property of dimensions also applies to dimensions which are placed in paperspace and are associated with model space entities. If necessary, you can use the DIMREGEN (6.11.20) command to update all associative dimensions. (1.1015) The following Entity Snaps (1.21.15) can be used to create associative dimensions: endpoint, midpoint, center, perpendicular, quadrant, insertion, point, intersection and apparent intersection.

1.29.3 Dimension Styles explorer

Command: DIMSTYLE (6.11.19) A dimension style is a collection of settings and definitions which determine the type of arrowheads, text style, color of text, lines and arrowheads, unit type, precision, etc. Dimension styles are saved in the drawing. You can create, edit and delete dimension styles. Dimension styles can be copied between drawings. Dimension styles which have the **Annotative** property create annotative dimensions (1.29.30).

NOTES

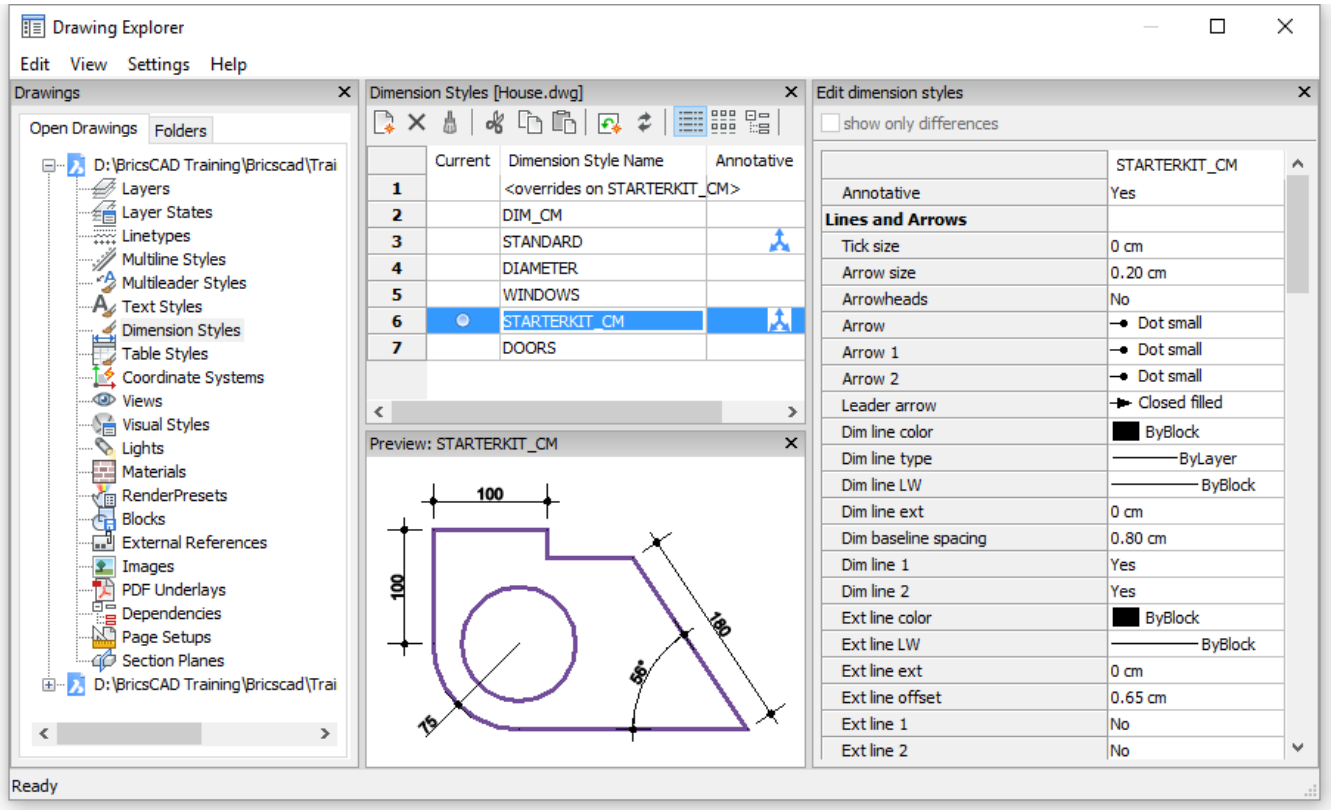
- You cannot delete the current dimension style.
- You cannot delete a dimension style that is used in the drawing.
- Each drawing contains at least one dimension style.

Exploring dimension styles

1. To open the **Dimension Styles Explorer** , do one of the following:
   - Choose **Dimension Styles ...** in the **Tools > Drawing Explorer** menu.
   - Double click the **Dimension Style** field in the Status bar (1.15.2).
   - Right click the **Dimension Style** field in the Status bar (1.15.2), then choose **Properties** in the context menu.
   - Type **dimstyle** in the command bar, then press Enter.

   (1.1016 on the next page) The current dimension style is marked in the **Current** column.
2. (option) Select a dimension style to see a preview.
3. (option) Select a dimension style then right click:
   - Choose **New** to create a new dimension style (1.29.5).
   - Choose **Delete** to delete the selected dimension style (1.29.5).
   - Choose **Cut** selected dimension style in the current drawing, then paste it in another open drawing (1.29.5).
   - Choose **Copy** , then paste it in another open drawing (1.29.5).
   - Choose **Paste** , to copy a previously cut or copied dimension style in the current drawing.
   - Choose **Rename** , to rename (1.29.5) of the selected dimension style.
   - Choose **Set current** in the context menu to make it the current dimension style (1.29.5).
   - Choose **Save overrides to current style** , to save all current overrides to the current style.
   - Choose **Save to new style,** to create a new dimension style as a copy of the selected dimension style.
4. (option) Modify a dimension style definition.
5. (option) Select **<overrides>** to define override settings for the current dimension style.

Figure 1.1016



Comparing Dimstyles

1. Open the Drawing Explorer > (1.29.3) Dimension Styles dialog.
2. Select 2 or more dimension styles. Press and hold the Ctrl-key to add more dimension style to the selection set. The properties of the selected styles display in the Editor pane. Properties that are different in one of the selected styles display on a yellow background. (1.1017 on the facing page)
3. Check the **Show only differences** option to display the properties that are different for at least one of the selected dimension styles only. (1.1018 on the next page)

Figure 1.1017

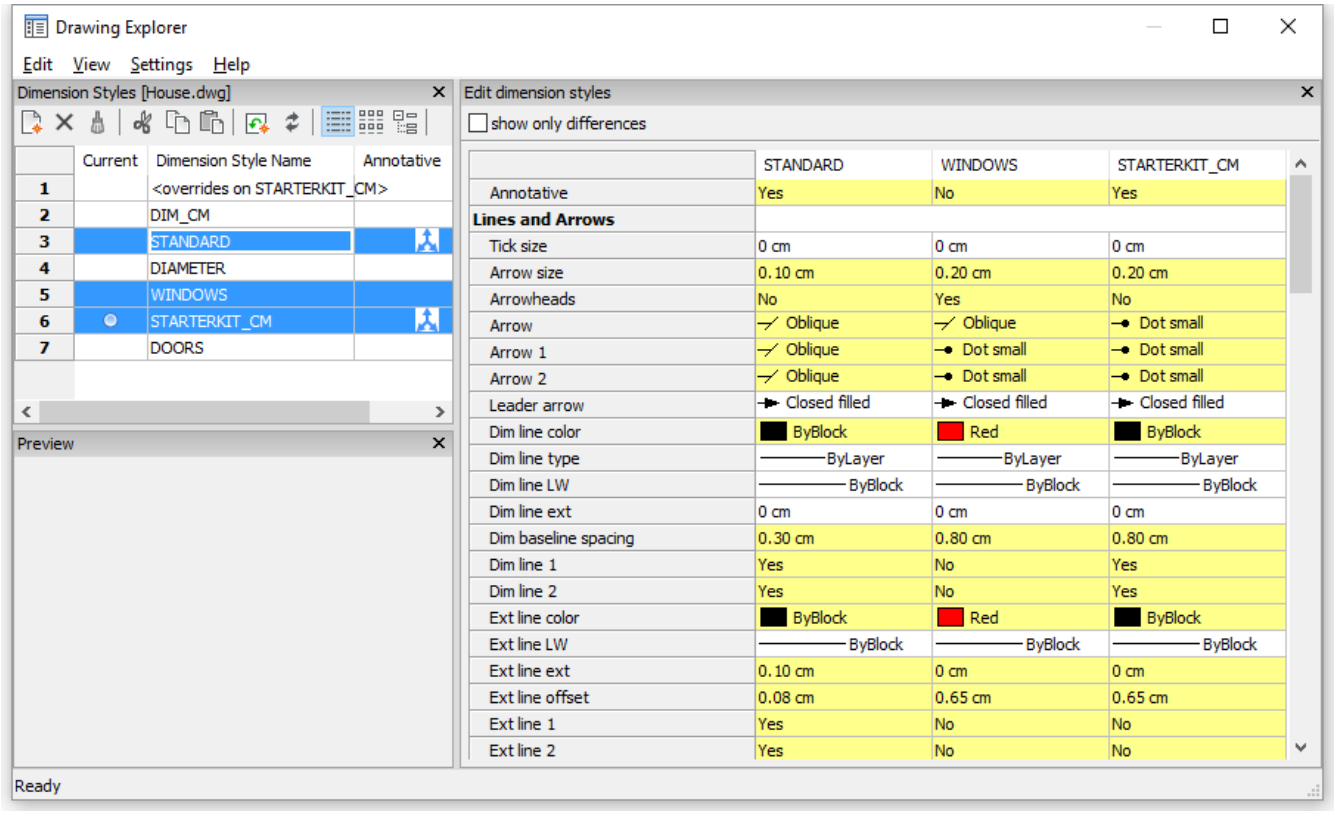


Figure 1.1018

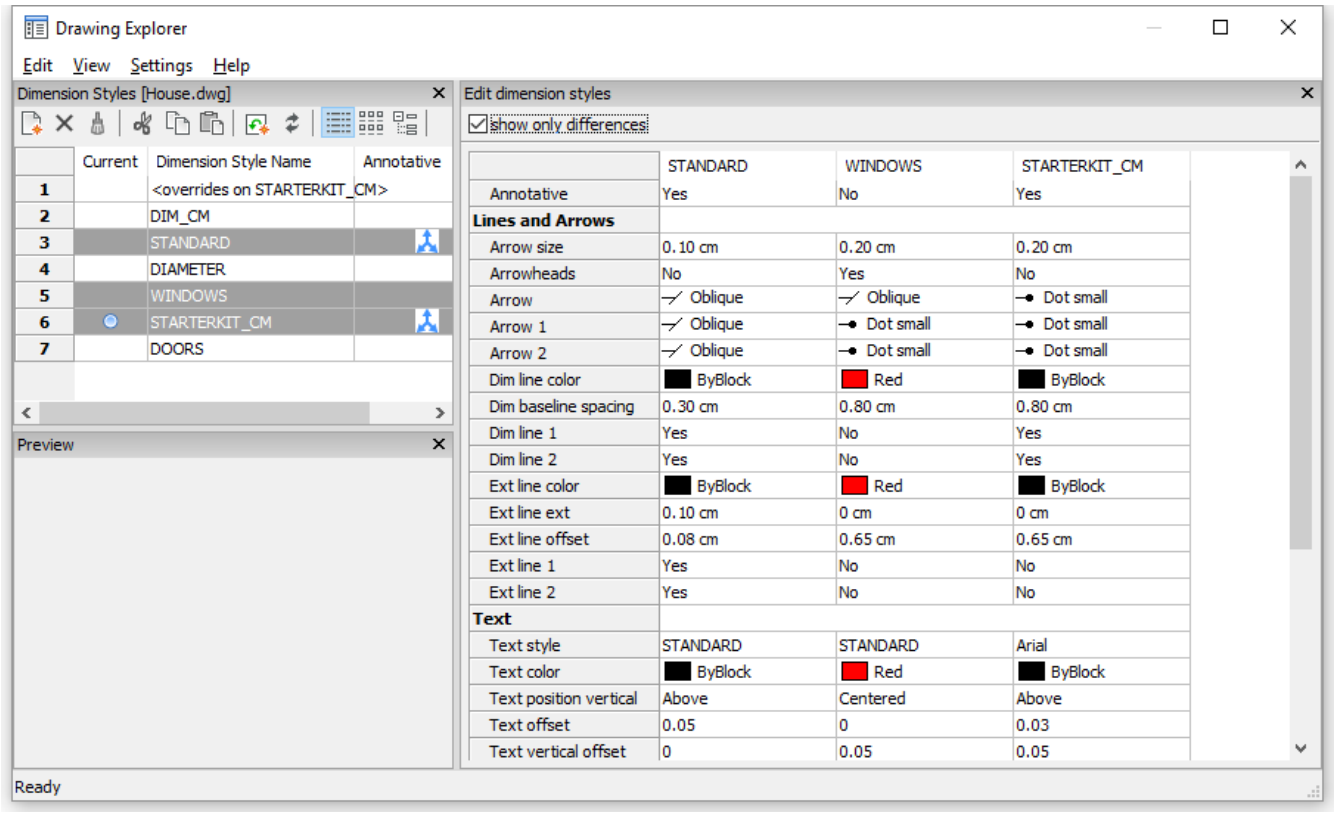


1.29.4 Dimension Settings

Commands: DIMSTYLE (6.11.19), -DIMSTYLE (6.11.21) A dimension style consists of six settings groups

- Lines and Arrows (6.11.19)
- Text (6.11.19)
- Fit (6.11.19)
- Primary Units (6.11.19)
- Alternate Units (6.11.19)
- Tolerances (6.11.19)

To list the current status of the dimension variables

1. Do one of the following:

   - Click the **Dimension Variable Status** tool button () on the **Dimensions** toolbar.
   - Choose **Dimension Variable Status** in the **Dimensions** menu.

   A list of all dimension variables displays in the command bar.

2. Press the **F2** function key to open the **BricsCAD Prompt History** window.
3. Press Enter to continue the listing.
4. Press the **F2** function key to close the **BricsCAD Prompt History** window.

1.29.5 Working with dimension styles

In the Dimension Styles explorer (1.29.3) you can:

- Create a new dimension style
- Edit a dimension style
- Define dimension style overrides
- Rename a dimension style
- Set a dimension style current
- Copy dimension styles between drawings
- Move dimension styles between drawings
- Delete a dimension style

To create a new dimension style

1. Open the Dimension Styles explorer (1.29.3) dialog.
2. Do one of the following:
   - Click the **New** button ( ).
   - Place the cursor on the dimension style list, then right click and choose **New** in the context menu.

   A **New Dimension Style** is added.
3. Select the **Name** field and type a name for the new dimension style.
4. Define the settings (1.29.4) for the new dimension style.

NOTE

- The **New** tool creates a new dimension style as a copy of the current dimension style.
- Use the **Save to new style** option of the context menu to create a new dimension style as a copy of the selected dimension style.
- Use the **Save overrides to current style** option of the context menu to create a new dimension style from the current override settings. This option is available if you select **<overrides>** only.
- Alternatively you can use the Save Style tool (1.29.6) to create a new dimension style.

To create a dimension child style

For each dimension style you can create a child style for each dimension type: Linear, Angular, Radius, Diameter, Ordinate and Leader. If the current dimension style has a child style for a dimension type, the child style will be used automatically when such dimension type is created.

1. Select the parent dimension style, then right click and choose a child style in the context menu. (1.1019 on the following page) The name of the child style is: <parent_style>:<child_style>
2. Select the child style and define the properties that need to be different from the parent style.

Figure 1.1019

To edit a dimension style

1. Open the Dimension Styles explorer (1.29.3) dialog in **Tree view** mode ( ).
2. Expand the dimension style.
3. Adjust the dimension settings (1.29.4).
4. Close the **Dimension Styles explorer** dialog.

To define dimension style overrides

1. Open the Dimension Styles explorer (1.29.3) dialog in **Tree view** mode ( ).
2. Select **<overrides>**.
3. Define the dimension override settings.
4. Close the **Dimension Styles explorer** dialog.

NOTES

- It is not recommended to create dimensions with overrides.
- Use the dimension override settings to test changes, without modifying the current dimension style definition, then use the **Save overrides to current style** or **Save to new style** option.
- Setting another style current will discard the existing dimension style overrides.

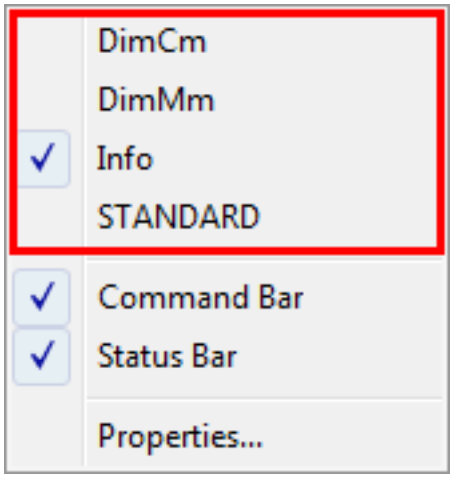
To rename a dimension style

1. Open the Dimension Styles explorer (1.29.3) dialog.
2. Select the dimension style you want to rename.
3. Right click, then choose **Rename** in the context menu.
4. Type a new name in the **Name** field, then press enter.

To set a dimension style current

1. Open the Dimension Styles explorer (1.29.3) dialog. The current dimension style is marked in **Tree view** and **Detail view** mode.
2. Select the dimension style.
3. Right click and choose Set current in the context menu. In **Tree view** and **Detail view** mode a mark indicates the selected dimension style is made current.

Figure 1.1020



2. Right click. A list of available dimension styles displays in the context menu. The current dimension style is checked. (1.1020)
3. Select the new current dimension style. The selected dimension style name displays in the **Dimension style** field of the **Status bar**.

NOTE Alternatively you can use the Restore Style tool (1.29.6) to make a dimension style current.

To copy a dimension style between drawings

1. Open the Dimension Styles explorer (1.29.3) dialog.
2. In the source drawing, select the dimension style you want to copy.
3. Do one of the following:
   - Click the **Copy** button ( ).
   - Right click, then choose **Copy** in the context menu.
4. In the **Open Drawings** section, expand the target drawing.
5. Select **Dimension Styles** in the target drawing. The list of the dimension styles in the target drawing displays in the **Details** section.
6. Do one of the following:
   - Click the **Paste** button ( )
   - Place the cursor on one of the existing dimension style names, then right click and choose **Paste** in the context menu.

NOTE To select multiple dimension styles, choose **Detail view** ( ) or **Icon view** ( ) in the **Drawing Explorer** dialog.

To move a dimension style between drawings

1. Open the Dimension Styles explorer (1.29.3) dialog.
2. In the source drawing, select the dimension style you want to move.
3. Do one of the following:
   - Click the **Cut** button ( ).
   - Right click, then choose **Cut** in the context menu.
4. In the **Open Drawings** section, expand the target drawing.
5. Select **Dimension Styles** in the target drawing. The list of the dimension styles in the target drawing displays in the **Details** section.

NOTE

- You cannot cut the current dimension style.
- You cannot cut a dimension style that is used in the drawing.
- To select multiple dimension styles, choose **Detail view** () or **Icon view** () in the **Drawing Explorer** dialog.

To delete a dimension style

1. Open the Dimension Styles explorer (1.29.3) dialog.
2. Select the dimension style you want to delete.
3. Do one of the following:
   - Click the **Delete** button ().
   - Right click, then choose **Delete** in the context menu.

The selected dimension style is deleted.

NOTE

- You cannot delete the current dimension style.
- You cannot delete a dimension style that is used in the drawing.
- To select multiple dimension styles, choose **Detail view** () or **Icon view** () in the **Drawing Explorer** dialog.

1.29.6 Using the dimension style tools

Command: -DIMSTYLE (6.11.21) Using the dimension style tools you can:

- Apply the current dimension style to a selection of dimension entities.
- Create a new dimension style.
- Restore a dimension style.
- List the current status of the dimension settings.

To apply the current dimension style

1. Do one of the following:

   - Click the **Apply Style** tool button () on the **Dimensions** toolbar.
   - Choose **Apply Style** in the **Dimensions** menu.
   - Type **-dimstyle** in the command window, press Enter then type **A** or **apply** and press Enter.

   You are prompted: Select dimensions to apply the current style.

2. Select the dimensions (1.32.7), then press Enter.

NOTE	Since the dimension style settings only apply to dimension entities, you can select all entities in step 2 to apply the current dimension style to all dimensions in the drawing.

To save a dimension style

1. Do one of the following:

   - Click the **Save Style** tool button () on the **Dimensions** toolbar.
   - Choose **Save Style** in the **Dimensions** menu.
   - Type **-dimstyle** in the command window, press Enter then type **S** or **save** and press Enter.

   You are prompted: Save style: ? to list styles/Name for new dimension style:

2. Type a name for the new dimension style, then press Enter.

3. (option) If the name already exists, the command bar prompts you to redefine it or not. **You are prompted:** That name is already in use. Redefine it? <N>: Do one of the following:

   - Press Enter to not overwrite the existing style. **You are prompted** to type a new name.
   - Type **Y** , then press Enter to update the existing dimension style.

To restore a dimension style

1. Do one of the following:

   - Click the **Restore Style** tool button () on the **Dimensions** toolbar.
   - Choose **Restore Style** in the **Dimensions** menu.
   - Type **-dimstyle** in the command window, press Enter then type **R** or **restore** and press Enter.

   You are prompted: ? to list styles/Enter to select dimension/<Dimension style>:

2. Do one of the following:

   - Type a dimension style name and press Enter.
   - Press Enter, then click a dimension entity in the drawing. The dimension style of the selected entity is the current dimension style now.
   - Type ? to see a list of the dimension styles in the current drawing.

To list the settings in the current dimension style

Do one of the following:

- Click the **Dimension Variable Status** tool button () on the **Dimensions** toolbar.
- Choose **Dimension Variable Status** in the **Dimensions** menu.
- Type **-dimstyle** in the command window, press Enter then type **ST** or **status** and press Enter.

The status of the settings in the current dimension style are listed in the **Prompt History** window.

1.29.7 Creating linear dimensions

Commands: DIMLINEAR (6.11.12), DIMALIGNED (6.11.3), DIMBASELINE (6.11.6), DIMCONTINUE (6.11.8), and DIMARC (6.11.5) Linear dimensions annotate linear distances or lengths and can be oriented either horizontally, vertically or aligned parallel to an existing entity or to the selected origin points. Starting from a linear dimension, you can add a **baseline** dimension or a **continued** dimension.

- A baseline dimension inserts an additional dimension from a common first extension line origin of a previous linear dimension.
- A continued dimension continues a linear dimension from the second extension line of a previous linear dimension.

To create a horizontal or vertical linear dimension

1. Do one of the following:

   - Click the **Linear** tool button ( ) on the **Dimensions** toolbar.
   - Choose **Linear** in the **Dimensions** menu.
   - Type **dimlinear** in the command bar, then press Enter.

   You are prompted: ENTER to select entity/<Origin of first extension line>:

2. Do one of the following:

   - Press Enter, then select the line or linear segment of a polyline you want to dimension.
   - Specify the origin of the first extension line, then specify the origin of the second extension line.

   The dimension line displays dynamically. Move the cross hairs vertically to create a horizontal dimension, or horizontally to create a vertical dimension.

3. Position the dimension line.

To create an aligned linear dimension

1. Do one of the following:

   - Click the **Aligned** tool button ( ) on the **Dimensions** toolbar.
   - Choose **Aligned** in the **Dimensions** menu.
   - Type **dimaligned** in the command bar, then press Enter.

   You are prompted: ENTER to select entity/<Origin of first extension line>:

2. Do one of the following:

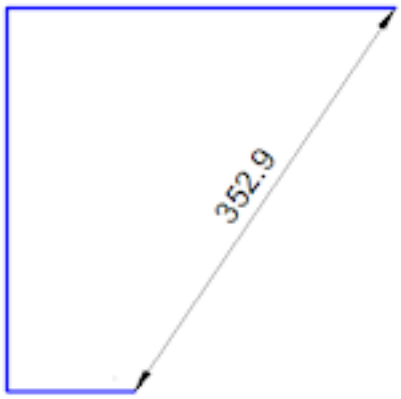
   - Press Enter, then select the line or linear segment of a polyline you want to dimension.
   - Specify the origin of the first extension line, then specify the origin of the second extension line.

3. Do one of the following:

   - Click a point to position the dimension line.
   - Press **0** (zero) to place the dimension line at the dimension points, thus omitting the extension lines.

(1.1021 on the following page)

Figure 1.1021



To create a rotated linear dimension

1. Do one of the following:

   - Click the **Rotated** tool button ( ) on the **Dimensions** toolbar.
   - Choose **Rotated** in the **Dimensions** menu.

   You are prompted: ENTER to select entity/<Origin of first extension line>:

2. Do one of the following:

   - Press Enter, then select the line or linear segment of a polyline you want to dimension.
   - Specify the origin of the first extension line, then specify the origin of the second extension line.

   You are prompted: Angle of dimension line <0>:

3. Do one of the following:

   - Type the rotation angle in the command bar, then press Enter.
   - Enter the rotation angle by specifying two points.

   The dimension line displays dynamically.

4. Position the dimension line. You can place the dimension line either at the specified rotation angle or perpendicular to this direction.

To create baseline dimensions

1. Do one of the following:

   - Click the **Baseline** tool button ( ) on the **Dimensions** toolbar.
   - Choose **Baseline** in the **Dimensions** menu.
   - Type **dimbaseline** in the command bar, then press Enter.

   You are prompted: Baseline: ENTER to select starting dimension/<Origin of next extension line>: A baseline dimension displays dynamically starting from the most recently added linear or angular dimension (if any).

2. (option) Press enter, then select the starting dimension (see note below).

3. Specify the origin of the next extension line. **You are prompted:** Baseline: ENTER to select starting dimension/<Origin of next extension line>:

4. Do one of the following:

   - Repeat steps 2 and 3.
   - Press the Esc key to stop creating baseline dimensions.

NOTES

- When selecting the starting dimension make sure to click the first extension line or the first half of the dimension line in order to use the first origin point of the starting dimension as the origin point for the baseline dimension.
- If you select an angular dimension, stacked angular dimensions are created.
- The distance between the stacked dimension lines is controlled by the **Dim baseline spacing** setting in the dimension style.

To create continued dimensions

1. Do one of the following:
   - Click the **Continue** tool button () on the **Dimensions** toolbar.
   - Choose **Continue** in the **Dimensions** menu.
   - Type **dimcontinue** in the command bar, then press Enter.

   You are prompted: Continue: ENTER to select starting dimension/<Origin of next extension line>: A continued dimension displays dynamically starting from the most recently added linear or angular dimension (if any).
2. (option) Press enter, then select the starting dimension (see note below).
3. Specify the origin of the next extension line. **You are prompted:** Continue: ENTER to select starting dimension/<Origin of next extension line>:
4. Do one of the following:
   - Repeat steps 2 and 3.
   - Press the Esc key to stop creating continued dimensions.

NOTE

- When selecting the starting dimension make sure to click the second extension line or the second half of the dimension line in order to use the second origin point of the starting dimension as the origin point for the continued dimension. Otherwise the new dimension line will partly overlap the starting dimension.
- If you select an angular dimension, continued angular dimensions are created.

To create an arc length dimension

1. Do one of the following:
   - Click the **Arc** tool button () on the **Dimensions** toolbar.
   - Choose **Arc** in the **Dimensions** menu.
   - Type **dimarc** in the command bar, then press Enter.

   You are prompted: Select arc or polyline arc segment:
2. Select the arc or polyline arc segment. The arc length dimension displays dynamically.
3. Position the dimension line.

1.29.8 Creating angular dimensions

Command : DIMANGULAR (6.11.4) Angular dimensions annotate the angle measured between two lines, two linear segments of a polyline or the angle of a circular arc. You can also dimension an angle by selecting an angle vertex and two endpoints. Starting from an existing angular dimension, you can add a baseline dimension (1.29.7) or a continued dimension (1.29.7). An angular baseline dimension inserts an additional dimension from a common first extension line origin. An angular continued dimension continues an angular dimension from the second extension line of a previous angular dimension.

(1.1022 on the next page) angular dimension measured between two lines	(1.1023 on the facing page) angular dimension of an arc	(1.1024 on the next page) angular dimension defined by a vertex and two endpoints

(1.1025 on page 1124) angular baseline dimensions (1.29.7)	(1.1026 on page 1124) angular continued dimensions (1.29.7)

To dimension an angle between two lines

1. Do one of the following

- Click the **Angular** tool button () on the **Dimensions** toolbar.
- Choose **Angular** in the **Dimensions** menu.
- Type **dimangular** in the command bar, then press Enter.

You are prompted: Press Enter to specify angle/<select line, arc, or circle>: 2. Select the first line or line segment. You are prompted: Other line for angular dimension: 3. Select the second line or line segment. The angular dimension displays dynamically. You are prompted: Angle/Text/<Location of dimension arc>: 4. Do one of the following:

- Position the dimension arc.
- Type **A** and press Enter to define the angle of the dimension text, then position the dimension arc.
- Type **T** and press Enter to modify the dimension text, then position the dimension arc.

To dimension an angle encompassed by an arc

1. Do one of the following

- Click the **Angular** tool button () on the **Dimensions** toolbar.
- Choose **Angular** in the **Dimensions** menu.
- Type **dimangular** in the command bar, then press Enter.

You are prompted: Press Enter to specify angle/<select line, arc, or circle>: 2. Select the arc. The angular dimension displays dynamically. You are prompted: Angle/Text/<Location of dimension arc>: 3. Do one of the following:

- Position the dimension arc.
- Type **A** and press Enter to define the angle of the dimension text, then position the dimension arc.
- Type **T** and press Enter to modify the dimension text, then position the dimension arc.

To create an angular dimension defined by a vertex and two endpoints

1. Do one of the following

- Click the **Angular** tool button () on the **Dimensions** toolbar.
- Choose **Angular** in the **Dimensions** menu.
- Type **dimangular** in the command bar, then press Enter.

You are prompted: Press Enter to specify angle/<select line, arc, or circle>: 2. Right click or press Enter. You are prompted: Vertex of angle. 3. Specify the vertex of the angle. You are prompted: first side of angle. 4. Specify the endpoint of the first side of the angle. You are prompted: Other side of angle. 5. Specify the endpoint of the second side of the angle. The angular dimension displays dynamically. You are prompted: Angle/Text/<Location of dimension arc>: 6. Do one of the following:

Figure 1.1022

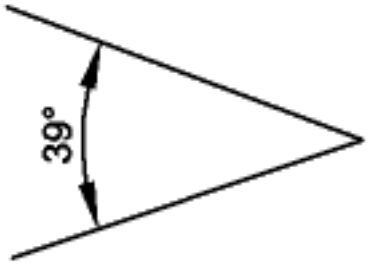


Figure 1.1023

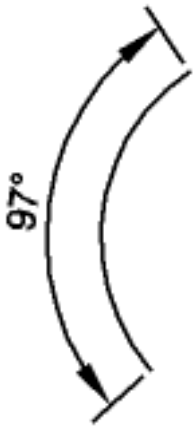

- Position the dimension arc.
- Type **A** and press Enter to define the angle of the dimension text, then position the dimension arc.
- Type **T** and press Enter to modify the dimension text, then position the dimension arc.

Figure 1.1024

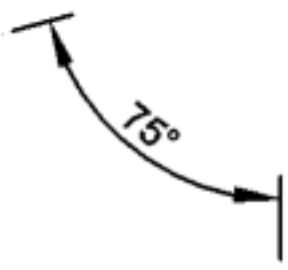

Figure 1.1025

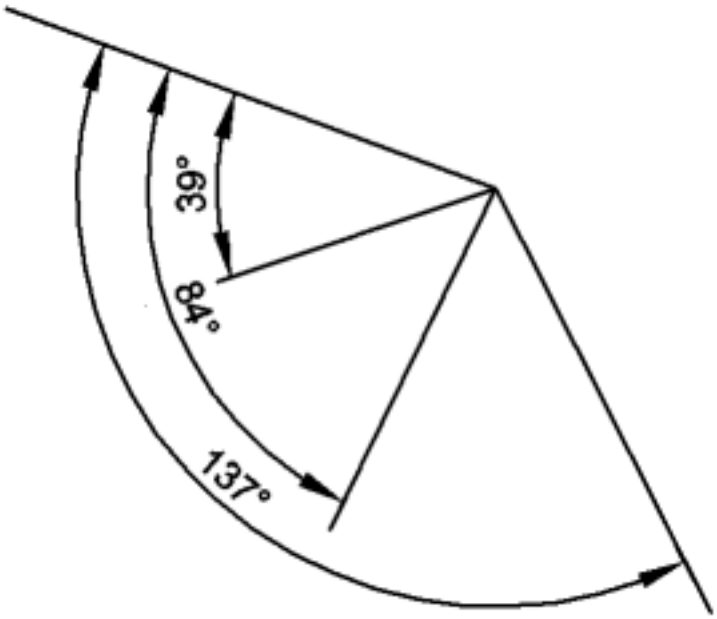

Figure 1.1026

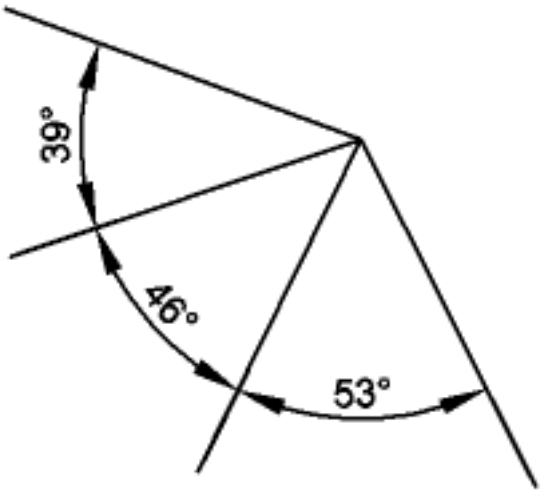


1.29.9 Creating diametrical and radial dimensions

Commands: DIMDIAMETER (6.11.9) and DIMRADIUS (6.11.16) Diametrical and radial dimensions annotate the radii and diameters of circles and circular arcs. The DIMCENTER (6.11.7) command creates center marks in the center point of circles and circular arcs.

To create a diametrical dimension

1. Do one of the following

   - Click the **Diameter** tool button () on **Circles** toolbar or the **Circles** flyout of the **Dimensions** toolbar.
   - Choose **Diameter** in the **Dimensions** menu.
   - Type **dimdiameter** in the command bar, then press Enter.

   You are prompted: Select arc or circle

2. Select the arc or circle you want to annotate. The diametrical dimension displays dynamically.
3. Position the dimension line.

To create a radial dimension

1. Do one of the following

   - Click the **Radius** tool button () on **Circles** toolbar or the **Circles** flyout of the **Dimensions** toolbar.
   - Choose **Radius** in the **Dimensions** menu.
   - Type **dimradius** in the command bar, then press Enter.

   You are prompted: Select arc or circle

2. Select the arc or circle you want to annotate. The radial dimension displays dynamically.
3. Position the dimension line.

Creating center marks or center lines

1. Do one of the following

   - Click the **Center** tool button () on **Circles** toolbar or the **Circles** flyout of the **Dimensions** toolbar.
   - Choose **Center** in the **Dimensions** menu.
   - Type **dimcenter** in the command bar, then press Enter.

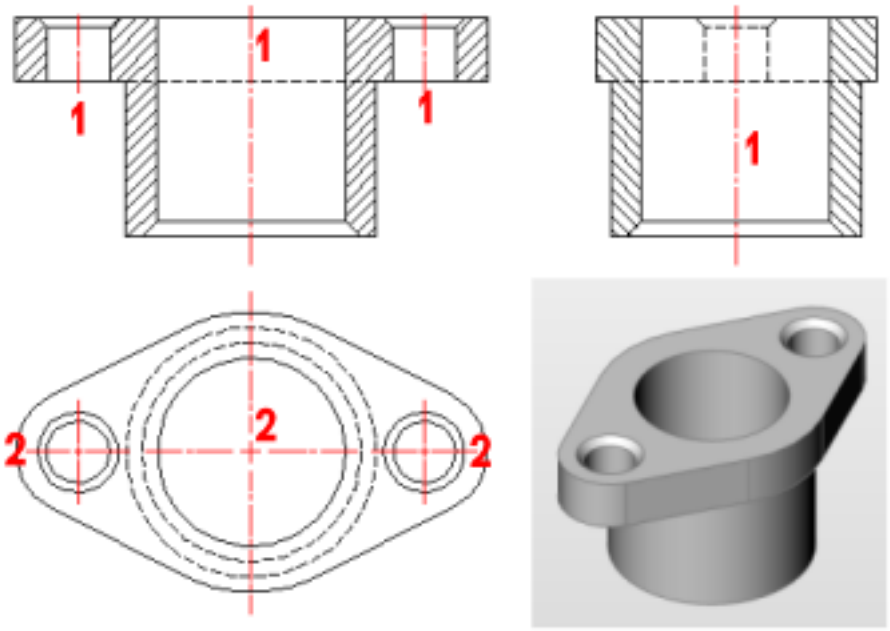
   You are prompted: Select arc or circle to dimension:

2. Select the arc or circle. The center marks are created.

NOTE

- The **Center mark** setting of the dimension style controls whether center marks or center lines are created. The **Center mark size** settings of the dimension style controls the size of the center mark.
- The center mark settings are saved to the **DIMCEN** system variable.

Figure 1.1027



1.29.10 Centerlines and Center Marks

Commands: CENTERLINE (6.9.5), CENTERMARK (6.9.6), CENTERREASSOCIATE (6.9.7), CENTERDISASSOCIATE (6.9.4), CENTERRESET (6.9.8) **CenterLine** command: creates a centerline entity associated with two selected lines. **CenterMark** command: creates a center mark entity associated with a selected circle or arc. **CenterReassociate** command: recreates the association between a centerline entity and two selected lines, or between a center mark and a selected circle or arc. **CenterDisassociate** command: breaks the association of centerline and a center mark entities. **CenteReset** command: resets centerline and center mark entities. Centerlines and Center Marks are drawing reference entities to indicate axes of symmetry and to centers of circular openings. Centerlines and Center Marks are associative entities: when the referenced lines, circles or circular arcs are modified they are adjusted automatically. (1.1027)

1. Centerline
2. Center Mark

System variables for center entities

The properties and geometry of centerline and center mark entities are controlled through system variables. (1.1028)

Name	Title	Description

Figure 1.1028

Center entities	
Center mark cross gap	0.05x
Center mark cross size	0.1x
Centerline extensions length	3.5
Default layer for center mark or centerline	.
Linetype file for center mark or centerline	iso.lin
Automatic extension for center mark or centerline	☑ Automatic extension

CENTERCROSSGAP	Center mark cross gap	Defines the gap between the center mark and its centerlines. (1.1029 on page 1129) Type **centercrossgap** in the command line. **You are prompted:** New value for CENTERCROSSGAP, or . for none/<"0.05x">: • Type a value to specify the absolute size of the gap in drawing units. • Type a value followed by x to set the size of the gap relative to the diameter of the circle or circular arc. The default value 0.05x creates a gap of 5/100 of the diameter. • . (dot) creates no gap.
CENTERCROSSSIZE	Center mark cross size	Defines the size of the associative center mark. Type **centercrosssize** in the command line. **You are prompted:** New value for CENTERCROSSSIZE, or . for none/<"0.1x">: • Type a value to specify the absolute size of the center mark lines in drawing units. • Type a value followed by x to set the size of the center mark relative to the diameter of the circle or circular arc. The default value 0.1x creates center marks 1/10th of the diameter. • . (dot) creates center marks with zero length lines.
CENTEREXE	Centerline extensions length	Defines the length of the centerline extensions. The value is expressed in drawing units. (1.1030 on page 1129)

CENTERLAYER	Default layer for center mark or centerline	Specifies the default layer for new centerlines and center marks. Type **centerlayer** in the command line. **You are prompted:** New value for CENTERLAYER, or . for none/<"">: • Type a name. If such layer not yet exists, the layer will be created when a centerline or centemark is created. • Type . (dot) to create centerlines and center marks on the current layer.
CENTERLTYPEFILE	Linetype file for center mark or centerline	Specifies the linetype file used to create centerlines and center marks. Default in imperial unit drawings: **default.lin** Default in metric unit drawings: **iso.lin**
CENTERLTYPE	Linetype for center mark or centerline	Specifies the linetype for newly created centerlines and center marks. Type **centerltype** in the command line. **You are prompted:** New value for CENTERLTYPE, or . for none/<"CENTER2">: • Type a new linetype name or press Enter to accept the current name. • Type . (dot) for continuous lines.
CENTERLTSCALE	Linetype scale for center mark or centerline	Specifies the linetype scale for newly created centerlines and center marks. Type
CENTERMARKEXE	Automatic extension for center mark or centerline	Determines whether centerlines extend (left) or not (right) from new center marks. (1.1031 on the facing page)

Figure 1.1029

Figure 1.1030

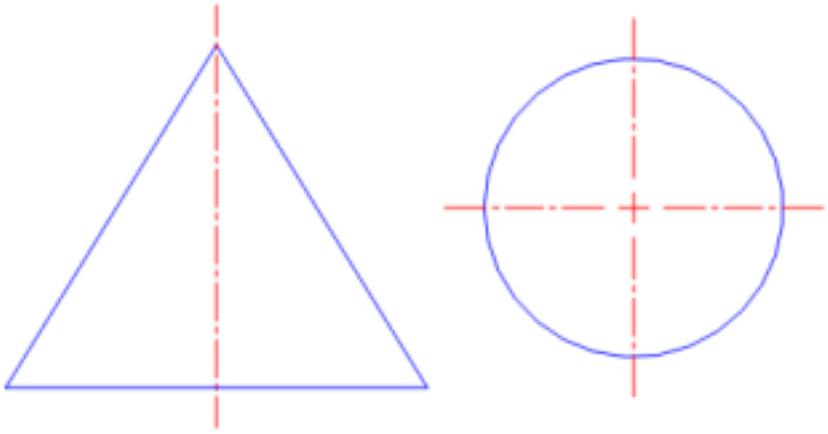


Figure 1.1031

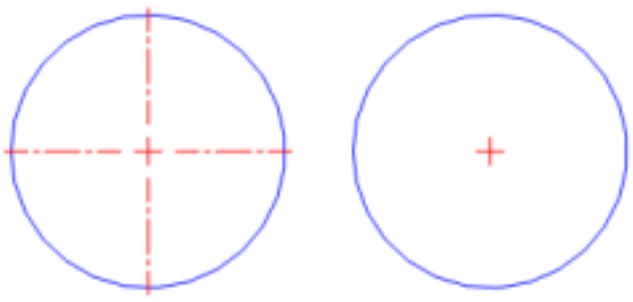

1.29.11 Creating leaders and annotations

Commands: DIMLEADER (6.11.13), LEADER (6.20.21) and QLEADER (6.25.3) A leader consists of an arrowhead, a line, polyline or a spline and an annotation. The general procedure to place an annotation is:

- Specify the position of the arrowhead.
- Create the leader line segments.
- Type the annotation text.

To create a leader and an annotation

1. Do one of the following:

   - Click the **Leader** tool button ( ) on the **Dimensions** toolbar.
   - Choose **Leader** in the **Dimensions** menu.
   - Type **leader** or **dimleader** in the command bar, then press Enter.

   You are prompted: Start of leader

2. Specify the position of the arrowhead. **You are prompted:** Next point.
3. Specify the endpoint of the first leader segment. **You are prompted:** To point: Format/Undo/<Annotation>: A prompt menu displays: (1.1032)
4. Add more segments to the leader, then press Enter or right click to stop adding segments. **You are prompted:** First line of annotation text/<options>:
5. Do one of the following:

   - Type the first line of the annotation text, then press Enter. **You are prompted:** Next line of annotation text: Do one of the following:
     - Press Enter or right click to create the leader and annotation.
     - Keep adding lines to the annotation text, then press Enter or right click to create the leader and annotation.
     - Press Enter or right click to see the annotation text options. **You are prompted:** Dimension text options: Block/Copy/None/Tolerance/<Mtext>: A prompt menu displays: (1.1033 on the facing page)
   - Press the Esc key to abort the **Leader** tool.

Figure 1.1032

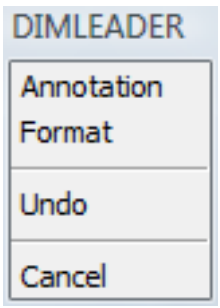

Figure 1.1033

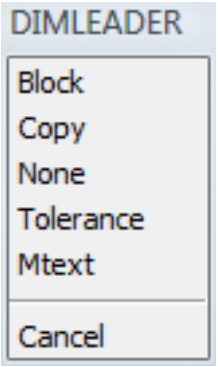


To create a leader only

1. Do one of the following:

   - Click the **Leader** tool button ( ) on the **Dimensions** toolbar.
   - Choose **Leader** in the **Dimensions** menu.
   - Type **dimleader** in the command bar, then press Enter.

   You are prompted: Start of leader

2. Specify the position of the arrowhead. **You are prompted:** Next point.
3. Specify the endpoint of the first leader segment. **You are prompted:** To point: Format/Undo/<Annotation>:
4. Add more segments to the leader, then press Enter or right click to stop adding segments. **You are prompted:** First line of annotation text/<options>:
5. Press Enter, then choose **None** in the prompt menu or type **N** .

1.29.12 Creating ordinate dimensions

Command: DIMORDINATE (6.11.14) An ordinate dimension annotates the perpendicular distance from an origin or base point (the origin of the current user coordinate system (1.21.21) [UCS]). Ordinate dimensions consist of an x- or y-coordinate and a leader. An x-ordinate dimension measures distances along the x-axis, while a y-ordinate dimension measures distances along the y-axis. As you select ordinate points, the program automatically determines whether the point is an x- or y-ordinate based on which direction you drag the second point. You can also specify whether the ordinate represents an x- or y-ordinate. Ordinate dimension text is always aligned with the ordinate leader lines, regardless of the text orientation specified by the current dimension style.

To create an ordinate dimension

1. Do one of the following:

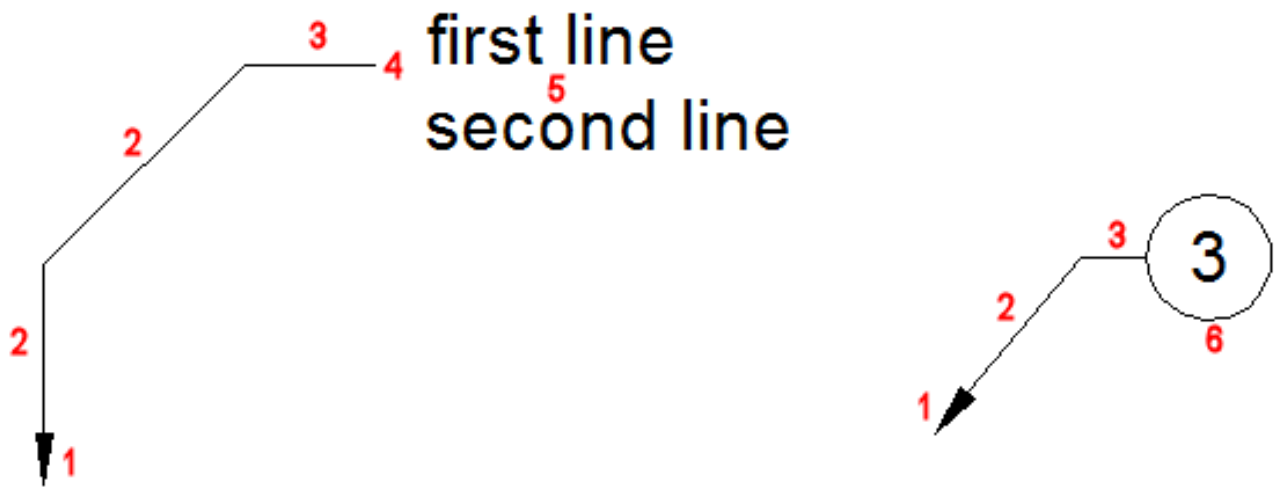
   - Click the **Ordinate** tool button ( ) on the **Dimensions** toolbar.
   - Choose **Ordinate** in the **Dimensions** menu.
   - Type **dimordinate** in the command bar, then press Enter.

   You are prompted: Select point for ordinate dimension:

2. Specify the origin point for the ordinate dimension. The ordinate dimension displays dynamically.
3. Position the ordinate dimension.

NOTE	Adjust the origin point of the current user coordinate system (1.21.21) (UCS) before placing ordinate dimensions if necessary.

Figure 1.1034



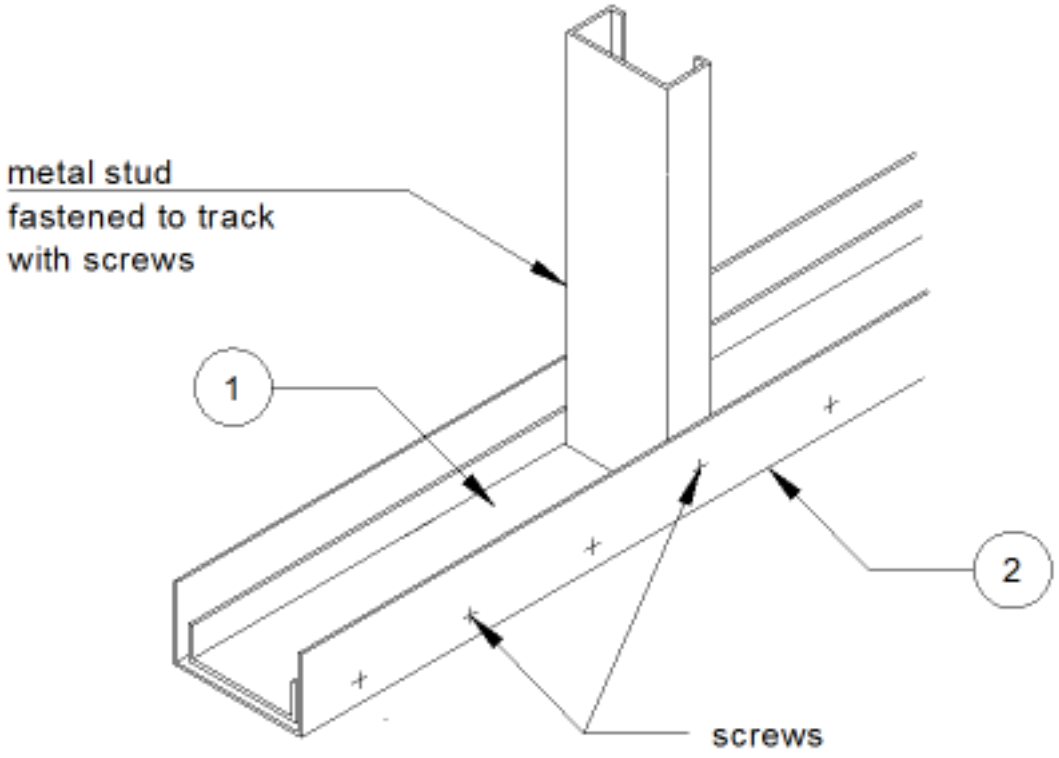
1.29.13 Working with Multileaders

Commands: MLEADER (6.21.19), MLEADERSTYLE (6.21.24), MLEADEREDIT (6.21.22) and MLEADEREDITEXT (6.21.23)
A multileader consists of:

- an arrowhead (1)
- one or more leader lines (2), which can be straight or curved
- optionally a horizontal landing (3) and landing gap (4)
- content: either a multiline text (5) or a block (6)

(1.1034) Multileaders are created using the current multileader style. Each drawing contains a **Default** leader style, which cannot be renamed or deleted; the **Default** leader style can be customized though. The **MLeader** command allows to define overrides on the current multileader style. Multileaders can be created arrowhead first, landing first or content first. (1.1035 on the following page)

Figure 1.1035



To create a multileader

1. (option) Launch the **MLeaderStyle** command, then make a multileader style current.

2. Do one of the following

- Click the **Multileader** tool button ( ) on the **Dimensions** toolbar.

Figure 1.1036

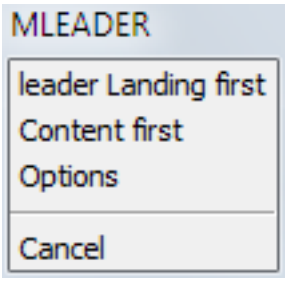


Figure 1.1037

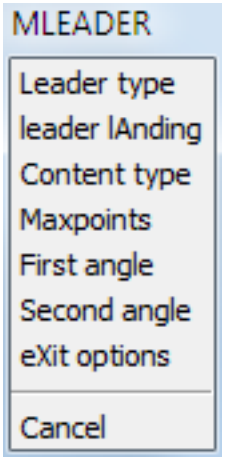


- Choose **Multileader** in the **Dimensions** menu.
- Type **multileader** in the command bar, then press Enter.

You are prompted: Specify leader arrowhead location or [leader Landing first/Content first/Options] <Options>: A prompt menu displays: (1.1036)

3. (option) Select a placement option:

   - arrowhead first
   - landing first
   - content first.

   The most recently used placement option is repeated. The default sequence is: arrowhead - landing - content.

4. (option) Choose **Options** in the prompt menu or type **O** , then press Enter, if you want to define overrides on the current multileader style. **You are prompted:** Enter an option [Leader type/leader lAnding/Content type/Maxpoints/First angle/Second angle/eXit options] <eXit options>: A prompt menu displays: (1.1037)
5. Specify a point to define the leader arrowhead location. **You are prompted:** Specify leader landing location:
6. Specify a point to define the leader landing location. Depending on the content type:

   - **MText** : The MText (6.21.38) command is launched.
   - **Block** : A block is inserted.
   - **None** : The command is concluded.

Adding vertices to a leader line of a multileader

1. If necessary press the **F12** function key to activate the Quad cursor menu (1.15.5).
2. Pause the cursor over the leader line you want to add a vertex to. The Quad cursor menu displays, showing the most recently used command (*).
3. Move the cursor to the Quad cursor menu and expand the **2D Editing** command group.
4. Click the **Add Vertex** tool ( ). A new vertex is added dynamically.

5. Specify the position of the vertex.
6. (option) Pause the cursor of a leader line, then right click to add another vertex.

(*) Right click to repeat the most recently used Quad command.

Removing vertices from a leader line of a multileader

1. If necessary press the **F12** function key to activate the Quad cursor menu (1.15.5).
2. Pause the cursor over the leader line close to the vertex to be removed. The Quad cursor menu displays, showing the most recently used command(*).
3. Move the cursor to the Quad cursor menu and expand the **2D Editing** command group.
4. Click the **Remove Vertex** tool (). The vertex is removed.
5. (option) Pause the cursor of a leader line close to a vertex, then right click to remove the vertex.

Adding leader lines to a multileader

1. If necessary press the **F12** function key to activate the Quad cursor menu (1.15.5).
2. Pause the cursor over a leader line of the multileader entity. The Quad cursor menu displays, showing the most recently used command(*).
3. Move the cursor to the Quad cursor menu and expand the **2D Editing** command group.
4. Click the **Add Leader** tool (). A new leader line displays dynamically.
5. Specify the origin of the new leader line. Another new leader line displays dynamically.
6. Do one of the following:
   - Specify the origin of the new leader line.
   - Right click or press Enter to stop adding leader lines.

(*) Right click to repeat the most recently used Quad command.

Removing leader lines from a multileader

1. If necessary press the **F12** function key to activate the Quad cursor menu (1.15.5).
2. Pause the cursor over the leader line you want to remove. The Quad cursor menu displays, showing the most recently used command(*).
3. Move the cursor to the Quad cursor menu and expand the **2D Editing** command group.
4. Click the **Remove Leader** tool (). The leader line is removed.

(*) Right click to repeat the most recently used Quad command.

1.29.14 Editing dimensions

Commands: DIMEDIT, (6.11.11) DIMTEDIT (6.11.23)
Dimension entities can be edited in the following ways:

- Use grips to edit dimensions
- Edit the dimension text
- Rotate dimension text
- Reposition the dimension text
- Restore the text position
- Make the extension lines oblique

Using grips to edit a linear dimension

1. Select the dimension entity. 5 grips display:
   - 2 origin point grips (1)
   - 2 dimension line grips (2)
   - 1 dimension text grip (3)

   (1.1038)
2. (option) Drag the origin point grips to adjust the dimension origin points. The dimension text is adjusted automatically.
3. (option) Drag dimension line grips to move the dimension line.
4. (option) Drag the text grip to move the dimension text.

NOTES

- Depending on the **Text movement** setting, the dimension line will move along with the text or the text will move independently. A leader will be drawn if the **Text movement** setting is set to **Move text, add leader** .
- If two adjacent dimensions (continued dimensions) are selected both, you can move their coinciding grips simultaneously.

Figure 1.1038

Editing the dimension text

Dimension text can be edited:

- in the MText editor:
  - using the DDEDIT (6.10.13) command
  - double clicking the dimension entity
- in the **Text override** field in the Properties Bar (1.15.4).
- using the **Edit Dimension Text** tool.

NOTES

The following tags can be used to format the dimension text:

- type **\L** (backslash upper case L) to start underlined text, **\l** (backslash lower case L) to stop underlined text
- type **<>** to add the default dimension text
- type **[]** to add the alternate units, if alternate units is currently switched off in the dimension style.
- type **%%d** to add the degree symbol (°)
- type **%%c** to add the diameter symbol (Ø)
- type **%%p** to add the plus/minus symbol (±)

e.g. if you type **%%c\L<> cm** in the **Text override** field, dimension text displays as: Ø 24,43 cm

To edit the dimension text in the MText editor

1. Double click the dimension entity. The **Text Formatting** toolbar displays.
2. Edit the dimension text.
3. Do one of the following:
   - Click the **OK** button on the **Text Formatting** toolbar.
   - Click outside the dimension text.

To edit the dimension text in the Properties Bar

1. Select the dimension entity.
2. In the Properties Bar (1.15.4), select the **Text override** field.
3. Type the new dimension text in the **Text override** field and press Enter.
4. Press the Esc key to stop editing the dimension entity.

To edit the dimension text using the Edit Dimension Text tool

1. Do one of the following:
   - Click the **Edit Dimension Text** tool (A) in the **Dimensions** toolbar.
   - Choose **Edit Dimension Text** in the **Dimensions** menu.
   - Type **Dimedit** in the command bar, press Enter, then type **new** and press Enter.

   You are prompted: New dimension text <>:

2. Type the new dimension text and press Enter. **You are prompted:** Select dimensions to replace with new text:
3. Select the dimensions (1.32.7) and press Enter.

To rotate the dimension text

1. Do one of the following:

   - Click the **Rotate Dimension Text** tool () in the **Dimensions** toolbar.
   - Choose **Rotate Dimension Text** in the **Dimensions** menu.
   - Type **Dimedit** in the command bar, press Enter, then type **R** and press Enter.

   You are prompted: Angle of dimension text:
2. Type the rotation angle, then press Enter. **You are prompted:** Select entities to rotate text:
3. Select the dimensions (1.32.7) and press enter.

To reposition the dimension text

1. Do one of the following:

   - Click the **Reposition Dimension Text** tool () in the **Dimensions** toolbar.
   - Choose **Reposition Dimension Text** in the **Dimensions** menu.
   - Type **Dimtedit** in the command bar, then press Enter.

   You are prompted: Select dimensions to reposition text:
2. Select the dimension. The dimension text moves dynamically.
3. Click to reposition the dimension text.

To restore the text position

1. Do one of the following:

   - Click the **Restore Text Position** tool () in the **Dimensions** toolbar.
   - Choose **Restore Text Position** in the **Dimensions** menu.
   - Type **Dimedit** in the command bar, then press Enter.

   You are prompted: Select dimensions to restore text to default position:
2. Select the dimensions (1.32.7) and press enter.

To make the extension lines oblique

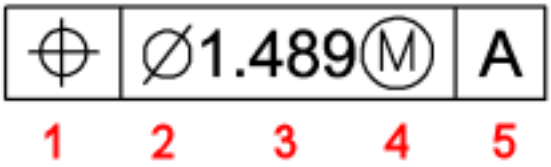
1. Do one of the following:

   - Click the **Make Oblique** tool () in the **Dimensions** toolbar.
   - Choose **Make Oblique** in the **Dimensions** menu.
   - Type **Dimedit** in the command bar, press Enter, then type **O** and press Enter.

   You are prompted: Select dimensions to make oblique:
2. Select the dimensions (1.32.7) and press enter. **You are prompted:** Enter obliquing angle:
3. Type the obliquing angle, then press Enter.

NOTE	To restore non-rotated extension lines, execute the above procedure and type 0 (zero) when asked to enter the obliquing angle.

Figure 1.1039



1.29.15 Adding Geometric Tolerances

Command: TOLERANCE (6.29.26) Geometric tolerances specify the maximum variation that is allowed in form or position from true geometry. The geometric tolerance is, in essence, the tolerance zone within which a surface or axis of hole or cylinder can lie which results in resulting feature being acceptable for proper function and interchangeability. BricsCAD draws geometric tolerances using a feature control frame, which is a rectangle divided into compartments. Each feature control frame consists of at least two compartments. The first compartment contains a geometric tolerance symbol that indicates the geometric characteristic to which the tolerance is applied, such as location, orientation, or form. For example, a form tolerance may indicate the flatness or roundness of a surface. The second compartment contains the tolerance value. When appropriate, the tolerance value is preceded by a diameter symbol and followed by a material condition symbol. The material conditions apply to features that can vary in size. The tolerance value can then be followed by primary, secondary, and tertiary datum reference letters, along with the material conditions of each datum. Datum reference letters are generally used as reference tolerances to one of up to three perpendicular planes from which a measurement is made, although datum reference letters can also indicate an exact point or axis. (1.1039)

1. Geometric characteristic symbol
2. Diameter symbol
3. Tolerance value
4. Material condition symbol
5. Datum reference

When two tolerances apply to the same geometry, you can also add a composite tolerance consisting of a primary tolerance value followed by a secondary tolerance value. To make a tolerance even more specific, it can also contain a projected tolerance consisting of a height value followed by a projected tolerance symbol. For example, you can use a projected tolerance to indicate the perpendicularity of an embedded part.

To create a geometrical tolerance frame

1. Do one of the following

   - Click the **Tolerance** tool button ( ) in the **Dimensions** toolbar.
   - Choose **Tolerance** in the **Dimensions** menu.
   - Type **tolerance** in the command bar, then press Enter.

   The Geometric Tolerance dialog (1.29.15) opens.

2. Compose the geometrical tolerance frame in the **Geometric Tolerance** dialog.
3. Click the **OK** button. The **Geometric Tolerance** dialog closes.
4. Click to insert the geometric tolerance frame in the drawing.

Geometric Tolerance dialog (1.1040 on the next page)

1. **Geometric Tolerance Symbol** buttons. Click to open the **Symbol** palette. (1.1041 on the following page)
2. **Diameter Symbol** option buttons. Click to add the diameter symbol.
3. **Material Condition** buttons. Click to open the **Material Condition** palette. (1.1042 on the next page)

Figure 1.1040

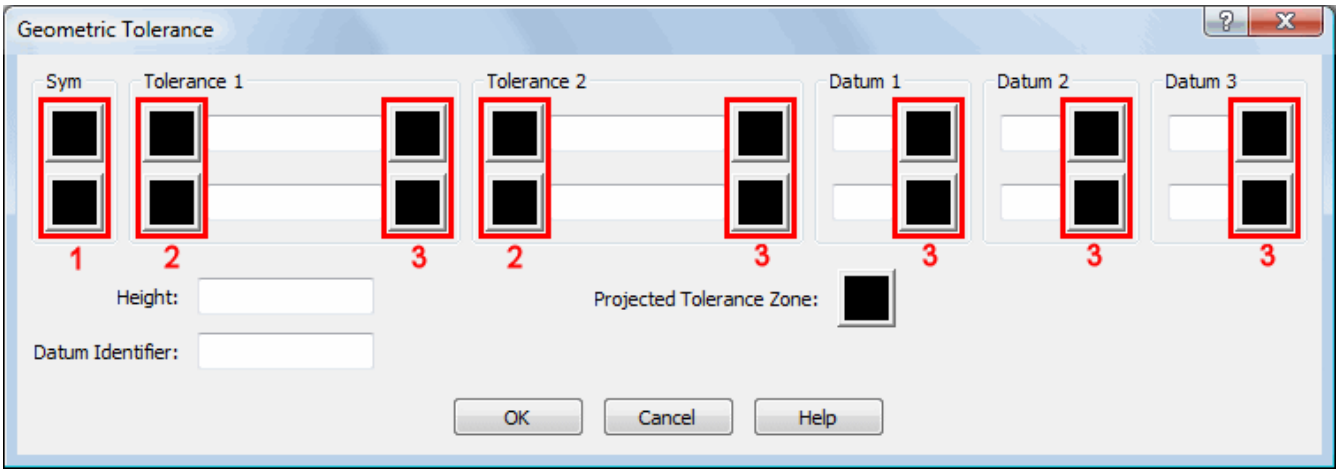


Figure 1.1041

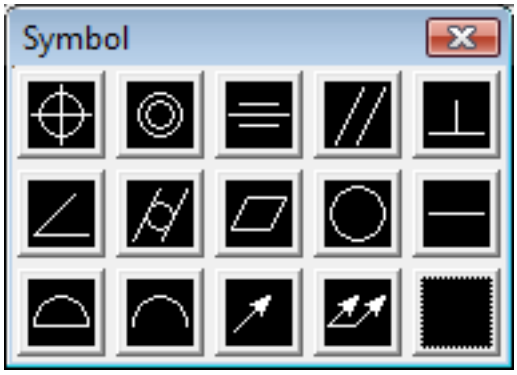

Figure 1.1042

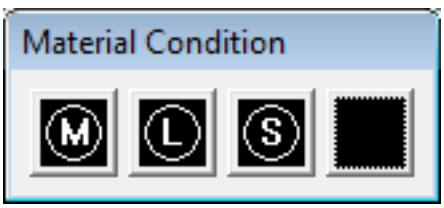

1.29.16 Editing text

Command: DDEDIT (6.10.13) You can edit and modify a text entity as you would any other drawing entity. That is, you can delete, move, rotate, and scale text. You can change the text color or layer in the Properties Bar (1.15.4). To edit a multiline text, you can use the built-in text editor or choose an external program, such as Wordpad. The MTEXTFIXED (1.17.10) system variable controls whether the view is zoomed, rotated and/or panned to fit the edited Mtext. The TEXTED (1.17.10) setting controls the text edit behavior:

- 0 = in-place editor
- 1 = pop up dialog
- 2 = in-place editor with repeated input

To edit a text entity

1. Do one of the following:
   - Type **DDEDIT** in the command bar. **You are prompted:** Select entity to modify:
   - Double click the text entity. Then go to step 3.
2. Click a single line text (1.29.20) entity. Depending on the value of the TEXTED system variable: TEXTED = 1: The **Edit Text** window opens. (1.1043) TEXTED = 0 or 2: The text is edited 'in place'. (1.1044 on the next page) Click a multiline text (1.29.20) entity The **Text formatting** toolbar opens. (1.1049 on page 1152)
3. Edit the text.
4. Press the **OK** button on the **Edit Text** window or **Text Formatting** toolbar to apply the changes.
5. Do one of the following:
   - Select another text entity to edit.
   - Right click or press Enter to stop editing text entities.

Figure 1.1043

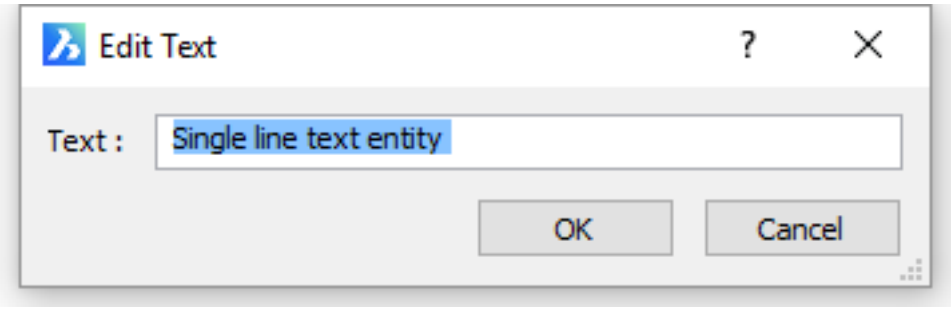

Figure 1.1044

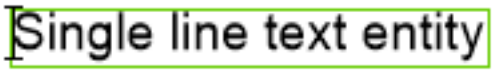

Figure 1.1045

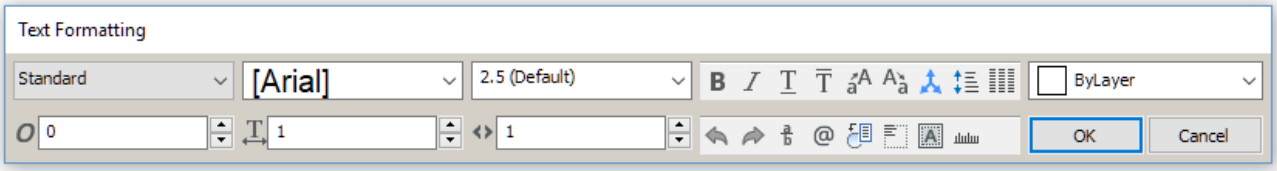


To edit a selection of Mtext entities

1. Select the Mtext entities.
2. In the Properties (1.15.4) bar select **Contents**.
3. Press the **Browse** button (...) on the right hand side of the **Contents** field (1.1046)
4. The **Text formatting** toolbar opens for the first Mtext entity in the selection.
5. Edit the Mtext.
6. Press the **OK** button or click in the drawing. The next Mtext entity in the selection can be edited now.
7. Repeat steps 5 and 6 until the last Mtext is edited.

Figure 1.1046

To select a different multiline text editor

Edit the **MTEXTED** system variable under **Drawing/Drafting/Texts/Multiline Texts** in the Settings (1.17.10) dialog.
Or

- Type **MTEXTED** in the command bar, then press Enter. **You are prompted:** New value for MTEXTED, or . for none/<current value>:
- Type the file name and full path of the alternate text editor in the command bar, then press Enter. e.g. C:\Program Files\Windows NT\Accessories\Wordpad.EXE

NOTE	To restore the built-in text editor, type a . (period) in step 2 of the above procedure, then press Enter.

Figure 1.1047

1.29.17 Text Variables

System variables can be set using the Settings dialog (1.17.10). Some system variables which apply to text entities are:

Variable Name	Variable Title	Description
FONTALT	Alternate font	Defines the font which will be used if a text font cannot be found.
HIDETEXT	Hide text on hide	Specifies whether the HIDE (6.16.9) command processes text entities.
MIRRTEXT	Mirror text	Determines whether text is mirrored by the MIRROR command or not.
MTEXTED	Multiline text editor	Sets the primary and secondary text editors to use for multiline text entities.
MTEXTFIXED	Multiline text fixed	Controls whether BricsCAD zooms, rotates and/or pans the view to fit the Mtext being edited.
QTEXTMODE	Quick text mode	Controls how text entities are displayed. If ON, displays text as a box.
TEXTANGLE	Text angle	Stores the angle of the last added text entity.
TEXTFILL	Text fill	Determines whether True Type fonts display either filled or outlined. (1.1047)
TEXTQLTY	Text quality	Defines the smoothness of True Type fonts for plotting and rendering.
TEXTSIZE	Text size	Sets the default height for new text entities. TEXTSIZE has no effect if the current text style has a fixed height
TEXTSTYLE	text style	Stores the name of the current text style.
TSPACEFAC	Text space factor	Specifies the line spacing distance of multiline text measured as factor of the text height. Values between 0.25 and 4 are accepted.
TSPACETYPE	Text space type	Specifies the type of line spacing used for multiline text. At least: adjusts line spacing based on the tallest character(s) in a line. Exactly: used the specified line spacing, regardless of in individual character sizes.
TSTACKALIGN	Text stack align	Determines the vertical alignment of stacked text: bottom, center or top.
TSTACKSIZE	Text stack size	Specifies the percentage a which the stacked text fraction height is relative to the current height of the selected text. Values between 25 and 125 are accepted.

1.29.18 Exploding text

Command: TXTEXP (6.29.36) The **TXTEXP** command explodes Text and Mtext entities into 2D polylines (1.25.12).

To explode text

1. Type **TXTEXP** in the command bar, then press Enter. **You are prompted:** Select text to be exploded:
2. Select a single text entity or multiple text entities, then press Enter. The selected text(s) are exploded.

NOTE	The solid fill of certain TTF fonts is removed when exploding such text, leaving the text outline only.

1.29.19 Working with text styles

Command: STYLE (6.27.55) When you add text to a drawing, it uses the current text style, which determines the font, size, angle, orientation and other properties of the new text entity. Every drawing has a default text style, named **Standard** , which initially uses the **Arial** font. You cannot delete or rename the **Standard** style, but you can modify it. If you change the **font** or **orientation** of an existing style, all existing text entities created using that style are automatically updated to reflect the change. Changing any other property has no effect on existing text. You can create and use an unlimited number of additional text styles. Annotative text styles create annotative text entities (1.29.32). In an annotative text style the **Height** defines the paper space height of the text; the model space height depends on the current annotation scale as defined by the CANNOSCALE and CANNOSCALEVALUE system variables.

To open the Text Style Explorer dialog

Do one of the following:

- In the **Tools > Drawing Explorer** menu choose **Text Styles ...**
- Double click the **Style** field in the Status Bar (1.15.2).
- Type style (6.27.55) in the command bar and press Enter.

The **Drawing Explorer - Text Styles** dialog opens.

To create a text style

1. Open the Text Style Explorer dialog.
2. Do one of the following:
   - Click the **New** tool button ( ) in the **Details** section of the **Drawing Explorer** dialog.
   - Select an existing style, then right click and choose **New** in the context menu.

   A **NewStyle** text style is created, inheriting the properties of the currently selected style.
3. Type a name in the **Text Style Name** field, replacing the **NewStyle** default name.
4. Define the text style properties.
5. Close the **Text Style Explorer** dialog.

To edit a text style

1. Open the text style explorer dialog.
2. Select the text style.
3. Define the text style properties.
4. Close the **Text Style Explorer** dialog.

To make a text style current

1. Open the text style explorer dialog.
2. Do one of the following:
   - When in **Detail view** ( ), click the blank tile in front of the text style name. A blue filled circle indicates the text style is set current.
   - When in **Detail view** ( ) or **Icon view** ( ), right click then choose **Set current** in the context menu.

NOTE

- Alternatively you can right click the **Text style** field in the Status Bar (1.15.2), then choose the new current style. The current style is marked in the style list.
- When you use the **Style** option in the create text procedures, the selected style will become the current text style.

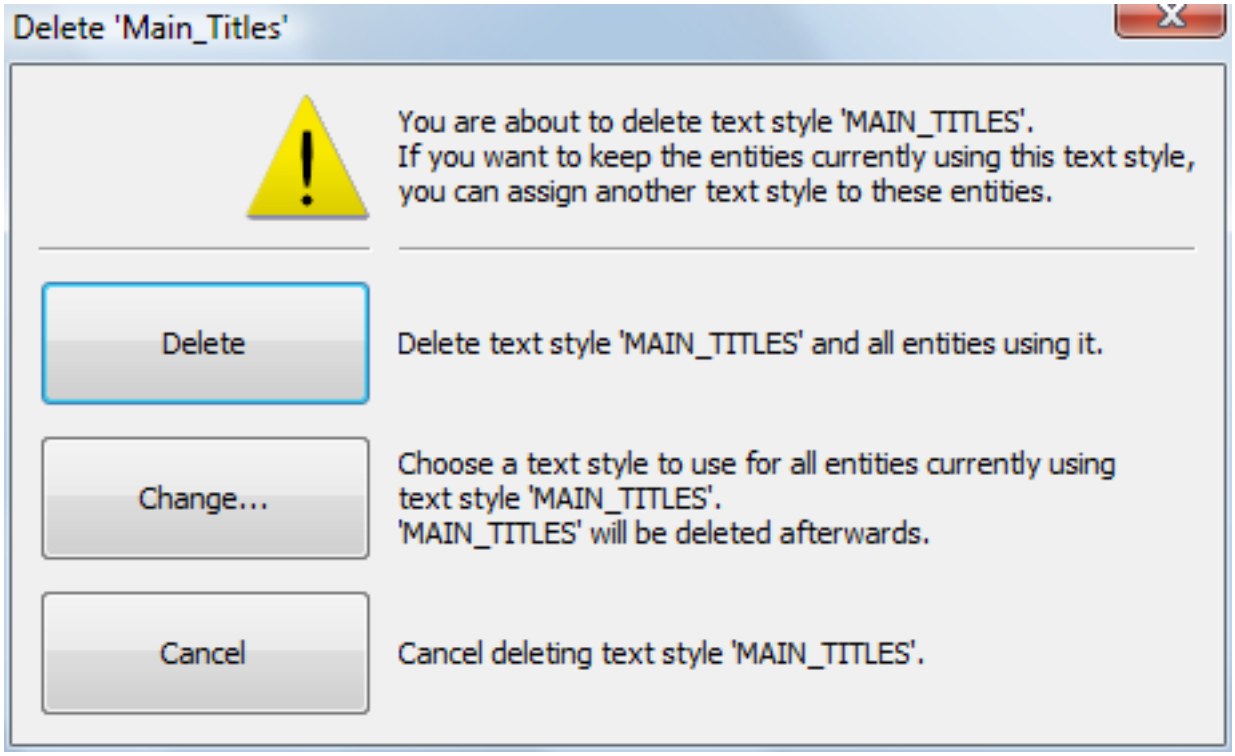
To delete a text style

1. Open the text style explorer dialog.
2. Select the text style.
3. Do one of the following:
   - Click the **Delete** tool button () in the **Details** section of the **Drawing Explorer** dialog.
   - Right click, then choose **Delete** in the context menu.

   If the text style is not used in the drawing or in a dimension style, the text style is deleted, else an alert box displays: (1.1048 on the next page)
4. Do one of the following:
   - Click the **Delete** button to delete the text style and all entities using it.
   - Click the **Change...** button to delete the text style and assign a different text style to the entities, which currently use the selected style.
   - Click the **Cancel** button to cancel the delete procedure.

NOTE It is not possible to delete the current text style.

Figure 1.1048



1.29.20 Creating text

Commands: TEXT (6.29.12) and MTEXT (6.21.38) The **Text** command creates single line text, while the **Mtext** command creates text entities which consist of multiple lines.

To create single line text

1. Do one of the following:

   - Click the **Text** tool button (A) on the **Draw** toolbar.
   - Choose **Text** in the **Text** submenu in the **Draw** menu.
   - Type **text** in the command bar, then press Enter.

   You are prompted: Text: Style/Align/Fit/Center/Middle/Right/Justify/<Start point>:

2. Specify the insertion point of the text. **You are prompted:** Height of text <current height>:

3. Do one of the following:

   - Press Enter or right click to accept the current text height.
   - Type the new text height in the command bar, then press Enter.
   - Define the new text height graphically by specifying two points in the drawing.

   You are prompted: Rotation angle of text <current angle>

4. Do one of the following:

   - Press Enter or right click to accept the current angle.
   - Type the new angle in the command bar, then press Enter.
   - Define the now angle graphically by specifying two points in the drawing.

   You are prompted: Text:

5. Type the text in the command bar, then press Enter. The text is placed in the drawing. **You are prompted:** Text:

6. Do one of the following:

   - Repeat step 5 to create another text entity. The new text is placed below the previous one.
   - Press Enter or right click to conclude the **Text** command.

NOTE	If you have already created text, the most recent text entity highlights when you repeat the **Text** command. If you want to place the new text right below the previously created text, press Enter in step 2 of the above procedure.

(1.1051 on page 1155) (1.1052 on page 1156)

Single line text justification

To create multiline text

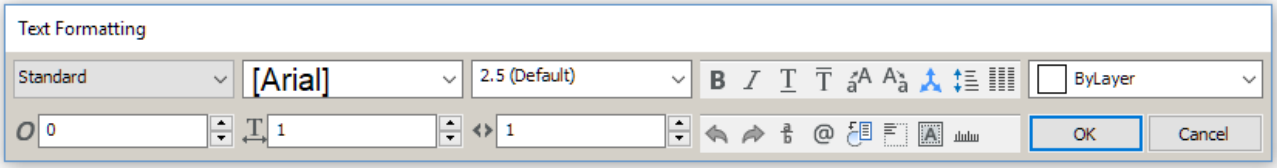
1. Do one of the following:

   - Click the **Multiline Text** tool button (A) on the **Draw** toolbar.
   - Choose **Multiline Text** in the **Text** submenu in the **Draw** menu.
   - Type **mtext** in the command bar, then press Enter.

   You are prompted: First corner for block of text:

2. Specify the first corner (insertion point of the multiline text). **You are prompted:** Justification/Rotation/Style/Height/Dire
   corner for block of text>:

Figure 1.1049



3. Do one of the following:

   - Specify the opposite corner of the text block to define the maximum width of the multiline text.
   - Type @ in the command bar, then press Enter for non-wrapped (zero width) text.
   - If Dynamic Dimensions (1.21.9) are active, the height and width of the text field display dynamically. Type the height and width in the dynamic dimension fields. Press the TAB key to switch; press Enter to confirm.

   The **Text formatting** toolbar opens right above the text block. (1.1049)

4. (option) Define the text properties.
5. Type your text.
6. To conclude the command and close the **Text formatting** toolbar do one of the following:

   - Click the **OK** button.
   - Press Ctrl+Enter.
   - Click outside the MText entity.

Button or setting	Name	Description
(1.1053 on page 1156)	Text Style	Sets the text style
(1.1054 on page 1156)	Text Font	Sets the text font
(1.1055 on page 1156)	Text Height	Sets the text height
	Bold	Creates bold text
	Italic	Creates italic text
	Underscore	Creates underscored text
	Overscore	Creates overscored text
	Uppercase	Converts selected text to uppercase
	Lowercase	Converts selected text to lowercase
	Annotative	Toggles the Annotative property
	Line Spacing	Sets the line spacing
	Columns	Arranges the text in columns
(1.1056 on page 1156)	Color	Sets the color
(1.1057 on page 1156)	Oblique Angle	Sets the oblique angle
(1.1058 on page 1156)	Width Factor	Sets the width factor
(1.1059 on page 1156)	Character Spacing	Sets the character spacing
	Undo	Undoes recent actions
	Redo	Redoes previously undone actions
	Stacked Fraction	Creates stacked fractions
	Special Character	Inserts special characters
	Field	Inserts a variable field
	Justify	Sets the text justification

	Background Mask	Adds a colored background
	Ruler	Toggles the display of the ruler
	OK	Closes the **Text formatting** toolbar and applies the changes
	Cancel	Closes the **Text formatting** toolbar and leaves the Mtext entity unchanged

NOTE	If the line length exceeds the **Width** of the multiline text, the text will be wrapped. Set the **Width** to zero for non-wrapped multiline text.

Text formatting toolbar tools and settings

(1.1060 on page 1157) Top left	(1.1061 on page 1157) Top center	(1.1062 on page 1157) Top right
(1.1063 on page 1157) Middle left	(1.1064 on page 1157) Middle center	(1.1065 on page 1157) Middle right
(1.1066 on page 1157) Bottom left	(1.1067 on page 1157) Bottom center	(1.1068 on page 1158) Bottom right

Multiline text justification. (The red dot indicates the insertion point of the multiline text entity)

Including special text characters and symbols

You can use control codes and unicode strings to include special characters in text entities. To include control codes, as you type text, type two percent symbols (%%) followed by the special control code or character. A single percent sign is treated as a normal text character.

Control Code	Unicode String	Result
%%d	\U+00B0	Draws a degree symbol (°)
%%p	\U+00B1	Draws a plus-or-minus symbol (±)
%%c	\U+2205	Draws a diameter symbol (Ø)
%%k	\U+0336	Starts to strikethrough text. Repeat the code to stop.
%%u	\U+005F	Starts to underscore text. Repeat the code to stop.
%%o	\U+203E	Starts to overscore text. Repeat the code to stop.

Name	Symbol (*)	Unicode String
Almost equal	≈	\U+2248
Angle	∠	\U+2220
Center line	℄	\U+2104
Delta	Δ	\U+0394
Electrical phase	Ф	\U+0278
Identity	≡	\U+2261
Not equal	≠	\U+2260

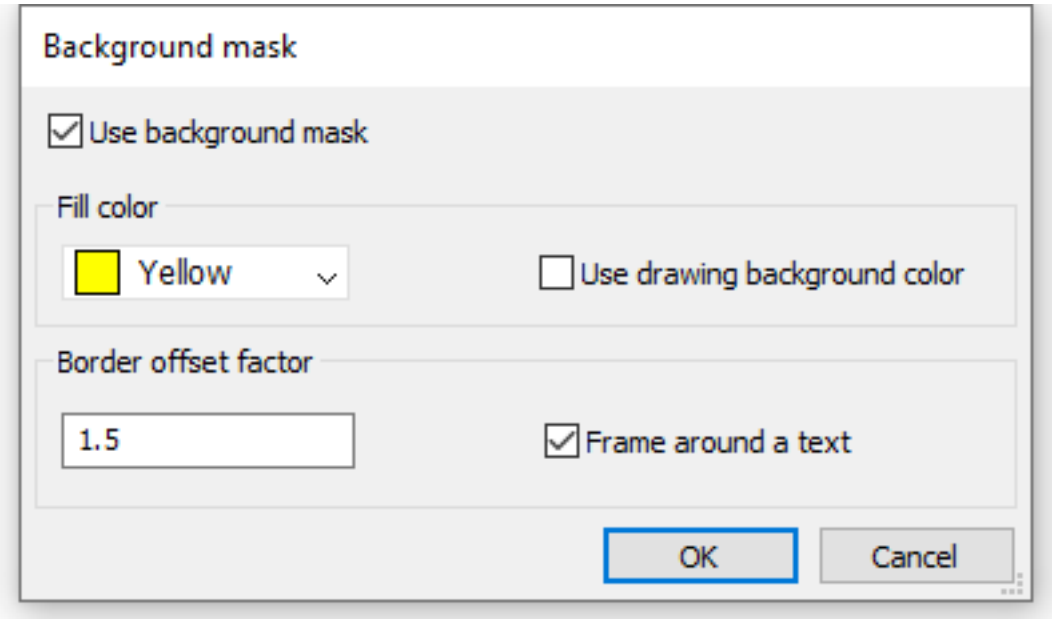
Omega	Ω	\U+03A9
Squared	²	\U+00B2
Cubed	³	\U+00B3

Symbols and Unicode strings (*) If supported by the text font.

To add a background mask

1. When creating or editing a multiline text entity, click the **Background Mask** tool button () on the **Text Formatting** toolbar. The **Background Mask** dialog displays: (6.1677 on page 4917)
2. Check the **Use background mask** option.
3. Do one of the following:
   - Choose a color in the **Fill color** drop-down list.
   - Choose **Select color...** in the **Fill color** drop-down list and choose an Index color (1.25.5) or a True color (1.25.5) in the **Select color** dialog.
   - Check the **Use drawing background color** option.
4. Define the **Border offset factor** , which defines the margin around the text for the background. The value is based on the text height and must be in the range 1-5. A factor of 1.0 exactly fits the multiline text entity.
5. (option) Tick the **Frame around a text** option to create a text frame.
6. Click **OK** to create the background mask.

Figure 1.1050



To add a text frame

1. Select the Mtext entity.
2. Click the **Text frame** property in the Properties (6.24.54) panel.
3. Click the down arrow and choose **Yes**.

1.29.21 Checking Spelling

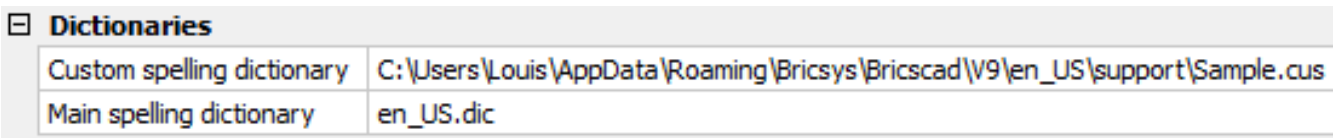
Command: SPELL (6.27.44) The spelling checker checks the spelling of text in the current drawing. You can check the spelling of one or more selected text entities or check the entire drawing. During the spelling check, the **Spell** command matches the words in the drawing or the current selection set to the words in the current main dictionary and the current custom dictionary. If a word is not found in either dictionaries you can select the correct spelling in the suggestions field or you can add the word to the current custom dictionary. Custom dictionaries are used for discipline-specific words, such as medical or mechanical.

Dictionary settings

Which dictionaries are used by the **Spell** command is defined by the **DCTMAIN** (main dictionary) and **DCTCUST** (custom dictionary) system variables (1.17.10). (1.1069)

NOTE	We only deliver the English dictionary because of the license type on the dictionary files : the English version can be distributed freely ; all other languages are not free. However, you can download other languages and use them for free (see To add (1.29.21) a main dictionary (1.29.21)).

Figure 1.1069



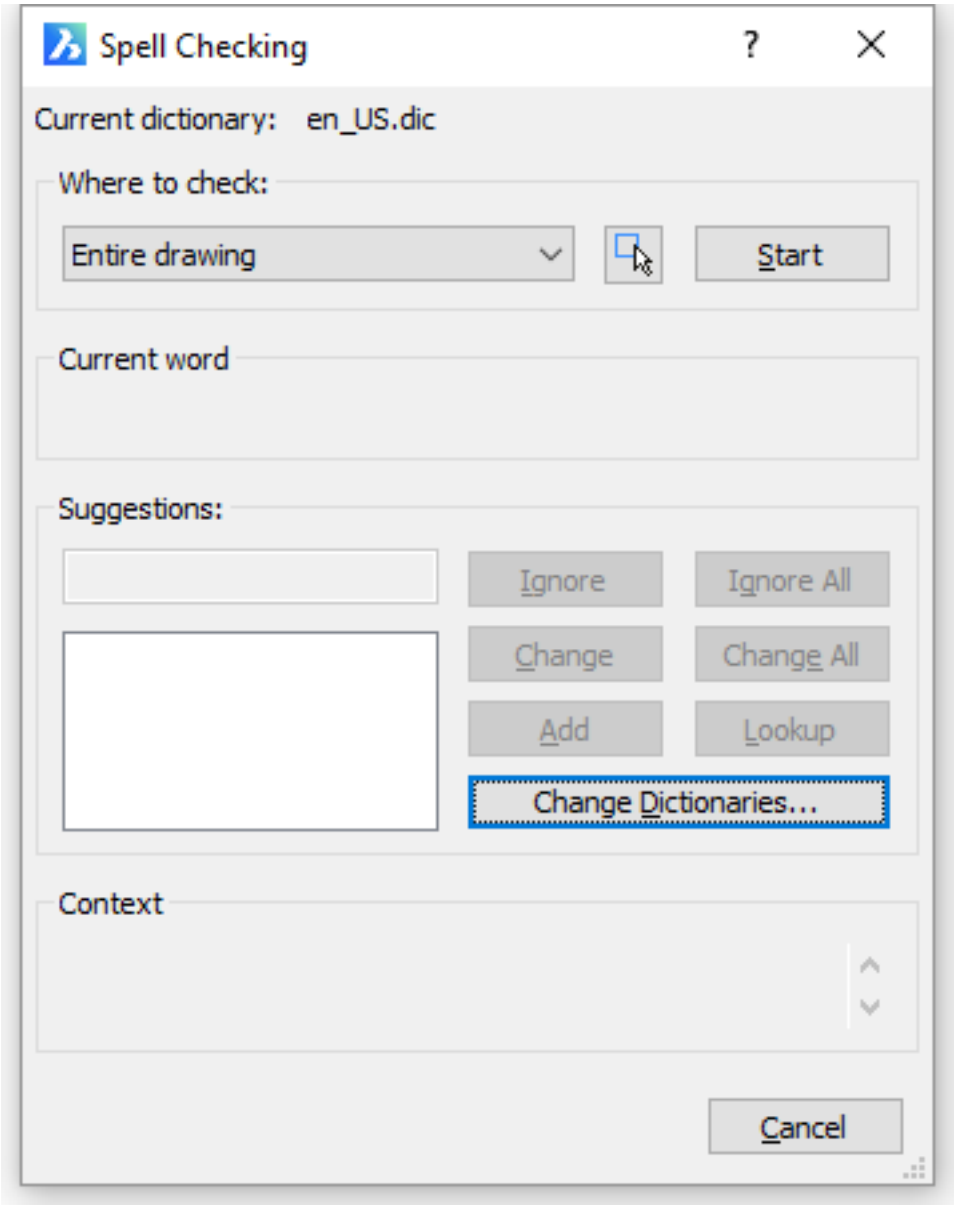
To open the Spell Checking dialog

Do one of the following:

- Choose **Check Spelling** in the **Tools** menu.
- Type **spell** in the command bar, then press Enter.

(1.1070 on the next page)

Figure 1.1070

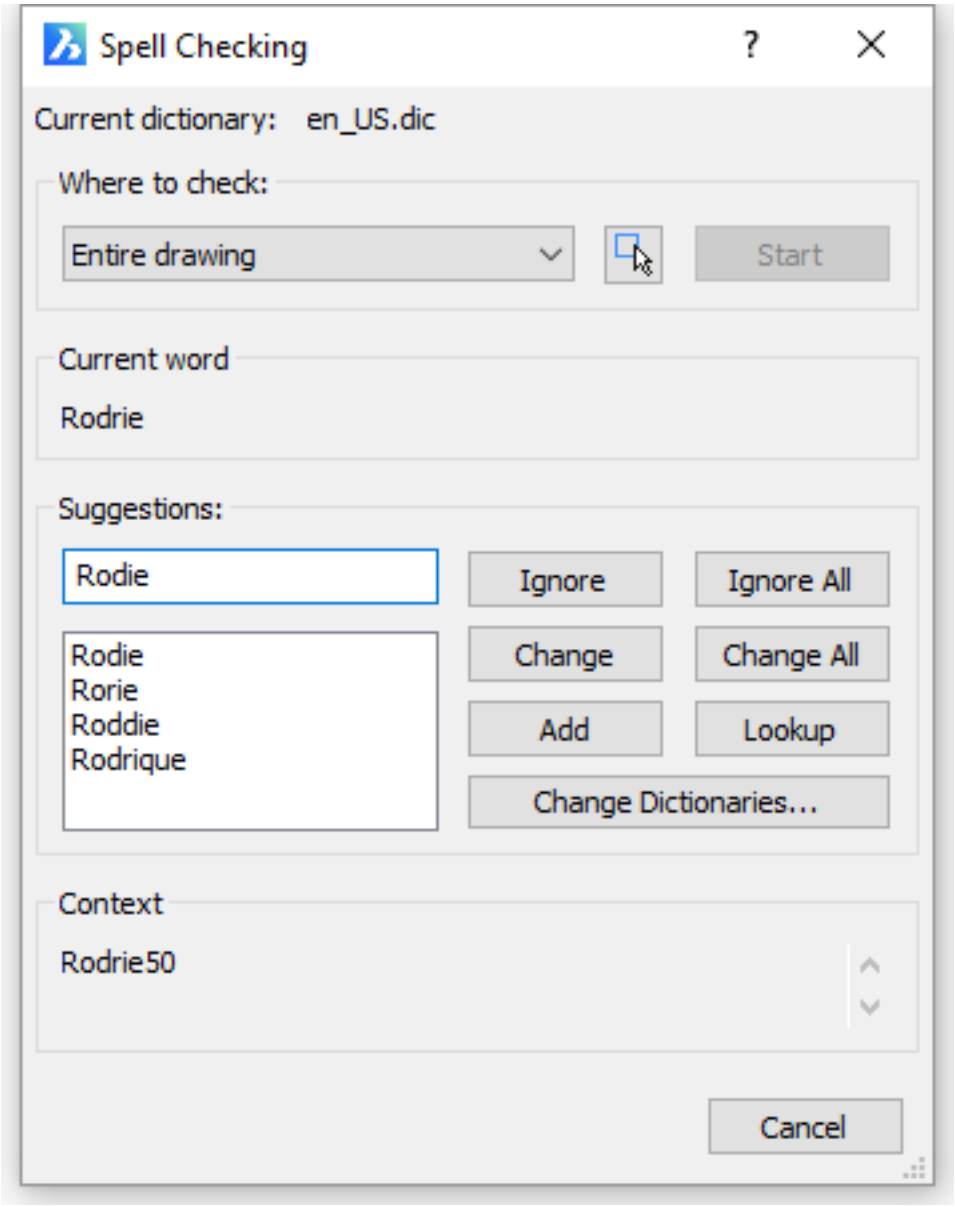


To check the spelling

1. Open the Spell Checking dialog (1.29.21).
2. (option) Click the **Select** button () to compose a selection set (1.32.7).
3. (option) Change the current dictionaries (1.29.21).
4. Click the **Start** button. The first possibly misspelled word displays in the **Current word** section. The content of the text entity in which the **Current word** is found displays in the **Context** section. (1.1071 on the facing page)
5. Do one of the following:
   - Click the **Ignore** button to leave this instance of the **Current word** unchanged.
   - Click the **Ignore All** button to leave all instances of the **Current word** unchanged.
   - Accept the word in the **Suggestions** field or select a word in the **Suggestions** list, then click the **Change** button to replace this instance of the **Current word** by the word in the **Suggestions** field.
   - Accept the word in the **Suggestions** field or select a word in the **Suggestions** list, then click the **Change All** button to replace all instances of the **Current word** by the word in the **Suggestions** field.
   - Click the **Add** button to add the **Current word** to the current custom dictionary.
   - Click the **Lookup** button to list words similar to the word in the **Suggestions** field.
6. Repeat step 5 until the **Spelling check is complete** message displays.

NOTE	If a selection is active when you launch the **Spell** command, only text entities in the selection set are checked.

Figure 1.1071



To change dictionaries

1. Open the Spell Checking dialog (1.29.21).
2. Click the **Change Dictionaries...** button. The **Change Dictionaries** dialog opens. (1.1072 on the next page)
3. Click the **Main dictionary** list button to change the main dictionary. (1.1073 on the facing page)
4. Select a new main dictionary.
5. (option) Click the **Browse...** button to select a new **Custom dictionary**.
6. (option) Type a word in the **Custom dictionary words** field, then click the **Add** button to add a word to the current custom dictionary.
7. Click the **Apply & Close** button.

NOTE

- Custom dictionaries are best saved in the **Support** folder of the Roamable root folder (1.17.2).
- If you want to share the custom dictionary with MS Word, point to the MS Word custom dictionary in step 5 in the above procedure. By default, **CUSTOM.DIC** is the custom dictionary in MS Word, which can be found under **C:\Users\<user name>\AppData\Roaming\Microsoft\Proof\CUSTOM.DIC**.

Figure 1.1072

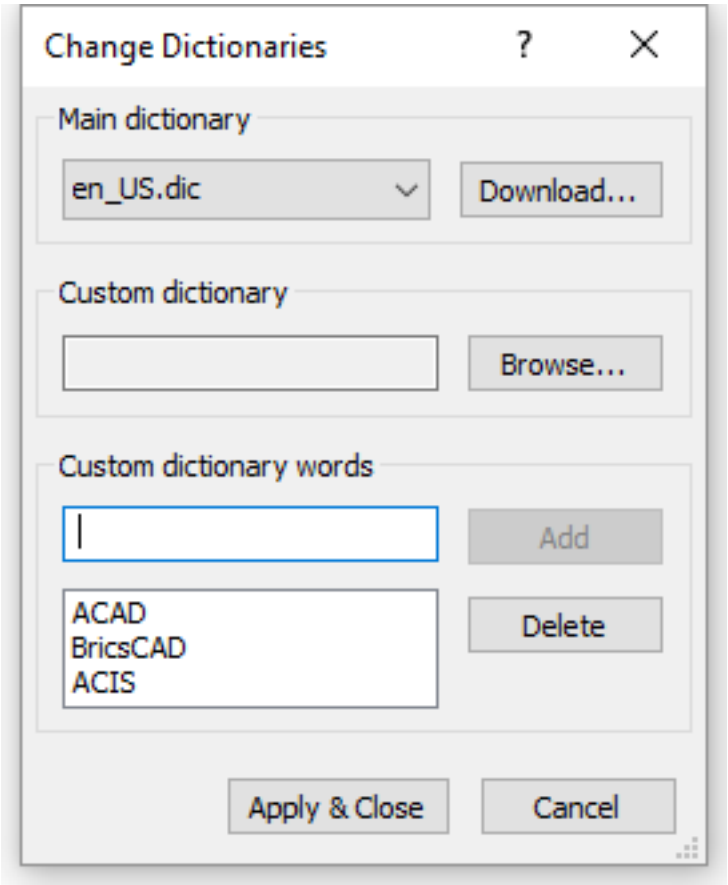


Figure 1.1073

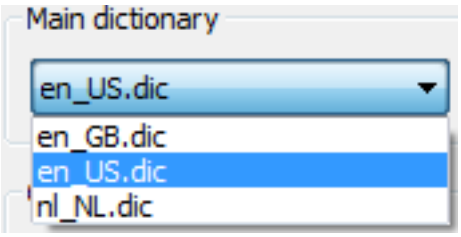

To add a new main dictionary

1. Open the Spell Checking dialog (1.29.21).
2. Click the **Change Dictionaries...** button.
3. Click the **Download...** button. Your browser opens: https://extensions.openoffice.org/dictionaries
4. Scroll down to the language of your choice, then click the link to open the page of the selected language.
5. Click the **Download extension** button to start downloading the ***.oxt** file. (1.1074 on the next page)
6. Change the **oxt** extension to **zip** .
7. Extract the ***.aff** and ***.dic** files from the ZIP file to the folder **C:\Program Files\Bricsys\BricsCAD Vx\Support**. (1.1075 on the facing page) The dictionary is now available in the **Main Dictionary** list on the **Change Dictionaries** dialog box. (1.1076 on the next page)

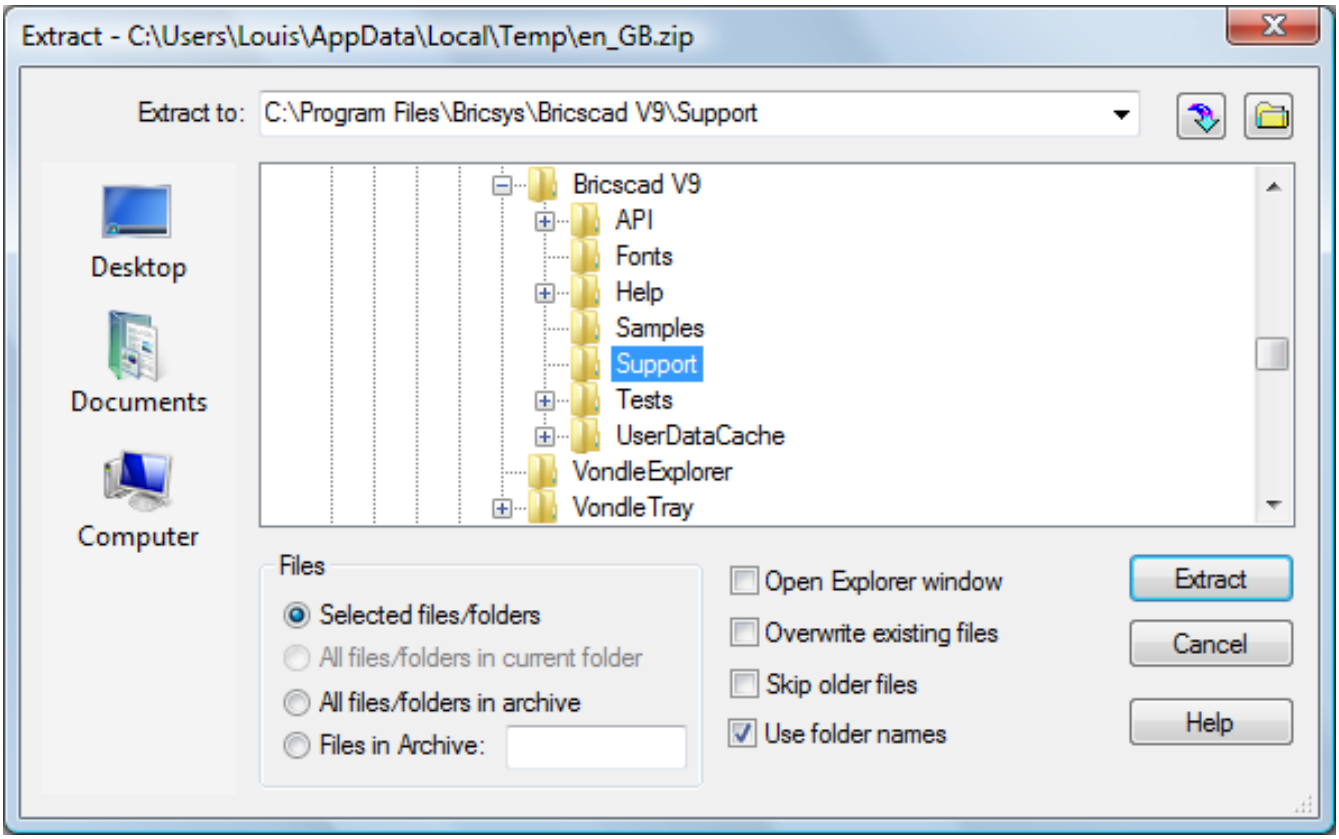

Figure 1.1076

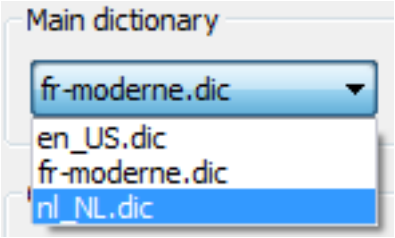


To add a new custom dictionary

1. Open a text editor, such as **Notepad**.
2. (option) Type the words you want to use in your custom dictionary. Each word must be on a separate line.
3. Save the file to the the **Support** folder of the Roamable root folder (1.17.2). Make sure the file extension is **.cus**.

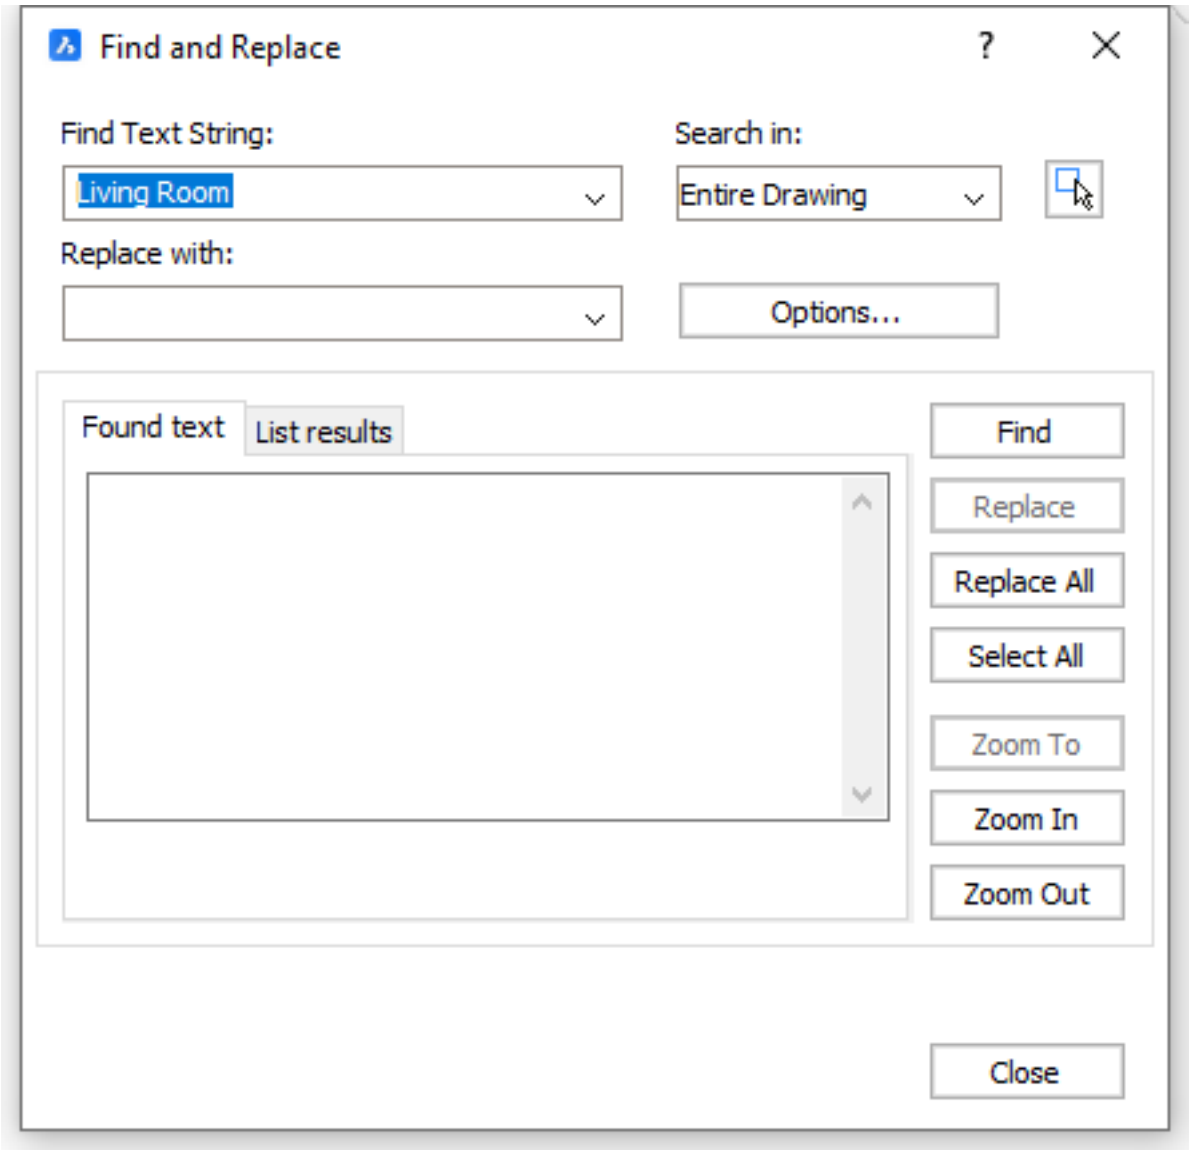
1.29.22 Finding and replacing text

Command: FIND (6.14.8) The **FIND** command lets you specify the text you want to find. You can than find or replace the text. Optionally you can zoom in on the various instances of the text entities that contain the search text.

To open the Find and Replace dialog

Launch the FIND (6.14.8) command. (6.1196 on page 4462)

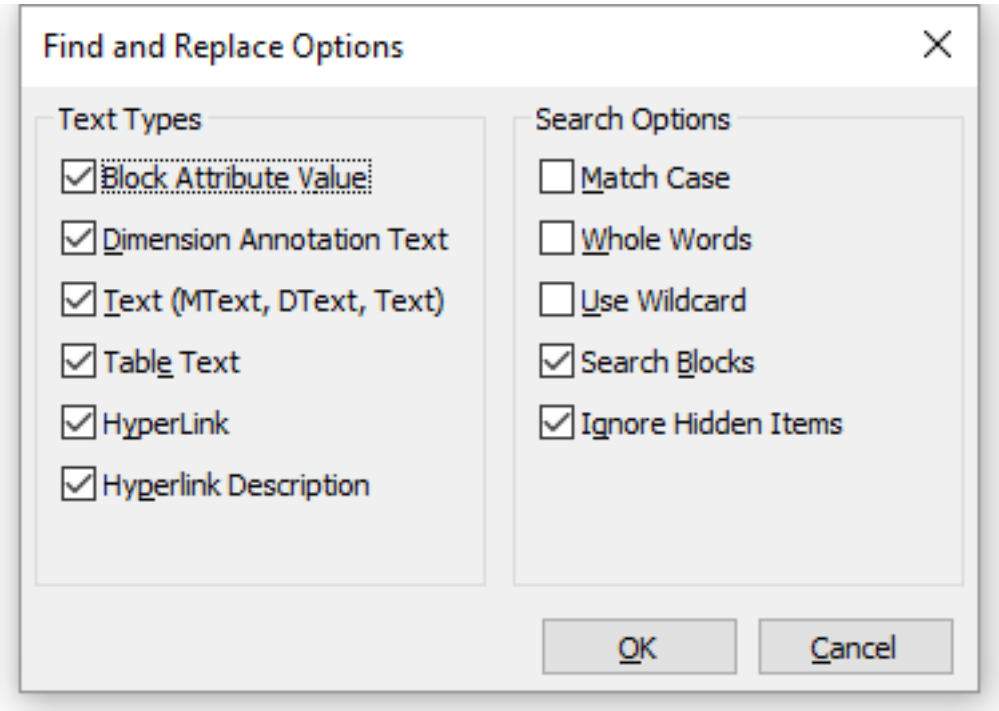
Figure 1.1077



To set the Find and Replace options

1. Launch the FIND (6.14.8) command.
2. Click the **Options** button. (1.1078 on the next page)
3. Set the **Find and Replace** options.
4. Click the **OK** button.

Figure 1.1078



To find text

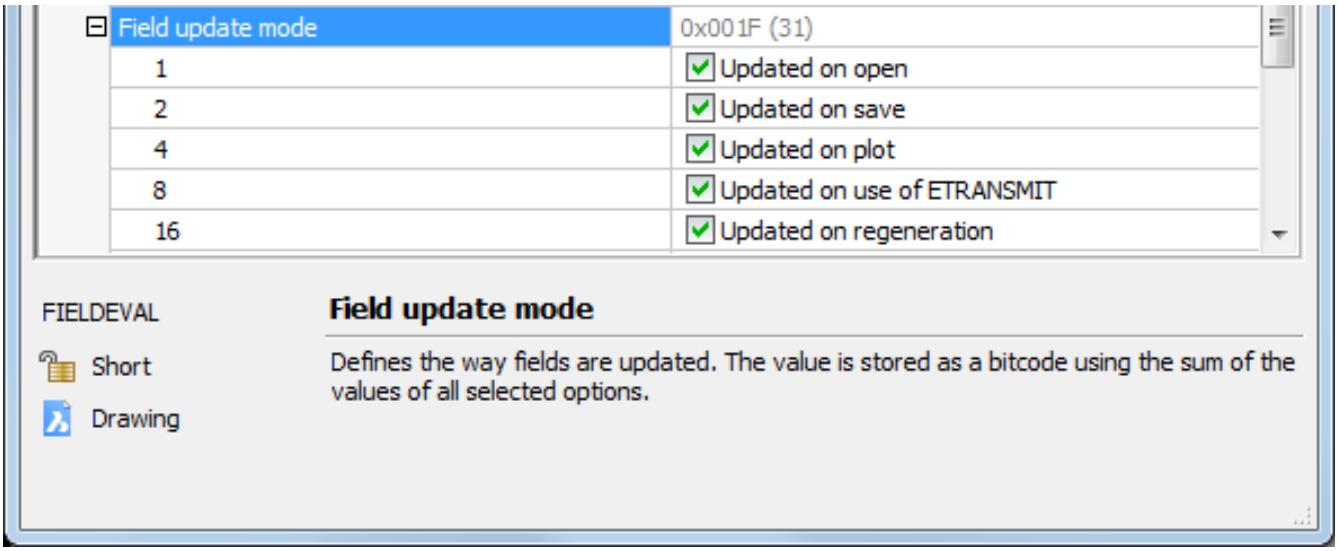
1. Launch the FIND (6.14.8) command.
2. (option) Set the Find and Replace options.
3. Type the text in the **Find Text String** field.
4. (option) Click the **Select Entities** button ( ) to compose a selection set.
   - The **Find and Replace** dialog temporarily closes to let you select entities (1.32.7).
   - Right click to conclude the selection of entities. The **Search in** field reads **Current Selection** instead of **Entire Drawing** .
5. Click the **Find Next** button. The content of the first text entity that contains the search string displays in the **Search results** pane.
6. (option) Click the **Zoom To** button. The drawing is zoomed in on the text entity.
7. Do one of the following:
   - Repeat steps 5 and 6 to find more instances of the same search string.
   - Repeat steps 2 through 6 to find another text string.
   - Press the Esc key or click the **Close** button to stop.

NOTE If a selection is active when you launch the **FIND** command, only text entities in the selection set are searched.

To replace text

1. Launch the FIND (6.14.8) command.
2. (option) Set the Find and Replace options.
3. Type the search text in the **Find Text String** field.
4. Type the replacement text in the **Replace with:** field.
5. (option) Click the **Select Entities** button ( ) to compose a selection set.
   - The **Find and Replace** dialog temporarily closes to let you select entities (1.32.7).
   - Right click to conclude the selection of entities. The **Search in** field reads **Current Selection** instead of

Figure 1.1079



1.29.23 Working with Fields

Commands: FIELD (6.14.7), UPDATEFIELD (6.30.10), MTEXT (6.21.38) and TABLE (6.29.2) A field is a variable text that. When a field is updated it displays the latest value of the data source it refers to. Fields can be used to insert drawing properties, custom properties or object properties in multiline texts or tables or as an attribute in a block. Fields in attributes are especially useful in title blocks: using drawing, sheet set, subset and sheet properties title blocks can be filled out automatically. See the DWGPROPS (6.10.46) command to learn more about default and custom drawing properties. See the SHEETSET (6.27.38) command to learn more about default and custom sheet set, subset and sheet properties. If no value is available, a field displays hyphens (----). If the FIELDDISPLAY (1.17.10) system variable is ON, fields display on a light gray background which does not print. The FIELDEVAL (1.17.10) system variable controls when fields are updated. (1.1079)

General procedure to create fields

1. Do one of the following:

   - Click the **Insert Field** tool button ( ) on the **Insert** toolbar.
   - Choose **Insert Field...** in the **Insert** menu.
   - Type **field** in the command bar, then press Enter.
   - Click the **Field** tool button ( ) on the **Text Formatting** toolbar when creating or editing Mtext (1.29.20) or a table (1.29.24) cell content.

   The **Field** dialog box displays. (1.1080 on the next page)

2. Under **Field Names** , expand a group, then choose a field name. The settings for the selected field display.

3. Adjust the settings, then click the **OK** button. The **Field** dialog box closes. The field is created in the Mtext or table cell being edited **Or You are prompted:** Specify start point or [Height/Justify]: A context menu displays:

   - (option) Type **H** or choose **Height** in the context menu to define the text height.
   - (option- Type **J** or choose **Justify** in the context menu to set the text justification. (1.1081 on the following page)
   - Specify the insertion point of the field in the drawing. An **Mtext** entity, containing the field is created.

Figure 1.1080

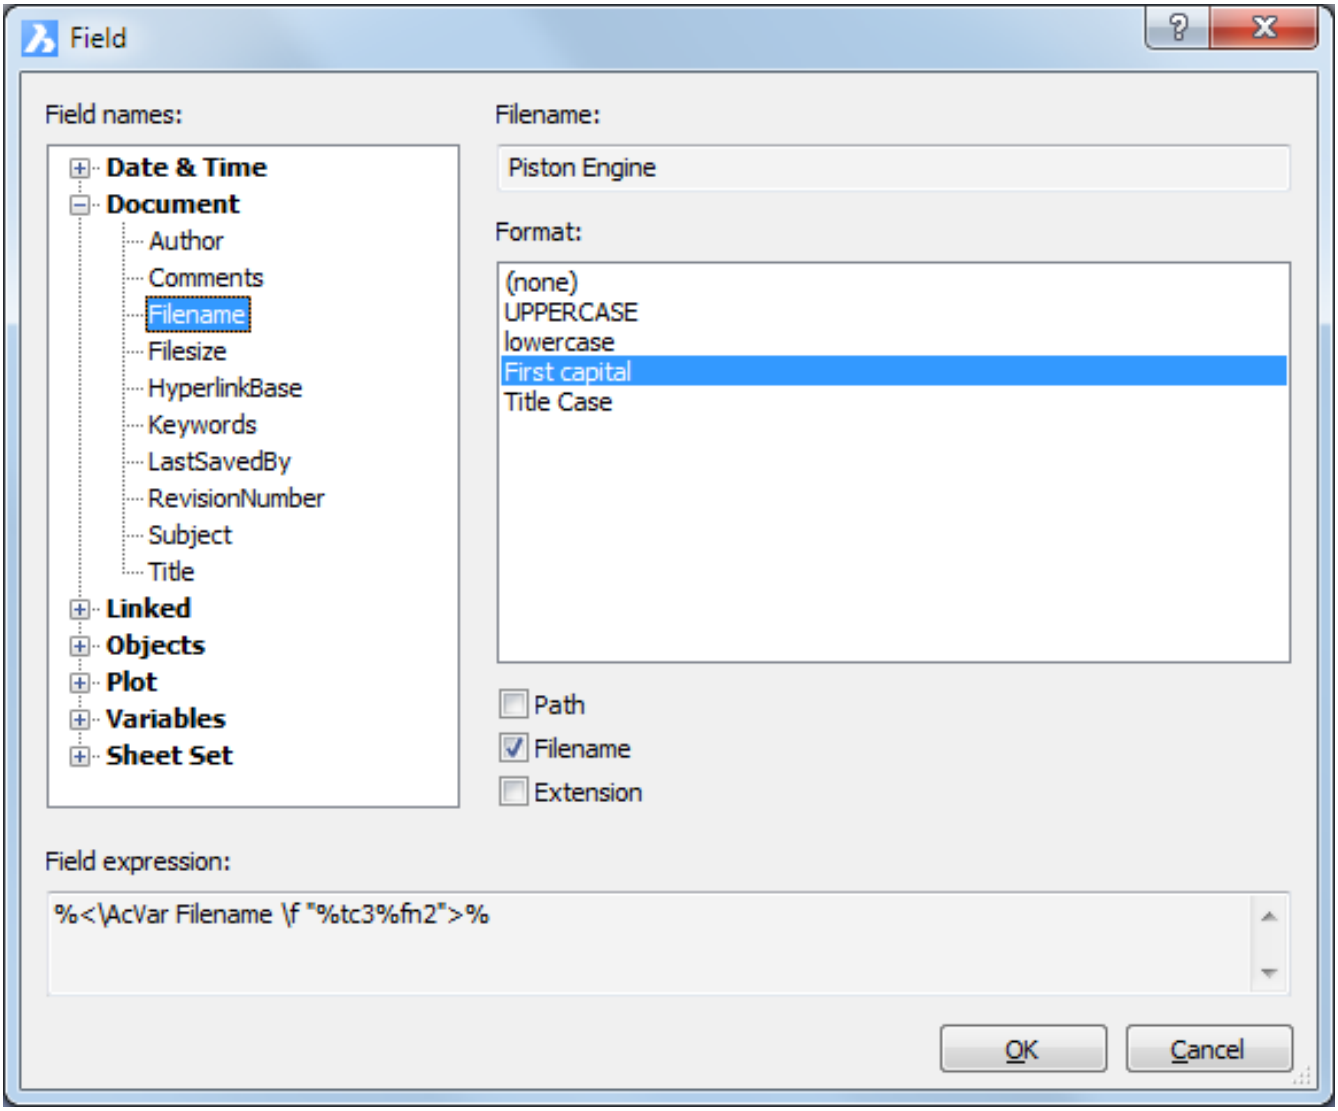


Figure 1.1081

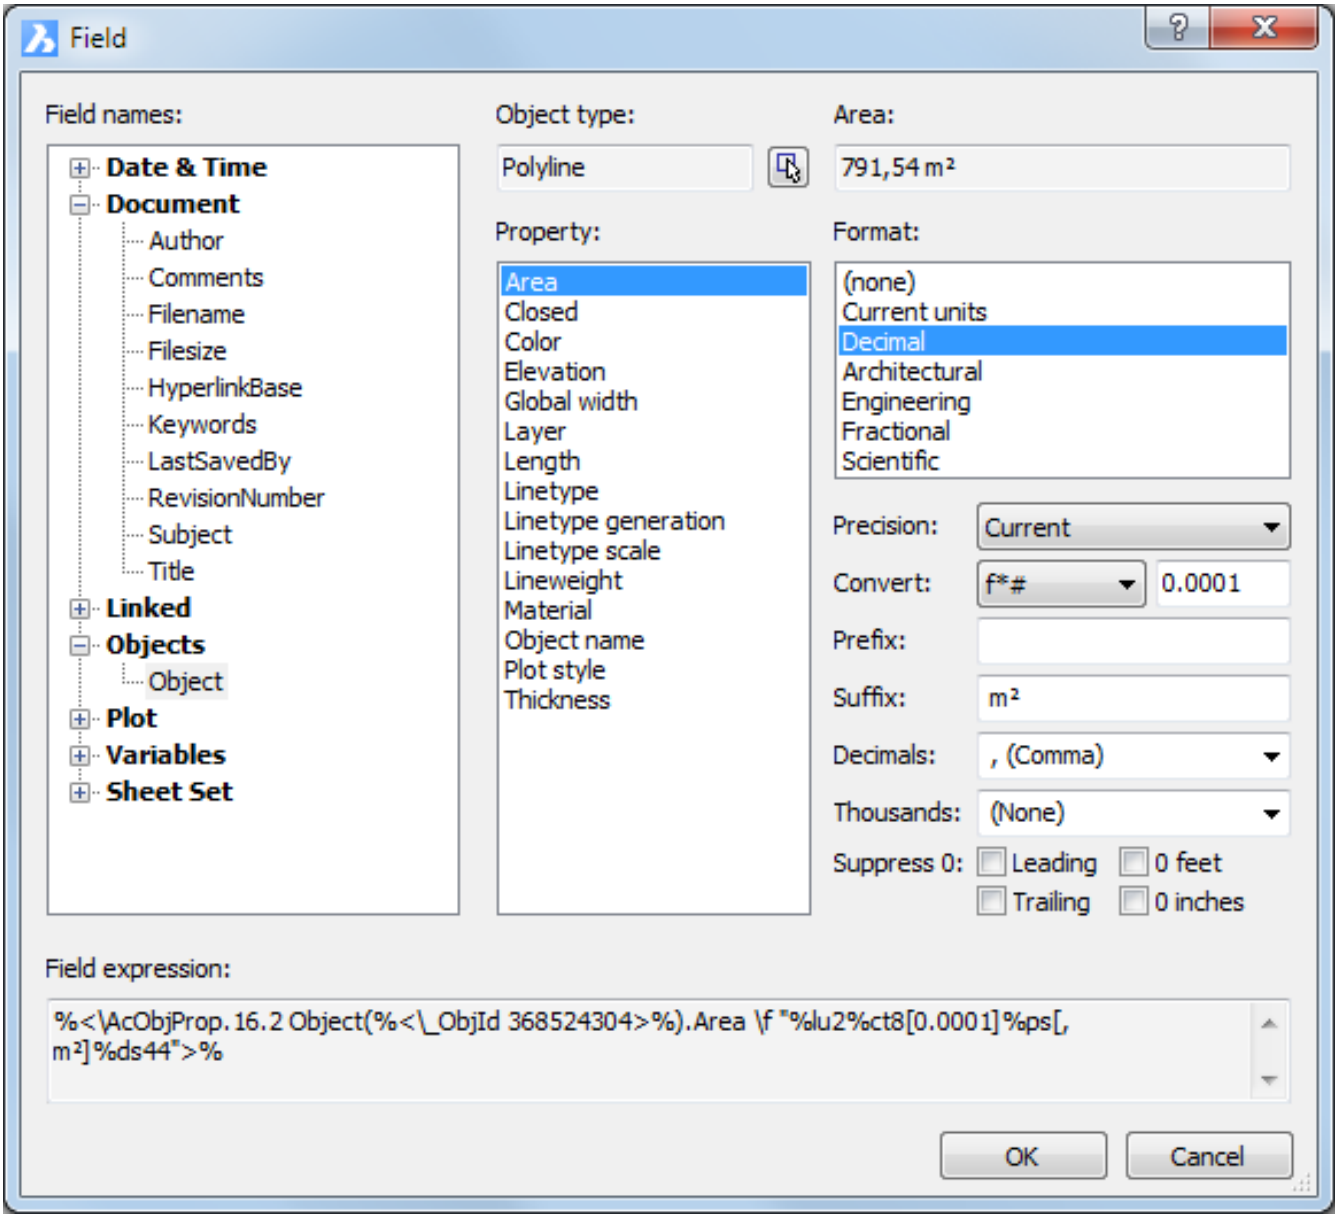
To display an entity property in a field

1. Launch the Field command (1.29.23).
2. Expand **Objects** in the **Field names** list and select **Object**.
3. Click the **Select Entity** button ( ) on the **Field** dialog box. The **Field** dialog box closes temporarily. **You are prompted:** Select Entity:
4. Click the entity you want to display a property of. The **Field** dialog box displays again.
5. Select the entity property in the **Property** list. (1.1082 on the next page)
6. Set the display layout:
   - **Format** : choose a unit format.
   - **Precision** : select a precision in the list button
   - **Convert** : this option allows to recalculate the field value.
     - Choose a formula in the list; e.g. f*#, where f is the factor you type in the Convert field and # is the field value.
     - Type a factor in the Convert field; e.g. 0.0001 to express the area of a polyline in square meters in a cm drawing.
   - **Prefix** : type a text string
   - **Suffix** : type a text string
   - **Decimals** : select a decimal separator character
   - **Thousands** : select a thousands separator character
   - **Suppress 0** : allows to suppress leading and/or trailing zeros
7. Click the **OK** button.
8. Specify a point to place the field in the drawing.

Figure 1.1082



To edit a field

1. Edit the table cell or Mtext entity that contains the field.
2. Do one of the following:
   - Double click the field.
   - Right click the field, then choose **Edit Field ...** in the context menu.
   - Select the field, then press **Ctrl + F** .

   The **Field** dialog box displays.
3. Adjust the properties of the field.
4. Click the **OK** button to apply the changes.

To update a field

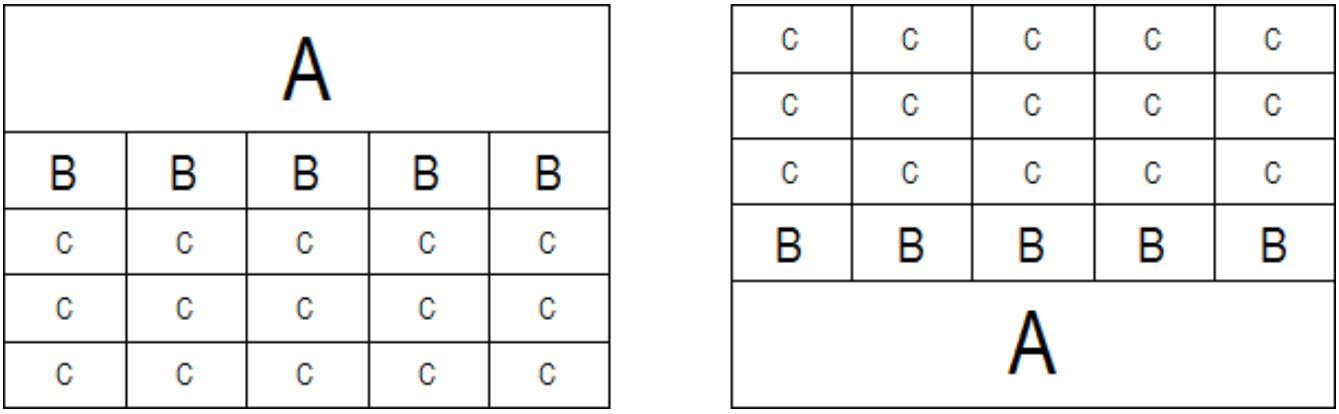
1. Do one of the following:
   - Click the **Update Field** tool button () on the **Redraw / Regen** toolbar.
   - Choose **Update Fields...** in the **Tools** menu.
   - Type **updatefield** in the command bar.

   You are prompted: Select field(s) to update:
2. Select the field(s) you want to update, then right click or press Enter. The selected fields are updated.

To convert a field to text

1. Edit the table cell or Mtext entity that contains the field.
2. Select the field.
3. Right click, then choose **Convert Field to Text** in the context menu.

Figure 1.1083



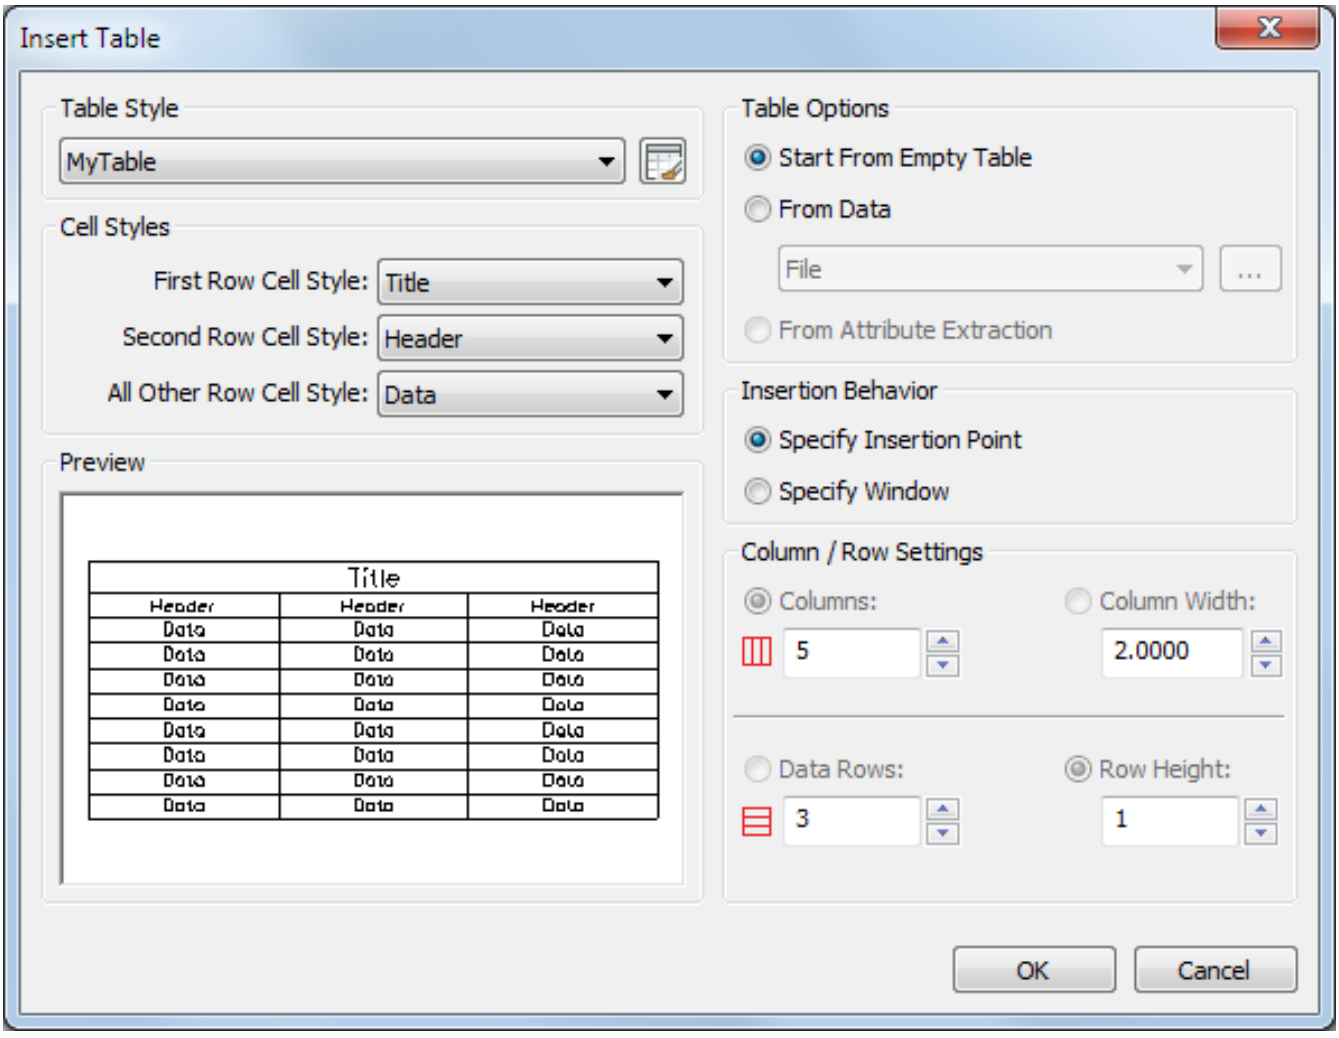
1.29.24 Tables

Commands: TABLE (6.29.2), -TABLE (6.29.1), TABLEDIT (6.29.3), TABLEEXPORT (6.29.4), TABLEMOD (6.29.5), TABLESTYLE (6.29.6) A table is an entity that is composed of rows and columns, much like a Microsoft Excel spreadsheet. A table entity can be created as an empty table or you can import data from a CSV (C omma S eparated V alues) file. The appearance of the table text and gridlines is controlled with a table style. Table styles are saved in the DWG file. A default table consists of a **Title** cell (A), a row of **Header** cells (B) and one or more rows of **Data** cells (C). A table can have one of two directions: **Down** (title row at the top) or **Up** (title row at the bottom). (1.1083) Table with a **Down** direction (left) and a **Up** direction (right).

To create an empty table

1. Do one of the following:
   - Click the **Table** tool button ( ) on the **Draw** toolbar.
   - Choose **Insert Table...** in the **Draw** menu.
   - Type **table** in the command bar, then press Enter.
2. The **Insert Table** dialog displays: (1.1084 on the next page) Choose a Table Style (1.29.26) from the **Table Style** list.
3. (option) Set the cell style for the first, second and other rows. By default the cell style for the first row is **Title**, the cell style for the second row is **Header** and the cell style for the other rows is **Data.**
4. Under **Table Options**, choose **Start from Empty Table**.
5. Under **Insertion Behavior** do one of the following:
   - Choose **Specify Insertion Point**, then specify the number of columns and the column width and number of data rows and the row height.
   - Choose Specify Window, then do one of the following:
     - Specify the number of columns and data rows.
     - Specify the column width and the row height.
     - Specify the column width and the number of data rows.
     - Specify the number of columns and the row height.
6. Click the **OK** button. Depending on your choice in step 5 **you are prompted** to specify an insertion point or a window. The table is created and the **Text Formatting** toolbar displays (see Create multiline text (1.29.20)).
7. Do one of the following:
   - Start adding text in the table (see Edit the table content (1.29.24)).
   - Click outside the table to close the **Text Formatting** toolbar.

Figure 1.1084



To create a table from data

When importing data from a CSV (Comma Separated Values) file, please make sure the list separator character on your system is the same as the one used in the CSV file (see Defining the list separator character).

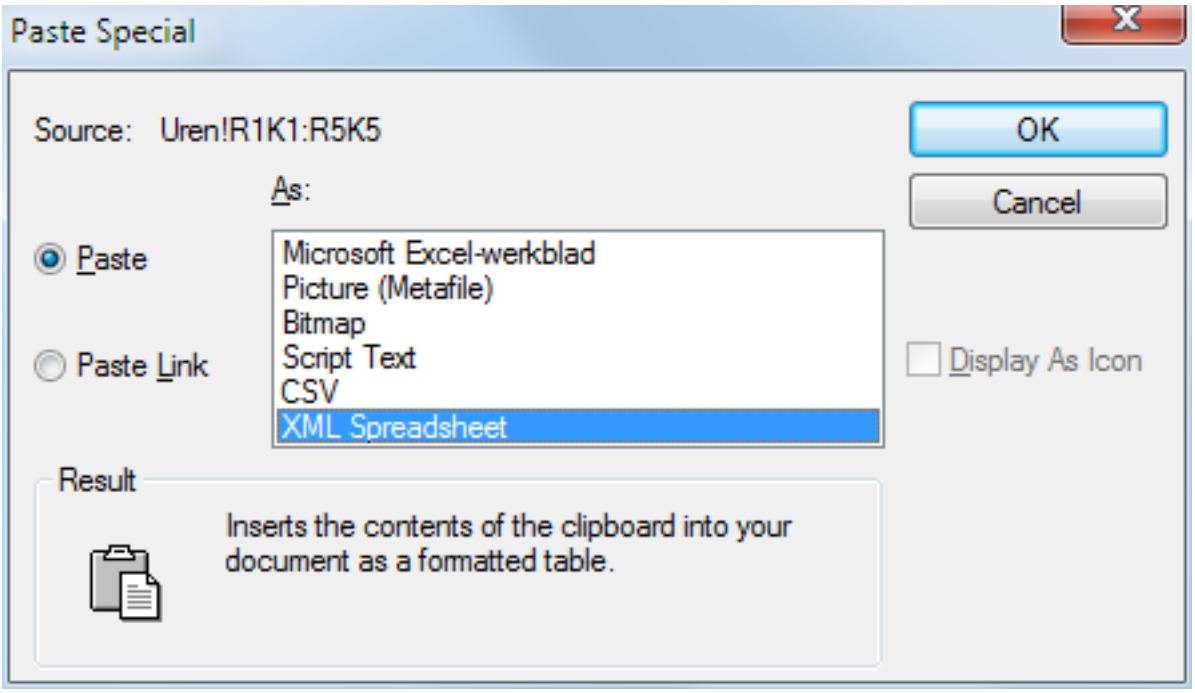
1. Do one of the following:
   - Click the **Table** tool button () on the **Draw** toolbar.
   - Choose **Insert Table...** in the **Draw** menu.
   - Type **table** in the command bar, then press Enter.
2. The **Insert Table** dialog displays. Choose a Table Style (1.29.26) from the **Table Style** list.
3. Under **Table Options**, choose **From Data**.
4. Click the Browse button ().
5. The **Open** dialog displays. Choose a CSV file, then press the **Open** button.
6. Click the OK button on the **Insert Table** dialog. The dialog box closes and the table is attached to the cursor.
7. Click a point in the drawing to place the table. The table is created and the **Text Formatting** toolbar displays (see Create multiline text (1.29.20)).
8. Do one of the following:
   - Start editing the text in the table (see Edit the table content).
   - Click outside the table to close the **Text Formatting** toolbar.
9. (option) Select the table and drag the grips to adjust the dimensions of the table.

To create a table from an Excel spreadsheet

1. Open the spreadsheet in **Microsoft Office Excel**.
2. Select the cells you want to create a table from.
3. Copy the selection to the clipboard:
   - Press **Ctrl+C**.
   - Right click and choose **Copy** in the context menu.
4. In BricsCAD, choose **Paste special...** in the **Edit** menu.
5. The **Paste Special** dialog box displays: (1.1085 on the facing page) Choose **XML Spreadsheet** in the **As** option list.
6. Click in the drawing to insert the table.

Tutorial: BricsCAD Spreadsheet Import Techniques Click here (1.9.8) to watch

Figure 1.1085



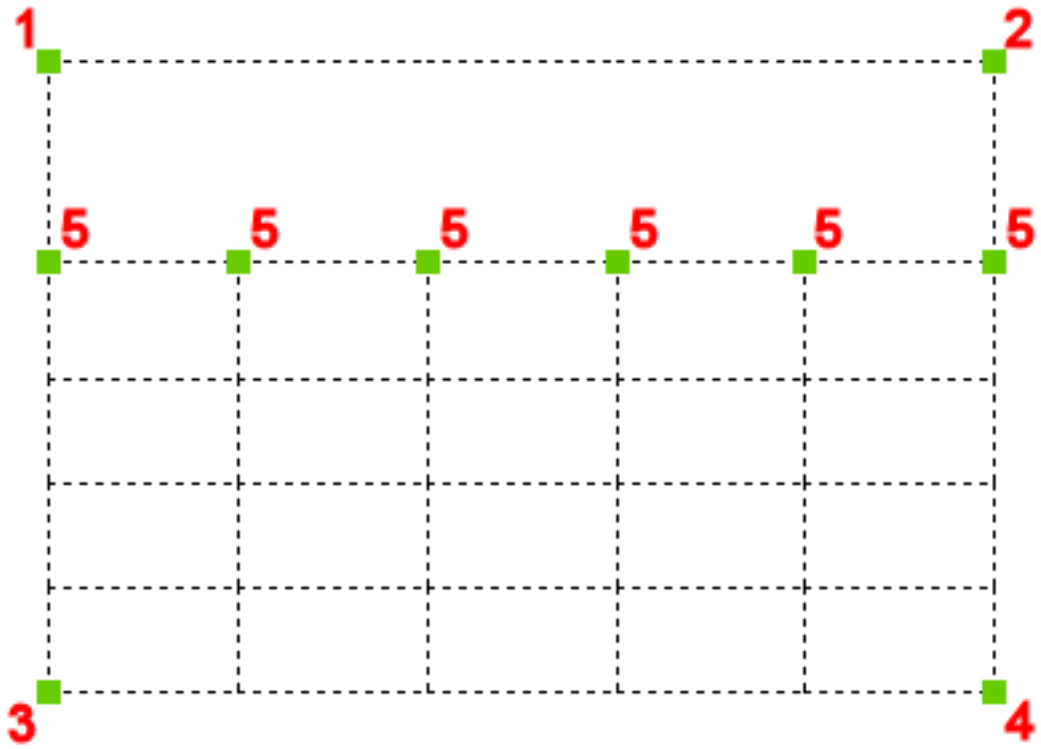
Editing a table using grips

When a table is selected, multiple grips display:

1. Moves the table.
2. Modifies the width uniformly.
3. Modifies the height uniformly.
4. Modifies the width and height uniformly.
5. Modifies the width of a column.

(1.1086 on the next page)

Figure 1.1086



Editing a table using the Table toolbar

1. To open the **Table** toolbar, do one of the following:
   - Click the cell you want to edit.
   - Press and hold the left mouse button then define a rectangle to select multiple cells
2. Column letters and row numbers display. The column(s) and row(s) of the selection hightlight. A rectangle with four handles is drawn around the selection. (1.1087 on the facing page) Do one of the following:
   - Click a cell to select it.
   - Press and hold the left mouse button, then drag the cursor to select multiple cells.
3. (option) Drag the grips of the selection to modify the dimensions.
4. (option) Click a tool in the Table toolbar.
5. (option) Right click to display a context menu: (1.1088 on the next page)
   - **Delete Cell Content** : deletes the text in the selected cells.
   - **Clear Cell Overrides** : resets all cell properties of the selected cells to the Cell Style settings as defined in the Table Style (1.29.26).
   - **Clear Table Overrides** : resets all cell properties of all cells to the Cell Style settings as defined in the Table Style (1.29.26).
6. (option) Repeat steps 3 and 4 to continue editing the table.
7. (option) Double click a cell to edit the cell text.
8. (option) Do one of the following:
   - Click another cell.
   - Press and hold the left mouse button, then drag the cursor to select multiple cells.
9. Click outside the table to close the **Table** toolbar.

Figure 1.1087

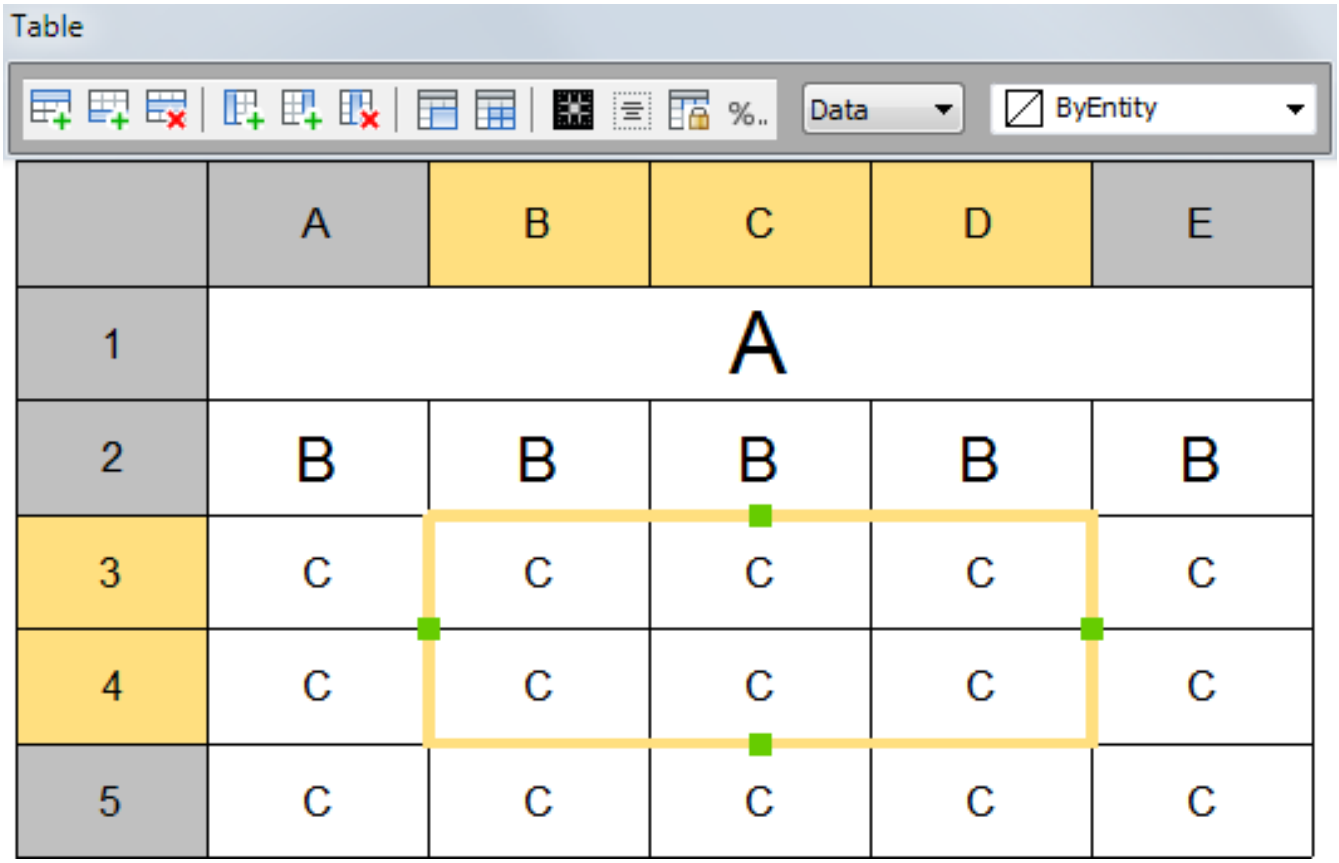


Figure 1.1088

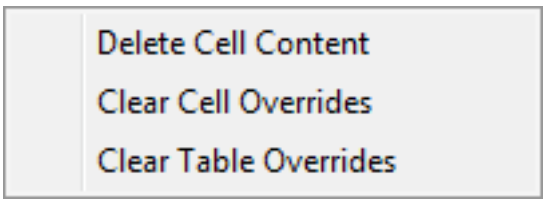


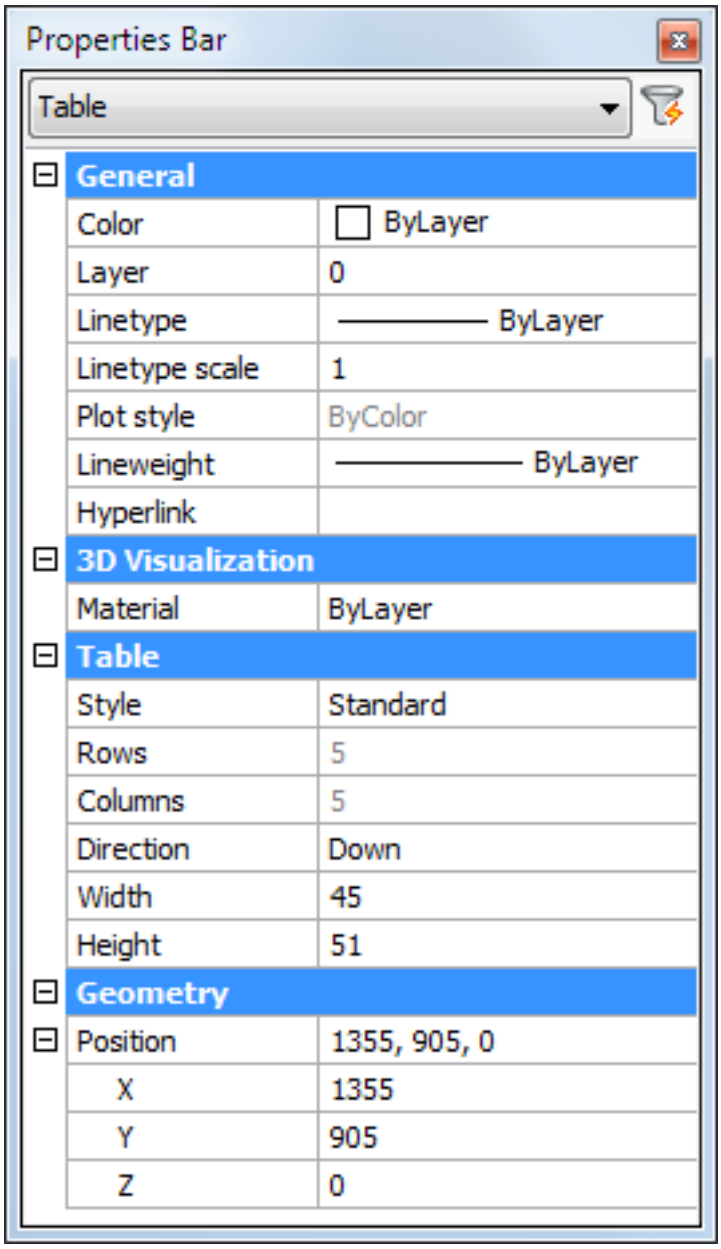
Icon	Tool name	Description
	Insert row above	Inserts an empty row above the selection.
	Insert row below	Inserts an empty row below the selection.
	Delete row	Deletes the row(s) of the selection.
	Insert column left	Inserts an empty column at the left of the selection.
	Insert column right	Inserts an empty column at the right of the selection.
	Delete column	Deletes the column(s) of the selection.
	Merge	Merges the selected cells.
	Unmerge	Splits previously merged cells.
	Border style	Sets the border style of the selection (not implemented yet).
	Text alignment	Sets the text alignment of the selection.
	Lock / Unlock	Locks / Unlocks the selection.
%..	Set cell format	Sets the cell format of the selection (not implemented yet)
	Set cell style	Sets the style of the selected cells: **Title** , **Header** or **Data** .
(1.1093 on page 1189)	Set cell background	Sets the background color of the selection.

Table tools

Editing a table in the Properties bar

1. Click one of the grid lines. The properties of the table display in the Properties bar (1.15.4). (1.1089 on the next page)
2. (option) Apply a different Table Style (1.29.26).
3. (option) Change the table direction.
4. (option) Modify the width and/or height of the table.
5. (option) Modify the vertical and/or horizontal cell margins.
6. Press the Esc key to stop editing the table.

Figure 1.1089



Editing a cell in the Properties bar

1. Click the cell. The properties of the cell display in the Properties bar (1.15.4). (1.1090 on the facing page)
2. (option) Modify the width and/or height of the cell. The width and height of the column and/or row of the cell are changed.
3. (option) Modify the text rotation. The options are: 0°, 90°, 180° and 270°.
4. (option) Edit the cell content.
5. (option) Choose a different text alignment option. (1.1091 on the next page)

Figure 1.1090

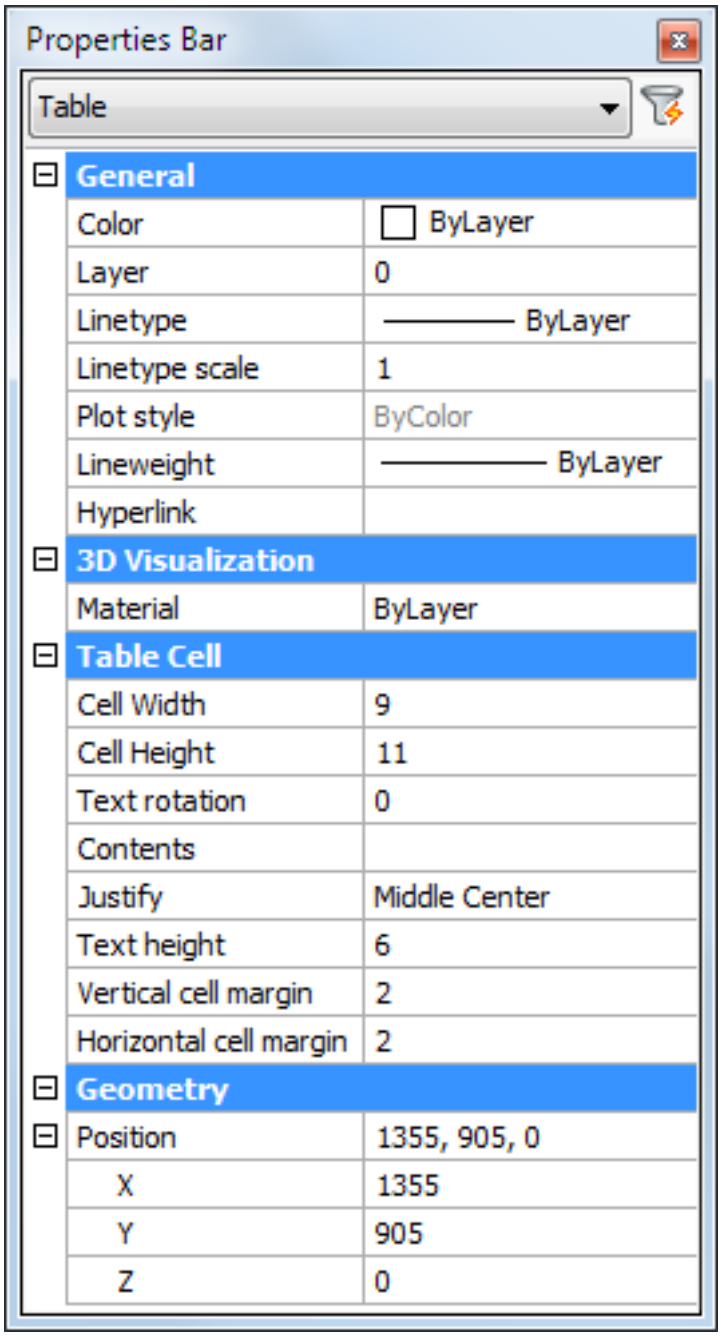


Figure 1.1091

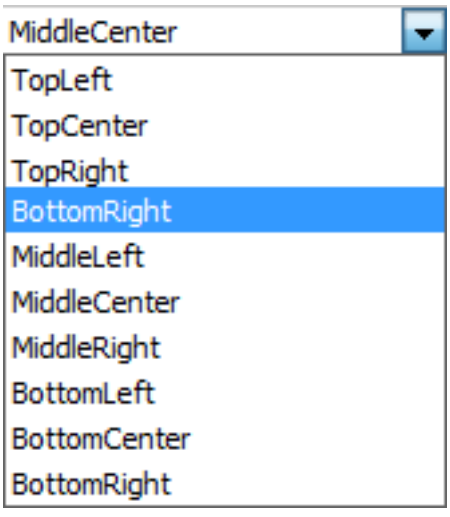

Evaluating formulas

Currently formulas are supported partially. There are more complex formulas which are not supported yet, but in most cases formulas in Excel sheets will remain functional when the Excel sheet is imported as a table. Editing and creating formulas through the field dialog is not supported yet, but in-place editing/creating is possible. E.g.: if you type =SUM(A2:A4) in a cell, it will be interpreted as a formula, and the sum of the values in the cells A2 through A4 is calculated.

To edit the table content

1. Do one of the following:
   - Double click the cell you want to edit.
   - Type **tabledit** in the command bar, then press Enter and click the cell you want to edit.
2. The **Text Formatting** toolbar displays above the selected cell (see Create multiline text (1.29.20)). Edit the text in thale cell. (option) Press Alt + Enter to create a second line in the same cell.
3. To edit another cell:
   - Press the TAB key to go to the next cell in the same row.
   - Press Shift + TAB to go to the previous cell in the same row.
   - Press Enter to go the next cell in the same column.
   - Press Shift + Enter to go to the previous cell in the same column.
   - Press one of the Arrow keys.
4. Click to stop editing the table content.

To export a table

When exporting data to a CSV (C omma S eparated V alues) file, the list separator character off your system is used in the CSV file (see Defining the list separator character).

1. Type **tableexport** in the command bar, then press Enter. **You are prompted:** Select table to export:
2. Click the table you want to export the data of. The Export Data dialog opens.
3. Select a folder to save the data in.
4. Type a name in the **File name** field.
5. Click the **Save** button. The data in the selected table are saved as a CSV (C omma S eparated V alues) file.

Defining the list separator character

1. Click the Start button in the Windows Taskbar, then choose Control Panel.
2. Do one of the following:
   - On the Control Panel Home window, choose: Clock, Language and Region > Regional and Language Options
   - On the Control Panel Classic View window, double click the Regional and Language Options icon.
3. On the Regional and Language Options dialog box click the Customize this format... button. The Customize Regional Options dialog box displays: (1.1092 on the facing page)
4. On the Numbers page of the Customize Regional Options dialog box, go to List separator , then click the down arrow and select either comma (,) or semicolon (;).
5. Click the OK button on the Customize Regional Options and Regional and Language Options dialog boxes.

Figure 1.1092

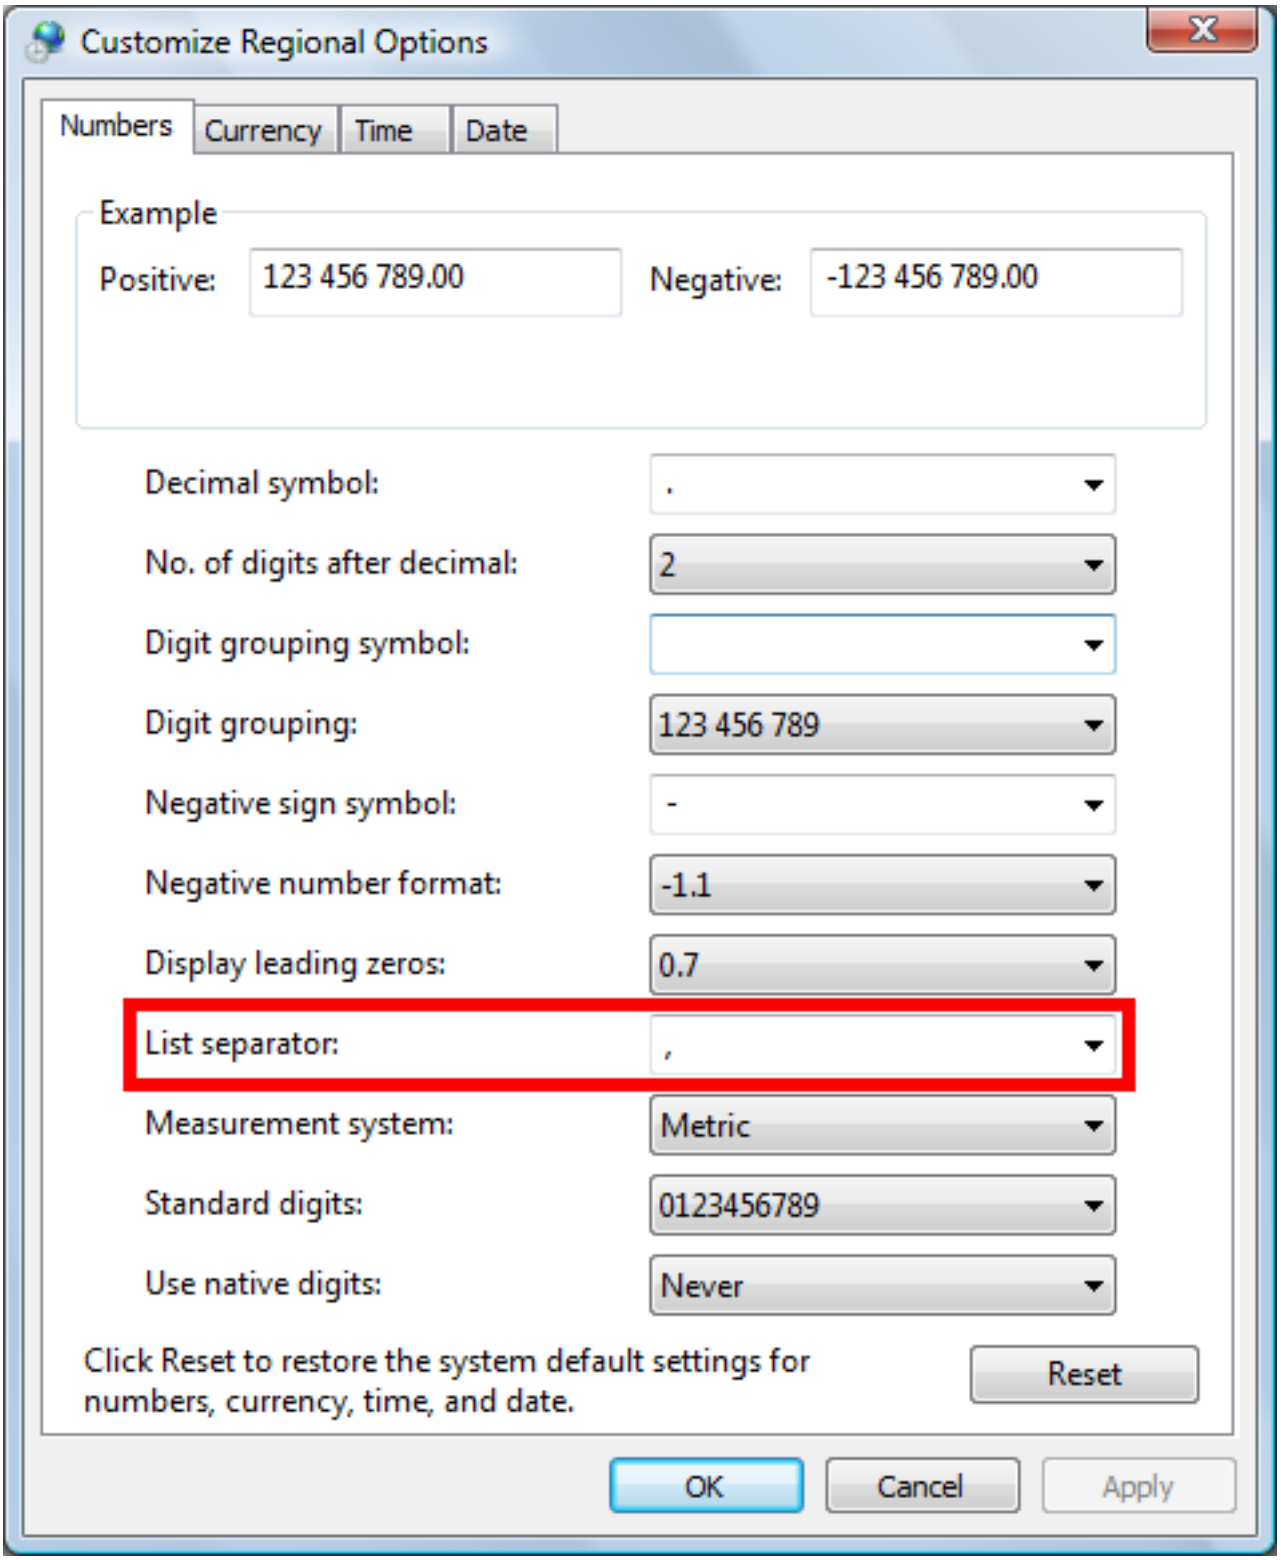

Figure 1.1093

1.29.25 Annotative Entities

https://www.youtube-nocookie.com/embed/BKsyXQ0X1hQ Annotations are all entities in your drawing which are not a model or geometry, such as dimensions, texts, symbols, etc. A common problem with annotations is that they are often scale dependent. Some annotations must be scaled to the plot scale, or are meant to be shown at certain scales only. Annotative styles and entities change the way in which they are displayed (size, location, and orientation) depending on the current scale factor and the viewport. The following entities can have the annotative property:

- text and multiline text (1.29.32)
- hatches (1.29.27)
- blocks and attributes (1.29.31)
- dimensions and tolerances (1.29.30)
- leaders and multileaders (1.29.33)

The following styles can have the annotative property:

- text styles (see the STYLE (6.27.55) command)
- dimension styles (see the DIMSTYLE (6.11.19) command)
- multileader styles (see the MLEADERSTYLE (6.21.24) command)

NOTES

- Entities that are created using an annotative style, get the current annotation scale assigned automatically.
- When an annotative style is applied to a non-annotative entity, the annotative property is not assigned automatically.

Commands

ANNORESET: Resets all scale representations of the selected annotative entities to the location of their current scale representation, thus synchronizing all scale representations. ANNOUPDATE (6.4.15): Updates the selected annotative entities to match their current style definition. OBJECTSCALE (6.23.1): Adds or removes supported scales for annotative entities through a dialog box. -OBJECTSCALE (6.23.2): Adds or removes supported scales for annotative entities at the command line. SCALELISTEDIT (6.27.7): Edits the scale list of a drawing, used in **Plot Scale** section of the **Print** and **Page Setup** dialogs and the **Standard scale** property of a paper space viewport. Defines the available annotation scales for annotative entities. -SCALELISTEDIT (6.27.20): Edits the scale list of a drawing at the command line.

System variables and user preferences

ANNOALLVISIBLE: Toggles the display of annotative enitities that do not support the current annotation scale. ANNOTATIVEDWG: Specifies whether or not the drawing behaves as an annotative block when inserted into another drawing. CANNOSCALE: Sets the name of the current annotation scale for the current space. Only scales that exist in the current scale list are accepted. The CANNOSCALE setting is saved with model space and with each layout viewport in the various layouts. When you create an annotative entity the current annotative scale is applied automatically. CANNOSCALEVALUE: Displays the value of the current annotation scale. E.g. the value of the 1:2 scale is 0.5. HPANNOTATIVE: Controls whether new hatch entities are annotative. MSLTSCALE: If ON, linetypes in model space are scaled to the current annotation scale. A regen is needed when you toggle the value of MSLTSCALE. This variable is the equivalent of the PSLTSCALE (Paperspace linetype scale) variable in paper space. MSOLESCALE: Controls the size of an OLE object containing text when pasted in model space. The MSOLESCALE system variable only affects the initial scaling. Existing OLE objects are not affected if the variable is modified. SAVEFIDELITY: Controls whether the current display of the drawing is preserved when opened in a program that does not support annotative entities. SELECTIONANNODISPLAY: Controls whether all scale representations display when an annotative entity is selected.

Setting the current annotation scale

To set the current annotation scale, do one of the following:

- Click the **Annotation Scale** field under **Misc** in the Properties Bar (1.15.4), then press the down-arrow button and select a scale in the list.
- Right click the **Annotation Scale** field in the Status Bar (1.15.2), then select a scale in the list. If the **Annotation Scale** field is not available, click the down arrow at the right hand side of the Status Bar and choose **Annotation Scale** in the list.

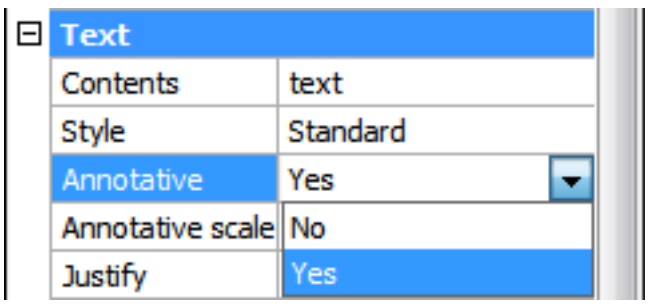
NOTE	Only scales that exist in the **Scale List** of the drawing are available. Use the SCALELISTEDIT (6.27.7) command to edit the **Scale List** .

To make an annotation entity annotative

Annotation entities which are created using a non-annotative style can be made annotative using the following procedure:

1. Select the annotation entity.
2. In the **Properties Bar**, click the **Annotative** property.
3. Select **Yes**. (1.1094) The current annotation scale is applied to the selected entity.

Figure 1.1094



1.29.26 Table Styles

Command: TABLESTYLE (6.29.6) The appearance of a table is controlled by a table style. Each drawing contains the Standard table style, which cannot be deleted. You can modify the Standard table style to fit your needs or create your own table styles. Table styles are created and edited in the Table Styles category of the Drawing Explorer (1.19.2) dialog. In a table there are 3 cell types: Data, Header and Title. Each cell type has its own cell style settings. By default all cells in a row share the same cell style settings, but you can edit the settings of each cell afterwards.

To open the Table Styles Explorer

Do one of the following:

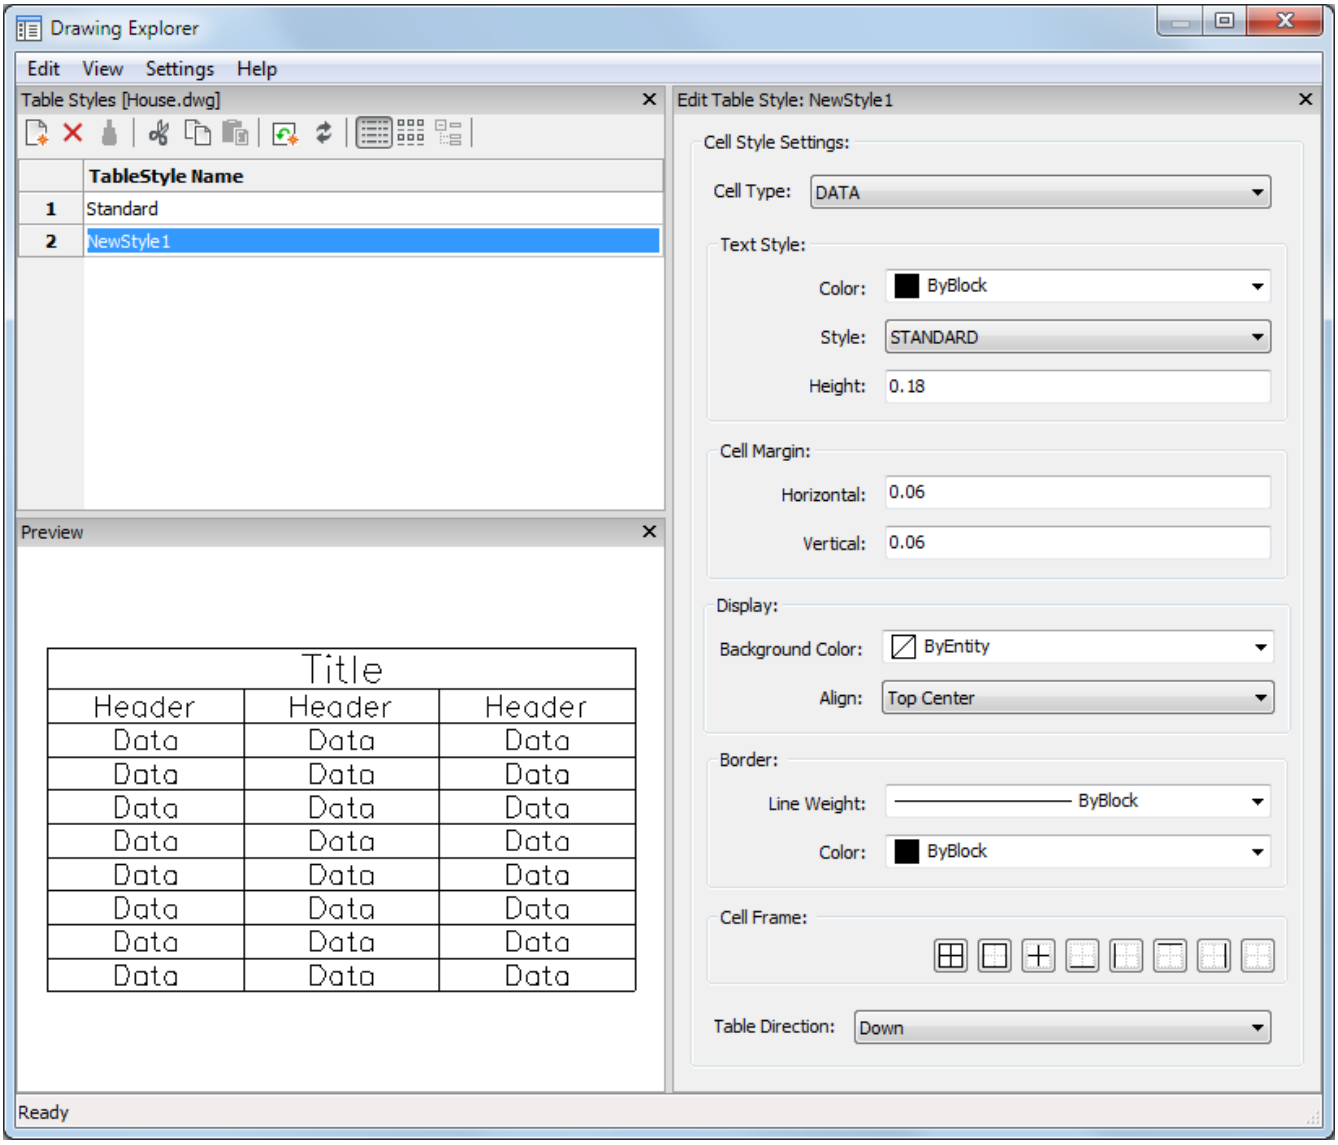
- Choose Drawing Explorer > Table Styles... in the Tools menu.
- Type tablestyle in the command bar, then press Enter
- Click the Explore Table Styles tool button () on the Insert Table (1.29.24) dialog.

To create a table style

1. Open the Drawing Explorer - Table Styles dialog displays.
2. In the Drawing Explorer - Table Styles dialog do one of the following:
   - Choose New in the Edit menu.
   - Click the New tool button ().

   A new style is created using default settings. (1.1095 on the facing page)
3. Rename the style, replacing the NewStyle1 default name.
4. Select a cell type: Data, Header or Title.
5. Define the cell style settings for the selected cell type.
6. Repeat the previous steps for each cell type.

Figure 1.1095



To edit a table style

1. Open the Drawing Explorer - Table Styles dialog displays.
2. In the Details pane of the Drawing Explorer - Table Styles dialog, select the table style you want to edit.
3. Select a cell type: Data, Header or Title.
4. Edit the cell style settings for the selected cell type.
5. (option) Repeat the previous steps for another cell type.

To apply a style to a table

See To edit a table using the Properties bar (1.29.24).

To delete a table style

1. Open the Drawing Explorer - Table Styles dialog displays.
2. Select the table style you want to delete. Press and hold the Ctrl key to select multiple table styles.
3. Do one of the following:
   - Right click, then choose Delete in the context menu.
   - Click the Delete button in the Details menu on the Drawing Explorer - Table Styles dialog

NOTE	It is not possible to delete a table style that is being used in the drawing.

Tutorial: BricsCAD Spreadsheet Import Techniques Click here (1.9.8) to watch

1.29.27 Annotative Hatches and Gradient Fills

Commands: HATCH (6.16.3), -HATCH (6.16.1), GRADIENT (6.15.20) The HPANNOTATIVE (1.17.10) system variable controls whether new hatch or gradient entities are annotative. HPANNOTATIVE is OFF by default. The system variable is not saved and is reset to its default value when BricsCAD closes.

To set the HPANNOTATIVE system variable

Do one of the following:

- In the **Settings** dialog, under **Drafting / Entity Creation / Hatches**.
- Check the **Annotative** option on the **Hatch and Gradient** dialog box of the HATCH (6.16.3) or GRADIENT (6.15.20) command.
- Choose the **Annotative** option in the command prompt of the -HATCH (6.16.1) command.

To make a hatch or gradient entity annotative

1. Select the hatch or gradient fill. The properties of the selected entity display in the Properties Bar (1.15.4).
2. In the Properties Bar, select the **Annotative** property.
3. Choose **Yes** from in the options list. The current annotation scale is applied to the selected hatch or gradient entity and the hatch is scaled accordingly.

To remove the annotative property

1. Select the hatch or gradient fill. The properties of the selected entity display in the Properties Bar (1.15.4).
2. In the Properties Bar, select the **Annotative** property.
3. Choose **No** from in the options list.

1.29.28 Link data from Excel sheets

Commands: DATALINK (6.10.1), DATALINKUPDATE (6.10.2), TABLE (6.29.2) **DataLink**: Links data from an Excel spreadsheet directly into drawing tables for bi-directional updating. **DataLinkUpdate**: Synchronizes the linked data in tables in the current drawing with data in the linked source file. **Table**: Creates a table entity in the drawing through a dialog box. Link data from an Excel spreadsheet directly into drawing tables for bi-directional updating. (1.1096)

1.29.29 Annotation Scales

Commands : OBJECTSCALE (6.23.1) and SCALELISTEDIT (6.27.7) Annotation scales are used to calculate the scaling factor for annotative entities. It defines the height of annotative text entities or the overall scaling of annotative blocks. In general the annotation scale allows to create annotative entities in model space at the correct paper space size automatically.

- Texts, MTexts, Dimensions, MLeaders: The current annotation scale is applied upon creation if the current style is annotative.
- Hatches and Gradient Fills: The current annotation scale is applied if the HPANNOTATIVE (1.17.10) system variable is ON.
- Blocks: The current annotation scale defines the scaling of annotative blocks upon insertion.

Annotative entities can support multiple annotation scales. When the SELECTIONPREVIEW (1.17.10) system variable is active or when using the Quad cursor menu (1.15.5), an icon displays next to the highlighted entity indicating whether a single annotation scale () applies to an annotative entity or multiple ()

To add or remove annotation scales to annotative entities

Use the following procedure to:

- Check which annotation scales currently apply.
- Add annotation scales.
- Remove annotations scales.

1. Select the annotative entity or entities.
2. In the Properties Bar (1.15.4), select the **Annotative Scale** field.
3. Click the **Browse** button () of the **Annotative Scale** field.

The **Annotation Object Scale** dialog displays. (1.1097 on the following page) 4. (option) If multiple entities were selected, choose whether to list all scales for the selection or the common scales only. 5. (option) Do one of the following:

- Select one or more scales in the list, then click the **Delete** button. The selected scale(s) are removed from the list.
- Click the **Add...** button, then select one or more scales in the list and click the **OK** button. The selected scale(s) are added are added to the list. (1.1098 on the next page)

6. Click the OK button to close the **Annotation Object Scale** dialog. The changes are applied to the selection set.

NOTE	Only scales that exist in the **Scale List** of the drawing are available. Use the SCALELISTEDIT (6.27.7) command to edit the **Scale List** .

Tutorial: Making Smarter Drawings with Annotative Scales Click here (1.14.12) to watch

Figure 1.1097

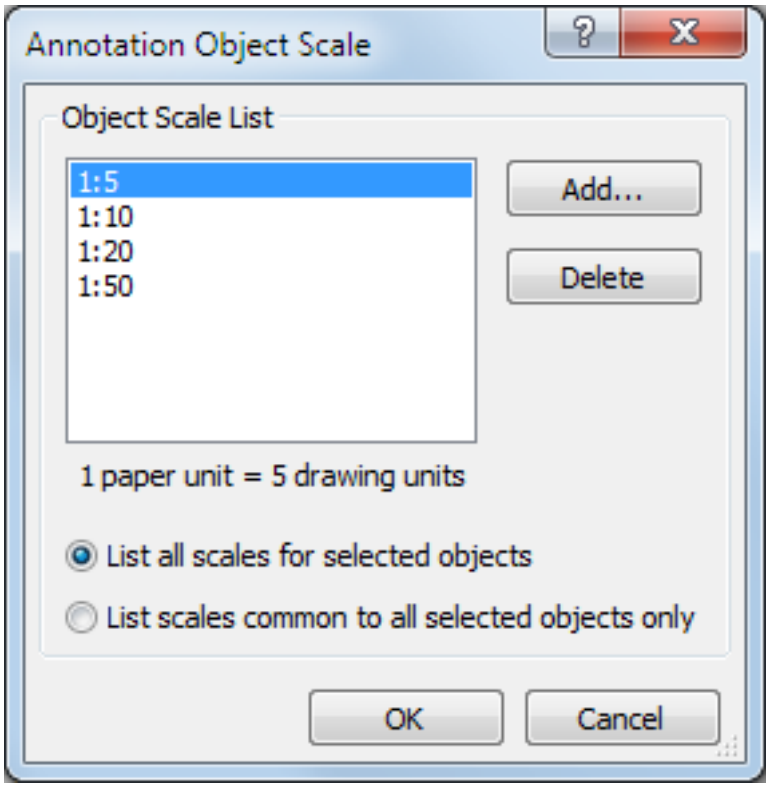

Figure 1.1098

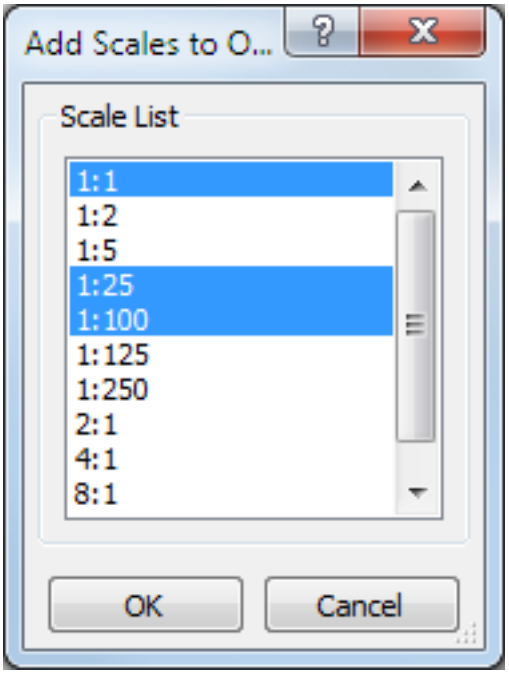

1.29.30 Annotative Dimensions

Dimension entities are created using the current dimension style (1.29.5):

- If the dimension style is annotative, the dimensions get the annotative property automatically and the current annotation scale is assigned.
- If the dimension style is not annotative, you need to make the dimensions annotative manually.

NOTE

- The **Dim Scale Overall** (DIMSCALE (1.17.10)) setting is not editable for annotative dimension styles, and is neglected for annotative dimensions.
- It is recommended to set **Dim Scale Overall** = 1 for annotative dimension styles.

To make a dimension entity annotative

1. Select the dimension entity. The properties of the selected dimension entity display in the Properties Bar (1.15.4).
2. In the Properties Bar (1.15.4), select the **Annotative** property.
3. Choose **Yes** from in the options list. The current annotation scale is assigned. The dimension entity is scaled with respect to the current annotation scale.

To remove the annotative property

1. Select the dimension entity. The properties of the selected dimension entity display in the Properties Bar (1.15.4).
2. In the Properties Bar, select the **Annotative** property.
3. Choose **No** from in the options list. The dimension entity is scaled with respect to the current value of the **Dim Scale Overall** setting.

1.29.31 Annotative Blocks

Commands: BLOCK (6.6.11) and EXPBLOCKS (6.13.11) The annotative property of a block is either set when creating the block definition (1.30.6) or afterwards, in the **Drawing Exlorer / Blocks** dialog. Annotative blocks can have an optional property to always match the orientation of a layout, independent from the rotation of the viewport content.

To make a block definition annotative

1. Open the Drawing Explorer / Blocks (1.30.11) dialog.
2. If necessary, choose Detail View (1.30.11). Annotative block definitions have the **Annotative** icon () displayed.
3. Click in the **Annotative** field of a block definition to toggle the annotative property on/off.

To match the orientation of a block to a layout

1. Open the Drawing Explorer / Blocks (1.30.11) dialog.
2. If necessary, choose Detail View (1.30.11).
3. Click the checkbox in the **Match Orientation** field of a block definition to toggle the **Match Orientation** property on/off.

1.29.32 Annotative Texts

Commands: TEXT (6.29.12), MTEXT (6.21.38) and STYLE (6.27.55) Text entities are created using the current text style:

- If the text style is annotative, the text entity gets the annotative property automatically and the current annotation scale is assigned.
- If the text style is not annotative, you need to make the text entity annotative manually.

Annotative texts have two height properties:

- **Model text height** : the display height on the screen in model space, with respect to the current annotation scale.
- **Paper text height** : the height on paper if printed on the supported annotation scale.

To make a text entity annotative

1. Select the text entity. The properties of the selected text entity display in the Properties Bar (1.15.4).
2. In the Properties Bar (1.15.4), select the **Annotative** property.
3. Choose **Yes** from in the options list. The current annotation scale is assigned. The text is not scaled: the current text height becomes the **Model text height**.

To remove the annotative property

1. Select the text entity. The properties of the selected text entity display in the Properties Bar (1.15.4).
2. In the Properties Bar, select the **Annotative** property.
3. Choose **No** from in the options list. If the text entity supports multiple annotation scales, the text is scaled back to its initial scale.

1.29.33 Annotative Leaders

Under Construction.

1.30 Blocks, Attributes, External References and Components

1.30.1 Parametrize

Fully constrain and parameterize solid models in a single operation. ===ERROR WITH DOWNLOADED IMAGE===

1.30.2 Blockify

Command: Blockify (6.6.13) **Overview:** In this lesson will you learn how to convert repetitive sets of entities to block definitions with the Blockify command. **Lesson Objectives:** After completing this lesson, you will be able to:

- Find identical sets of entities in the drawing (both 2D as 3D) and replace them by block references.
- Automatically find and replace all equal solids by block references.

Tutorial: Blockify in BricsCAD Click here to watch

About

The BricsCAD Blockify tool can be applied to 2D entities as well as to 3D solids. The Blockify tool enables you to automatically convert repetitive sets of entities to block definitions. Select a set of 2D entities or 3D solids and Blockify searches the drawing for identical sets of entities and automatically replaces them by block references.

 For more information about this command, visit the Command Reference article Blockify (6.6.13).

Blockify from a selected input

1. Launch the Blockify command. You can apply the command on 2D entities or on 3D entities.
2. **You are prompted:** Select input entities or [Find all groups]. Select the entities you want to convert into a block and press Enter.

(1.1102 on page 1207)	(1.1103 on page 1207)
2D	3D

Note: The 'Find all groups' option will be explained later.

3. **You are Prompted:** Select search space or [Entire drawing]. Set the search space **or** type 'E' to scan the entire drawing, then press Enter.
4. In the commandline you can read:

(1.1104 on page 1208)	(1.1105 on page 1208)
2D: Blockify recognizes 6 chairs.	3D: Blockify recognizes 2 chairs.

5. **You are prompted:** Select a block insertion point or [use Default point]. Press 'D' to use a default point. **Or** Select the point that you want as the insertion point of the block

(1.1106 on page 1208)	(1.1107 on page 1209)
2D	3D

6. **You are prompted:** Specify block name or [use Default name]. Type in your preferred block name **Or** press 'D' to use a default name. For this example, name the block 'Chair'. Press Enter.
7. The block definition is now created for the chair. In the Structure Browser, you can see that all identical sets of entities are replaced with a block reference. The separate entities forming the chair are grouped to form one block.

(1.1108 on page 1209)	(1.1109 on page 1210)
2D	3D

Apply the 'Find all groups' - option

In the current drawing, you can see that the drawing only contains 3D solid. The legs and seat of the chair are separate solids. (1.1099 on the facing page)

Figure 1.1099

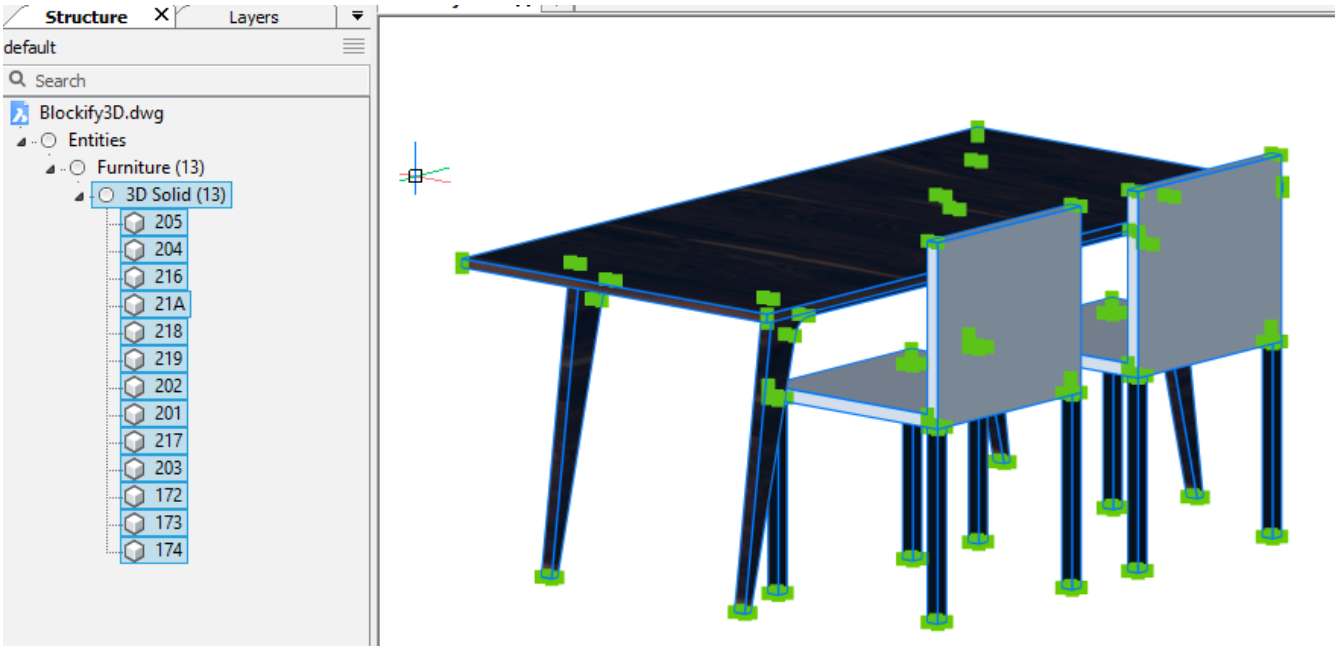

Figure 1.1100

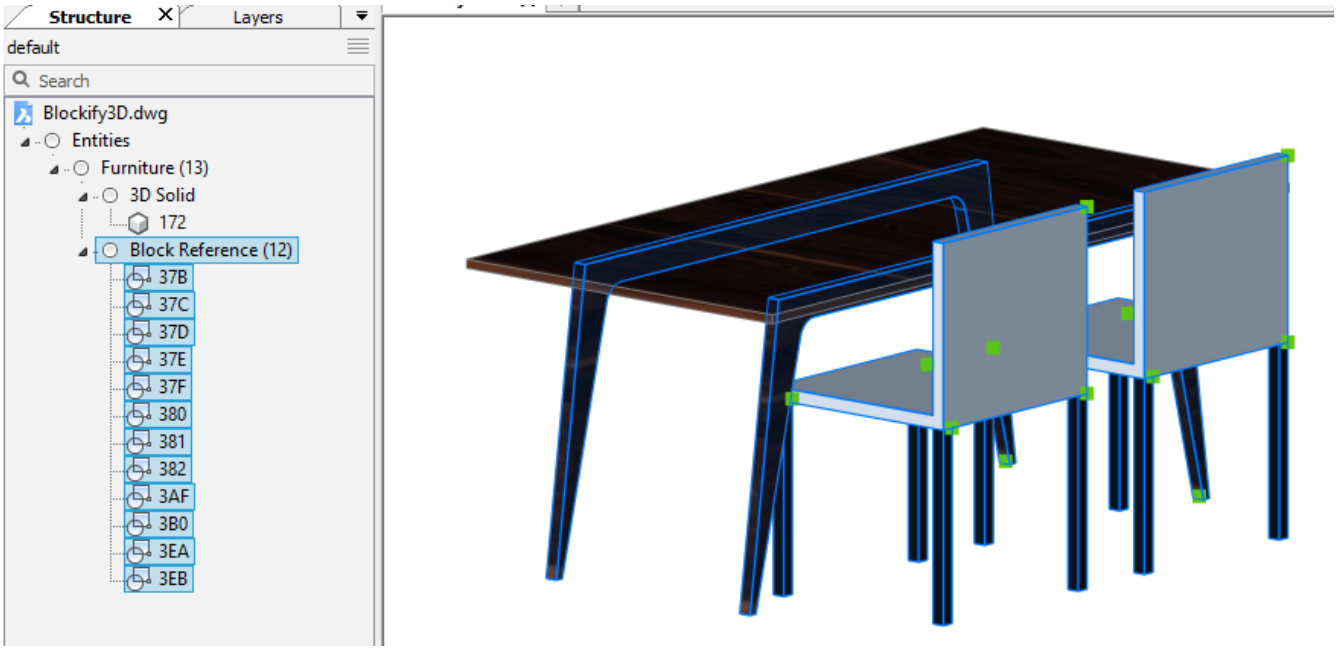
```
3 different groups
18 similarity checks
Duration: 1.590489 sec
```

1. Launch the Blockify command. **You are prompted:** Select input entities or [Find all groups]. Type 'F' to find all groups. Blockify will now automatically detect identically-shaped solids.
2. **You are Prompted:** Select search space or [Entire drawing]. Press Enter to scan the entire drawing.
3. The commandline will display: (1.1100) Blockify will recognize 3 different groups of similar 3D solids: the chair legs, the chair seats, and the table legs. In the Structure Browser, you can see that all of these 3D solids are now converted into 3 different groups of block references. (1.1101 on the following page)

Figure 1.1101



Existing block definitions

One of the aims of the BLOCKIFY command is to automatically add and improve the structure of a model. In both procedures described above, if the model already contains block definitions, the existing block definitions are checked.

- **Use a selected input set of entities:** When one of the existing block definitions matches the BLOCKIFY input set, no definition needs to be created. All instances of the input set should be replaced by block references to the existing block definition.
- **Find all groups:** before checking all 3D solids in the drawing, all existing block definitions are used as the input set for BLOCKIFY. As such, repeated solids corresponding to a block definition are replaced by block references to that existing definition. No new block definition is created.

1.30.3 Working with Blocks

Define Blocks

The process to define a block using the BLOCK command is the same in BricsCAD as in AutoCAD®. It displays the Block Definition dialog box with the necessary controls to create a new block definition in the current drawing. (1.1110 on the next page) Note: The Block Definition dialog box in BricsCAD doesn't have options for Hyperlink, Quick select or Block Editor. You can, however, attach hyperlinks, select objects, and edit blocks using alternate methods. The familiar WBLOCK command allows you to write out a block definition as a separate drawing file, external to the current drawing. (1.1111 on page 1213) BricsCAD doesn't have a Block Editor. Instead, you create and edit block geometry using the drawing editor with all the tools and functionality it has to offer available.

Figure 1.1110

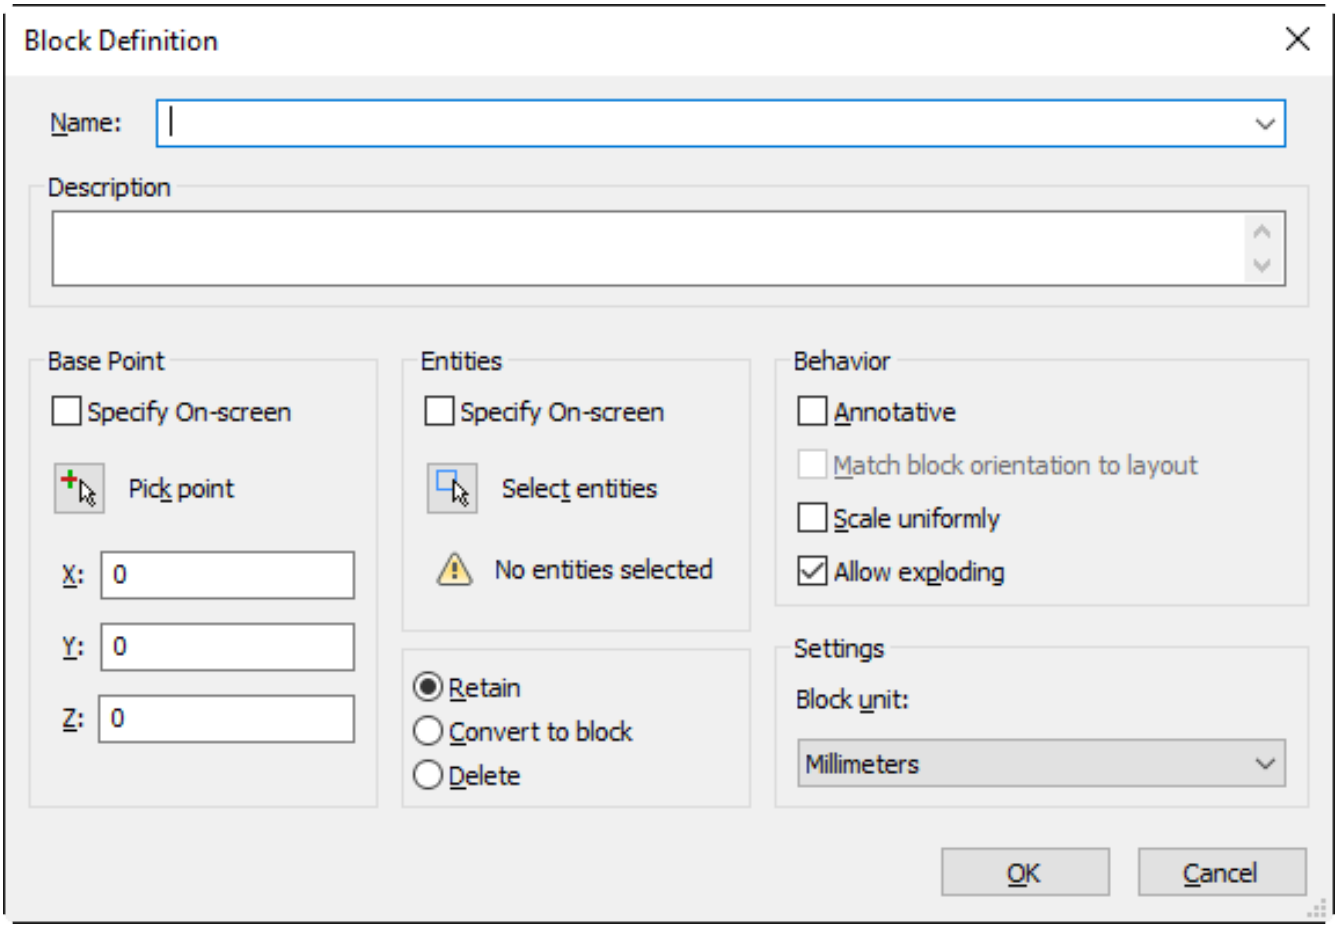

Figure 1.1111

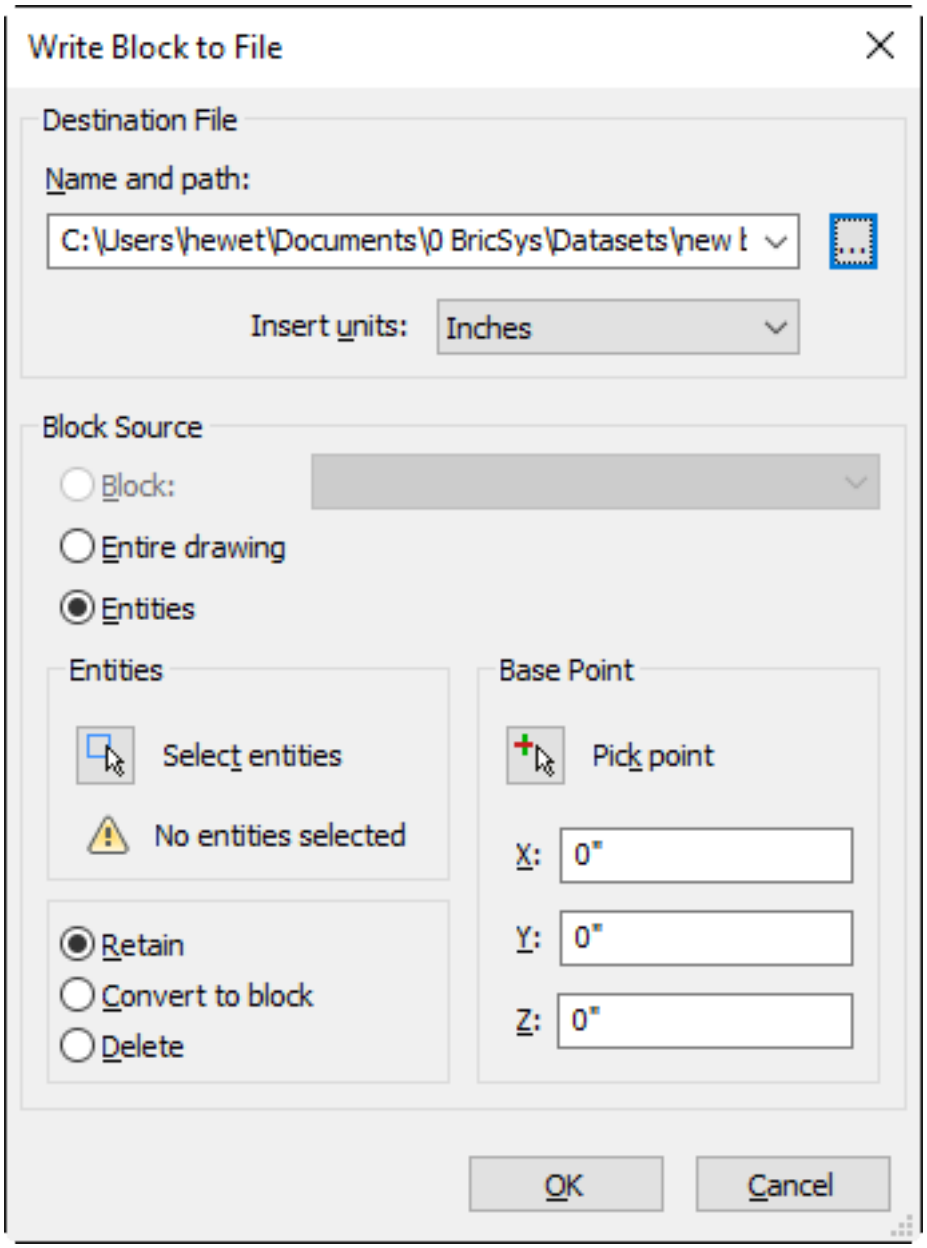

Insert Blocks

You can select a block to insert in your drawing from the Insert Block dialog box. It's easily accessible from the Insert tab on the Quad. You can also access it via other methods including the INSERT command. (1.1112 on the next page) The Insert Block dialog box will look familiar to you as a former AutoCAD user. It includes typical options to specify the insertion point, scale and rotation angle for the block. (1.1113 on the facing page) Note: The Insert Block dialog box doesn't include an option to insert a block using geographic data. The Insert Block dialog box doesn't include a preview image. Instead, BrisCAD offers a more intuitive way to preview, insert, and manage your blocks!

Figure 1.1112

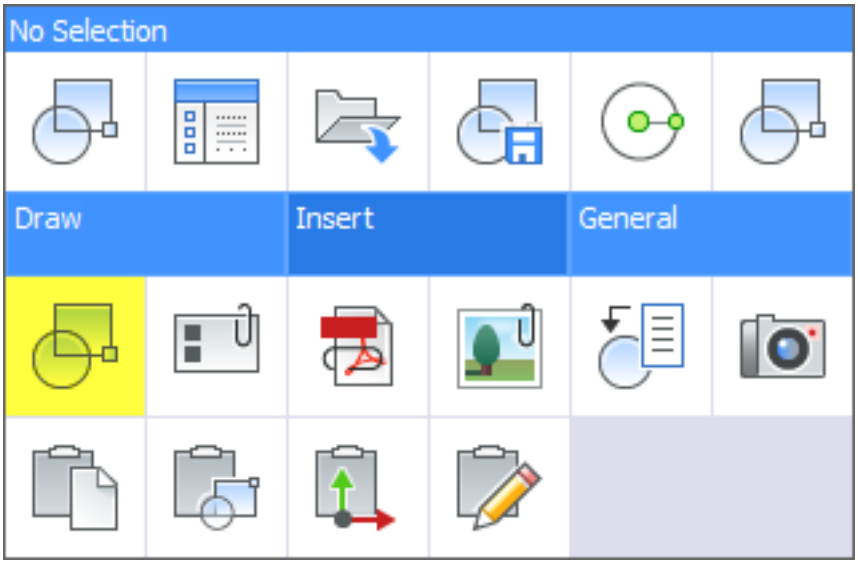

Figure 1.1113

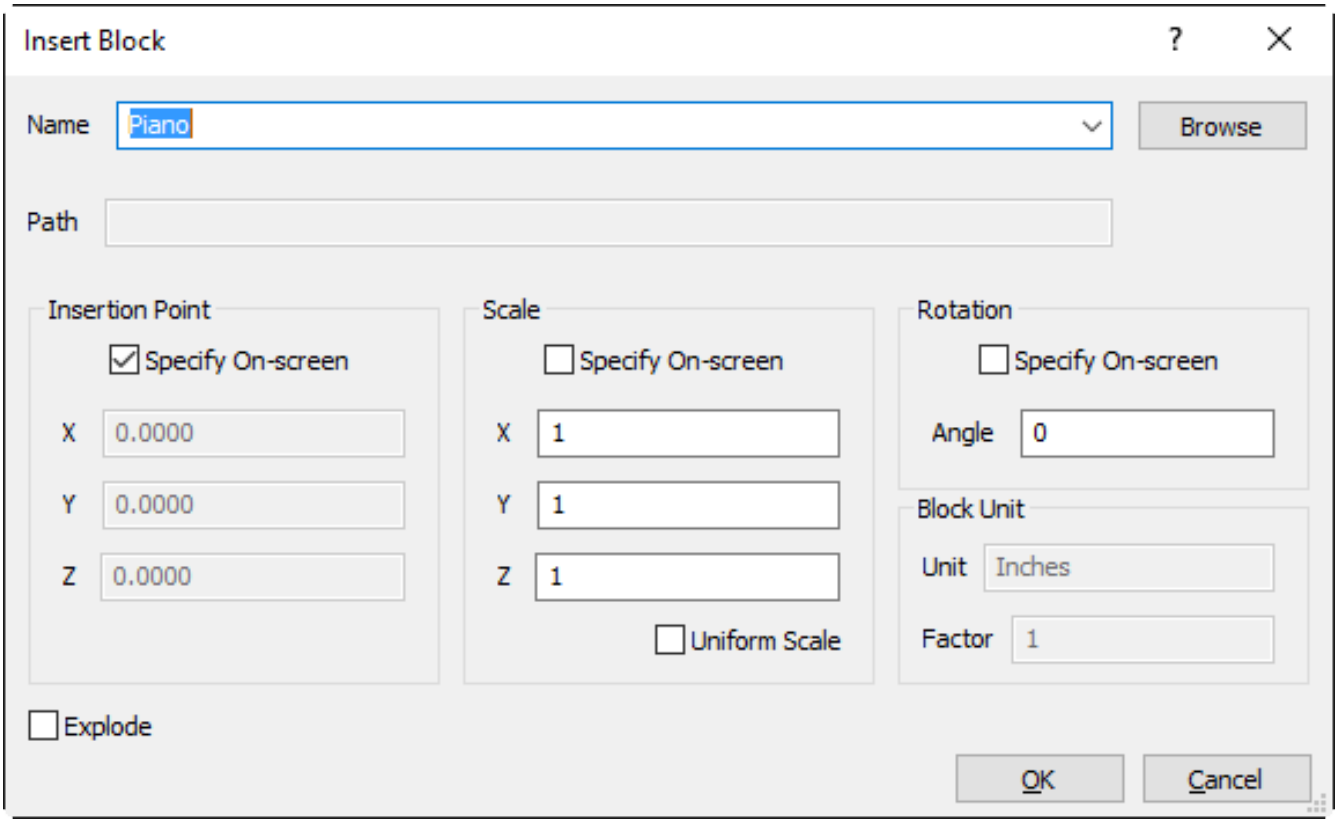

Manage Blocks in Drawing Explorer

You may remember that Drawing Explorer offers a central location to manage all the style definitions in your drawing. In fact, Drawing Explorer does much more than that. It centralizes all named drawing content, including blocks, in a single dialog box. Access Drawing Explorer from the General menu on the Quad. It's also accessible via other methods including the EXPLORER command. If you launch Drawing Explorer with the EXPBLOCKS command (XB alias), it automatically displays the panels for Blocks. (1.1165 on page 1275) Drawing Explorer lists all block definitions in the drawing and includes relevant information and controls. You can see how many instances of a block are in the drawing and you can modify basic block properties. For example, you can specify whether a block is Annotative or Explodable. (1.1115 on the facing page) Another option, unique to BricsCAD, ensures the block always faces the camera. This can be particularly useful (and fun) for 3D visualization. For example, I created a block with an image of my photo and inserted it in a 3D model. As I orbit around the model, the block/image always faces forward. (1.1116 on the next page) The right-click menu and toolbar offer additional controls. You can easily create a new block definition, delete a block definition and all its insertions, and purge an unused block definition. Insert blocks and even add them to the current tool palette. Anything you want to do with blocks is easily accessible from the Drawing Explorer! (1.1117 on page 1218)

Tutorial: Manage blocks with the Drawing Explorer Click here (**??**) to watch

Figure 1.1114

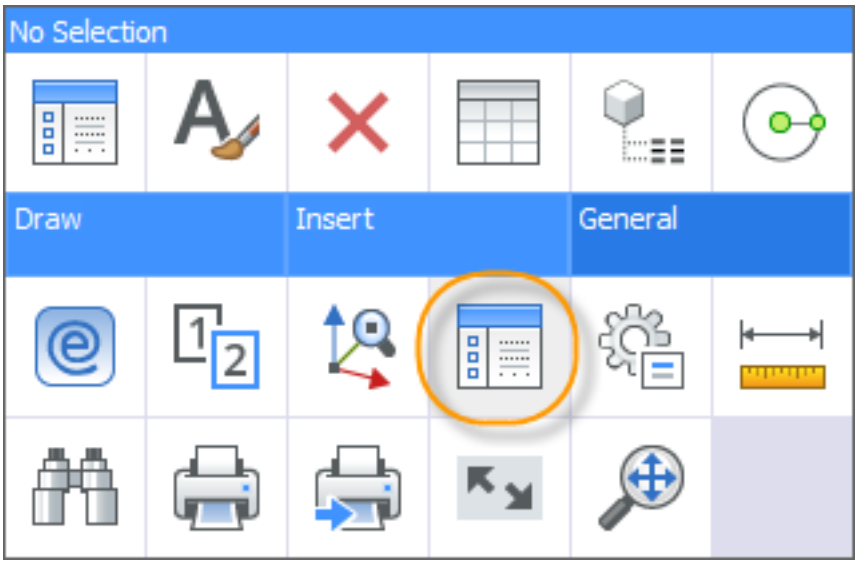

Figure 1.1115

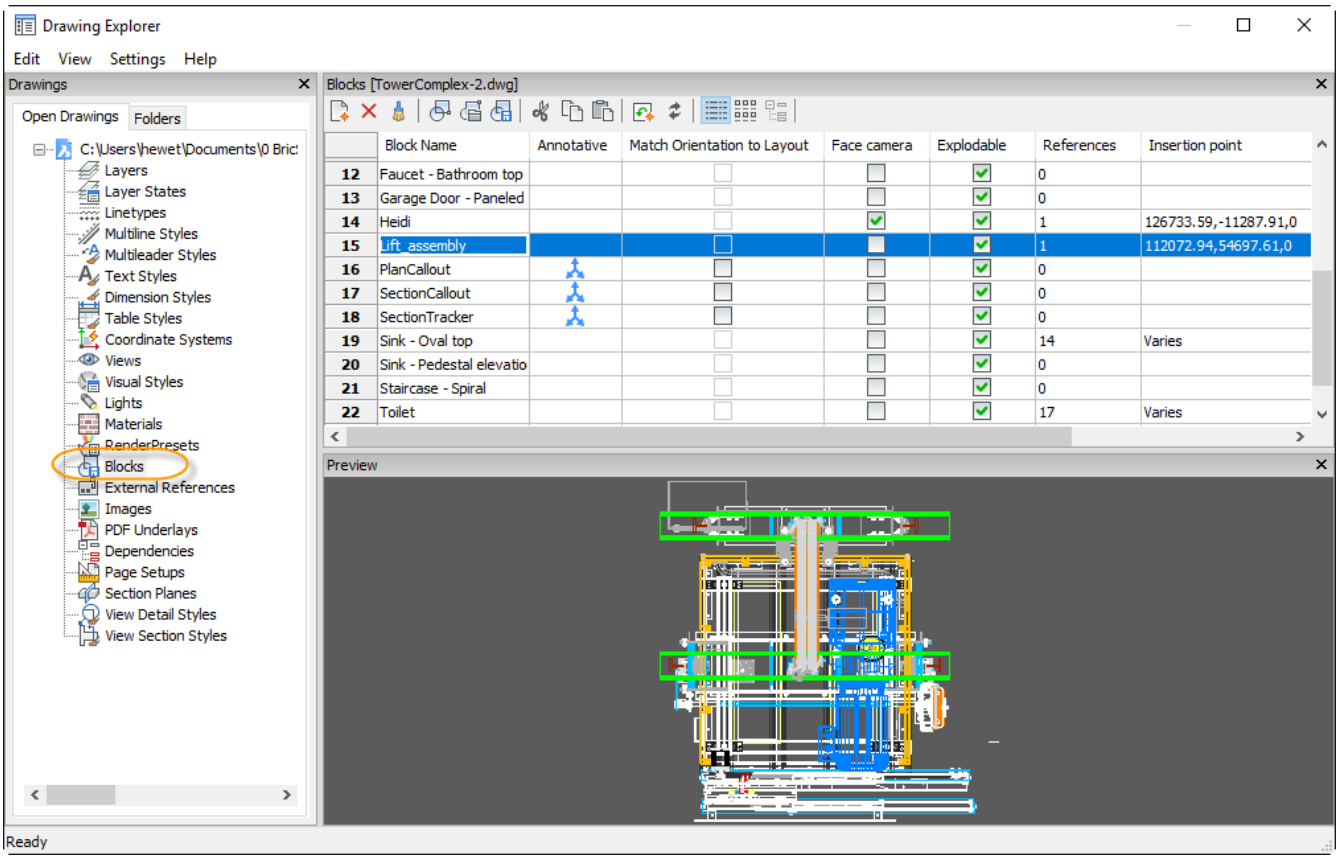

Figure 1.1116

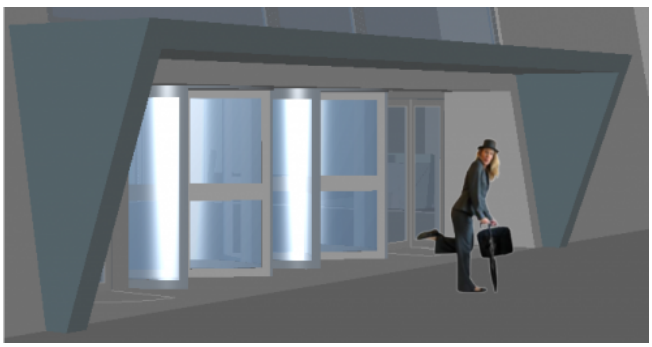

Figure 1.1117

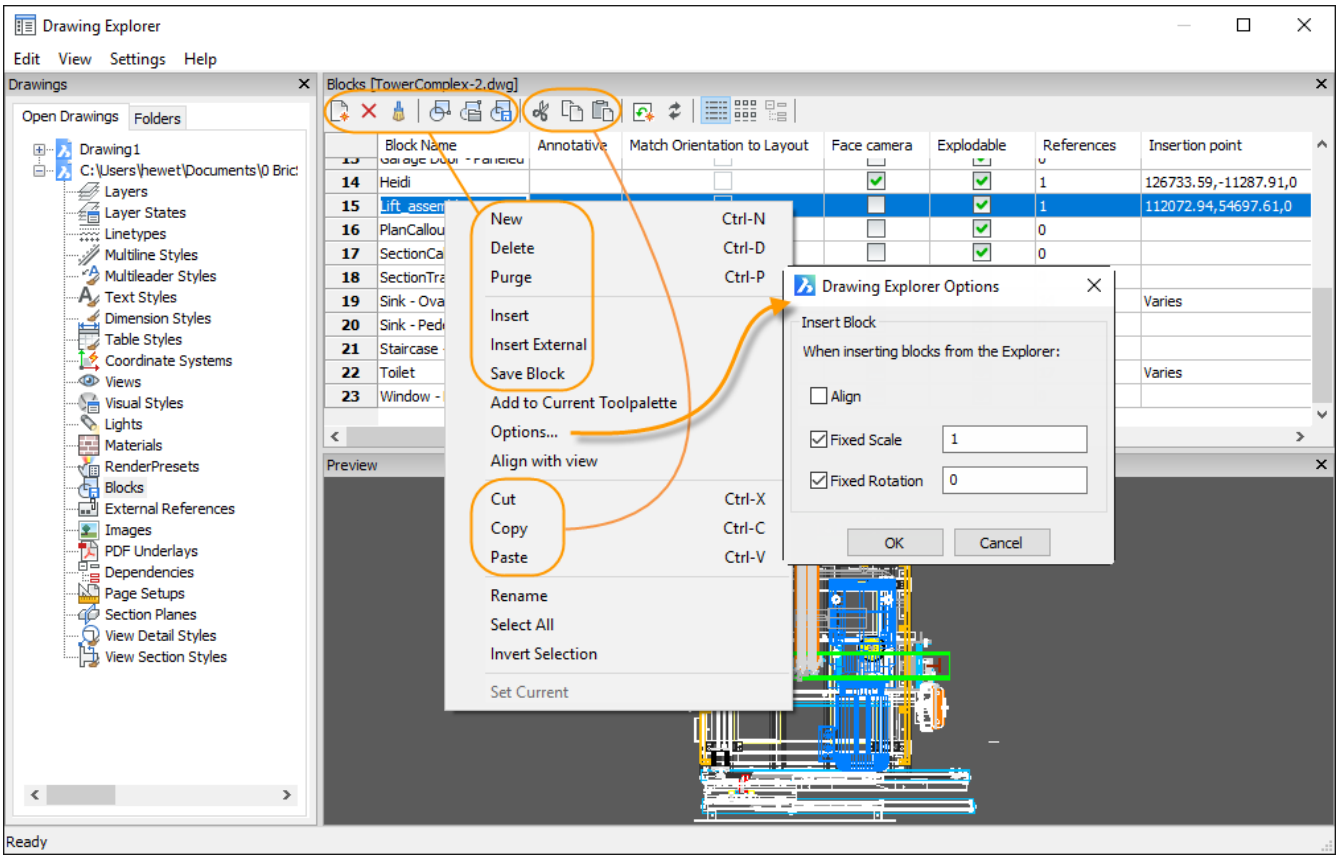

Figure 1.1118

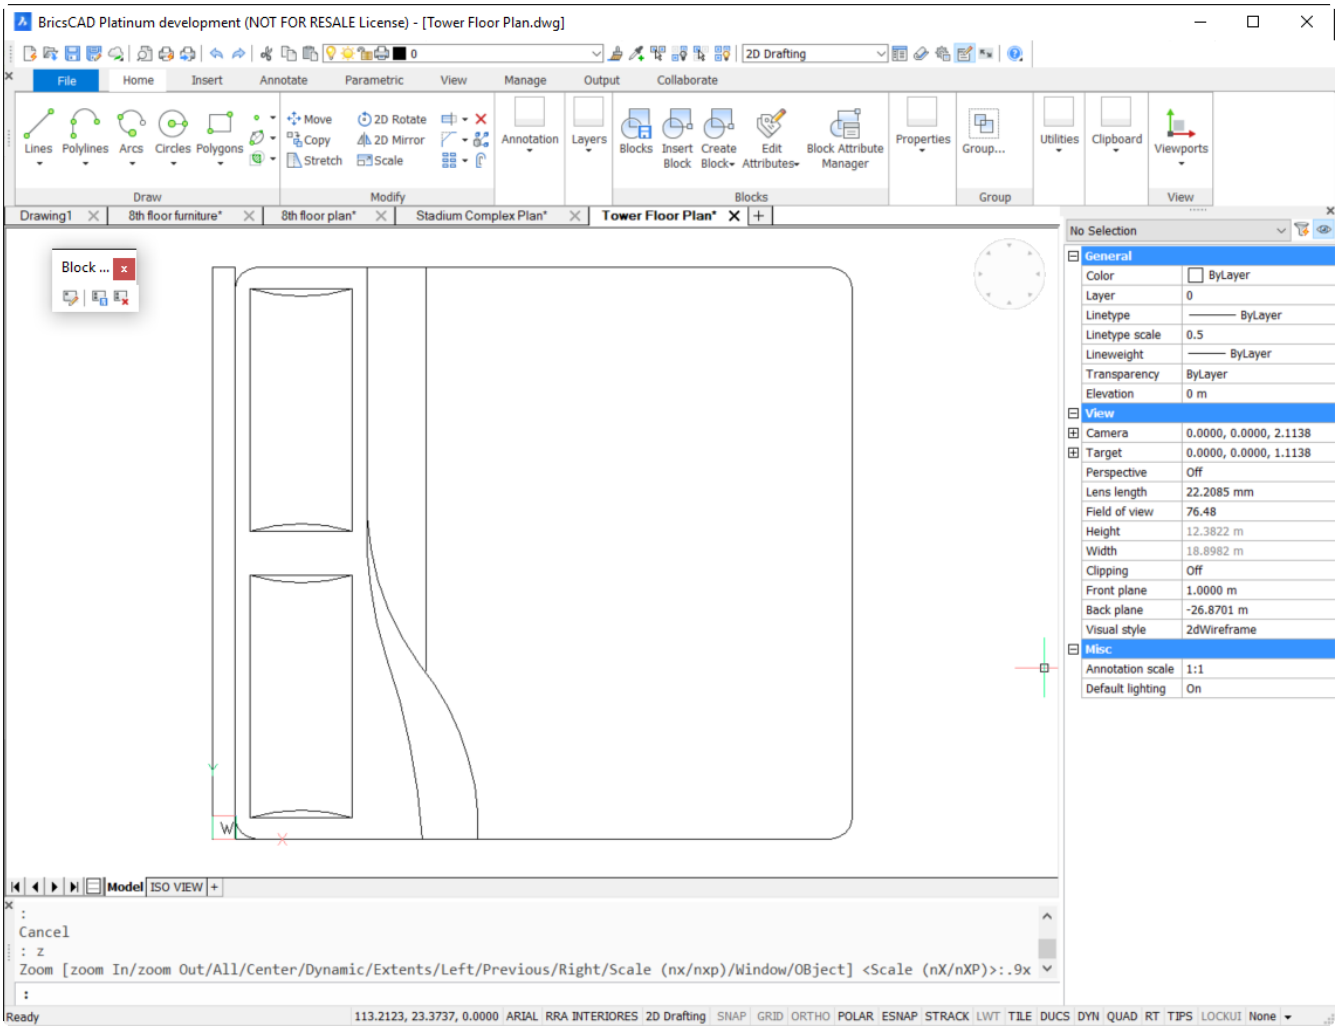


1.30.4 Block editor

Commands: BEDIT (6.6.7) and BCLOSE (6.6.4) You can access the Block editor with the BEDIT command or by double-clicking on the block you wish to edit. When using the block editor, BricsCAD displays the block entities in a temporary drawing session. It includes all the tools you need to create and edit a block definition. To exit the block editing session, use the BCLOSE command and choose whether to save or discard the changes. If you select the Save tool while in the Block editing session, BricsCAD saves the changes to the block definition and exits the block editor. (1.1118)

1.30.5 Inserting Blocks

Commands: INSERT (6.17.13), -INSERT (6.17.14), INSERTALIGNED (6.17.15) and MINSERT (6.21.15) The **Insert** command lets you insert blocks through a dialog box. The **-Insert** command inserts blocks by prompting in the command bar. BricsCAD will lookup the block name in the block definitions in the current drawing. If the block is not found in the current drawing, the paths defined by the **SRCHPATH** system variable are searched. If the block is not found there either, BricsCAD responds 'Could not find file <blockname>' The **Insertaligned** command inserts a block entity, with easy alignment on existing entities. The **Insertaligned** command is similar to the **Insert** command, but during the placement the block will be dynamically aligned with existing lines, polylines, arcs or circles. The block is aligned with the entity to which the cursor snaps. If no entity is snapped, the block is aligned with the X-axis of the WCS. The **Minsert** command Inserts a block as a rectangular array; combines the **-Insert** and **Array** commands (short for "multiple insertion"). You can choose to select an existing block definition or to insert an entire drawing as a block. When you insert a drawing, a new block definition is created in the current drawing. If you change the original drawing file, those changes have no effect on the current drawing unless you redefine the block by reinserting the changed drawing. When a block is inserted in a drawing, it is treated as a single entity.

Tutorial: Manage blocks with the Drawing Explorer Click here (**??**) to watch

General procedure to insert a block:

- Specify a block definition or drawing file.
- Specify the insertion point.
- Specify the scale.
- Specify the rotation angle.

NOTES

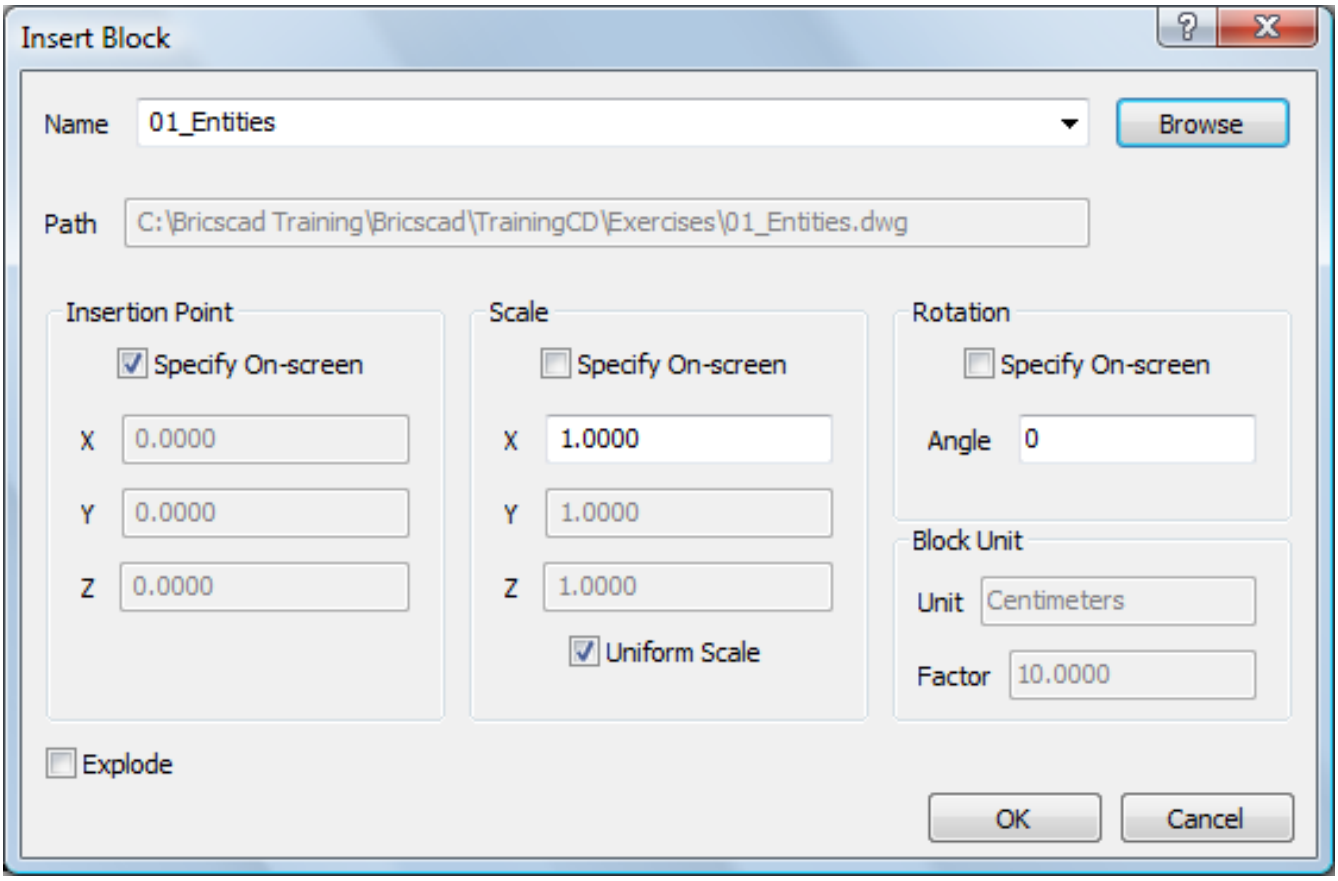
- When inserting a drawing as a block, the base point, as defined by the **INSBASE** system variable, of the inserted drawing is the origin point of the block. The **INSBASE** system variable is set by the BASE (6.6.2) command.
- If a block contains attributes you will be prompted to fill out the text for each attribute in the command bar.
- If the **DRAGOPEN** system variable is set to zero (OFF), drawings can be inserted as a block by dragging them from the **Windows Explorer** dialog into the current drawing; if **DRAGOPEN** = 1 (ON), the drawing will be opened instead.
- The **INSUNITS** system variable defines a drawing units value for automatic scaling when inserting blocks or attaching Xrefs (1.30.19).

In the **Insert Block** dialog:

- The **Unit** field under **Block Unit** is set by the **INSUNITS** (Insertion Units) system variable in the source drawing or the **Block Unit** property of a block definition (see To create a block in a drawing (1.30.6)).
- The **Factor** field expresses the relation between the value of the **INSUNITS** variable in the source drawing and the target drawing. E.g. if **INSUNITS** is Millimeters in the source and the target, the value of the **Factor** field is 0.1.
- If **INSUNITS** in the source drawing is **Unspecified** , **INSUNITSDEFSOURCE** is used instead.
- If **INSUNITS** in the target drawing is **Unspecified** , **INSUNITSDEFTARGET** is used instead.

The values of **INSUNITSDEFSOURCE** and **INSUNITSDEFTARGET** are saved in the registry and therefore apply to all drawings in which **INSUNITS** is unspecified (unitless).

Figure 1.1119



To insert a block

1. Do one of the following

   - Click the **Insert Block...** tool button ( ) on the Insert toolbar.
   - Choose **Insert Block...** in the Insert menu.
   - Type **insert** in the command bar, then press Enter.

   The **Insert Block** dialog opens. (1.1119)

2. In the **Insert Block** dialog, do one of the following:
   - Select an existing block definition in the **Name** list.
   - Click the **Browse** button and select a drawing file.
3. (option) Check the Explode (1.32.36) option to explode the block after insertion.
4. (option) Uncheck the **Specify On-Screen** option, then specify the **Insertion Point** by keying in the coordinates in the **X** , **Y** and **Z** fields.
5. (option) Uncheck the **Specify On-Screen** option, then specify the **Scale** by keying in the scaling factors in the **X** , **Y** and **Z** fields. Check the **Uniform Scale** option to equal the **X** , **Y** and **Z** scale factors.
6. (option) Check the **Specify On-Screen** option to specify the Rotation angle when inserting the block.
7. Click the **OK** button. **You are prompted:** Insertion point for block. A prompt menu displays. (1.1120 on the next page)
8. Specify the insertion point. **You are prompted:** Corner/XYZ/X scale factor <1.000000>: A prompt menu displays.

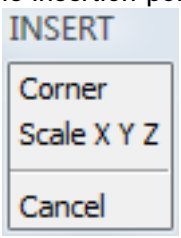


Figure 1.1120

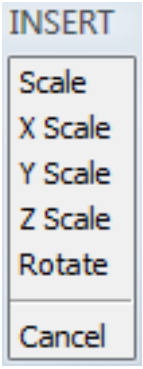

9. Right click or press Enter to accept the default **X scale factor** . You are prompted: Y scale factor: <Equal to X scale (1.000000)>:
10. Right click or press Enter to set the **Y scale factor** equal to the **X scale factor** . The block is inserted.

To insert a block using the Drawing Explorer

Inserting internal blocks

1. Open the Drawing Explorer - Blocks (1.30.11) dialog.
2. (optional) Choose either **Detail View** ( ) or **Icon View** ( ).
3. (option) Edit the insert options:
   - Choose **Options...** in the Settings menu or select a block, then right click and choose **Options ...** in the context menu.
   - Set the insert options in the Drawing Explorer Options dialog box. (1.1124 on page 1225)
4. Do one of the following: Select a block, then do one of the following:
   - Click the **Insert Block** button ( ) on the **Details** toolbar.
   - Right click and select **Insert** from the context menu
   - When in **Icon View**, double click the block.

   To select an external drawing, do one of the following:
   - Click the **Insert External** tool button ( ) on the **Details** toolbar.
   - Choose **Insert External** in the **Edit** menu.
   - Right click, then choose **Insert External** in the context menu.

   The Drawing Explorer - Blocks window closes. **You are prompted:** Multiple blocks/Scale/<Insertion point for block>: A prompt menu displays (1.1125 on page 1225)
5. Follow the instructions in the command bar to insert the block. The Drawing Explorer - Blocks window reopens.
6. (option) Insert more blocks.
7. Close the Drawing Explorer - Blocks window.

Figure 1.1121

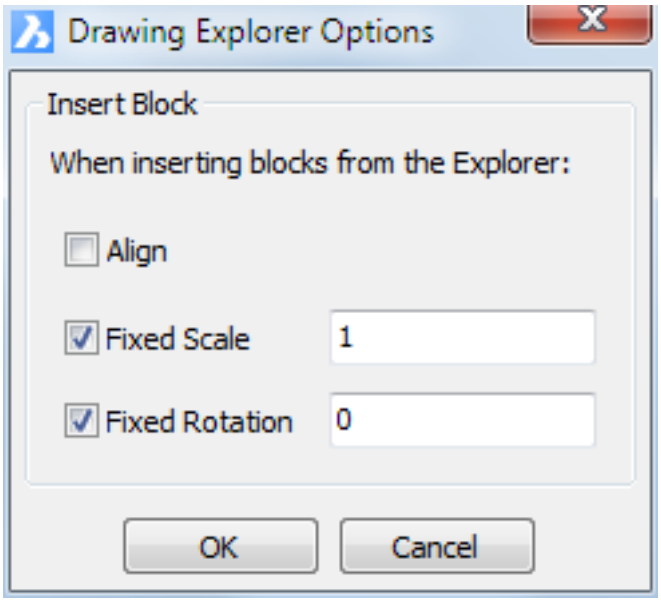

Figure 1.1122

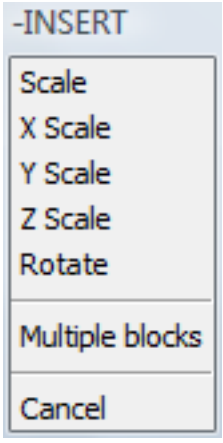

Inserting blocks from another drawing

1. Open the Drawings Explorer (1.19.2).
2. In the **Drawings** pane, click the Folders tab.
3. (option) If not yet available in the **Local Folders** tree, add the folder (1.19.2) of the drawing.
4. Expand the folder.
5. Click the **Expand** icon (+) in front of the drawing. The **Blocks** icon of the drawing displays. (1.1123)
6. Click the **Blocks** icon. The blocks in the drawing display in the **Details** pane. If necessary, click the **Icon View** button ( ) in the Details toolbar to see thumbnail images of the blocks.
7. (option) Edit the insert options:
   - Choose **Options...** in the **Settings** menu or select a block, then right click and choose **Options ...** in the context menu.
   - Set the insert options in the Drawing Explorer Options dialog box. (1.1124 on the next page)

   The available options are:
   - **Align**: If checked, launches the InsertAligned (6.17.15) command to insert the block. When the **Align** option is checked, the **Fixed Scale** and **Fixed Rotation** options are not available.
   - **Fixed Scale**: If checked, allows to insert the block at a fixed scale.
   - **Fixed Rotation**: If checked, allows to insert the block at a fixed rotation.
8. To insert a block, do one of the following:
   - Click the **Insert Block** button ( ) on the Details toolbar.
   - When in Icon View (1.30.11), double click the thumbnail image of the block.
   - When in Detail view (1.30.11), double click the number in front of the block name.

   The Drawing Explorer dialog closes temporarily to let you insert the block in the drawing. **You are prompted:** Multiple blocks/<Insertion point for block>: A prompt menu displays (1.1125 on the facing page)
9. Follow the instructions in the command bar to insert the block. The Drawing Explorer window reopens.
10. (option) Insert more blocks.
11. Close the Drawing Explorer - Blocks window.

Figure 1.1123

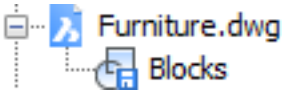

Figure 1.1124

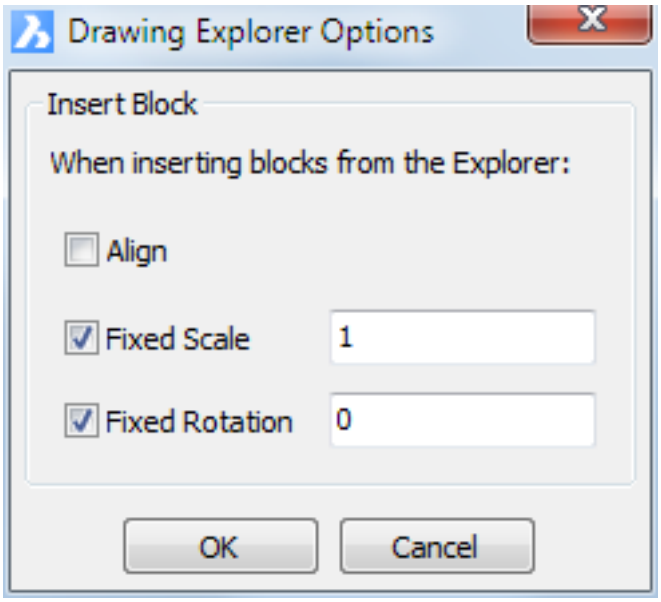

Figure 1.1125

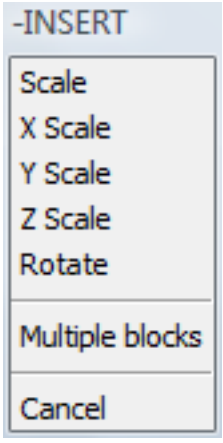


To insert a block aligned with an entity

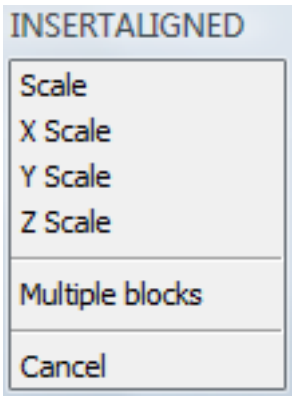
1. Make sure the appropriate Entity Snaps are active.
2. Type **insertaligned** or **insal** in the command bar, then press Enter. You are prompted: ? to list blocks in drawing/~ to open the file dialog/<Block to insert> <name>:
3. Do one of the following:
   - Press Enter or right click to insert the most recently placed block again.
   - Type the name of an existing block definition in the command bar, then press Enter.
   - Type the name of an external block file in the command bar, then press Enter.
   - Type **~** (tilde) then press Enter to open the file dialog.

   You are prompted: Multiple blocks/<Insertion point for block>: A prompt menu displays. (1.1126)
4. Snap to an entity. The block is aligned with the entity.
5. Click to define the insertion point. When you move the crosshairs, the block is mirrored about the selected entity or a about a line tangent to the selected entity.
6. Click to specify the mirroring of the block.

NOTES

- If you type the name of block in step 3, BricsCAD will lookup the block in the block definitions in the current drawing. If the block is not found in the current drawing, the paths defined by the **SRCHPATH** system variable are searched. If the block is not found there either, BricsCAD responds 'Could not find file <blockname>'
- The block is aligned as follows: The block is rotated so that its local Z-axis is parallel with the Z-axis of the active UCS, and its local X-axis should be parallel with the tangent to the entity at the position of the snap point. When you click a point on an entity the block is aligned with the entity. Then, by moving the mouse pointer around the insertion point, you can choose how the block should be mirrored. The origin point of the block lies on the entity.

Figure 1.1126



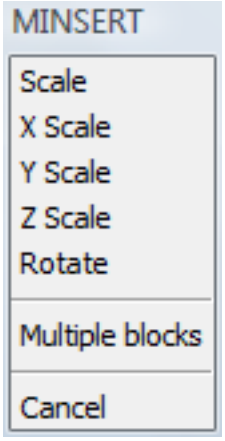
To insert multiple instances of a block in a rectangular array

1. Type **minsert** in the command bar, then press Enter. **You are prompted:** ? to list blocks in drawing/~ to open the file dialog/<Block to insert>:
2. Do one of the following:
   - Type **~** (press and hold the **alt gr** key, then press the **~** key), then press Enter. The **Insert Block** file dialog displays. Select the drawing file you want to insert and press the **Open** button (or double click the file name).
   - Press Enter to accept the <Block to insert>.
   - Type a block name, then press Enter. Optionally, type ? to display search for existing block definitions.
3. The block is attached to the cursor. **You are prompted:** Multiple blocks/<Insertion point for block>: (1.1127)
4. Specify the insertion point. **You are prompted:** Corner/XYZ/X scale factor <1.00>:
5. To define the X scale factor, do one of the following:
   - Press Enter to accept the default .
   - Type the X scale factor, then press Enter.
   - Click to define the X scale factor graphically.

   You are prompted: Y scale factor: <Equal to X scale (current X scale)>:
6. Repeat step 5 to define the Y scale factor. **You are prompted:** Rotation angle for block <0>:
7. Do one of the following:
   - Press Enter to set the rotation angle to 0°.
   - Type a rotation angle, then press Enter.

   Click to define the rotation angle graphically. **You are prompted:** Number of rows in the array <1>:
8. Type the number of rows, then press Enter or press Enter for one row. **You are prompted:** Number of columns <1>:
9. Type the number of columns, then press Enter or press Enter for one column. **You are prompted:** Vertical distance between rows, or spacing rectangle:
10. Type the row spacing distance, then press Enter. **You are prompted:** Horizontal distance between columns:
11. Type the column spacing distance, then press Enter. The block array is created as a single entity.

Figure 1.1127



NOTES

- If you choose **Multiple blocks** in step 3, you are prompted to create multiple instances of the block array.
- It is not possible to explode a **MInsert Block** entity..
- If you type the name of block in step 2, BricsCAD will lookup the block in the block definitions in the current drawing. If the block is not found in the current drawing, the paths defined by the **SRCHPATH** system variable are searched. If the block is not found there either, BricsCAD responds 'Could not find file <blockname>'

1.30.6 Creating Blocks

Commands: BLOCK (6.6.11), -BLOCK (6.6.12), WBLOCK (6.33.1), PASTEBLOCK (6.24.11) and SECTIONPLANETOBLOCK (6.27.13) The **Block** command groups entities into a block using a dialog box. The **-Block** commands prompts you in the command bar. The **Wblock** command writes blocks and other drawing parts to a separate drawing file (short for "write block"). The **Pasteblock** command pastes entities from the **Clipboard** as a block in the current drawing (see Paste a selection as a block (1.32.17)). The **SectionPlaneToBlock** command saves the selected section plane to a 2D cross section / elevation block or a 3D cutaway section block.

General procedure to create a block

- Specify the name.
- Specify the insertion point. The insertion point is the base point for the block and serves as the reference point when you later insert the block into a drawing.
- Select entities.

To create a block in a drawing

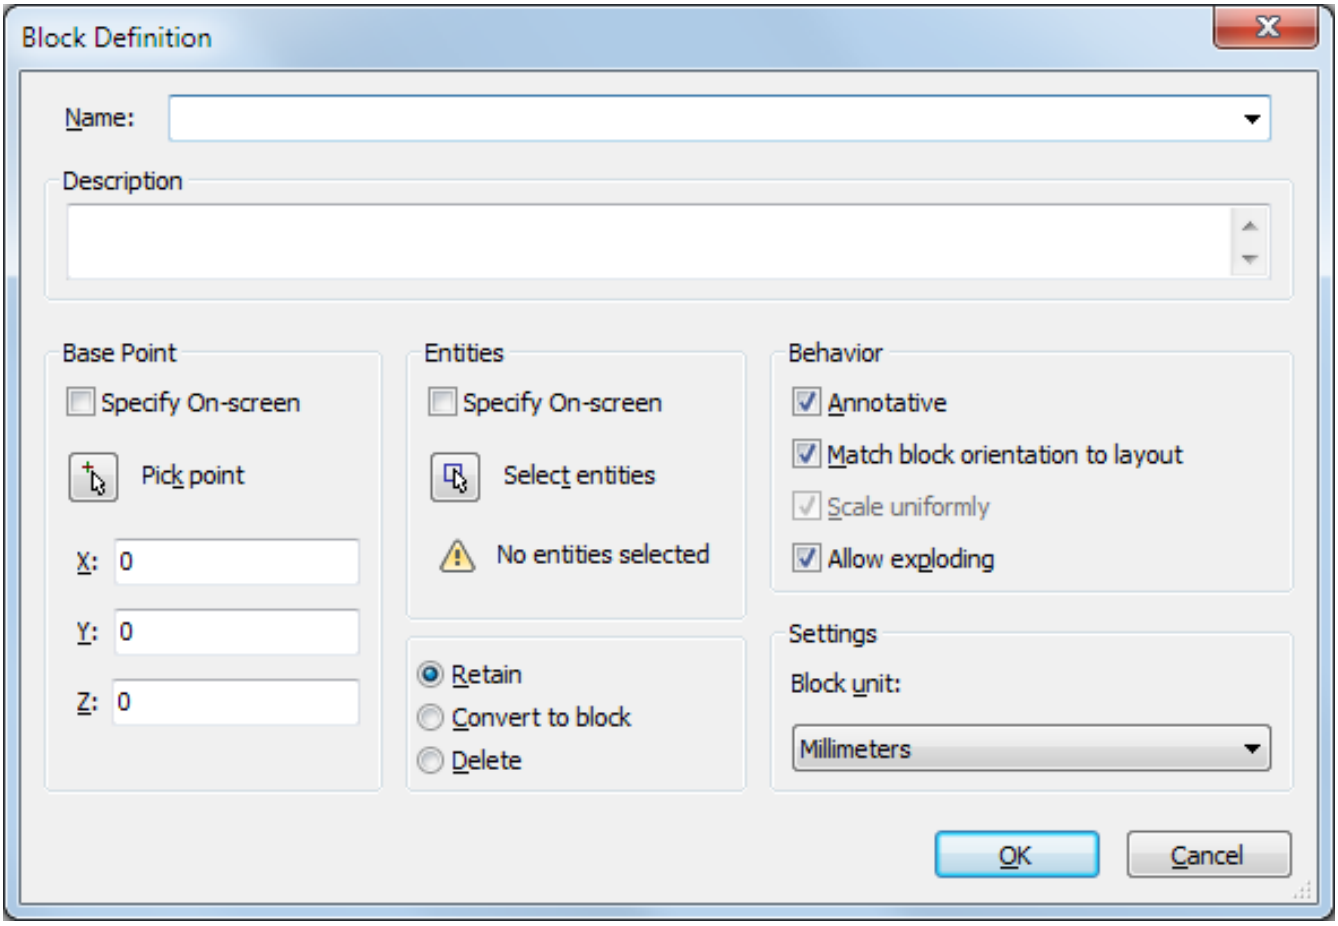
1. Do one of the following:
   - Click the **Create Block** tool button ( ) on the Tools toolbar.
   - Choose **Create Block** in the Tools menu.
   - Type **block** in the command bar, then press Enter.

   The Block Definition dialog displays: (1.1128 on the next page)
2. Type a name for the new block in the **Name** field.
3. Do one of the following to specify the **Base Point**:
   - Check the **Specify On-screen** option. You will be prompted to specify the base point after clicking the **OK** button.
   - Click the **Pick point** button ( ). The Block Definition dialog closes temporarily to let you pick a point in the drawing.
   - Type the coordinates of the base point in the X-, Y- and Z-field.
4. Do one of the following to select the entities to be included in the block definition:
   - Check the **Specify On-screen** option. You will be prompted to select the entities after clicking the **OK** button.
   - Click the **Select entities** button ( ). The Block Definition dialog closes temporarily to let select the entities in the drawing.
5. Set the block properties:
   - **Annotative**: creates an annotative block (1.29.31).
   - **Match block orientation to layout**: if checked, the orientation of an annotative block (1.29.31) is preserved in a rotated viewport.
   - **Scale uniformly**: if checked, the X-, Y- and Z-scaling cannot be set differently.
   - **Allow exploding**: if not checked, prevents the block from being exploded.
   - **Block unit**: set the insertion unit for the block (see also: To insert a block (1.30.5)).
6. Set the behavior of the selected entities after the block is created:
   - **Retain**: The selected entities remain in the drawing.
   - **Convert to block**: The selected entities are replaced by the newly created block.
   - **Delete**: The selected entities are deleted.
7. Click the **OK** button to create the block.

Note: If the **Delete** option in step 6 was set, the OOPS (6.23.7) command brings back the erased block entities.

Tutorial: Tip on how to create blocks quickly on the fly Click here (1.14.3) to watch

Figure 1.1128



To create a block using the Blocks Explorer

1. Do one of the following:

   - Choose **Blocks...** in the Settings menu.
   - Type **explblocks** in the command bar, then press **Enter**.

   The Drawing Explorer - Blocks (1.30.11) dialog opens.

2. In the **Drawing Explorer** dialog do one of the following:

   - Click the **New** button ( ) on the Details toolbar.
   - Choose **New** in the Edit menu.

   The Drawing Explorer dialog closes. **You are prompted:** Insertion point for new block:

3. Specify the insertion point of the new block. You are prompted: Select entities for block.

4. Select the entities (1.32.7) for the new block.

5. Right click to create the block. The selected entities are removed from the drawing. The Drawing Explorer dialog reopens. The **Name** field of the new block is selected.

6. Type a name in the **Name** field, replacing the default **NewBlock1** name.

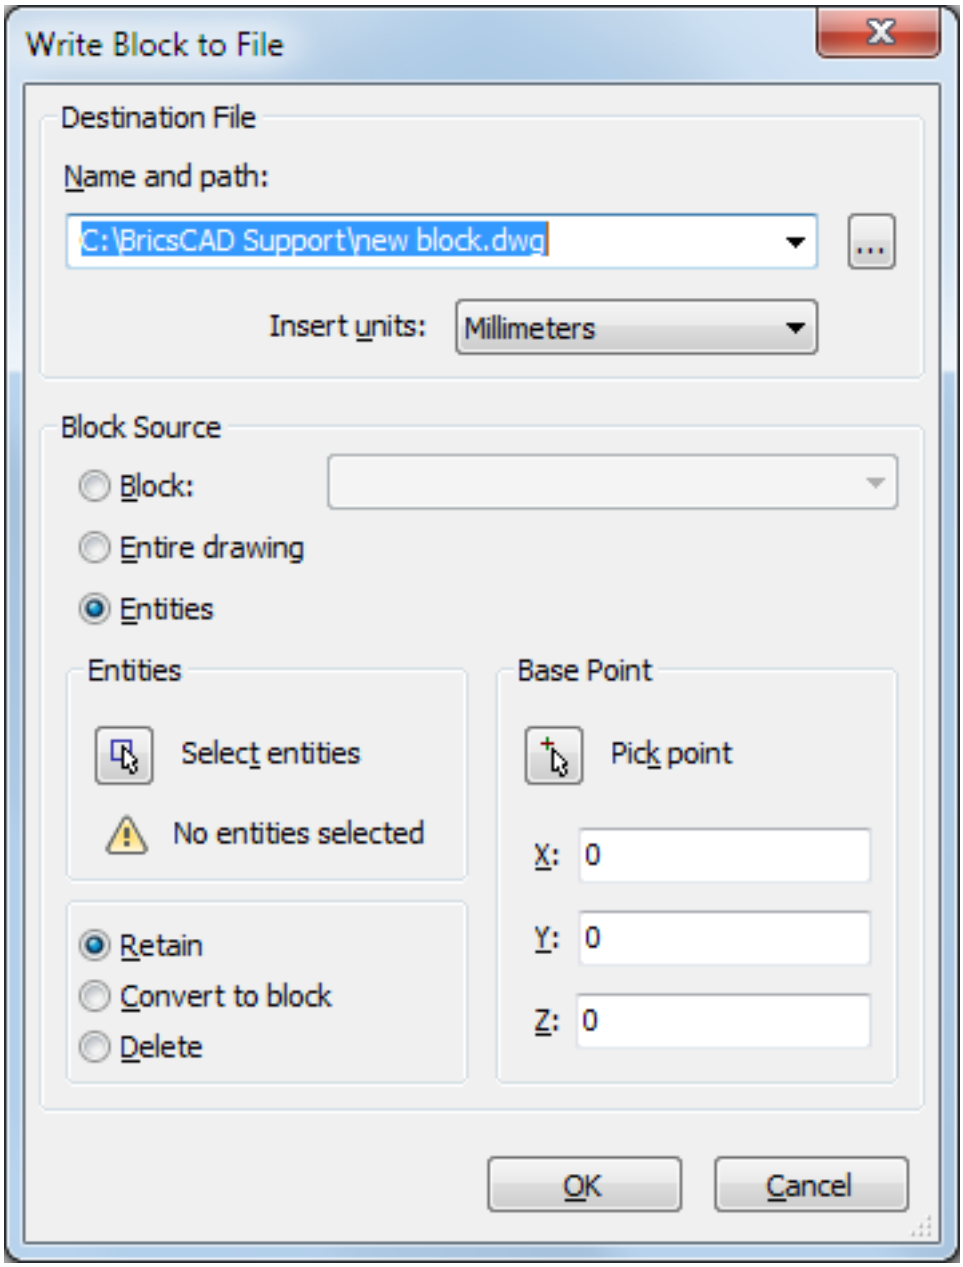
7. Close the Drawing Explorer dialog.

8. (option) Type **oops** in the command bar, then press Enter to bring back the selected block-entities.

To save a block to a separate file

1. Do one of the following:

Figure 1.1129



- Click the **Save Block...** tool button ( ) on the Tools toolbar.
- Choose **Save Block...** in the Tools menu.
- Type **wblock** in the command bar, then press Enter.

The **Write Block to File** dialog opens. (1.1129)

2. Click the browse button ( ) next to the **Name and path** field. The Save Block dialog opens.
3. On the Save Block dialog, select a folder and type a name in the **File name** field, then click the **Save** button. The Save Block dialog closes.
4. **Insert units**: set the insertion unit for the block (see also: To insert a block (1.30.5)).
5. To select the source entities for the new block, do one of the following:
   - Click the **Block** radio button, then select a block from the drop-down list.
   - Click the **Model** space radio button, to select all the entities in the model space of the current drawing.
   - Click the **Entities** radio button, then click the **Select Entities** button ( ). The **Write Block to File** dialog temporarily closes to let you select entities in the drawing. Right click to stop selecting entities. Click the **Pick point** button ( ) to define the **Base point** of the new drawing **Or** Type the coordinates of the base point in the X-, Y- and Z-field. Set the behavior of the selected entities after the block is created:

- **Retain**: The selected entities remain in the drawing.
- **Convert to block**: The selected entities are replaced by the newly created block.
- **Delete**: The selected entities are deleted.

6. Click the **OK** button to create the drawing file.

Note: If the **Delete** option in step 5 was set, the OOPS (6.23.7) command brings back the erased block entities.

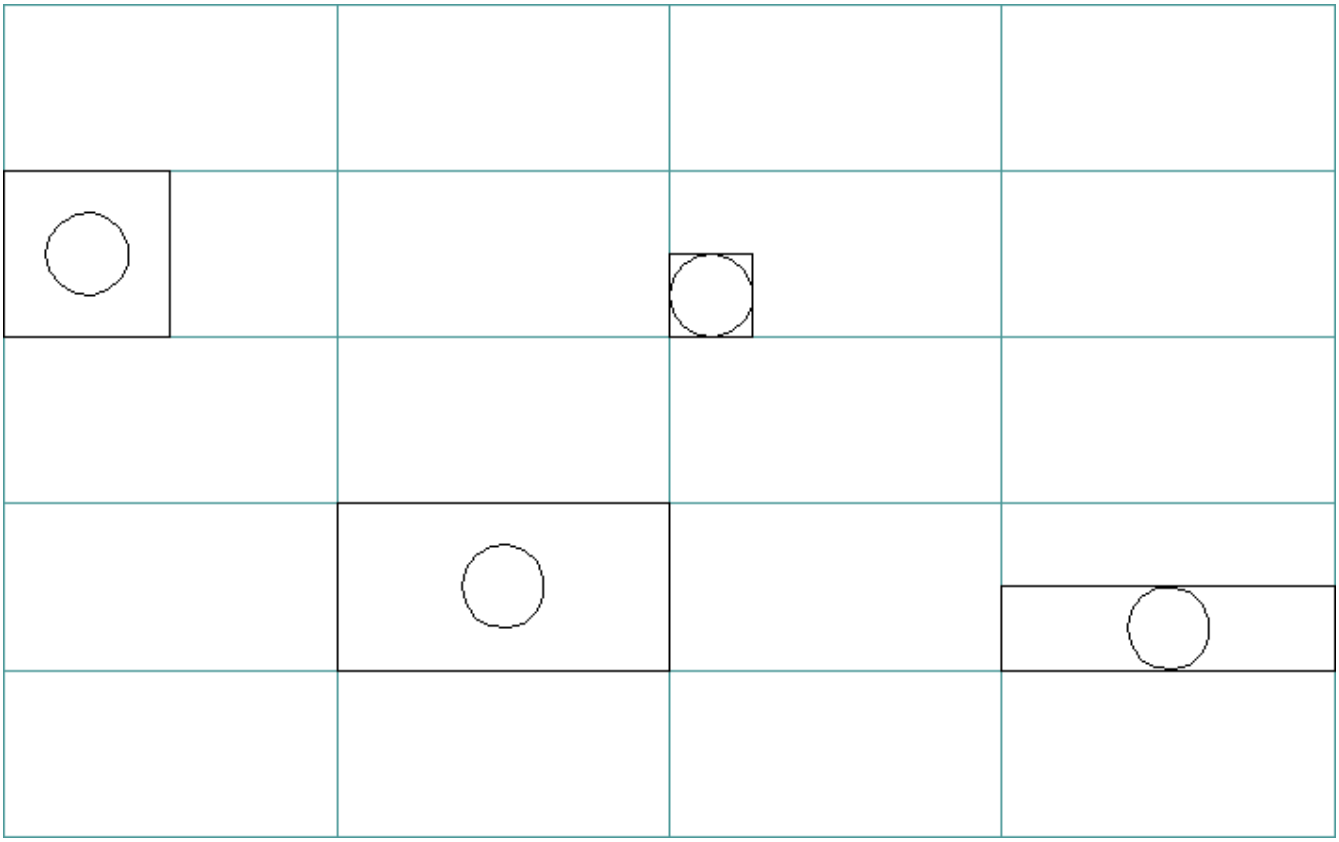
1.30.7 Dynamic blocks vs. 2D Parametric Blocks

If you come from an AutoCAD® design environment, you may be familiar with Dynamic Blocks (1.30.10). You may also be familiar with 2D parametric constraints (1.21.6). They are two different functionalities that somewhat overlap. If you insert AutoCAD dynamic blocks into your BricsCAD drawing, you can, in most cases, edit those block instances. You cannot, however, create or edit dynamic block definitions in BricsCAD. Instead of offering dynamic block functionality, BricsCAD focuses entirely on parametrics. It allows you to create both 2D and 3D block definitions using the same set of tools and workflow. If you've never worked with parametric constraints, they may sound scary. But, they're quite intuitive and logical. And, incredibly powerful!

To define a parametric 2D light fixture block

If you create architectural lighting plans, you probably have a library of blocks like these: 2' x 2', 1' x 1', 2' x 4', 1' x 4' (1.1130 on the next page) Using traditional blocks, each symbol requires a separate block definition. And, if you want to change your design to use a different size, you must delete the existing block instances and insert new ones. Defining a single parametric block to accommodate all the potential sizes, is a great solution!

Figure 1.1130



Set the workspace To ensure all the necessary tools are easily accessible, it's helpful to set the Drafting workspace (1.6.3). For this exercise, I'll use the Quad (1.15.5) and other default UI elements. You can, of course, use the Command line as well.

1. Right-click on the current workspace in the status bar.
2. Select **Drafting**.
3. Start a new drawing.

Drawing the geometry Draw the basic geometry for the block you want to define. The exact size doesn't matter but it's helpful to draw it close to the scale you want. If you already have the geometry as a block, open the block as its own drawing (DWG).

1. Right-click in the drawing area to display the Quad.
   - From the Draw tab, choose Rectangle. (1.1131 on the facing page)
   - Enter 0,0 for the first corner of the rectangle. This will be the insertion point of the block.
   - Enter 48
   - Press the Tab key
   - Enter 24
2. Right-click in the drawing area to display the Quad.
   - From the Draw tab, choose Circle. (1.1132 on page 1236)
   - Pick a point inside the rectangle to place the center of the circle.
   - Enter 6 for the radius.

(1.1133 on page 1236)

Figure 1.1131

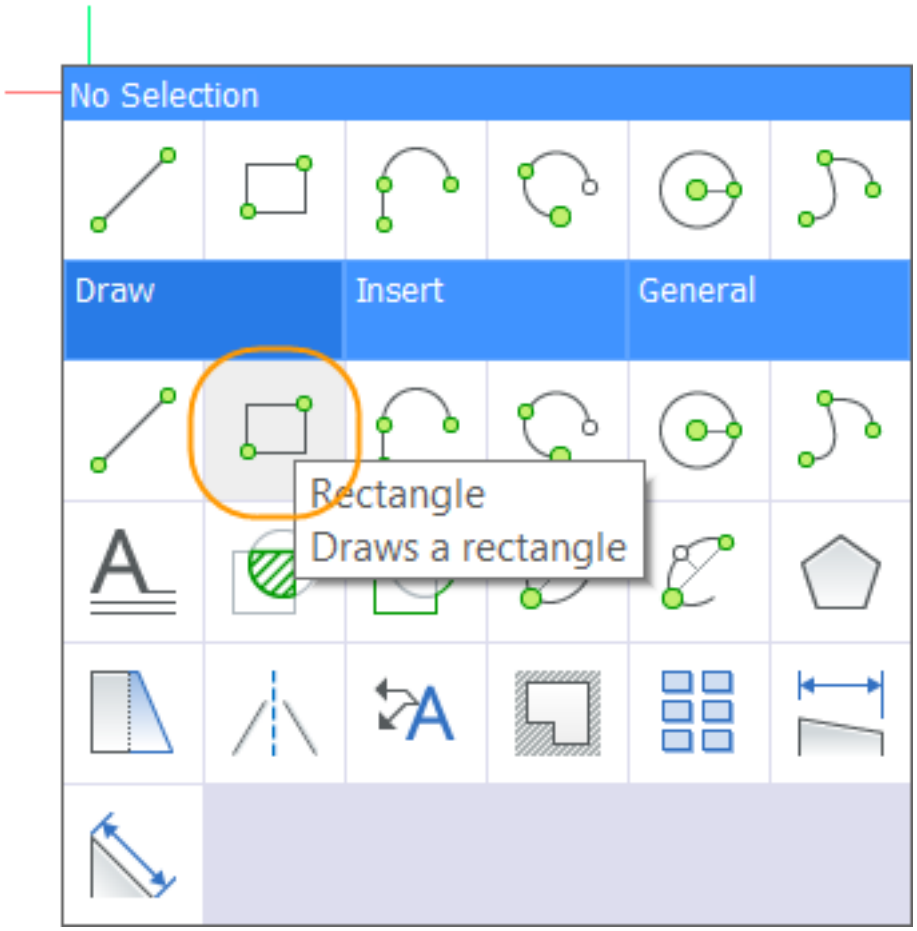


Figure 1.1132

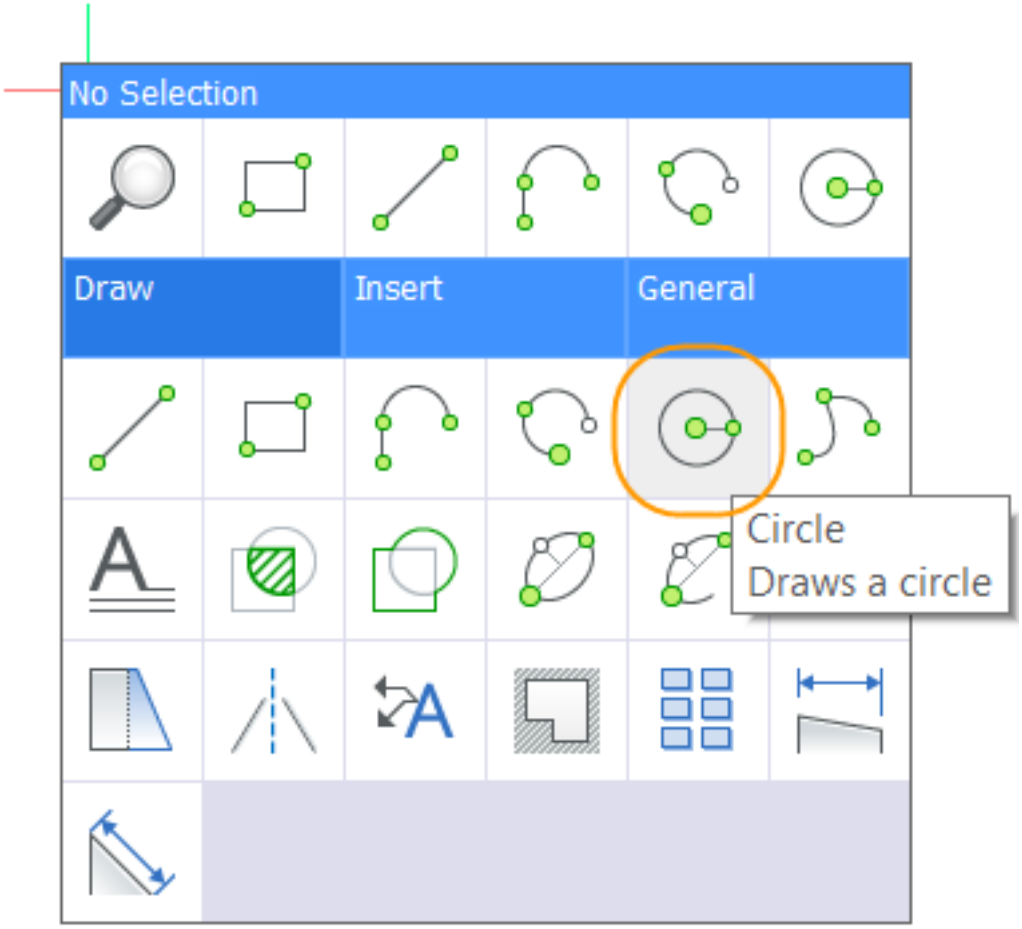

Figure 1.1133

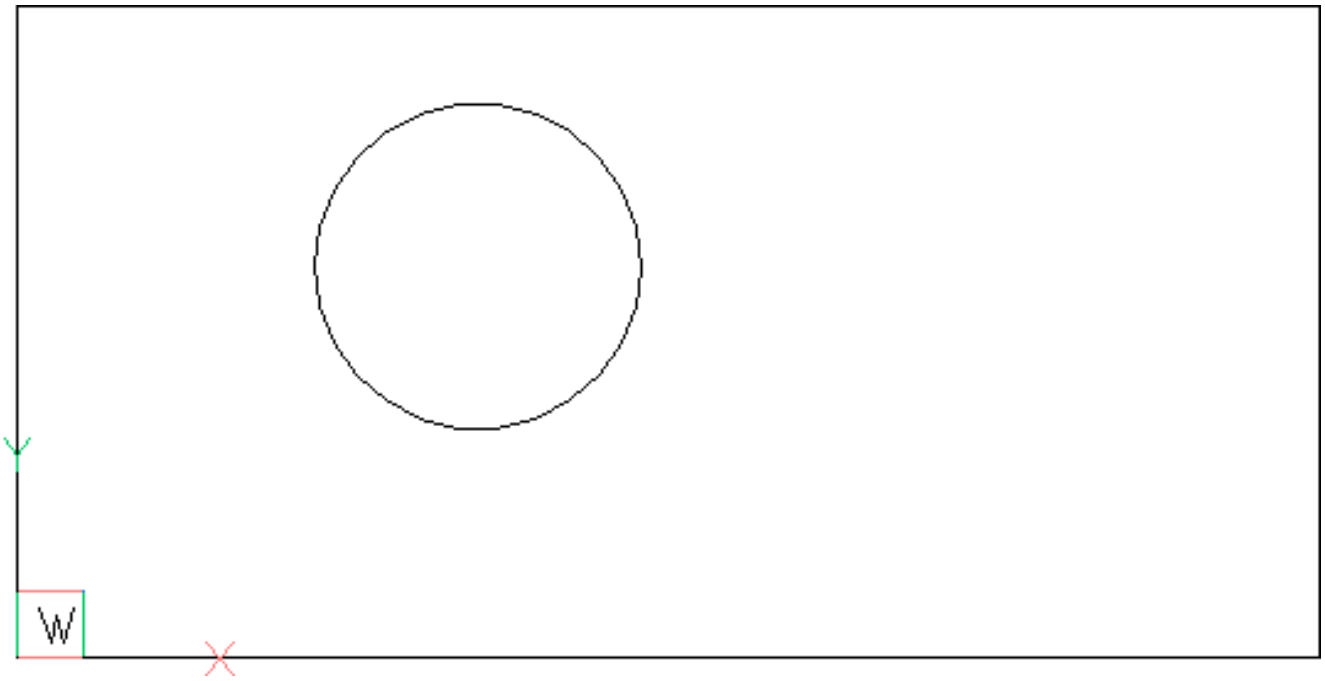


Adding geometric constraints to the rectangle A rectangle is nothing more than a closed polyline. If you try to edit it, it may lose its rectangular shape. To ensure a rectangle maintains its shape, you must add geometric constraints. They establish non-numerical relationships between the various parts of geometry. Geomatric constraints are available in the **2D Geometric Constraints** panel on the **Parametric** ribbon tab.

1. Choose Fix () and select the bottom left corner of the rectangle. Applying a Fix constraint at the insertion point of the block ensures that point will remain fixed even though geometry may move and resize around it.

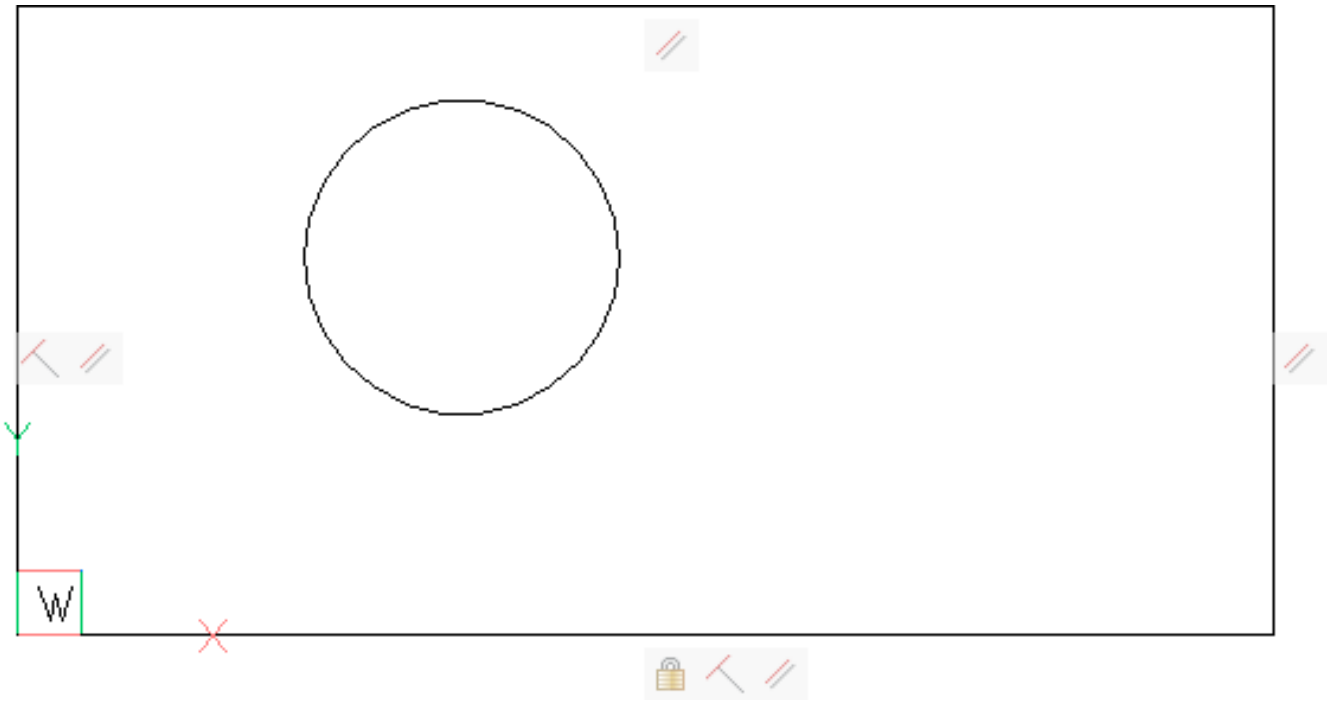
2. Choose Perpendicular () and select the two lines at the lower left corner of the rectangle to ensure they always remain perpendicular to each other.

3. Choose Parallel () and select the two horizontal lines to ensure they always remain parallel to each other.

4. Choose Parallel again and select the two vertical lines to ensure they always remain parallel to each other.

(1.1134 on the next page)

Figure 1.1134



Add dimensional constraints to the rectangle and circle Dimensional constraints are available in the **2D Dimensional Constraints** panel on the **Parametric** ribbon tab. They drive the size of geometric elements and the distances or angles between them.

1. Choose Linear () and press enter to accept the default <Entity> option.
   - Select the left vertical line.
   - Place the dimension to the left of the rectangle.
   - Press Enter to accept the default value.
2. Press Enter twice to repeat the previous command and <Entity> option.
   - Select the bottom horizontal line.
   - Place the dimension below the rectangle.
   - Press Enter to accept the default value.

   (1.1135 on the facing page)
3. Press Enter to repeat the previous command.
   - Select* the bottom endpoint of the left vertical line and the center of the circle.
   - Place the dimension to the left of the rectangle.
   - Press Enter to accept the default value.
4. Press Enter to repeat the previous command.
   - Select* the left endpoint of the bottom horizontal line and the center of the circle.
   - Place the dimension below the rectangle.
   - Press Enter to accept the default value.

*Use the corresponding Entity Snaps (1.21.15) to select the required points. After adding the dimensional constraints, your drawing should look like the following image. The dimension values between the circle and rectangle will vary but you'll fix that next. You'll also change the default names (d1, d2, d3, etc.) to something more meaningful. (1.1136 on the next page)

Figure 1.1135

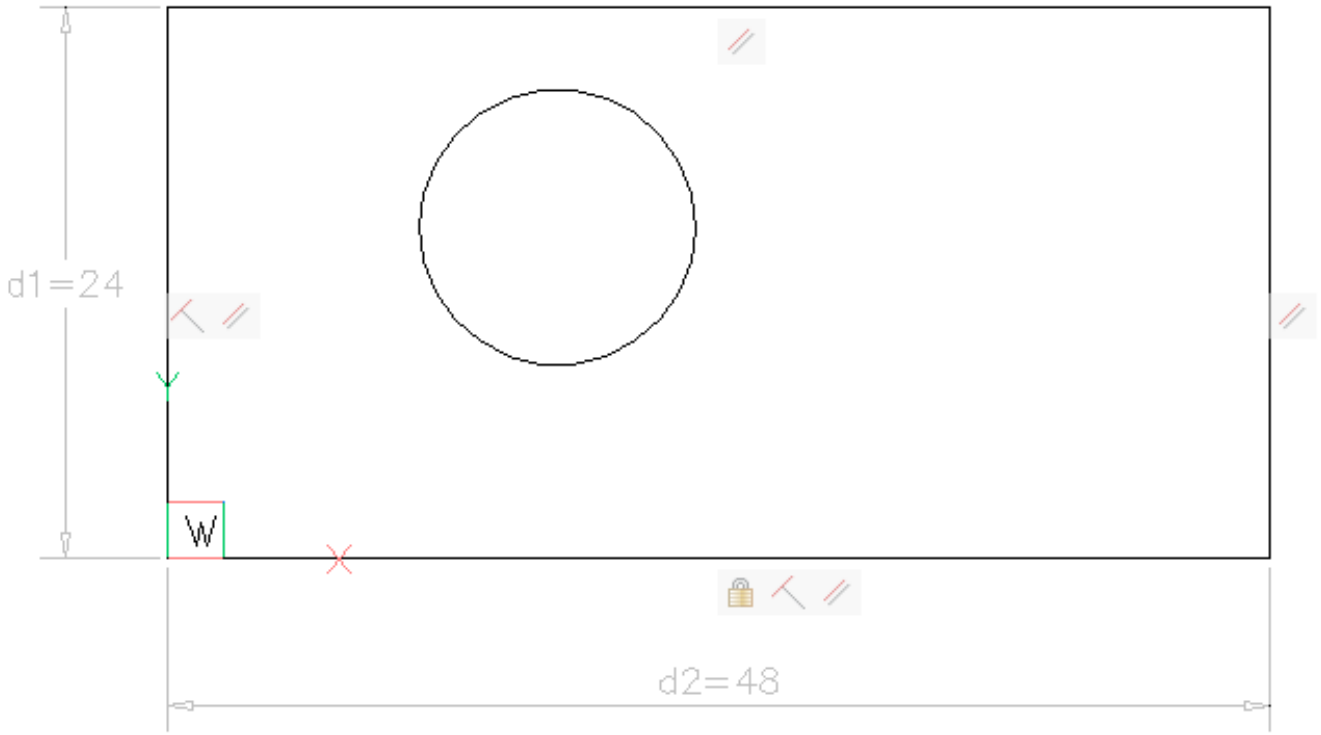


Figure 1.1136

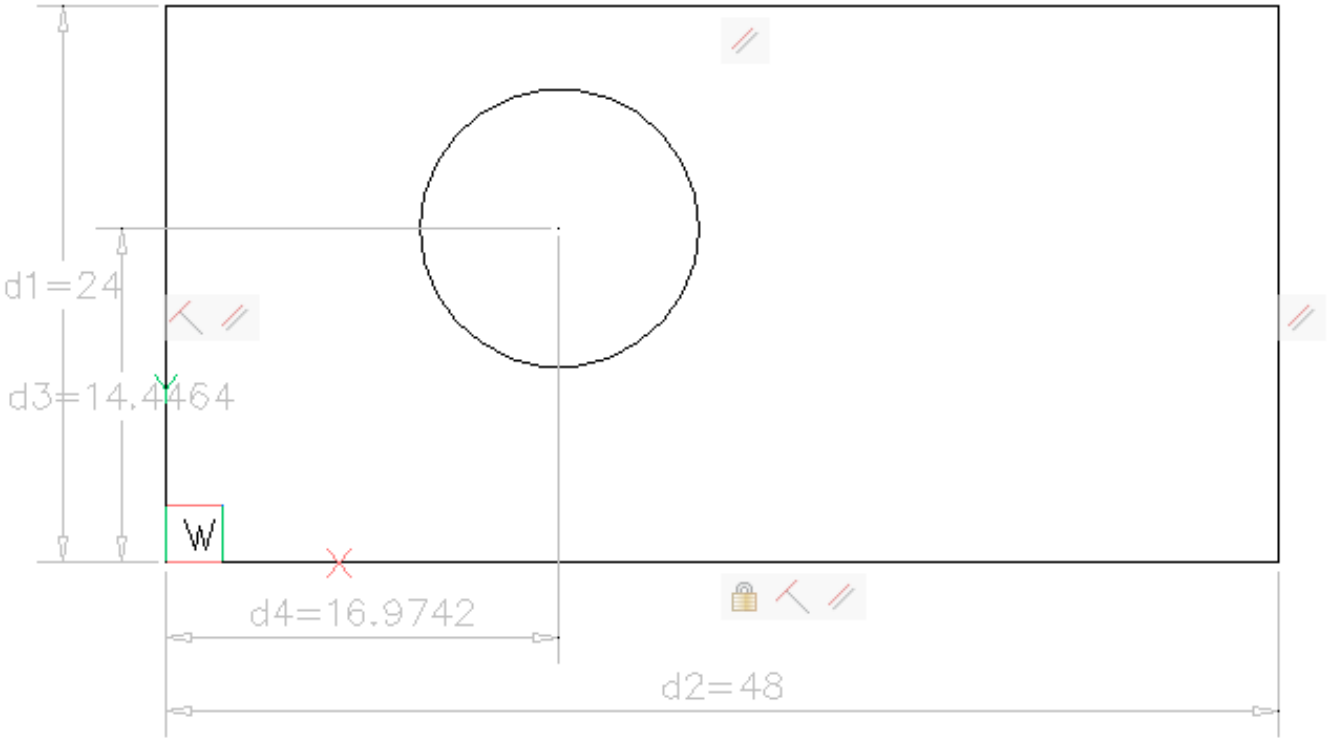
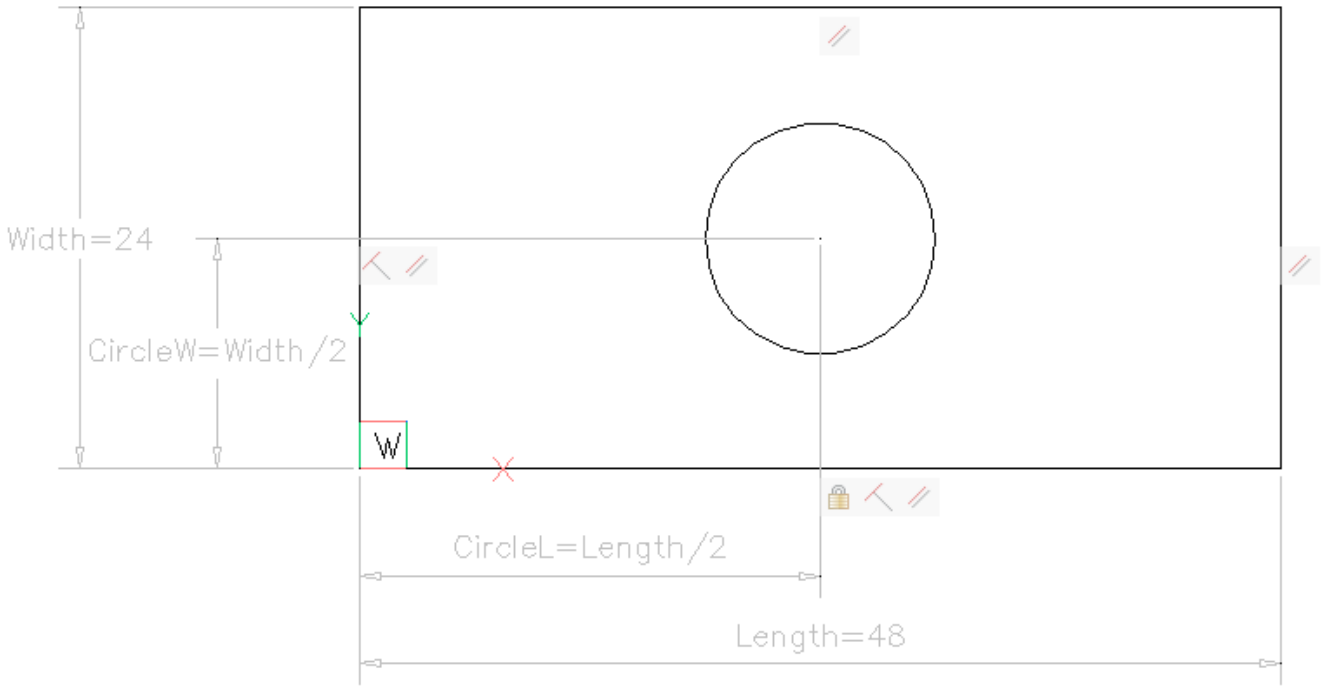


Editing dimensional constraint values You accepted the default value for each dimensional constraint as you created it, but you could have entered different values. Either way, you can change the dimension values later. You can also enter expressions as values to create dependencies on other dimensions. In this example, you always want the circle to remain at the center of rectangle. Therefore, the distance from the lower left corner of the rectangle to the center of the circle should be half the width and length of the rectangle.

1. Select the vertical dimension representing the width of the rectangle and, in the Properties panel, change its name to Width.
2. Select the horizontal dimension representing the length of the rectangle and, in the Properties panel, change its name to Length.
3. Select the vertical dimension representing the distance to the center of the circle. Change its name to CircleW and its expression to Width/2.
4. Select the horizonal dimension representing the distance to the center of the circle. Change its name to CircleL and its expression to Length/2.

As you change the expressions for the circle dimensions, you'll see the circle move to the center of the rectangle. (1.1137 on the facing page)

Figure 1.1137



Saving the parametric drawing To take advantage of parametric blocks, each block must be saved as its own drawing (DWG) file. And if you don't want the constraints to show on the inserted block, you must hide them when you save the block definition (DWG).

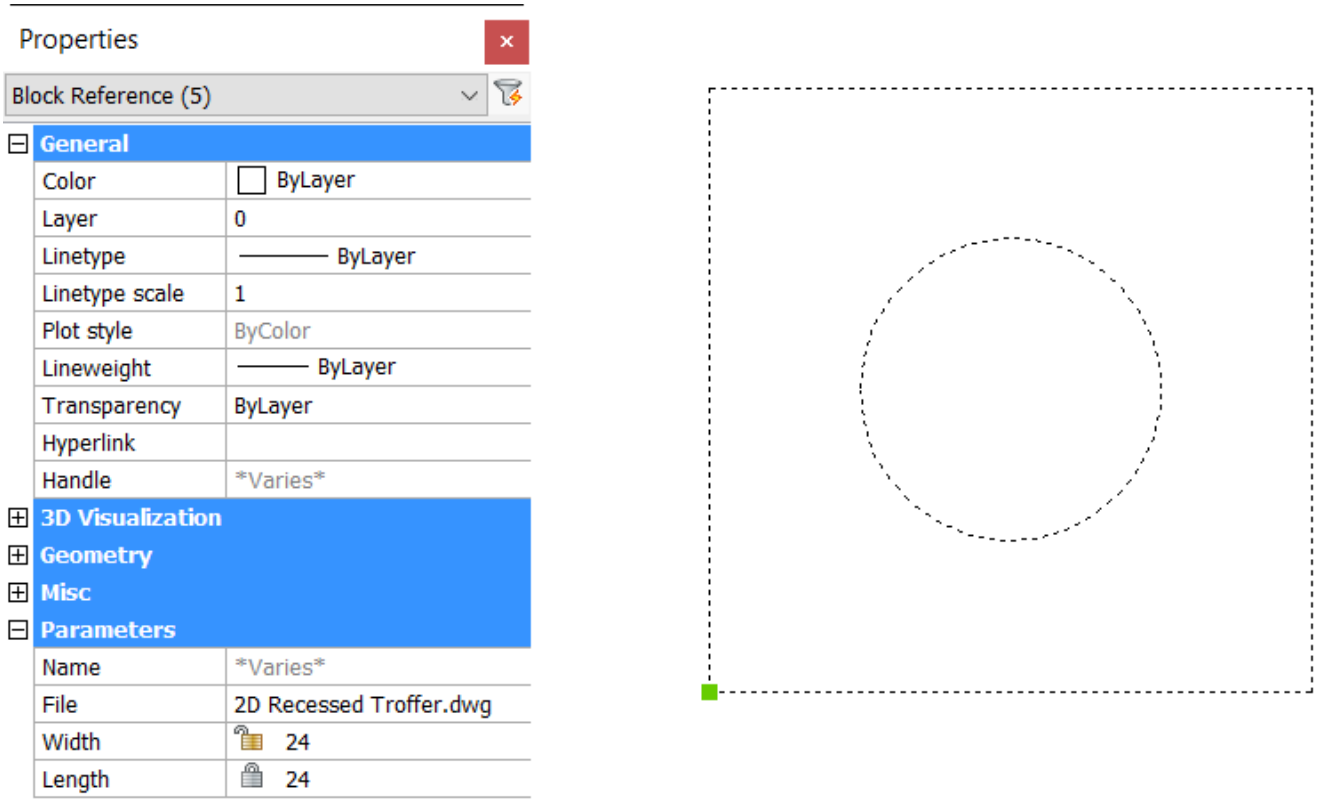
1. From the 2D Geometric Constraints ribbon panel, choose Hide All.
2. From the 2D Dimensional Constraints ribbon panel, choose Hide All.
3. From the File menu, choose SaveAs and enter 2D Recessed Troffer for the file name.

To insert a parametric drawing as a block

All the tools you used to define the 2D parametric drawing are available in every edition of BricsCAD including BricsCAD Lite. However, to insert the drawing as a parametric block, you must have the Pro license level or higher.

1. Run the SETLICENSELEVEL (6.27.37) command and choose the BricsCAD option to ensure it's set to Pro at least.
2. Open the drawing in which you want to insert the 2D Recessed Troffer.
3. Run the BMINSERT (6.8.16) command and select 2D Recessed Troffer.dwg.
   - Choose the Multiple option.
   - Place several instances of the block in your current drawing.
4. Select any of the inserted blocks and open the Properties panel.
5. Modify the Width or Length parameters. The dimensions of the selected block are modified accordingly. (1.1138 on the next page)

Figure 1.1138



1.30.8 Exploding Blocks

Command: EXPLODE (6.13.16) If the **Explodable** property of a block is set, you can explode an inserted block to its original component entities. Exploding a block affects that single instance of the block only. The original block definition remains in the drawing and you can still insert additional copies of the original block. If you explode a block that contains attributes, the attributes are lost, but the original attribute definitions remain.

To explode a block

1. Do one of the following:

   - Click the **Explode** tool button ( ) on the Modify toolbar.
   - Choose **Explode** in the Modify menu.
   - Type **explode** in the command bar, then press Enter.

   You are prompted: Select entities to explode.

2. Select (1.32.7) the block(s).

3. Press Enter or right click to explode the blocks.

Note: Exploding dissociates component entities to their next simplest level of complexity: nested blocks or polylines in a block become blocks or polylines again.

Setting the Explodable property of a block

1. Do one of the following:

   - Choose **Drawing Explorer > Blocks...** in the Tools menu.
   - Type **expblocks** in the command bar, then press Enter

   The Drawing Explorer - Blocks dialog displays.

2. If necessary, click the **Detail View** tool button ( ) in the Drawing Explorer - Blocks toolbar.

3. Click the checkbox in the **Explodable** field of a block to toggle the property.

1.30.9 Redefining Blocks

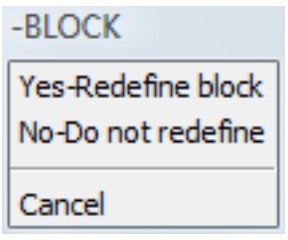
Commands: BLOCK (6.6.11), -BLOCK (6.6.12) and INSERT (6.17.13) To redefine a block that was created in the current drawing, you create a new block using the same name. If the block was inserted from a separate drawing, reinsert that block. When a block definition is redefined all instances of that block in the current drawing are updated automatically. See also: Editing blocks and external references (1.30.21).

To redefine an internal block definition

1. Type **-block** in the command bar, then press Enter. **You are prompted:** Name for new block, or ? to list existing blocks:
2. Type the name of the block in the command bar and press Enter. **You are prompted:** The block <name> already exists. Do you want to redefine it? <N>. A prompt menu displays. (1.1139)
3. To redefine the block definition, do one of the following:
   - Type **Y** , then press Enter.
   - Choose **Yes-Redefine block** in the prompt menu.

   You are prompted: Insertion point for new block:
4. Specify the insertion point of the new block. You are prompted: Select entities for block.
5. Select the entities (1.32.7) for the new block.
6. Right click to create the block. The selected entities are removed from the drawing. All existing instances of the block are updated.
7. (option) To bring back the selected block entities, type **oops** in the command bar, then press Enter.

Figure 1.1139



To reload an external drawing as a block

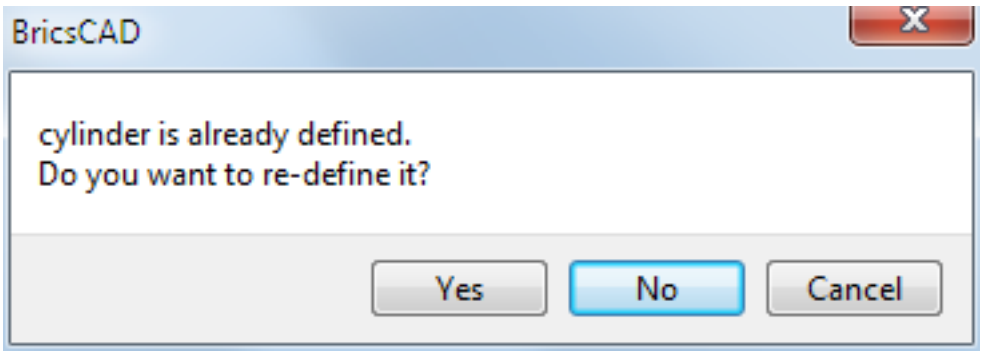
1. Do one of the following:

   - Click the **Insert Block...** tool button ( ) on the **Draw** toolbar.
   - Choose **Insert Block...** in the **Draw** menu.
   - Type **insert** in the command bar, then press Enter.

   The **Insert Block** dialog opens.

2. On the **Insert Block** dialog click the **Browse** button, then select the external drawing file.
3. Click the **Insert** button. An alert box displays. (1.1140)
4. Click the **Yes** button to redefine the existing block definition. You are prompted: Insertion point for block:
5. Continue with step 3 of the Inserting Blocks (1.30.5) procedure.

Figure 1.1140



1.30.10 Dynamic Blocks

BricsCAD partly supports dynamic blocks, you can:

- insert dynamic blocks from your existing dynamic blocks libraries
- edit the custom properties in the Properties Bar (1.15.4)
- grip edit dynamic blocks

The creation of new dynamic blocks is not possible yet. Instead of offering dynamic block functionality, BricsCAD focuses entirely on parametrics. (1.30.7) Youtube

Editing dynamic blocks

1. Select the dynamic block in the drawing. The properties of the selected block display in the Properties Bar. (1.1141 on the facing page)
2. Under **Attributes > Custom** : edit the properties needed. The dynamic block is updated automatically. (1.1142 on the next page)

Figure 1.1141

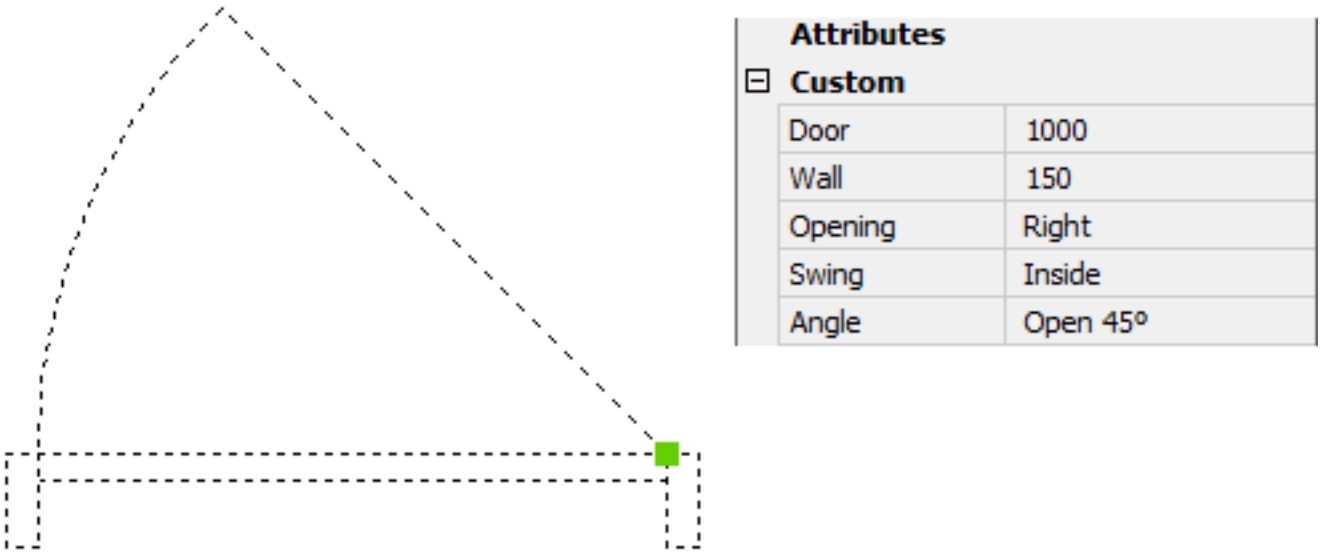


Figure 1.1142

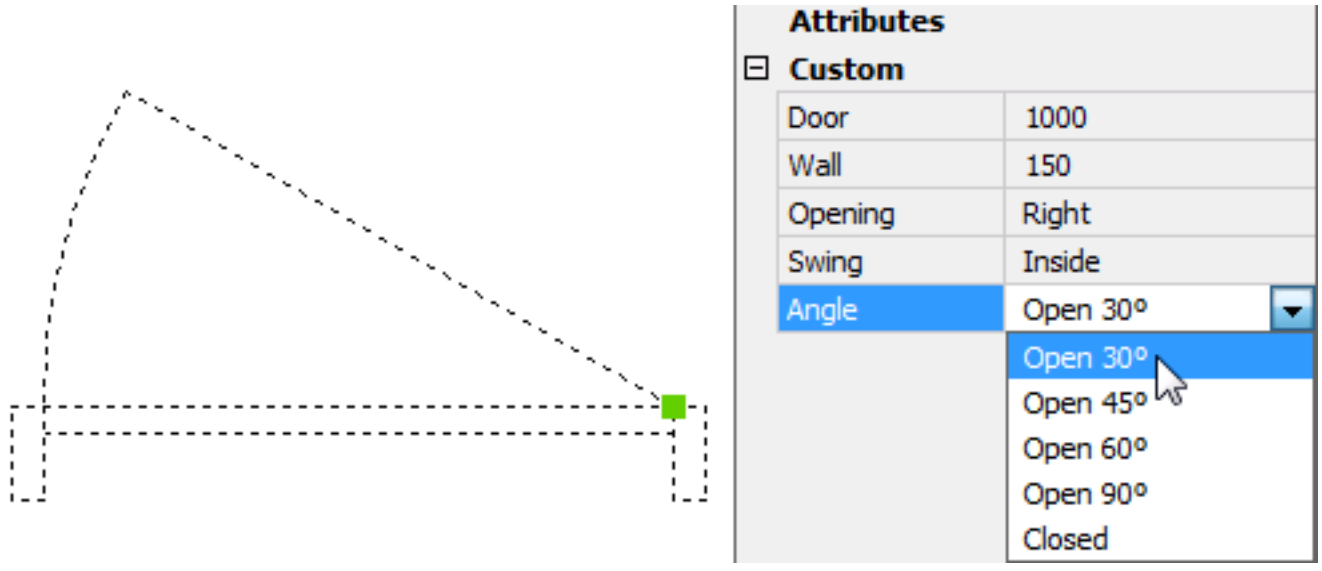
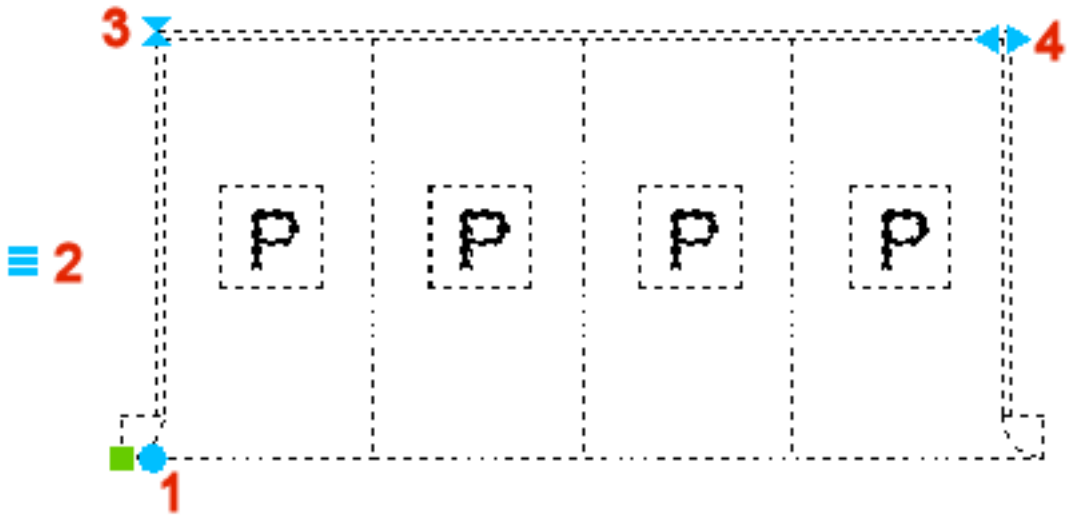


Grip editing dynamic blocks

1. Select the dynamic block in the drawing. The following grip types display:
   - Point
   - XY
   - Linear
   - Polar
   - Rotation
   - Flip
   - Visibility
2. Drag a grip to edit the block. In the example below:
   - Rotate the block (1): drag the grip to rotate the block dynamically or type a value in the dynamic entry field.
   - Show/hide entities (2): click to select an option.
   - Flip (3): click to mirror the block
   - Edit the length (4): select the grip to dynamically edit the length or type a value in the dynamic entry field.

(1.1143 on the facing page)

Figure 1.1143



1.30.11 Exploring Blocks

Command: EXPBLOCKS (6.13.11) The **Explblocks** command opens the **Blocks** section of the Drawing Explorer dialog box (short for "explorer blocks"). In the **Blocks Explorer** you can:

- **Create** new blocks ( )
- **Delete** blocks ( )
- **Purge** unused block definitions ( )
- **Insert** blocks ( ) in the current drawing
- **Insert** external block files ( )
- **Save** a block as a (new) drawing ( )
- **Cut** ( ) or **Copy** ( ) a block definition, then **Paste** ( ) the block definition in another drawing
- **Rename** a block.

Open the Blocks Explorer

To open the **Blocks Explorer** do one of the following:

- Choose **Drawing Explorer > Blocks...** in the Tools menu.
- Type **expblocks** in the command bar.

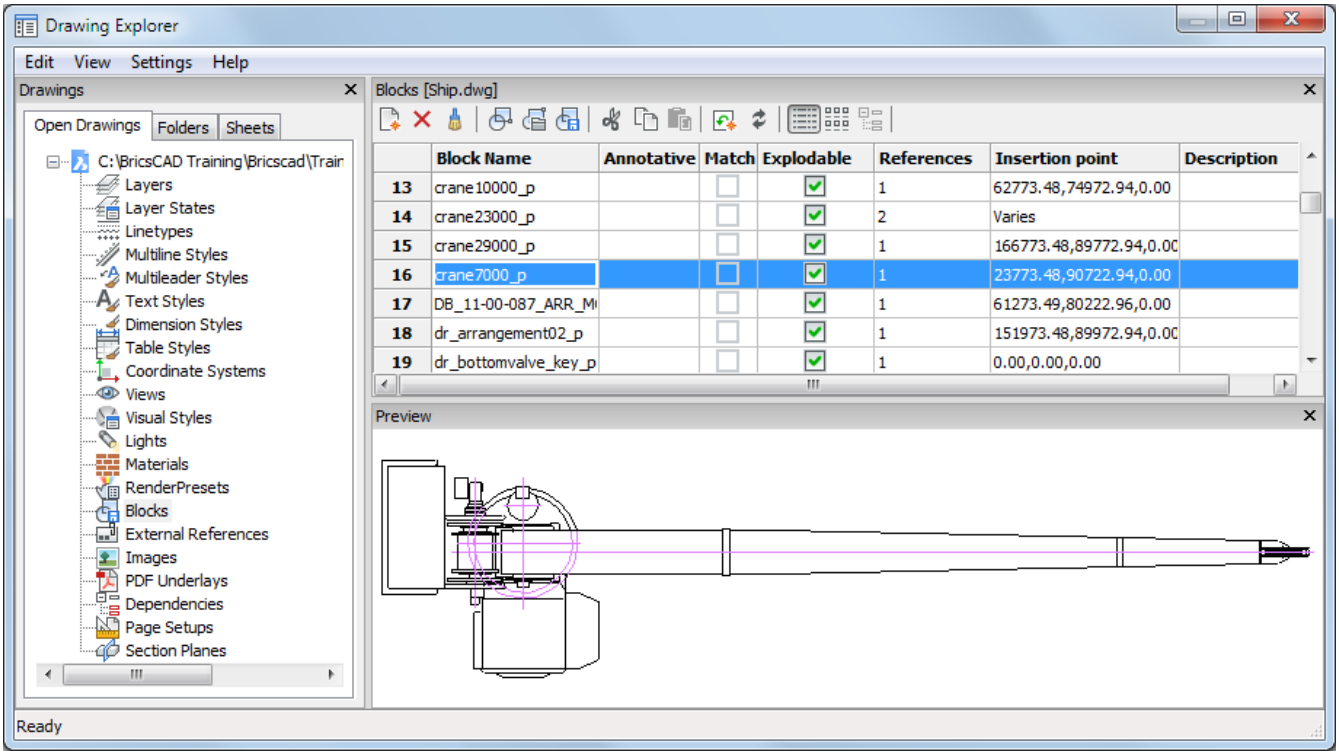
The Blocks Explorer display options

You can choose between **Detail View** (list) and **Icon View** (thumbnails) to see the blocks in the current drawing.

Open the Detail View of the Blocks Explorer

Click the **Detail View** button ( ) in the **Drawing Explorer** toolbar. The **Detail View** button is now pressed indicating the block details are displayed. A preview of the selected block displays in the **Preview** sub-window of the **Drawing Explorer**. (1.1144 on the next page) Detail View of the blocks in the current drawing.

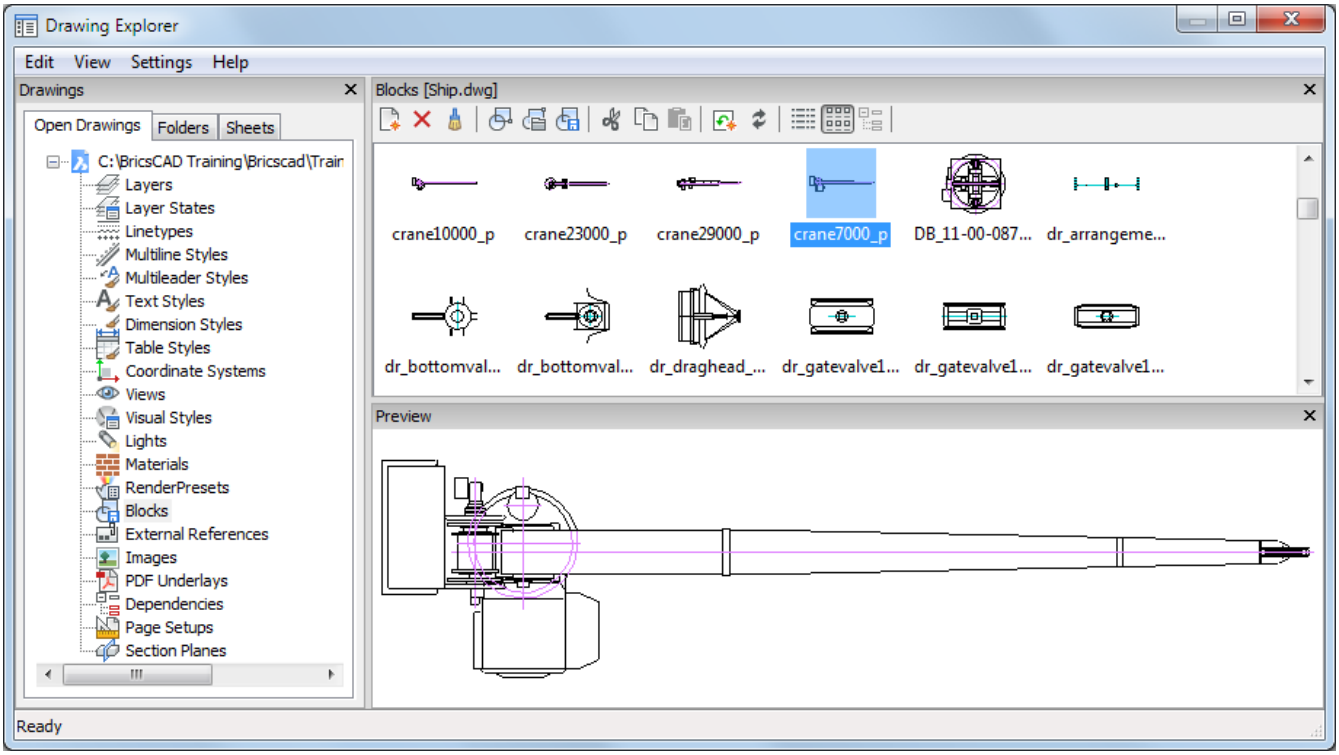
Figure 1.1144



Open the Icon View of the Blocks Explorer

Click the **Icon View** button ( ) in the **Drawing Explorer** toolbar. The **Icon View** button is now pressed indicating the block icons are displayed. A preview of the selected block displays in the **Preview** sub-window of the **Drawing Explorer**. (1.1145 on the following page) Icon View of the blocks in the current drawing.

Figure 1.1145



To rename a block

1. Open the Blocks Explorer (1.30.11) dialog.
2. Select the block, then click the **Block Name** field.
3. Type a new name in the **Block Name** field and press Enter.

1.30.12 Working with attributes

An attribute is a particular entity that you can save as part of a block definition. Attributes consist of text-based data. You can use attributes to track such things as part numbers and prices. Attributes have either fixed or variable values. When you insert a block containing attributes, the program adds the fixed values to the drawing along with the block, and you are prompted to supply any variable values. After you insert blocks containing attributes, you can extract the attribute information to a separate file and then use that information in a spreadsheet or database to produce a parts list or bill of materials. You can also use attribute information to track the number of times a particular block is inserted into a drawing. Attributes can be visible or hidden. Hidden attributes are neither displayed nor plotted, but the information is still stored in the drawing and written to a file when you extract it.

General procedure to work with attributes

1. Define the attributes.
2. Create a block.

You can attach attributes to a block. Include the attributes when the program prompts you to select the entities to be included in the block definition. If a block contains attributes, the program prompts you each time you insert the block, so you can specify different values for the attributes each time you insert it into a new drawing.

1. Insert the block in a drawing.
2. (option) Edit the attributes in a block.
3. Extract attribute information.

1.30.13 Defining Attributes

Command: ATTDEF (6.4.31) and -ATTDEF (6.4.32) The **Attdef** command defines how a block's attributes will be created through a dialog box. The **-Attdef** command creates block's attribute definitions at the command prompt.

General procedure to define attributes

- Specify the characteristics of the attribute, including its name, prompt, and default value;
- Specify the location;
- Define the text formatting;
- Optionally: set the attribute flags (hidden, fixed, validate or predefined).

To define an attribute

1. Do one of the following:

   - Click the **Define Attributes...** tool button () on the **Tools** toolbar.
   - Choose **Define Attributes...** in the **Tools** menu.
   - Type **attdef** in the command bar, then press Enter.

   The **Define Attribute** dialog opens. (1.1146 on the next page)

2. Define the Attribute:

   - Type a name in the **Tag** field. The **Tag** Identifies each occurrence of an attribute in the drawing. The name you type in the **Tag** field can be any combination of characters except spaces. Lowercase letters are automatically converted to uppercase.
   - Type a prompt in the **Prompt** field. The attribute prompt displays when you insert a block containing the attribute. If a prompt is omitted, the **Tag** is used as the prompt instead.
   - Do one of the following:
     - Type a default value in the Default text field. For variable attributes, the default value is replaced by the actual value when you insert a block containing the attribute.
     - Click the Insert Field button () to assign a field value to the attribute (see Using sheet set and sheet properties in a title block).
     - If the Multiple lines flag is checked, the Default text field is dimmed.

   (1.1147 on the facing page) Click the button next to the **Default text** field. The **Define Attribute** dialog temporarily closes to let you **create** a Mtext (1.29.20) entity.

   - Do one of the following:
     - Specify the x-, y-, and z-coordinates for the attribute insertion point.
     - Click the Pick Point button () to specify the insertion point in the drawing. You are prompted: Select insertion point. The Define Attribute dialog closes temporarily.
   - (option) Set the **Invisible** attribute flag. Attributes with the **Invisible** flag set do not display nor print. If the **ATTMODE** (Attribute Display Mode) variable is set to **2** , all attributes display, including **Hidden** attributes.
   - (option) Set the **Constant** attribute flag. Attributes with the **Constant** flag set cannot be edited.
   - (option) Set the **Verify** attribute flag. Attributes with the **Verify** flag set must be explicitly validated when a block containing such attributes is inserted.
   - (option) Set the **Preset** attribute flag. When inserting a block you are not prompted to define attributes of which the **Preset** flag is set. You can edit attribute afterwards though.
   - (option) Set the **Lock Position** attribute flag to lock the position of the attribute within the block reference. Unlocked attributes can be moved relative to the rest of the block using grip editing and multiline attributes can be resized.
   - Define the **Text** properties: **Text Style** , **Justification** , **Annotative** , **Text height** and **Rotation** .

3. Click the **OK** button to create the attribute in the drawing. The **Define Attribute** dialog closes.

4. (option) Right click to reopen the **Define Attribute** dialog, then repeat steps 2 and 3 to create another attribute.

Figure 1.1146

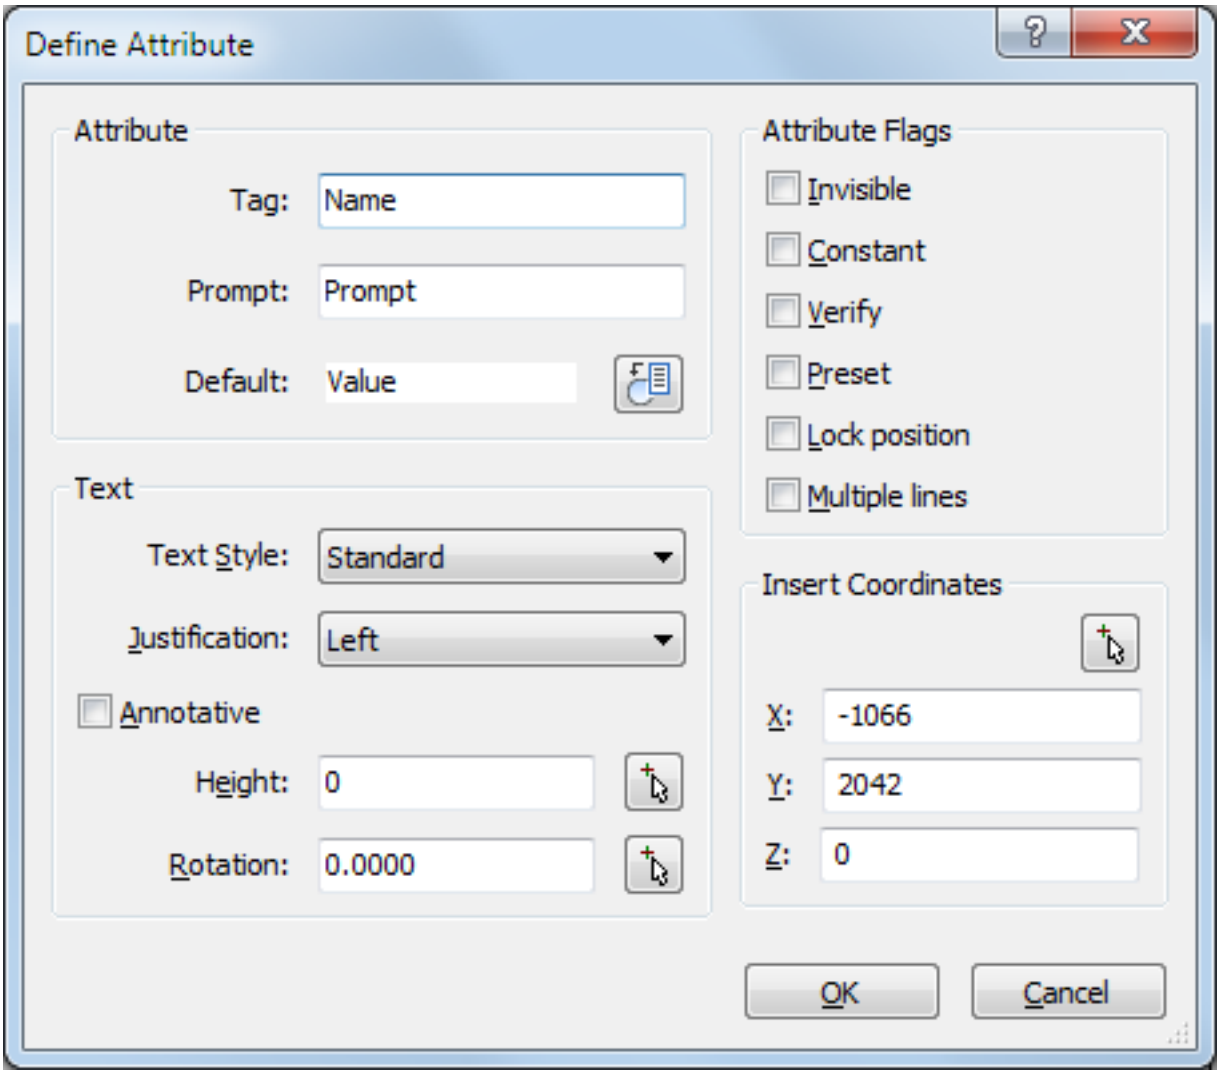


Figure 1.1147

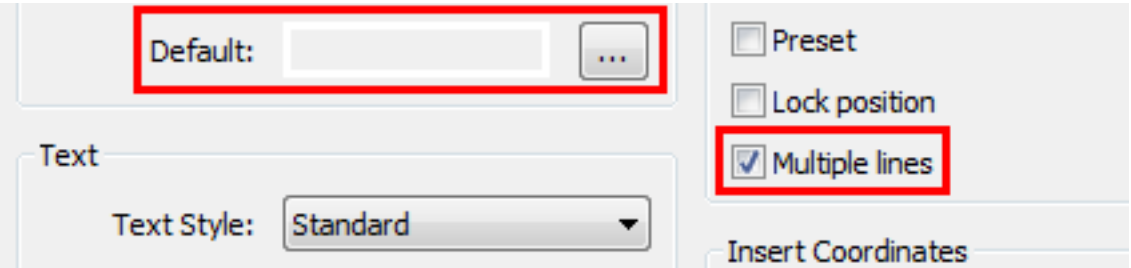

Using sheet set properties in a title block

1. Create the sheet set.
2. Define the custom sheet set and sheet properties.
3. Open a sheet (layout) from the sheet set.
4. Create the title block source entities in the paper space layout:
   - Create the borders, line work and fixed texts.
   - Create attributes with fields (1.29.23) that refer to sheet set, subset and sheet properties (see To define an attribute (1.30.13)).

   See the SHEETSET (6.27.38) command to learn more about default and custom sheet set, subset and sheet properties. Custom sheet set properties: (1.1148 on the next page) Sheet properties and sheet custom properties: (1.1149 on the facing page)
5. Create a block (1.30.6) from the title block source entities.
6. Copy the block to drawing in one of your block folders (see To insert a block form another drawing (1.30.5)).
7. Delete the title block source entities.
8. The title block can be inserted in the other sheets of the sheet set and in any other sheet set where the same custom sheet set and sheet properties exist. All fields that refer to default or custom sheet set, subset or sheet properties are filled out automatically. If no value is available, a field displays hyphens (----) (see also Placing blocks with attributes (1.30.15)).

1.30.14 Editing attributes attached to blocks

Command: EATTEDIT (6.13.1) The **Eattedit** command edits the attributes in blocks. You are prompted to select a block with editable attributes. When you select such block, the Attribute Editor dialog displays. If the selected block does not contain attributes or if the selected entity is not a block you are prompted to select another block.

Using the Attribute Editor

1. Do one of the following:

   - Click the **Edit Block Attributes...** tool button ( ) on the Attributes toolbar.
   - Choose **Edit Block Attributes...** in the Tools | Attributes menu.
   - Type **eattedit** in the command bar, then press Enter.

   You are prompted: Select a block. **Or** double click a block containing attributes, then go to step 3.

2. Select a block with attributes. The Attribute Editor dialog opens. (1.1150 on the next page)

3. Select an attribute in the list. The current value of the selected attribute displays in the **Value** field.

4. (option) Type a new value in the **Value** field.

5. (option) Click the **Properties** tab to modify **Layer** , **Color** , **Lineweigth** and/or **Linetype** .

6. (option) Click the **Text Options** tab to edit the text properties. (1.1151 on the facing page)

7. (option) Click the **Apply** button to apply the changes.

8. (option) Repeat steps 3 through 6 to edit another attribute.

9. Do one of the following:
   - Click the **OK** button to close the Attribute Editor dialog and apply the changes.
   - Click the Apply button to apply the changes and keep the Attribute Editor dialog open.
   - Click the **Cancel** button to close the Attribute Editor dialog. Changes that are not applied yet are not saved.
   - Click the **Select** button ( ) to select another block. The Attribute Editor dialog temporarily closes to let you select another block in the drawing.

Figure 1.1150

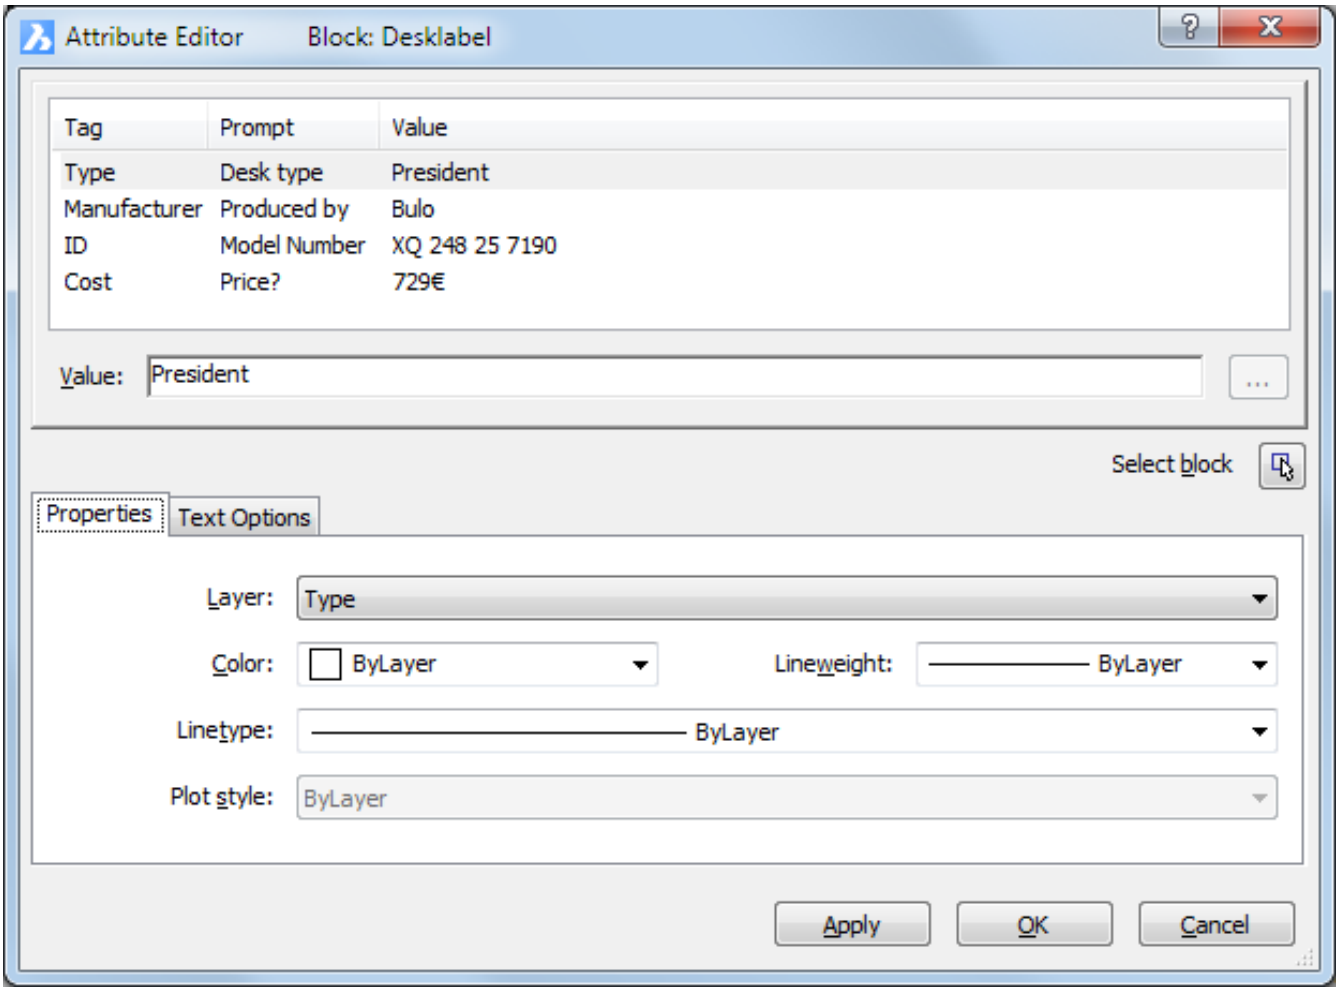

Figure 1.1151

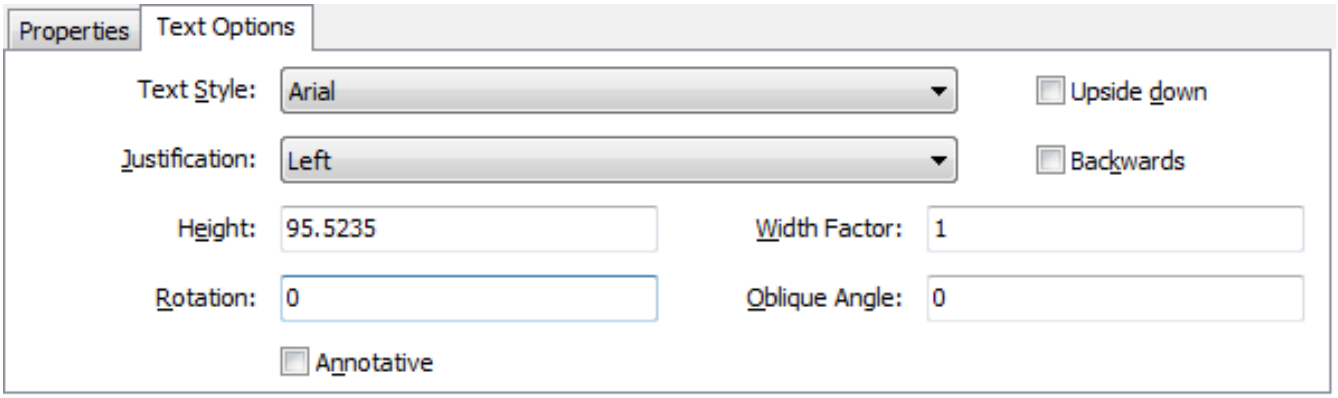
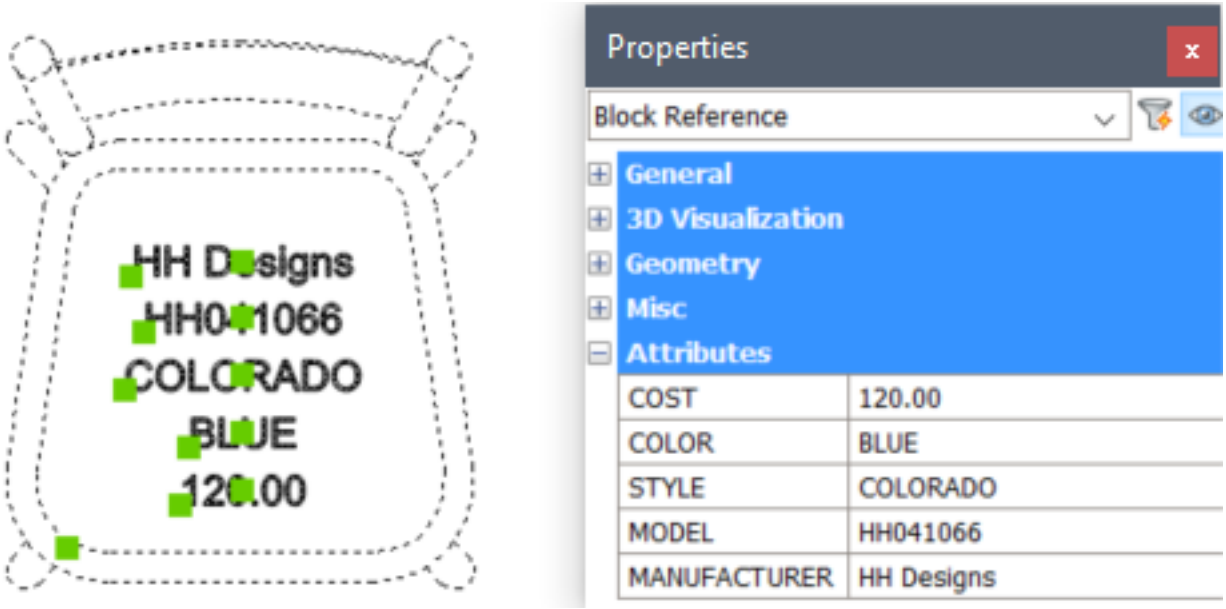


Editing attributes in the Properties bar

1. Select a block containing attributes. The current value of the attributes display in the Properties bar (1.15.4).
2. Click the attribute you want to edit. The settings field of the selected attribute is active. (1.1152 on the next page)
3. Type a new value, then press enter or select another attribute.

Figure 1.1152



1.30.15 Placing blocks with attributes

Commands: INSERT (6.17.13) and -INSERT (6.17.14) When you place a block which contains attributes, you will be prompted to define the attributes in the command bar or through a dialog box. If the ATTDIA (1.17.10) system variable is ON, attributes display in a dialog box. If the ATTDIA (1.17.10) system variable is OFF, you are prompted in the command bar to define the attributes.

To place a block with attributes

1. Launch the Insert Block... (1.30.5) tool.
2. Position the block in the drawing. All block entities are placed in the drawing, except the attributes. **You are prompted:** <Attribute Prompt> <Default Text>: **Or** a dialog box displays: (1.1153 on the facing page)
3. Do one of the following:
   - In the command bar: The command bar reads: <Attribute Prompt> <Default Text>:
     - Press Enter or right click to accept the default text.
     - Type a new text in the command bar, then press Enter and define the next attribute.
   - In the **Edit Attributes** dialog box:
     - Select an attribute in the list. The current value displays in the **Value** field.
     - Type a new value in the **Value** field.
     - Press **OK** when all attributes are properly defined.

Figure 1.1153

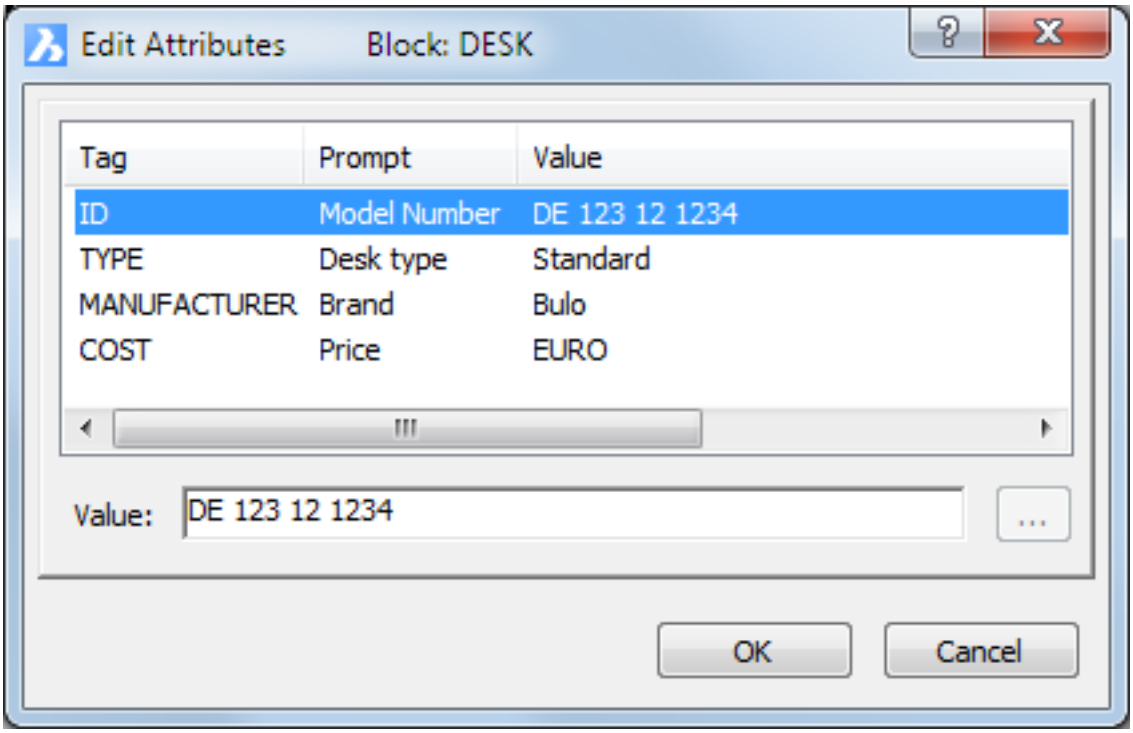


Figure 1.1154

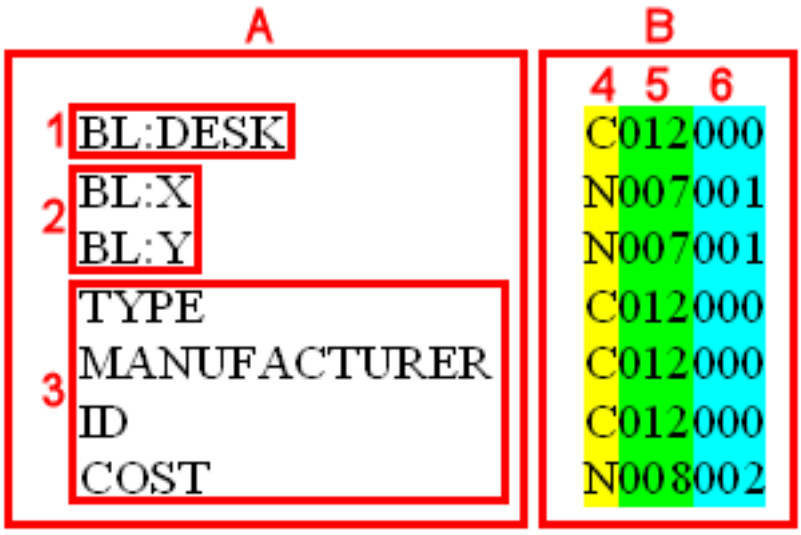


1.30.16 Extracting attribute information

Command: ATTEXT (6.4.38) and -ATTEXT (6.4.35), DATAEXTRACTION (6.10.4) The **Attext** command copies data from attributes to a text file via a dialog box. The **-Attext** command copies data from attributes to a text file via the command line. The text file can the be imported in a database or a spreadsheet. You can save the file in any of the following formats:

- **Comma Delimited Format** (CDF): Contains one line for each instance of a block, with individual attribute fields separated by commas. Character string fields are enclosed with single quotation marks. You must specify a template file when extracting to a CDF file.
- **Space Delimited Format** (SDF): Contains one line for each instance of a block. Each attribute field has a fixed length; there are no separators or character string delimiters. You must specify a template file when extracting to a SDF file.
- **Drawing Exchange Format** (DXF): Creates a subset of a standard DXF file (a *.dxx file) containing all the information about each block, including the insertion points, rotation angles, and attribute values. No template file is required.

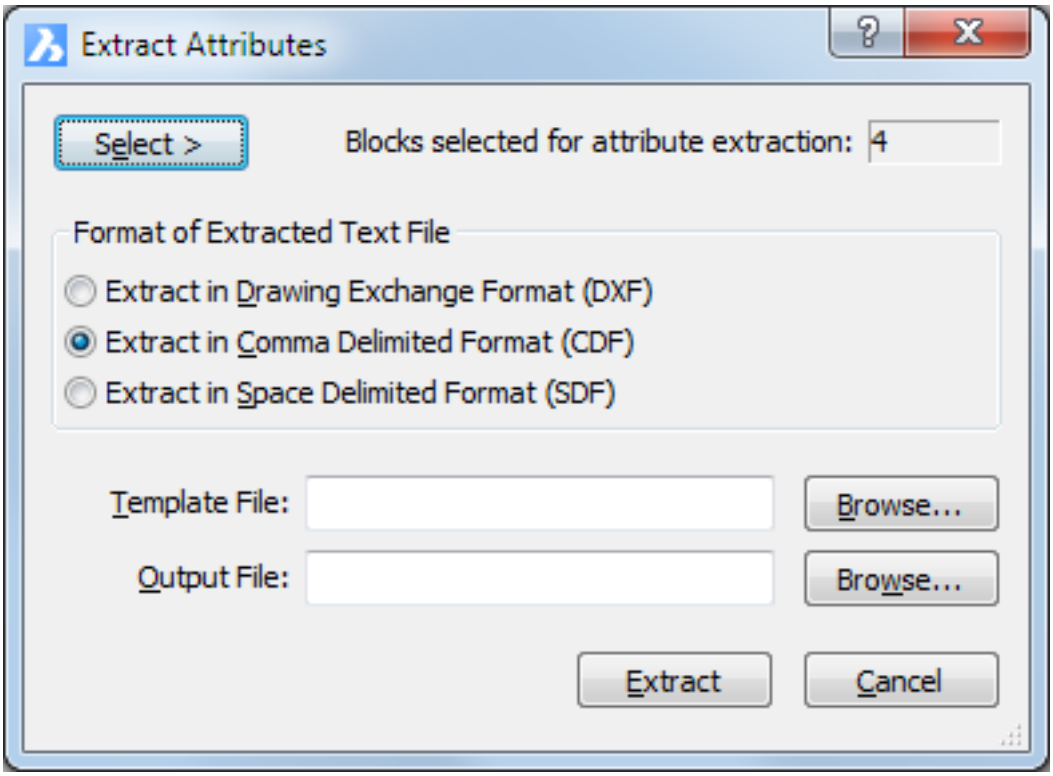
Before extracting attributes to a CDF or SDF file, you must create a template file. The template file is an ASCII text file that specifies the attribute data fields to be written in the extract file. Each line of the template file specifies one attribute field. BricsCAD recognizes 15 different fields, which contain elements such as the block name, the x-, y-, and z-coordinates of its insertion point, the layer on which it is inserted, etc. You can include any of these fields. The template file must include at least one attribute name. Each line in the template file must start with the field name. Block name and insertion-point values must begin with BL:. The next nonblank character must be either a C (indicating a character string field) or an N (indicating a numeric field). This character is then followed by three digits indicating the width of the field (in characters). The final three digits indicate the number of decimal places (for numeric fields). In the case of character fields, the last three digits must be zeros (000). A typical template file is similar to the one shown here: (1.1154) A. Field name B. Field format 1. Block name (must be preceded by **BL:**) 2. Coordinate fields (must be preceded by **BL:**) 3. Attribute tags 4. Indicates the field data type: **C** for character fields, **N** for numeric fields 5. Field width (number of characters) 6. Number of decimal places for numeric fields, **000** for character fields

To extract attribute information

1. Do one of the following:
   - Click the **Extract Attributes** tool button on the Tools toolbar.
   - Choose **Extract Attributes** in the tools menu.
   - Type **attext** in the command bar, then press Enter.

   The Extract Attributes dialog opens. (1.1155 on the facing page)
2. Click the **Select** button. The **Extract Attributes** dialog closes temporarily.

Figure 1.1155



3. Select the blocks, then press Enter or right click. The **Extract Attributes** dialog reopens.
4. Select the text file format: **DXF** (drawing exchange format), **CDF** (comma delimited format) **or SDF** (space delimited format).
5. Select the **Template file** .
6. Specify the **Output file** name.
7. Click the **Extract** button. **You are prompted:** <number> records extracted.

1.30.17 Managing Xrefs

Command: XREF (6.13.23) The Xref command opens the External References section of the Drawing Explorer dialog box. (1.1156) The Drawing Explorer - External References dialog allows to:

- Attach (1.30.19) a drawing as an external reference ( ).
- Detach an external reference ( ).
- Reload an external reference ( ).
- Unload an external reference ( ).
- Bind an external reference ( ).
- Insert an external reference ( ).
- Modify the attachment type: Attach or Overlay.
- Modify the Saved Path of an xref.
- Modify the Found Path of an overlay.

To detach external references

1. Select the xref(s) you want to detach. Press and hold the Ctrl key to select multiple xrefs or to unselect a selected xref.
2. Click the Detach Xref tool button ( ) on the Details toolbar. The selected xref(s) are detached. You are not prompted to confirm the detachment.

To unload external references

Do one of the following:

- Click the Loaded column of a loaded Xref.
- Select the Xref(s), then either click the Unload Xref tool button ( ) on the Details toolbar or click the Loaded column of one of the selected Xrefs.

To reload external references

Do one of the following:

- Click the Loaded column of an unloaded Xref.
- Select the Xref(s), then either click the Reload Xref tool button ( ) on the Details toolbar or click the Loaded column of one of the selected Xrefs.

1.30.18 Editing attribute definitions

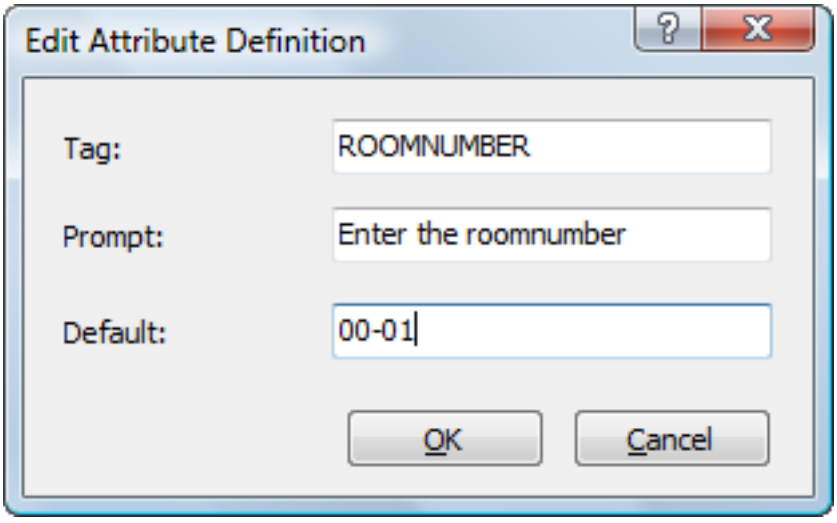
Command: DDEDIT (6.10.13) The **Ddedit** command edits single-line text, multi-line text, attribute definitions, and attribute text (short for "dynamic dialog editor"). You can edit an attribute definition only before it is saved as part of a block definition.

To edit tag, prompt or default text of an attribute

1. Do one of the following:
   - Type **ddedit** in the command bar, then press Enter and select the attribute.
   - Double click the attribute.

   The **Edit attribute definition** dialog opens. (1.1157)
2. (option) Type a new name in the **Tag** field. Lowercase letters are converted to uppercase automatically.
3. (option) Type a new prompt in the **Prompt** field. If you leave the **Prompt** field empty, the attribute **Tag** will be used as the prompt instead.
4. (option) Type a new text in the **Default** field.
5. Press the **OK** button to save your changes.

Figure 1.1157

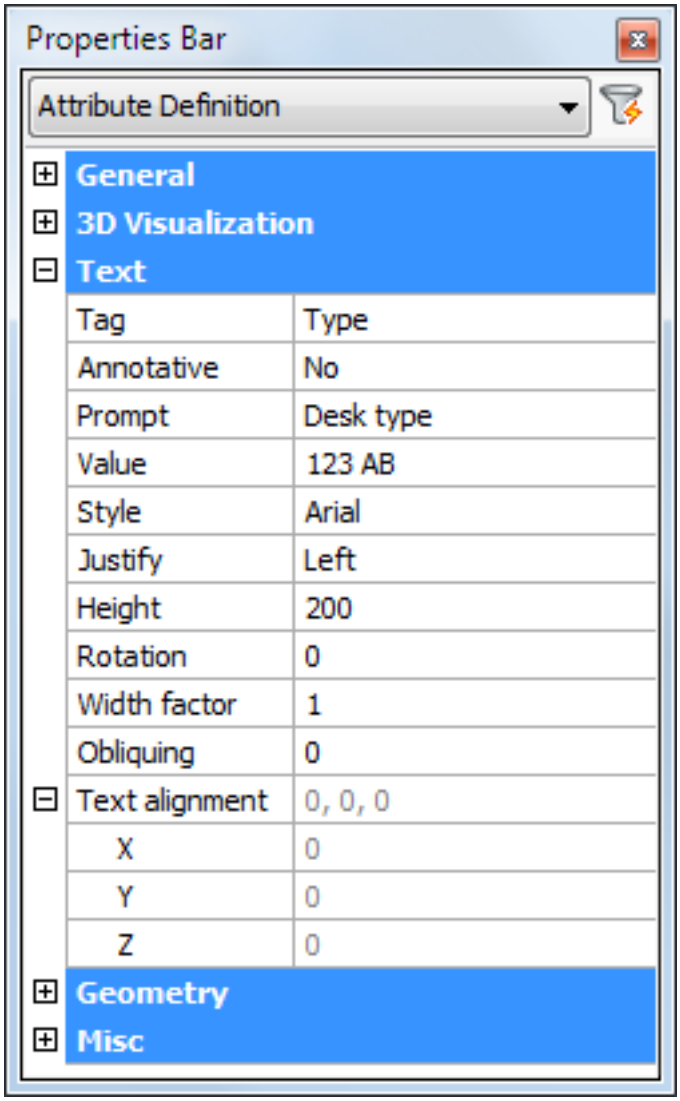


To edit an attribute definition

1. Click the attribute. The attribute properties display in the Properties Bar (1.15.4). (1.1158 on the next page)
2. Modify the attribute properties in the **Properties Bar** fields.
3. Press the Esc key to stop editing.

Note: Make sure the Properties Bar (1.15.4) is open before starting this procedure.

Figure 1.1158



1.30.19 Attaching an external reference

Command: XATTACH (6.34.1) The **Xattach** command attaches a drawing as an external reference (xref). The attached xref appears as an insert in the current drawing. Like blocks, attached xrefs can be nested. The attached drawing is based on the most recently saved version. The origin point used when attaching an external reference is controlled by the **INSBASE** (insertion base point) settings variable. Use the BASE (6.6.2) command to define the **INSBASE** variable in the external reference drawing.

To attach an external reference

1. Do one of the following:
   - Click the **Attach Xref...** tool button () on the Insert toolbar.
   - Choose **Attach Xref...** in the **Insert** menu.
   - Type **xattach** in the command bar, then press Enter.
   - Click the **Attach Xref** tool button () on the Details toolbar on the Drawing Explorer / Xrefs (1.19.2) window.

   The **Attach External Reference** dialog window displays.
2. Select the drawing you want to attach, then press the **Open** button on the Open dialog window. The **Attach External Reference** dialog window opens: (1.1159 on the facing page)
3. The full path to the selected drawing displays in the **Path** field. (option) Select the **Path Type**:
   - (1.1160 on the next page)
   - (1.1161 on the facing page)
   - (1.1162 on the next page)
4. Choose the **External Reference Type**:
   - **Attachment** : If the current drawing is attached as an xref to another drawing, an attachment becomes a nested xref.
   - **Overlay** : An overlay is ignored when the drawing to which it is attached is then attached as an xref to another drawing.
5. Choose whether to specify the **Insertion Point** on screen or in the X-, Y-, Z-fields.
6. Choose whether to specify the **Scale** on screen or in the X-, Y-, Z-fields. Check the **Uniform Scale** option to specify the scale in the X-field.
7. Choose whether to specify the **Rotation** angle on screen or in the **Angle** field.
8. Click the **OK** button to attach the Xref. Depending on the options in steps 5, 6 and 7 you are prompted to specify the insertion point, scale and/or rotation angle.

Note: The **Unit field** under **Block Unit** is set by the INSUNIT (Insertion Units) system variable (1.30.5) in the external reference. The Factor field expresses the relation between the value of the INSUNIT system variable in the xref and the parent drawing.

Figure 1.1159

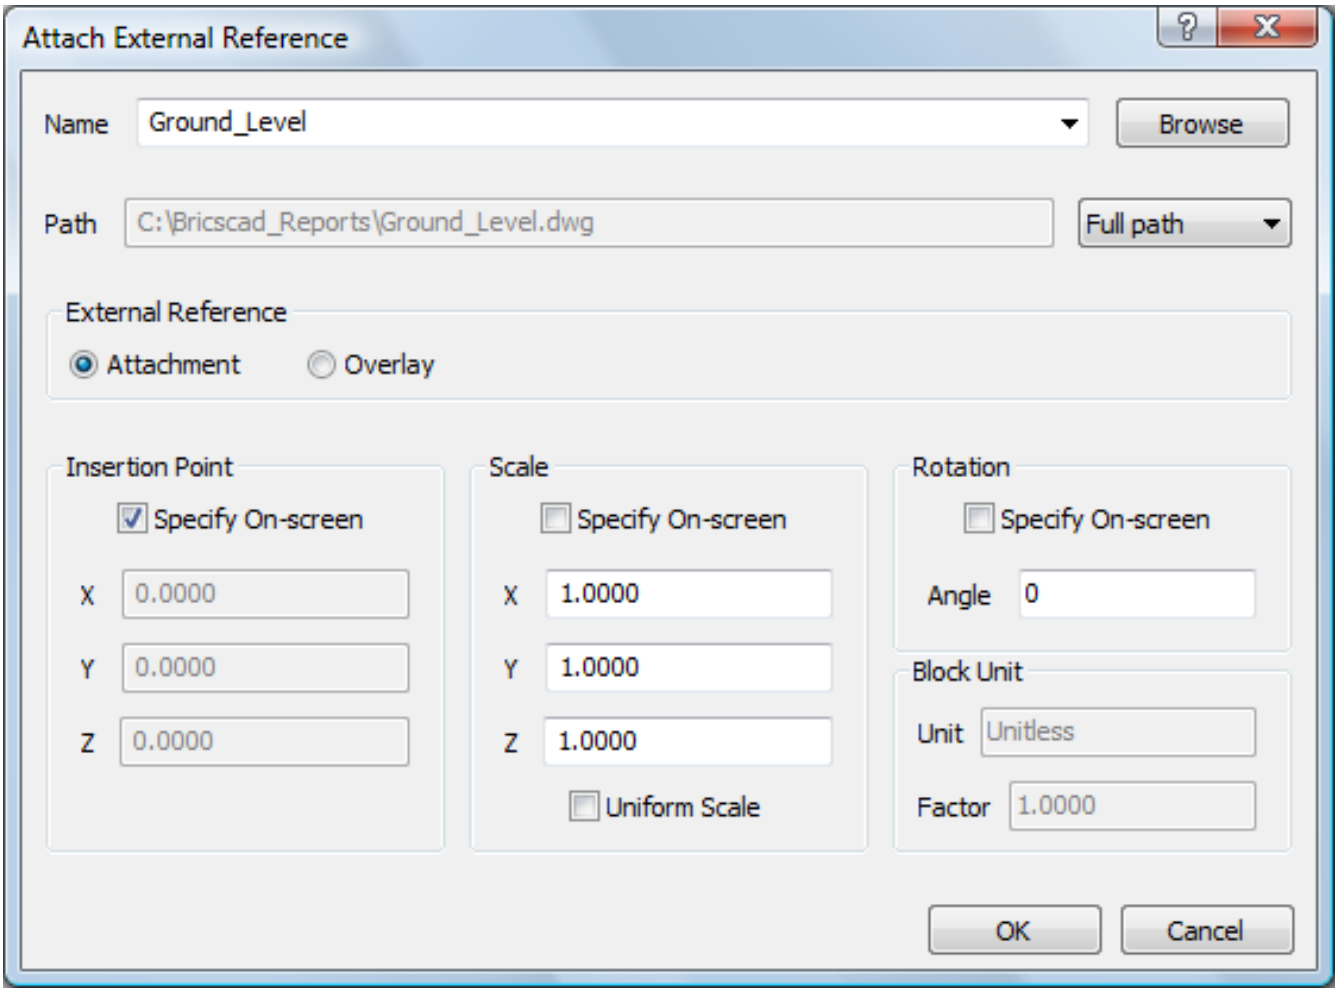


Figure 1.1160

Figure 1.1161

Figure 1.1162

1.30.20 Working with References

Attach Reference Files

BricsCAD allows you to attach externally referenced drawings, images, and pdf files to the current drawing. Easily access the attach tools from the Insert tab on the Quad. You can also access them via other methods including the Command line (XATTACH, IMAGEATTACH, PDFATTACH). (1.1163 on the facing page) You attach reference files in BricsCAD the same way you do in AutoCAD®. First select a valid file type: DWG, Raster image, or PDF. Then, specify attach options in the relevant Attach dialog box. Supported raster images include: BMP, JPG, JPEG, PCX, PNG, GIF, TGA, TIF, TIFF, JP2, J2K, ECW, and SID. (1.1164 on the next page) Note: The dialog boxes do not include preview images. However, when attaching a PDF file, you can select which page to attach from the page list.

Figure 1.1163

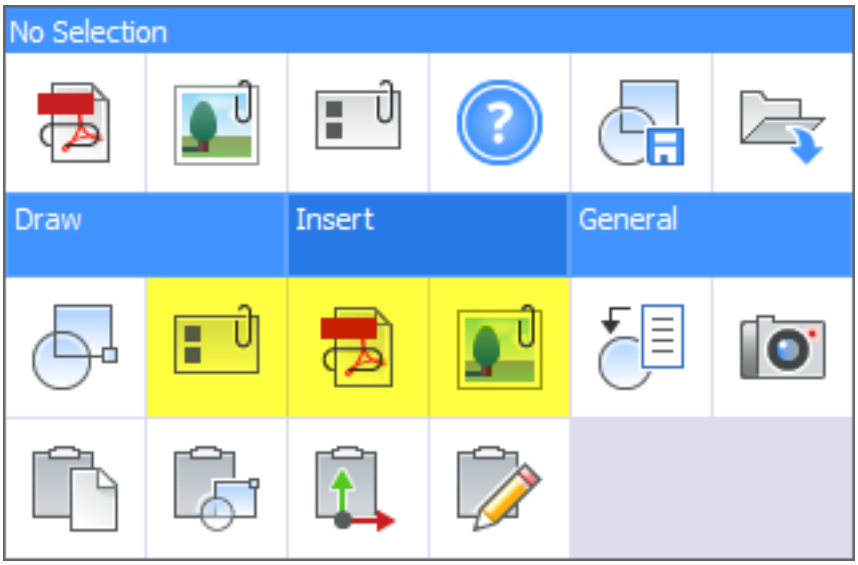

Figure 1.1164

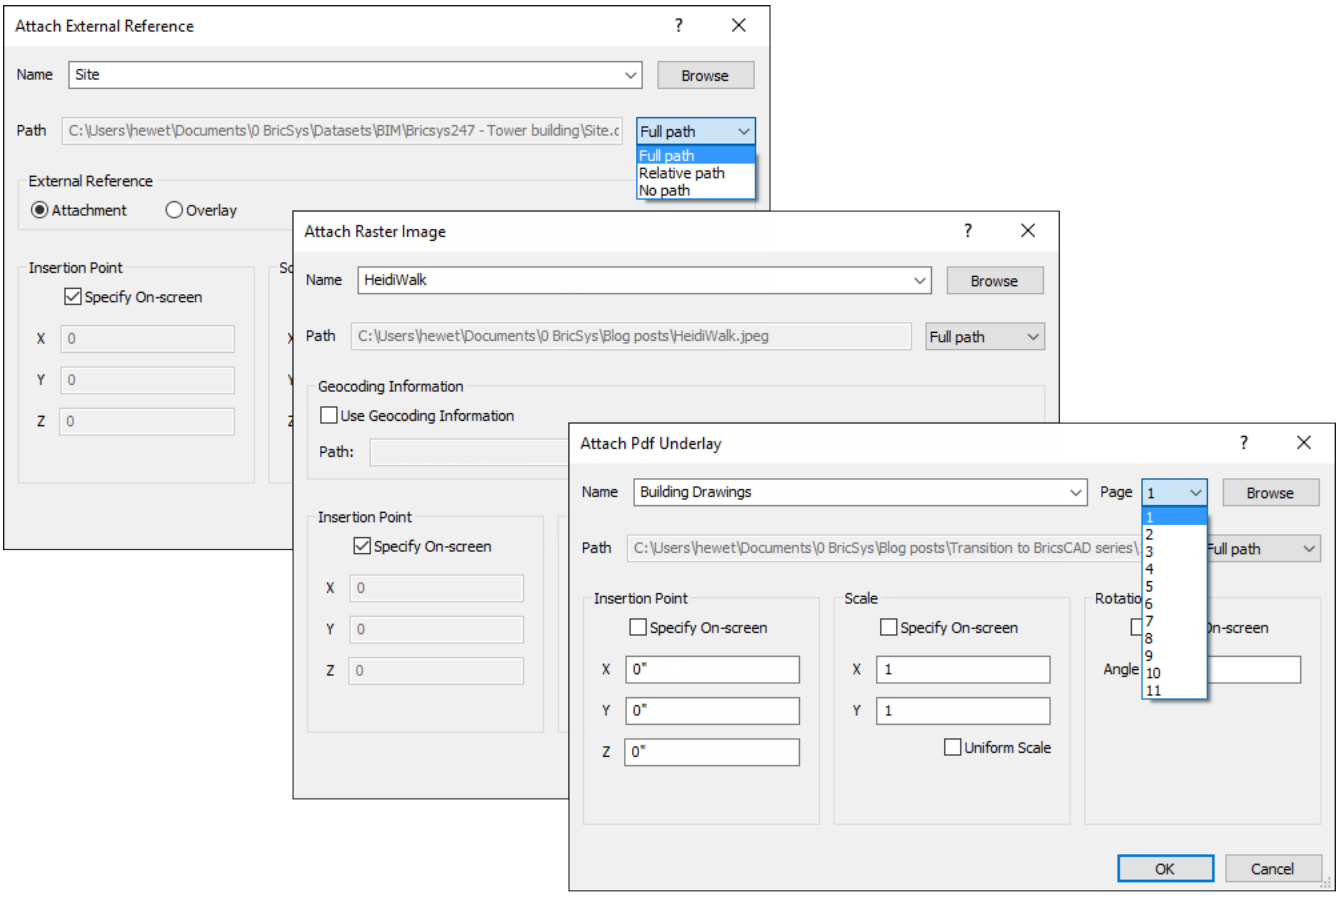
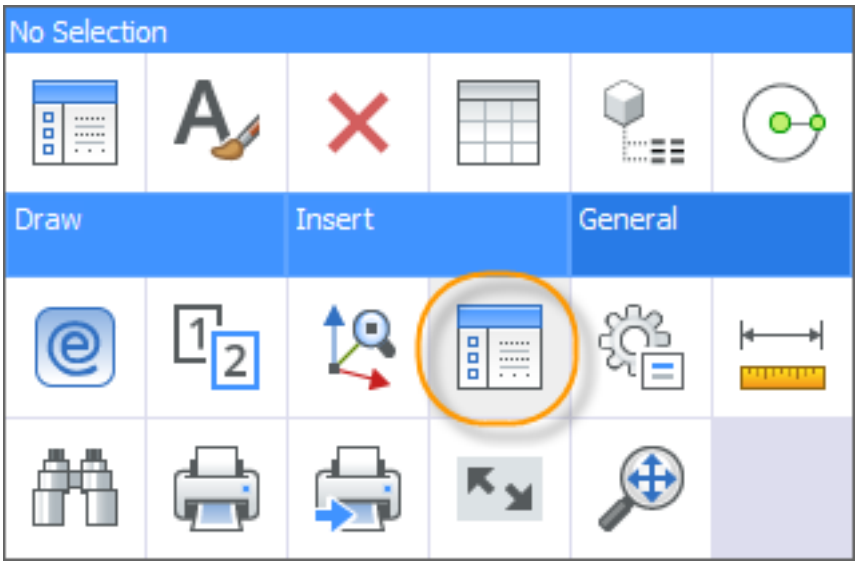


Manage Reference Files in Drawing Explorer

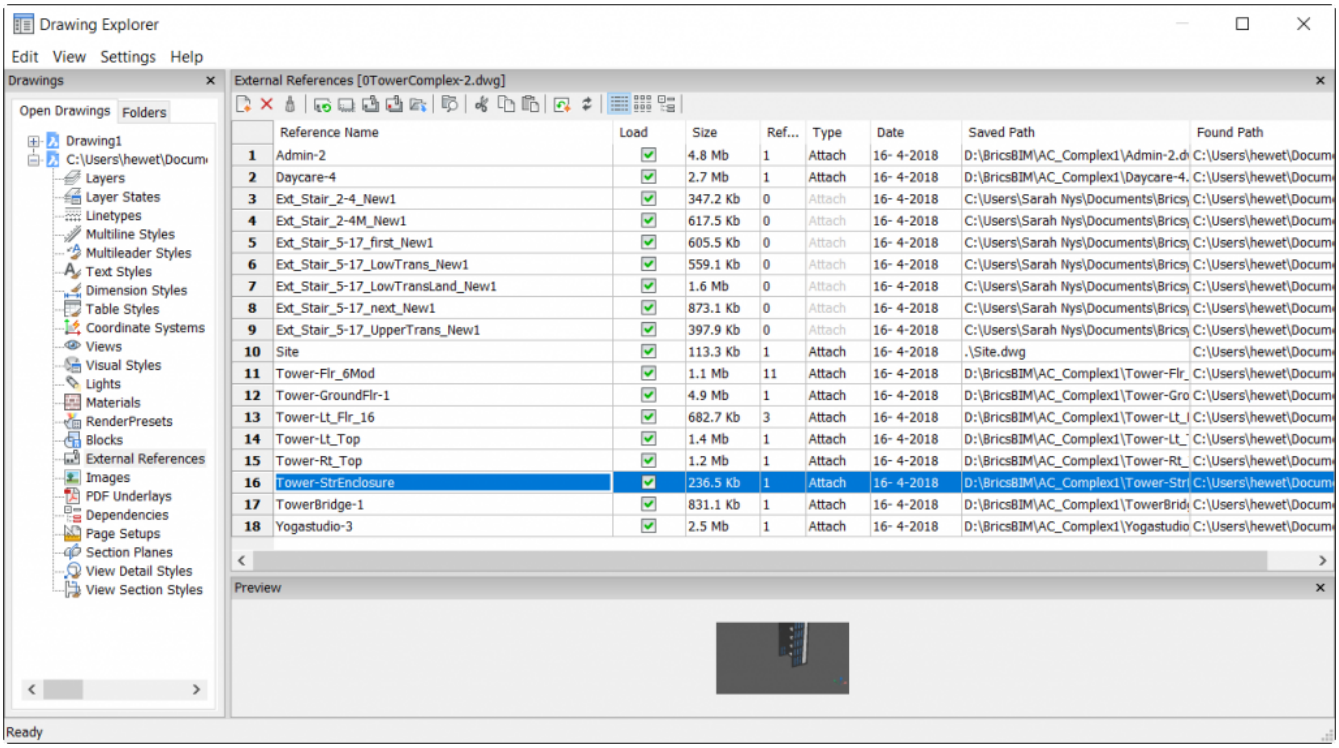
After you attach an external file to the current drawing, BricsCAD creates a reference link to the file. You can view and manage those links like in AutoCAD. However, instead of using an External References palette, you use Drawing Explorer. Access Drawing Explorer from the General menu on the Quad. It's also accessible via other methods including the EXPLORER command. (1.1165 on the facing page) Or, you can use the familiar XREF, IMAGE, or PDF commands. Doing so automatically opens Drawing Explorer with relevant panels displayed for that reference type.

Figure 1.1165



External References The External References panels include detailed information such as the referenced DWG file name and size. Additionally, it displays the number of insertions for each DWG reference. Nested references are clearly indicated by the greyed-out attachment type. (1.1166 on the next page) To help you visualize the individual references and relationships between them, you can change to icon or tree view. The right-click menu and toolbar offer additional controls. You can easily attach new xrefs, detach existing ones, or purge those that are unused. And you can reload, unload, bind, insert, and open attached references. Additional items on the right-click menu make it easy to switch the saved path between relative, absolute, or just the file name. And, on the toolbar, the "Run extended search for missing attachments" tool enables you to easily fix broken reference paths either individually or for multiple references simultaneously.

Figure 1.1166



Images The Images panels display detailed information about the images that are linked to the drawing. The menu and toolbar offer tools similar to Xrefs but specifically relevant for images. (1.1167 on the facing page) When you add images in BricsCAD, you can select and attach multiple images at the same time, unlike in AutoCAD. (1.1168 on the next page)

Figure 1.1167

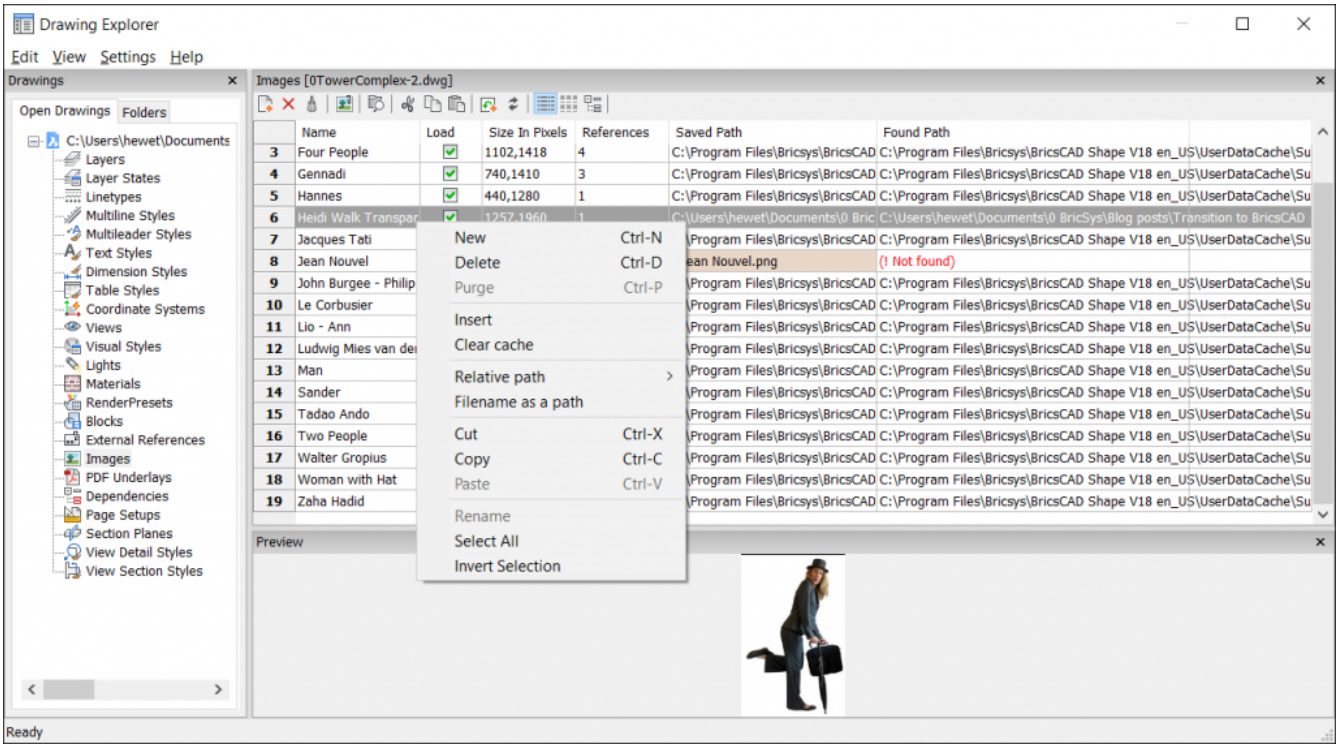


Figure 1.1168

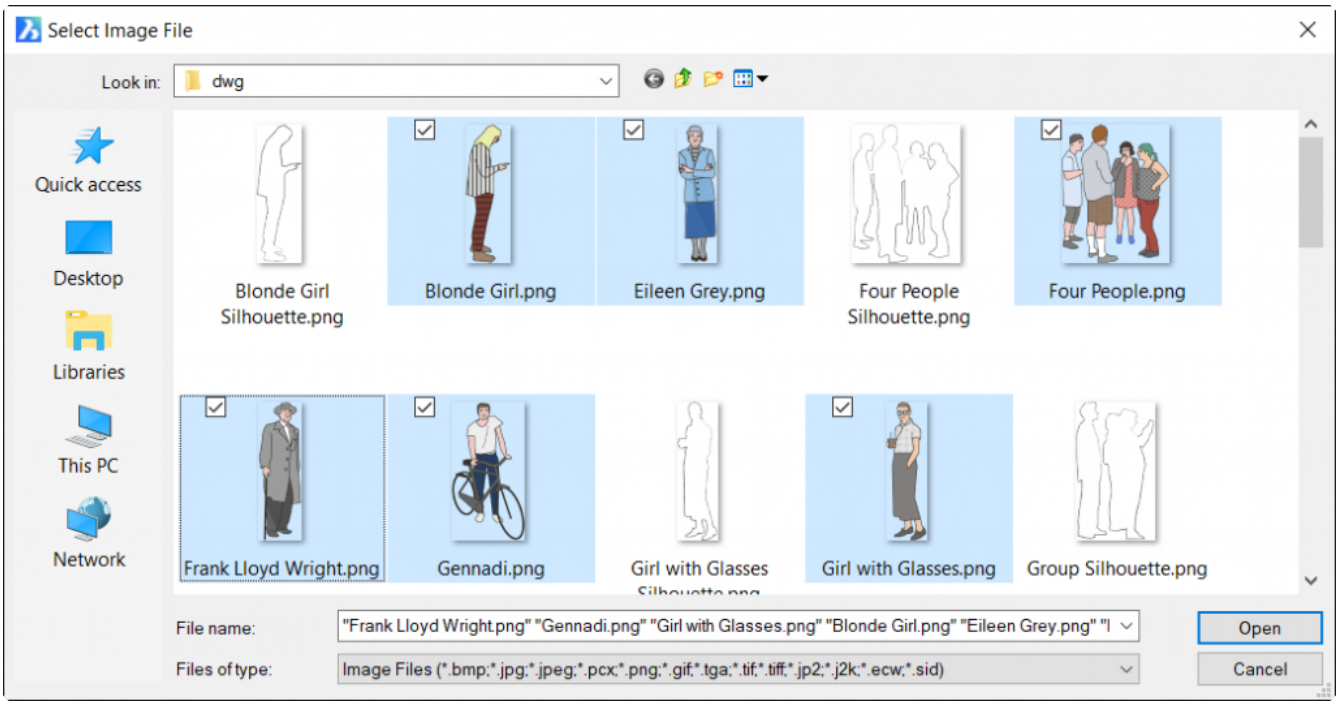
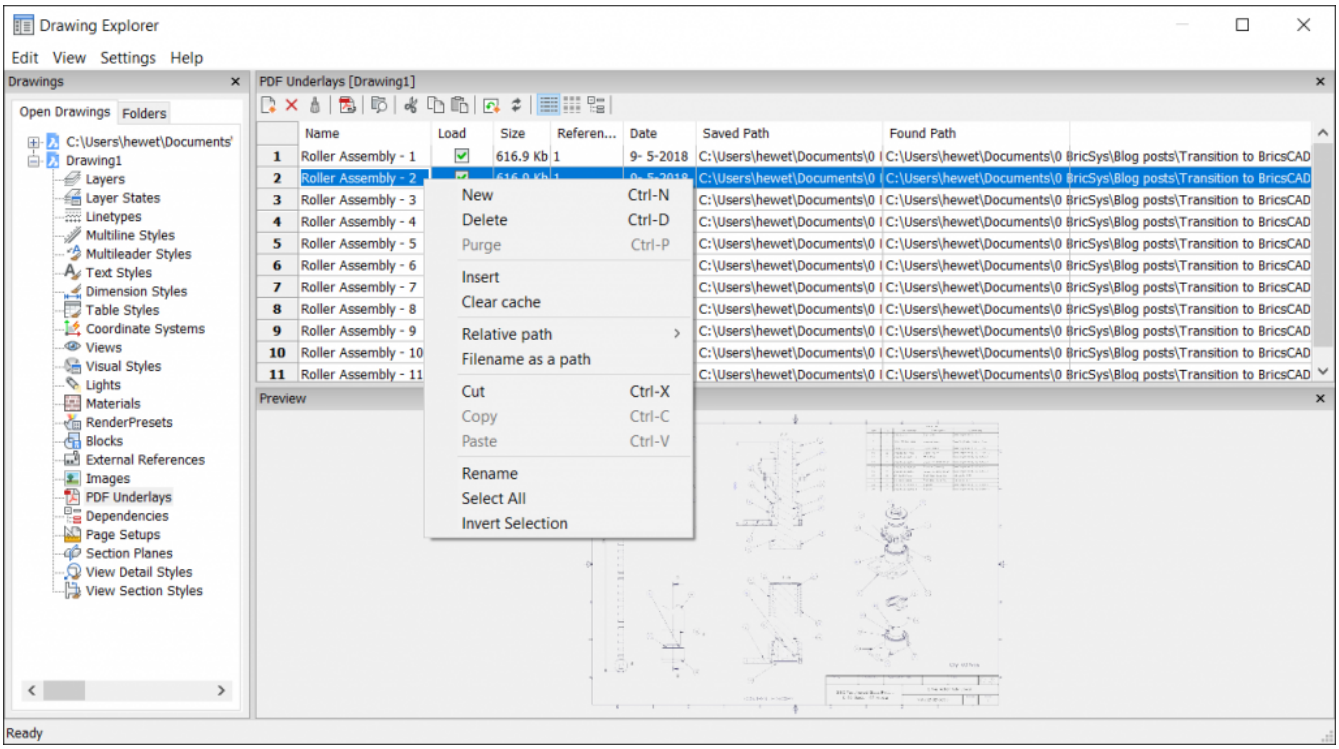


PDF Files The PDF Underlays panels display detailed information about PDF files that are linked to the drawing. The menu and toolbar offer the same tools as for images. (1.1169 on the facing page) Note: The PDFIMPORT (6.24.29) command imports geometry from PDF files and converts the content to simple CAD entities; also converts a PDF underlay already attached to the drawing to CAD entities.

Figure 1.1169



Tutorial: Clipping Attached Images and PDF Files

Click here (1.12.16) to watch

1.30.21 Editing blocks and external references

Commands: REFEDIT (6.26.13), -REFEDIT (6.26.14), REFSET (6.26.16), REFCLOSE (6.26.12), BEDIT (6.6.7), -BEDIT (6.6.8) The **Refedit** command edits block references and externally-referenced drawings (Xrefs) through a dialog box (short for "reference editor"). **Refedit** is referred to as **in-place reference editing** . **RefEdit** either works on a portion of the reference or on the entire drawing or all entities in the block. The **-Refedit** command edits block references and externally-referenced drawings through the command bar. The **Refset** command adds and removes entities from the reference being edited. The **Refclose** command closes the reference editor. The **Bedit** command edits the entities that make up blocks in a temporary drawing session called the Block Editor, which uses the local coordinate system of the block. The **-Bedit** command prompts for the name of a name at the command line, and then opens the Block Editor environment The **XFADECTL** system variable sets the fading level for the entities which are not in the working in the current refedit session. Values between 0 (no fading) and 90 are accepted.

To edit Xrefs or blocks

1. Do one of the following:

   - Click the **Refedit** tool button () on the Refedit toolbar.
   - Type **refedit** in the command bar, then press Enter.
   - You are prompted: Select reference: Click the Xref or block.
   - Double click the Xref or block.

   The Reference Edit dialog opens. (1.1170 on the next page)

2. The **Reference Edit** dialog helps you to visually identify the reference to edit and controls how the reference is selected.
   - **Path** : Location of the selected reference; if the reference is a block, no path is displayed.
   - **Reference Name** : The name of the currently selected reference and any references, that are nested within the selected reference.
   - **Preview** : Displays the reference as it was last saved in the drawing. Please note that the preview image is not updated when changes are saved back to the reference.

3. (option) If multiple nested references display in the **Reference name** tree, select a reference to modify. Click the expand/collapse button to show/hide nested references. You can edit only one reference a time.

4. Select one of the following to **Select nested entities ...** :

   - **Automatically** : All the entities and nested blocks in the selected reference are included in the reference editing session.
   - **Prompt** : After you close the **Reference Edit** dialog, you are prompted to select the enties and nested blocks in the reference that you want to edit. Only these entities will be temporarily extracted and be made available for modification within the context of the current drawing.

   This temporary working set of entities can be edited and then saved back to update the reference being edited. To distinguish 'current drawing' from 'editing set' BricsCAD displays all the entities of the current drawing as faded. The fading level is controlled through the **XFADECTL** settings variable, of which the default value is set to **50**.

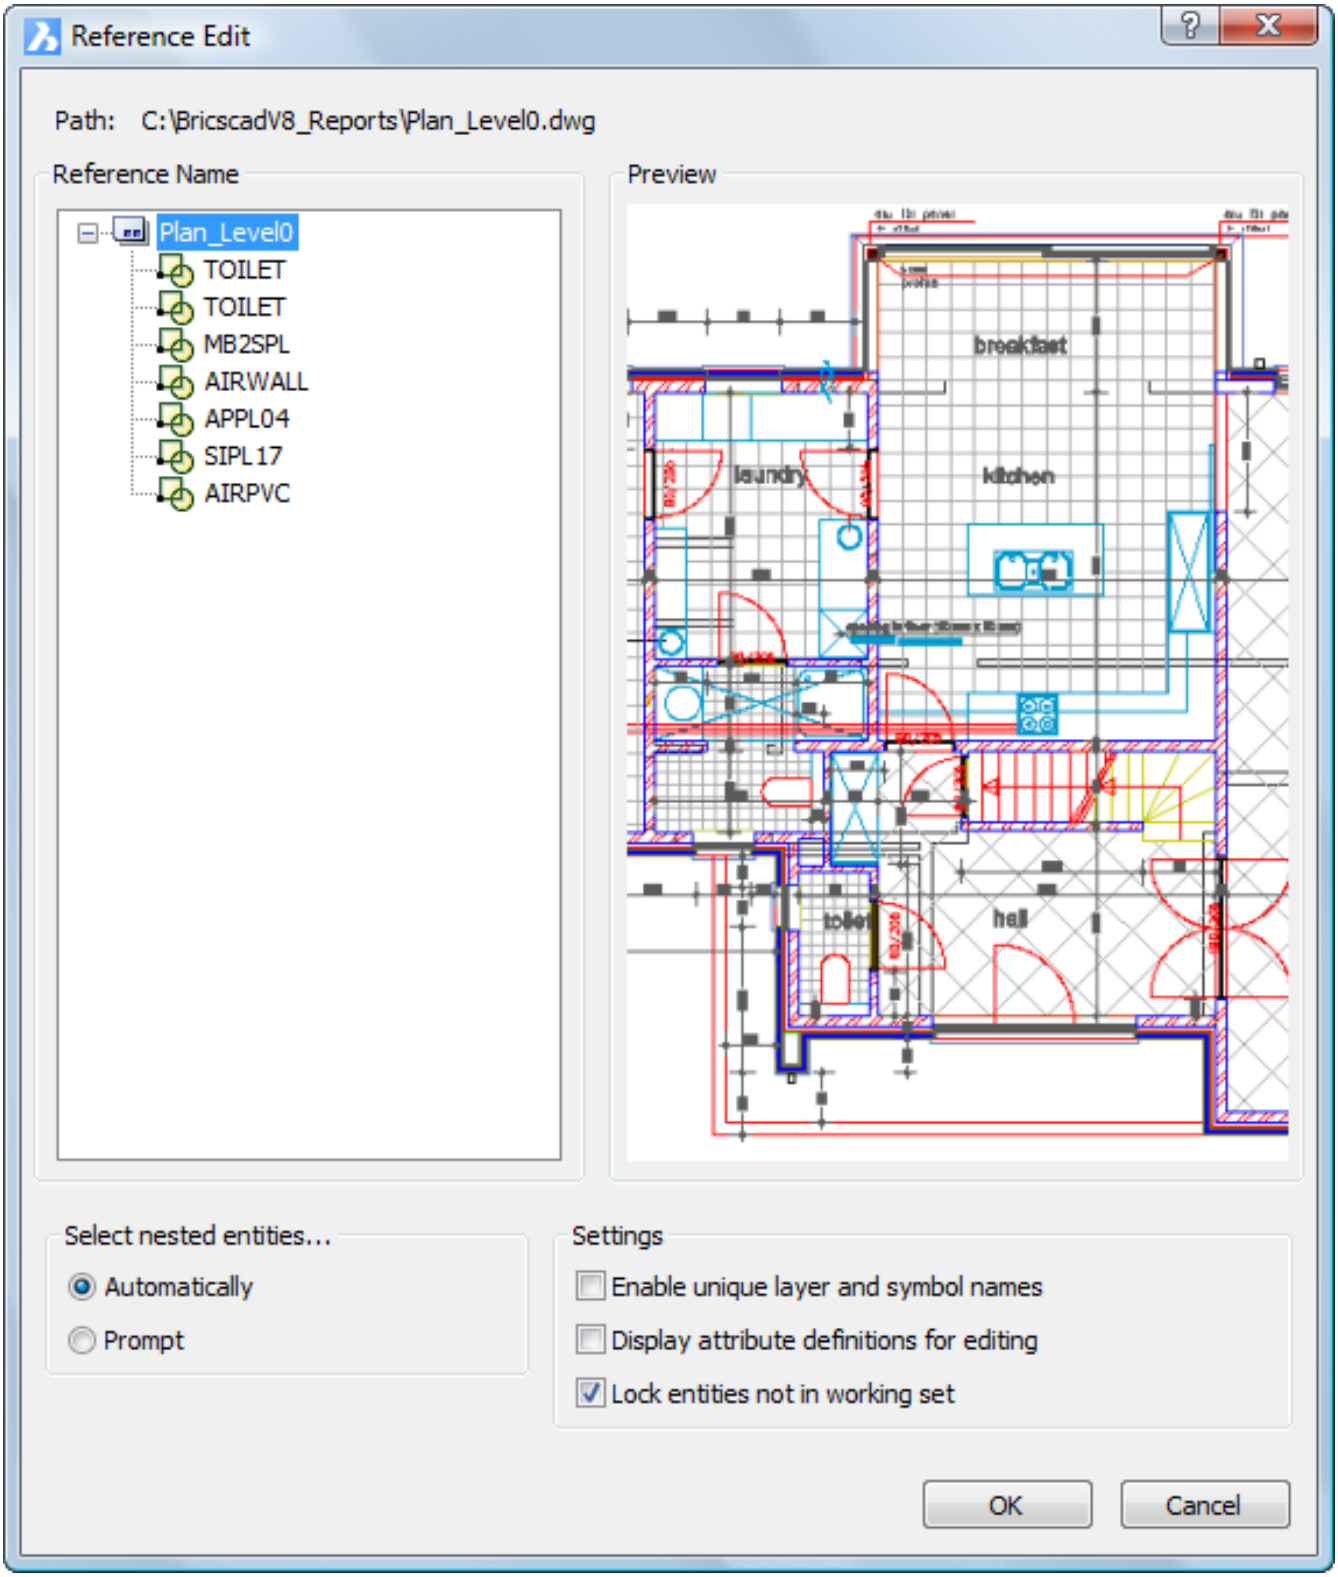
5. Check the **Settings**:

   - **Enable unique layer and symbol names** :
     - If selected, named objects in xrefs are altered, adding a **$#$** prefix.
     - If cleared, the names of layers and other named objects remain the same as in the reference drawing.
   - **Display attribute definitions for editing**: Controls whether attribute definitions in blocks are extracted and displayed during reference editing.
   - **Lock entities not in working set** : Entities in the reference being edited that are not included in the temporary working set (see step 5) cannot be manipulated, nor entities in the host drawing or other Xrefs. This behavior is similar to objects on locked layers.

6. Click the **OK** button to start editing the working set (see step 5). The Reference Edit dialog closes.

7. (option) Click the **Add to Refedit** tool button () to add entities to the working set. The selected entities will be removed from the host drawing and added to the reference being edited when the working set is saved back.

Figure 1.1170



8. (option) Click the **Remove from Refedit** tool button () to remove entities from the working set. The selected entities will be removed from the reference being edited when the working set is saved back. These entities are added to the host drawing.

9. Do one of the following:

   - Click the **Refclose and Save** button () to save the changes back to the Xref source drawing or the block definition in the current drawing.
   - Click the **Refclose and discard** button () to stop the refedit session without saving. The source drawing or block definition is left unchanged.

1.30.22 Working with groups

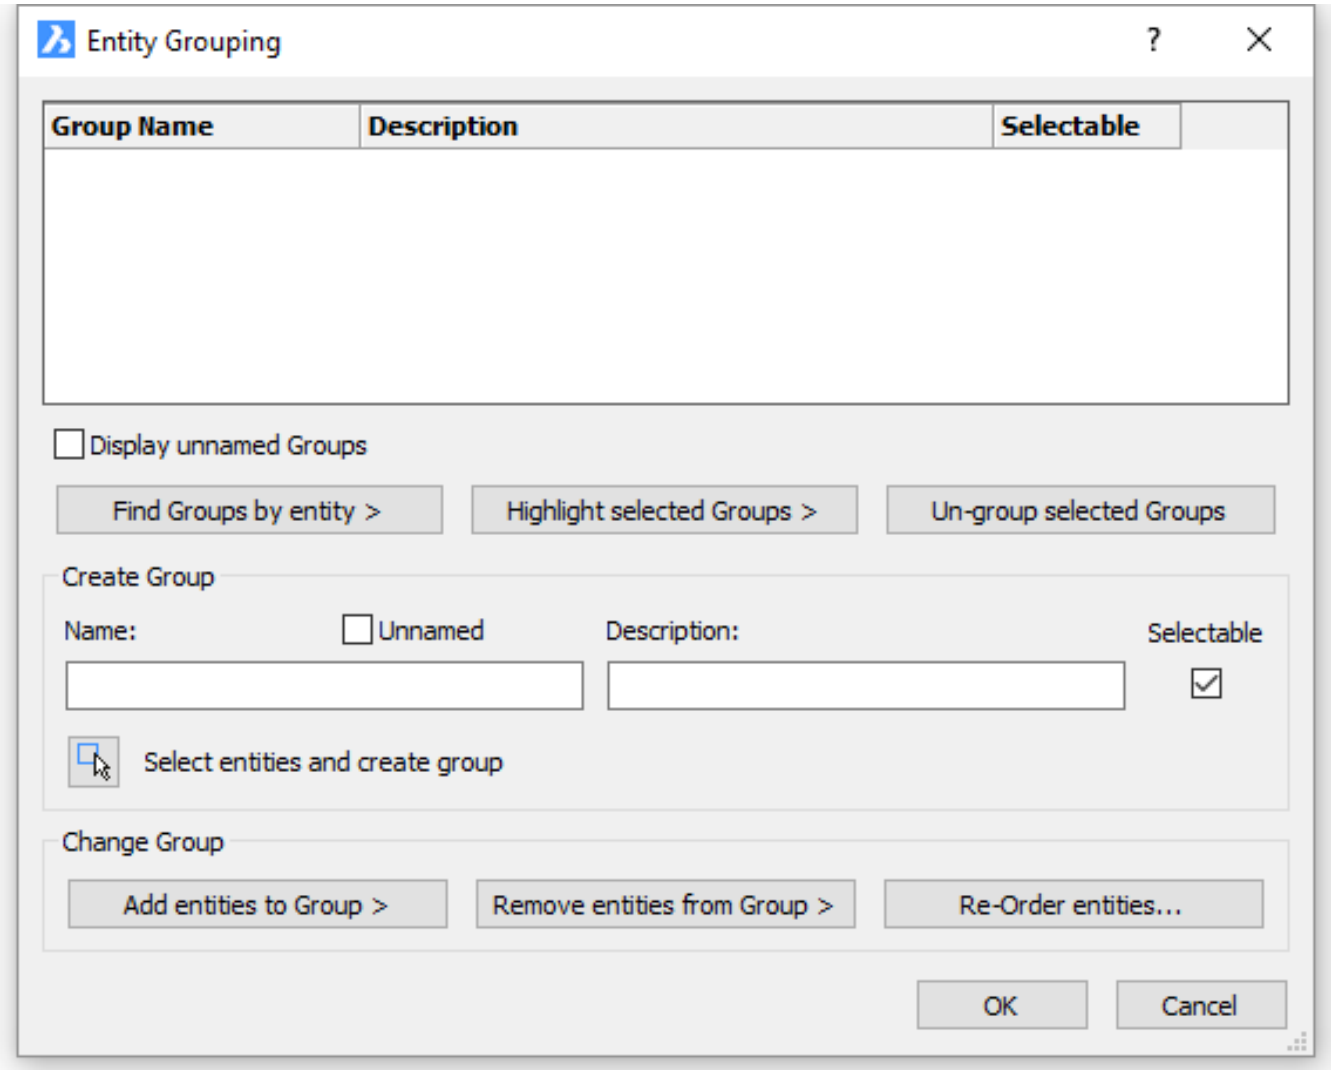
Commands: GROUP (6.15.26) and -GROUP a (6.15.27) The **Group** command creates and modifies named groups of entities, in a dialog box. The **-Group** command creates and modifies named groups of entities, at the command line. Working with groups is a technique to manipulate a set of several objects as though it were a single object. A group can also be considered as a 'Named Selection'. You can pick a single object and the entire set is selected as though it were a block, or you can edit individual objects without affecting the rest of the group and without breaking up the group. You can use nested groups if necessary and a single entity can be a member of different groups. **Note:** Make sure the value of the **PICKSTYLE** variable is set to either 1 or 3 to enable the selection of groups.

To create a group

1. Do one of the following:
   - Click the **Group** tool button ( ) on the Tools toolbar.
   - Choose **Group** in the **Tools** menu.
   - Type **group** in the command bar, then press Enter.

   The **Entity Grouping** dialog window opens: (1.1171 on the following page)
2. Do one of the following:
   - Type a name in the **Name** field.
   - Check the **Unnamed** option to create an unnamed group.
3. (option) Type a description in the **Description** field.
4. (option) Check / uncheck the **Selectable** option.
5. Click the **Select entities and create group** button. The **Entity Grouping** dialog temporarily closes to let you select entities.
6. Select the entities (1.32.7) you want to include in the new group.
7. Right click to conclude the selection of entities. The **Entity Grouping** dialog reopens. The newly created group is added.
8. Click the **OK** button to close the Entity Grouping dialog

Figure 1.1171



To modify a group

1. Do one of the following:

   - Click the **Group** tool button ( ) on the Tools toolbar.
   - Choose **Group** in the Tools menu.
   - Type **group** in the command bar, then press Enter.

   The **Entity Grouping** dialog window opens.

2. Select the group you want to modify.
3. (option) Double click in the **Name** field to edit the group name.
4. (option) Double click in the **Description** field to edit the group description.
5. (option) Click in the **Selectable** column to toggle the **Selectable** option on/off.
6. (option) Click the **Add entities to group** button to add new entities to the group. The **Entity Grouping** dialog temporarily closes to let you select the new group entities.
7. (option) Click the **Remove entities from group** button to remove entities from the group. The Entity Grouping dialog temporarily closes to let you select the entities.
8. Click the **OK** button to close the Entity Grouping dialog

To ungroup entities

1. Do one of the following:

   - Click the **Group** tool button ( ) on the Tools toolbar.
   - Choose **Group** in the Tools menu.
   - Type **group** in the command bar, then press Enter.

   The Entity Grouping dialog window opens.

2. Select the group or groups you want to delete.
3. Click the Un-group selected groups button. The selected groups are removed.

Note: When you ungroup entities, the entities remain in the drawing but the group is deleted from the drawing.

To change the order of entities

1. Do one of the following:

   - Click the **Group** tool button ( ) on the Tools toolbar.
   - Choose **Group** in the Tools menu.
   - Type **group** in the command bar, then press Enter.

   The **Entity Grouping** dialog window opens.

2. Click the **Re-Order entities** button. The Order Group dialog opens: (1.1172 on the next page)
3. (option) Click the **Highlight** button to see the current position of each entity. The **Object Grouping box** opens. (1.1173 on the following page)
4. (option) Click the **Reverse Order** button to reverse the order of all entities in the group.
5. (option) To change the order of a single entity do the following:
   - In the **Remove from position** field type the current position of the entity you want to move.
   - In the **Enter new position number for the object** field type the new position.
   - (option) Type the number of objects you want to reorder in the **Number of objects** field.
6. Click the **Re-Order** button. A message box displays. (1.1174 on page 1287)

Figure 1.1172

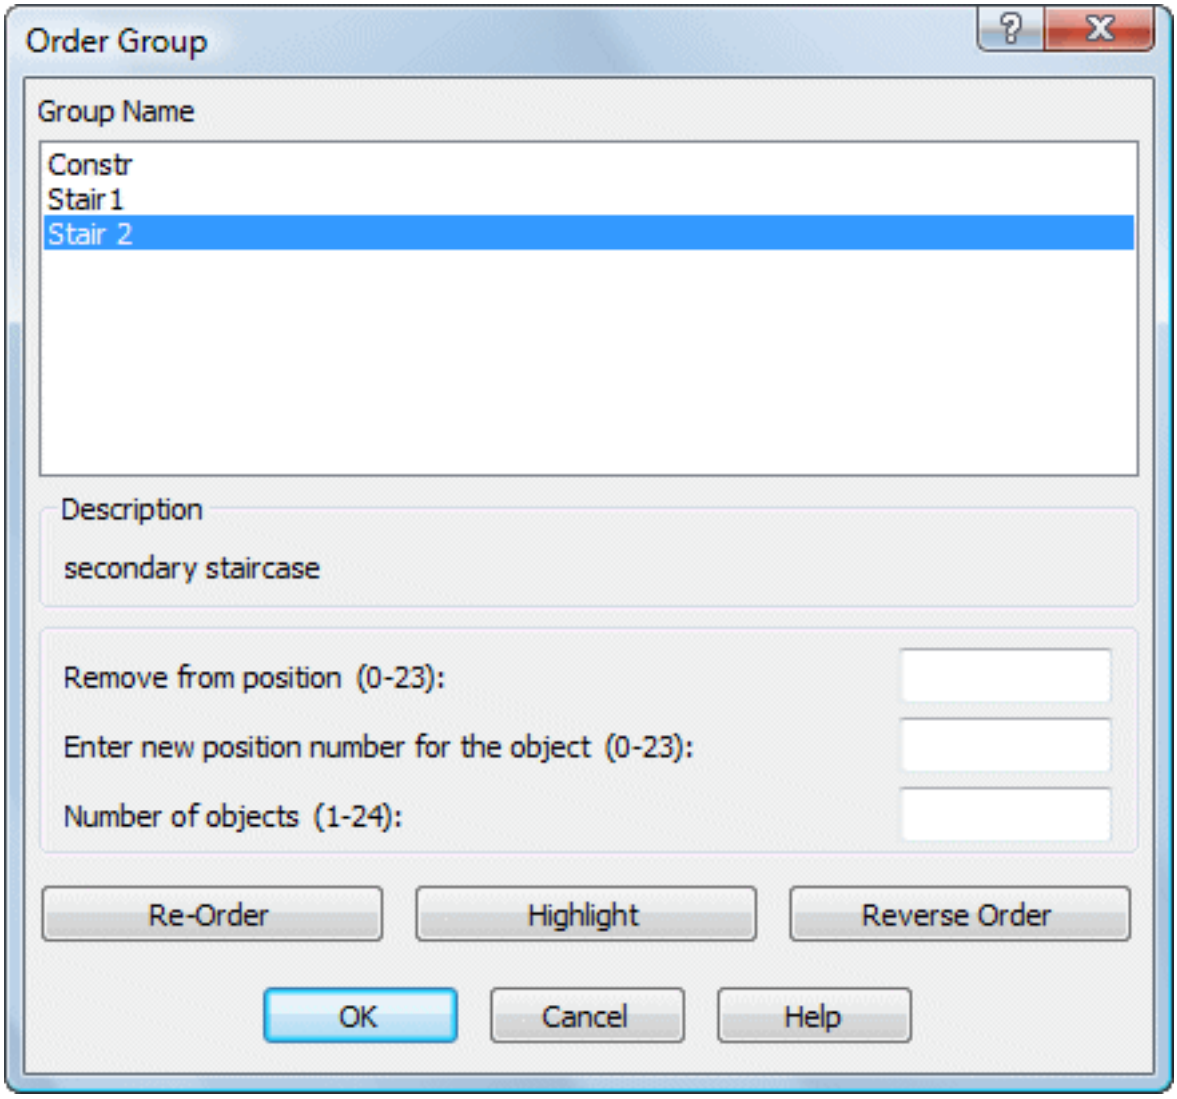


Figure 1.1173

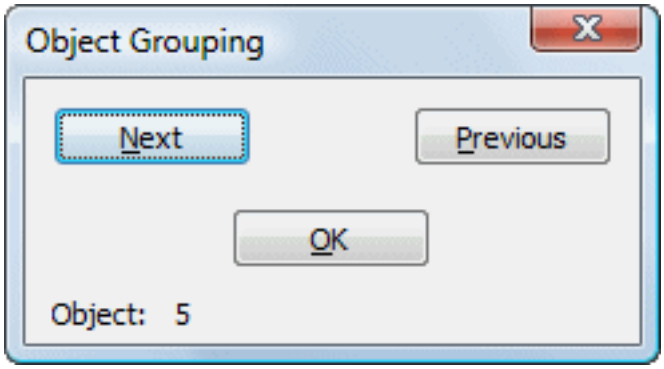

Figure 1.1174

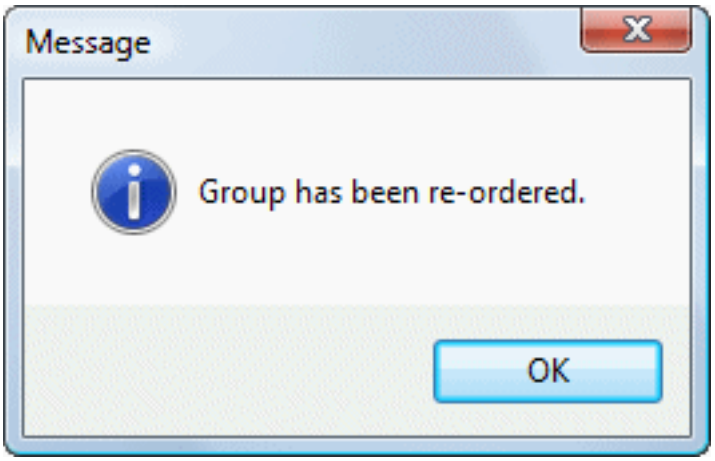


1.30.23 Working with underlays

Commands: PDFADJUST (6.24.17), PDFATTACH (6.24.16), -PDFATTACH (6.24.18), PDFLAYERS (6.24.22), PDFCLIP (6.24.19) PDF files can be attached as an underlay to a drawing file. Much like raster image files and external references (Xrefs) a PDF underlay is not part of the drawing, but is linked to it. In the parent drawing the path to the underlay is saved. You can edit the path to make sure the correct PDF is found. By default the folder of the parent drawing is search first. If the PDF underlay is not found there, the saved path folder is searched. If the PDF underlay is not found there either, BricsCAD reports a 'Missing or invalid reference' in the drawing. The **PdfAdjust** command allows to adjust the fade, contrast and monochrome settings of a PDF-underlay in the command bar. The **PdfAttach** and **-PdfAttach** commands insert a PDF file as an underlay into the current drawing. The **PdfLayers** commandaAllows to control the display of layers in a PDF underlay. The **PdfClip** command crops the display of a PDF. You can choose between a polygonal or a rectangular boundary. Each instance of the same PDF underlay file can have a different boundary.. The **PDFOSNAP** system variable allows to snap to the geometry in the PDF underlay if the system variable is On. The **PDFNOTIFY** system variable controls whether warnings for missing or modified pdf underlays are issued. The **XNOTIFYTIME** system variable defines the frequency to check for modified externally referenced resources: xrefs, images and pdf attachments if **XREFNOTIFY, IMAGENOTIFY** and/or **PDFNOTIFY** is ON. If the value of the **Frame** system variable = 3, the **PDFFRAME** system variable controls the visibility of PDF frames. The options are:

- 0: Hide PDF frames.
- 1: Display and plot PDF frames.
- 2: Display but do not plot PDF frames.

To control the PDF underlay caching

A multi-resolution persistent image cache is used to display attached Pdf underlays, enabling (very) fast zoom and pan operations. The highest cached resolution is 5000 x 5000 pixels. Still, when zooming in very close, the display of the Pdf underlay will become pixelated. So a hybrid modus can be used which switches to real-time generation of crisp Pdf underlay display when zooming in very close. The initial generation of the image cache may take a few seconds, from then on processing gets (very) fast, and remains like that in subsequent sessions. PDFCACHE (1.17.10): System variable that controls how pdf caching is applied

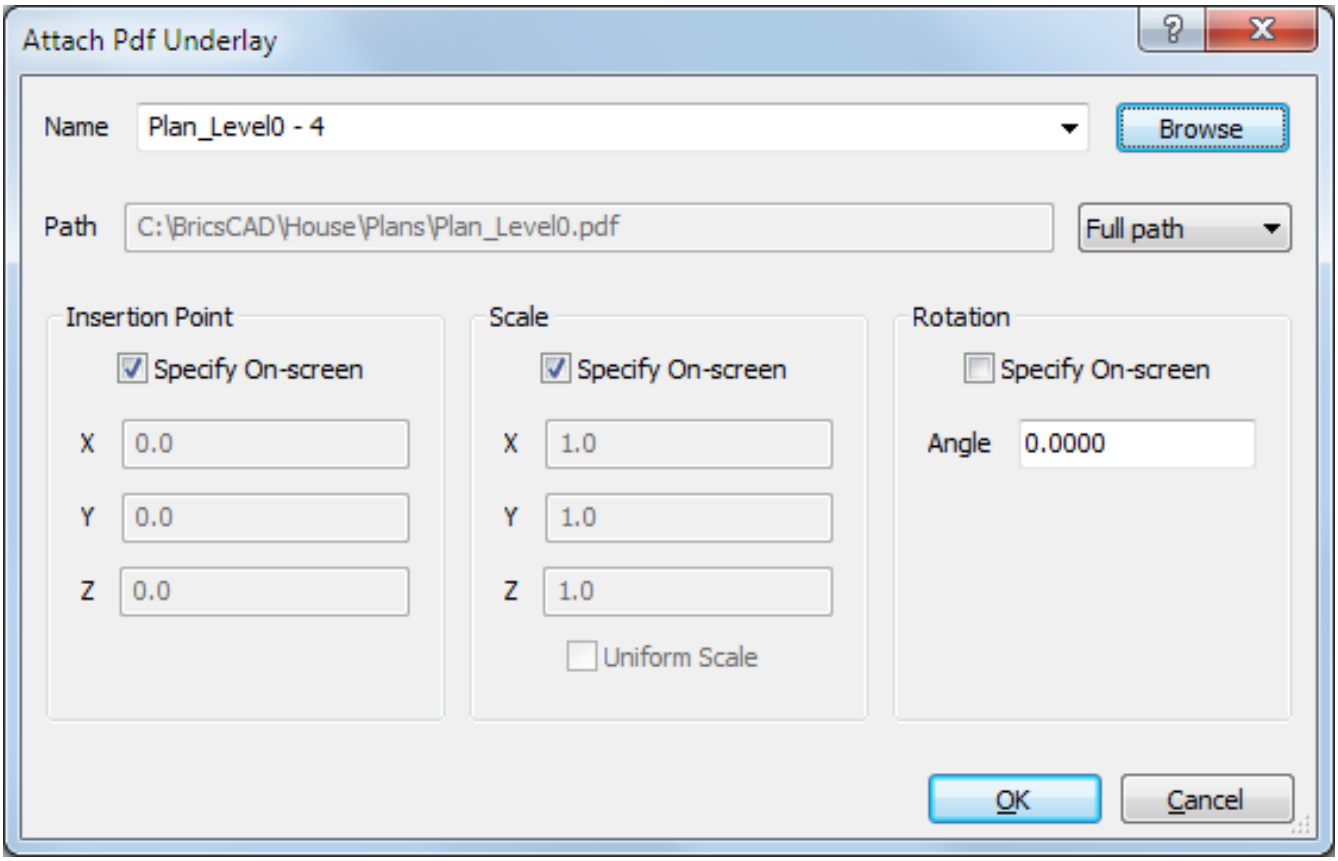
- 0 = don't use Pdf cache, always use real-time generation of the Pdf underlay image. (this mode was the default in previous BricsCAD versions)
- 1 = use Pdf cache, switch to real-time generation when zooming in very close.
- 2 = always use Pdf cache (default).

To attach a PDF underlay

1. Do one of the following:
   - Click the **Attach pdf** tool button ( ) on the Insert toolbar.
   - Click the **New** tool button ( ) on the Details toolbar of the Drawing Explorer - PDF Underlays (1.19.2) dialog.
   - Type **PDFattach** in the command bar, then press Enter.

   The Select PDF Underlay File dialog opens.
2. Select the file, then double click the file or click the **Open** button on the Select PDF Underlay File dialog. The Attach PDF Underlay dialog opens. (1.1175 on the facing page)
3. In case of a multi-page PDF, click the down arrow in the **Name** field, then select the page of the PDF you want to load.
4. Click the **Path** option button, then select either:
   - **Full path**: The full path will be searched when the drawing is loaded. If the overlay is not found there, the folder of the parent drawing is searched. If the overlay file is not found there either, "Missing or invalid reference" displays at the insertion point of the PDF overlay.
   - **Relative path**: The relative path, with respect to the folder of the parent drawing, will be searched when the drawing is loaded. If the overlay is not found there, the folder of the parent drawing is searched. If the overlay file is not found there either, "Missing or invalid reference" displays at the insertion point of the PDF overlay.

Figure 1.1175



- **No path**: Only the folder of the parent drawing is searched when the drawing is loaded. If the overlay file is not found there, "Missing or invalid reference" displays at the insertion point of the PDF overlay.

5. Choose whether you want to specify the **Insertion Point** , **Scale** and the **Rotation** angle on-screen or not.
6. Click the **OK** button. The Attach PDF Underlay dialog closes.
7. Depending on the insertion options chosen in the previous step you are prompted to specify the **Insertion Point**, **Scale** and/or **Rotation** angle.

To insert a PDF underlay

If you want to insert a second instance of a PDF that is already attached or another page of such underlay do the following:

1. Choose **Drawing Explorer > PDF Underlays...** in the Tools menu. The Drawing Explorer - PDF Underlays dialog opens.
2. Select the PDF underlay.
3. Do one of the following:

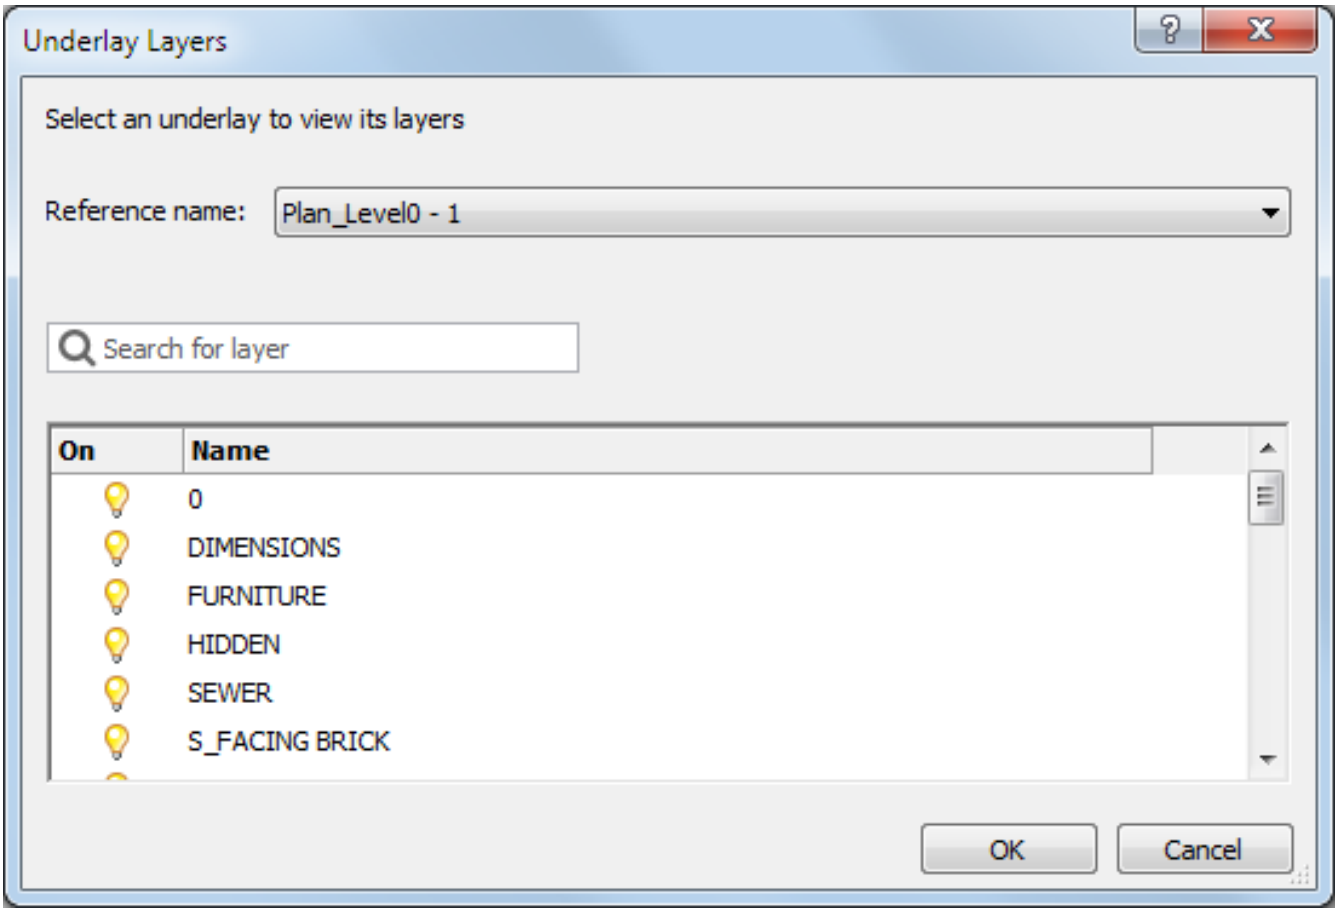
   - Right click and choose Insert in the context menu.
   - Choose insert in the Edit menu on the Drawing Explorer - PDF Underlays dialog.

   The Drawing Explorer - PDF Underlays dialog closes.
4. Continue with steps 3 through 7 of the previous procedure.

To control the display of a PDF underlay

1. Click the frame of the PDF underlay. The frame of the selected PDF highlights. The properties of the underlay display in the Properties Bar (1.15.4).
2. Under **Misc** , click **Show underlay** in the Properties Bar, then select **Yes** or **No**.

Figure 1.1176



To set the layer display in a PDF underlay

1. Type **PDFlayers** in the command bar, then press Enter. You are prompted: Select PDF underlay.
2. Click the frame of the PDF underlay. The frame of the selected PDF highlights. The Underlay Layers dialog opens. (1.1176) The icon in the **On** column indicates the current state of the layers On ( ) or Off ( ).
3. Click the icon in the **On** column to toggle the display of a layer.
4. (option) Click the **Search for layer** field, then type a layer name to search for a layer. Use wildcard characters (? or *) to limit the number of layers in the list: (1.1179 on page 1293) Layernames starting with 'S_' only. (1.1178 on the next page) Layernames of which the second and third character is '_F' only.
5. Do one of the following:
   - Click the **Reference name** button to select another PDF underlay.
   - Click the **OK** button to stop.

Figure 1.1177

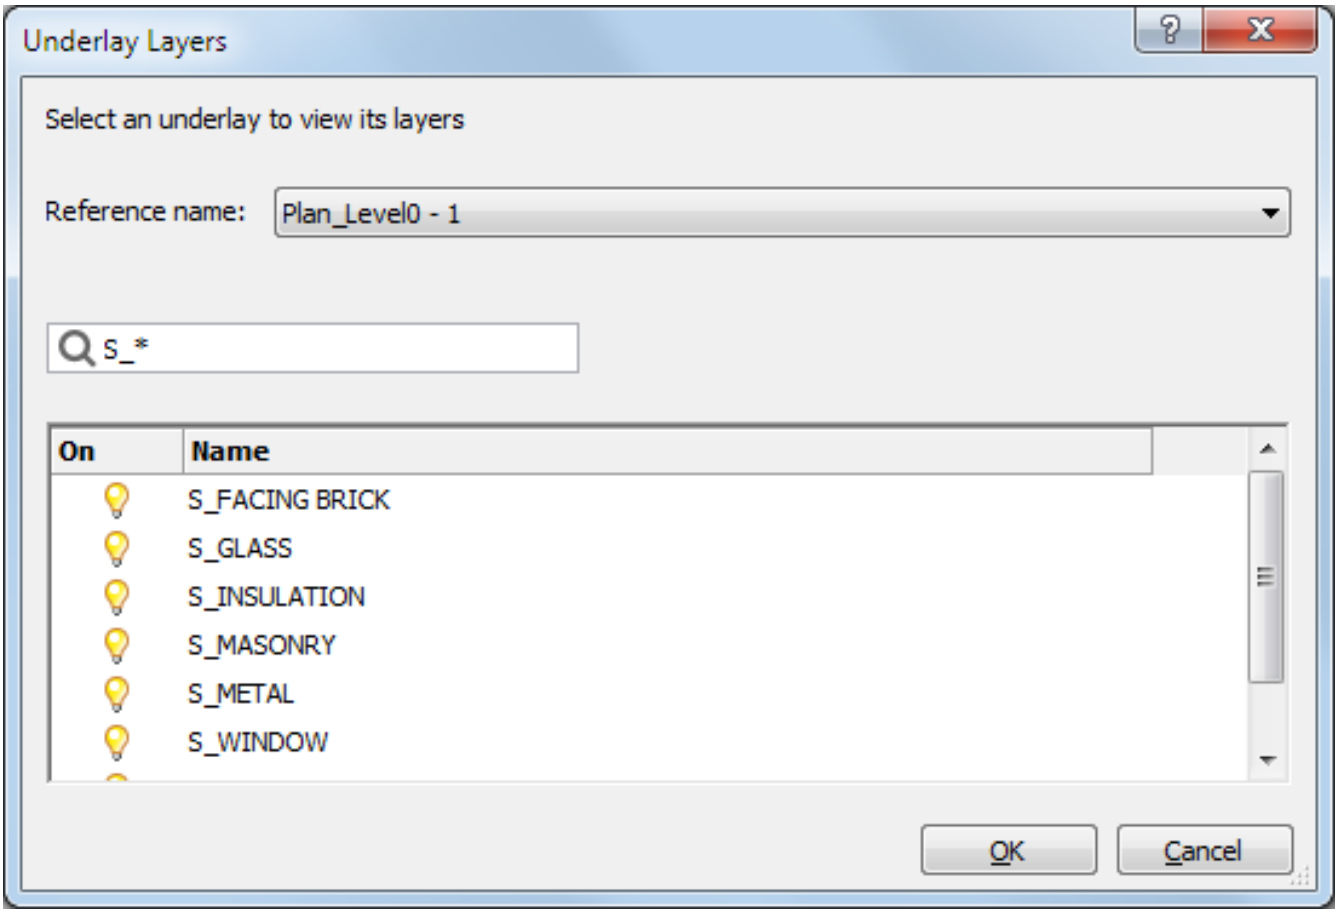


Figure 1.1178

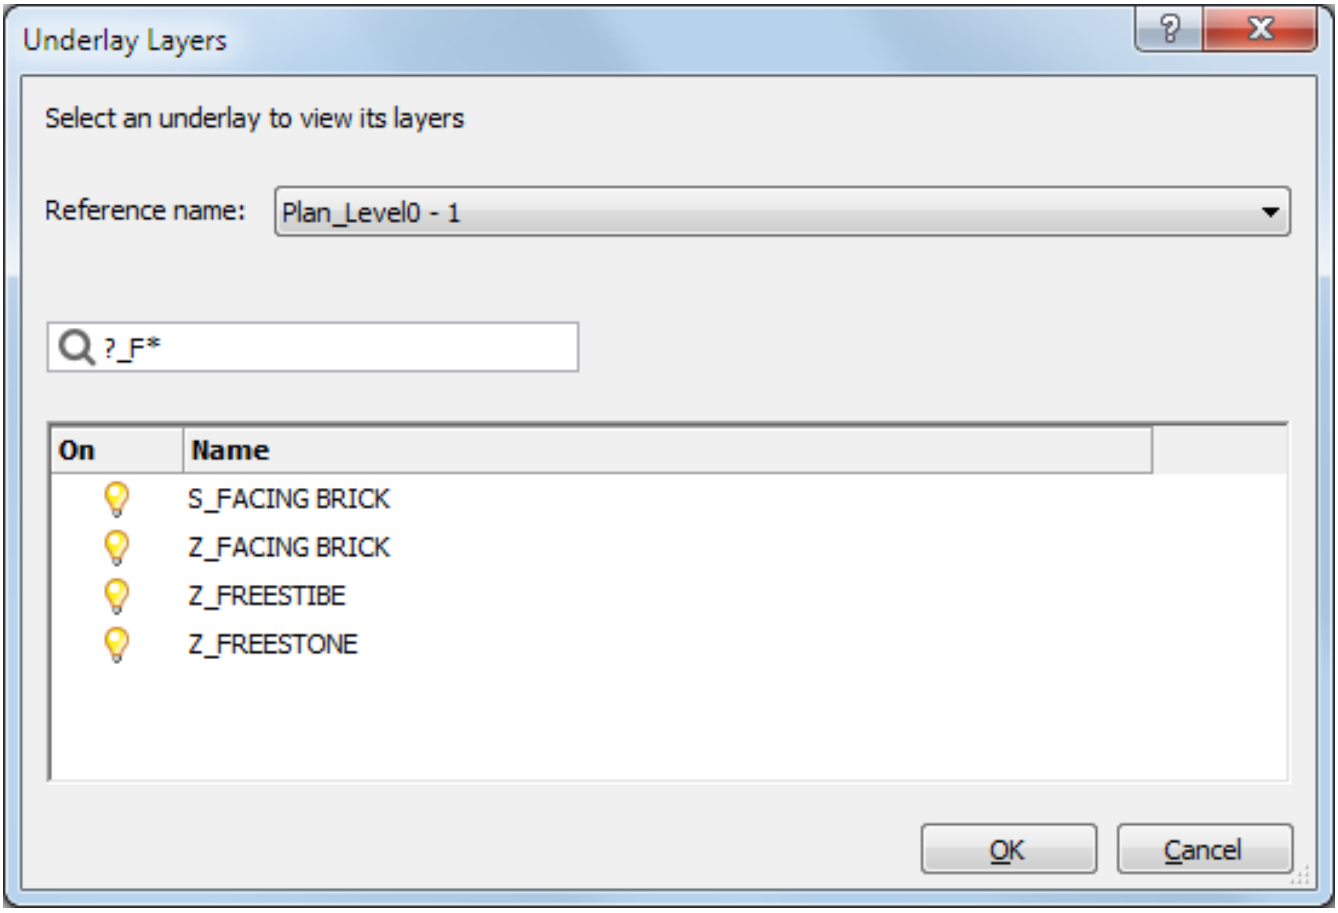
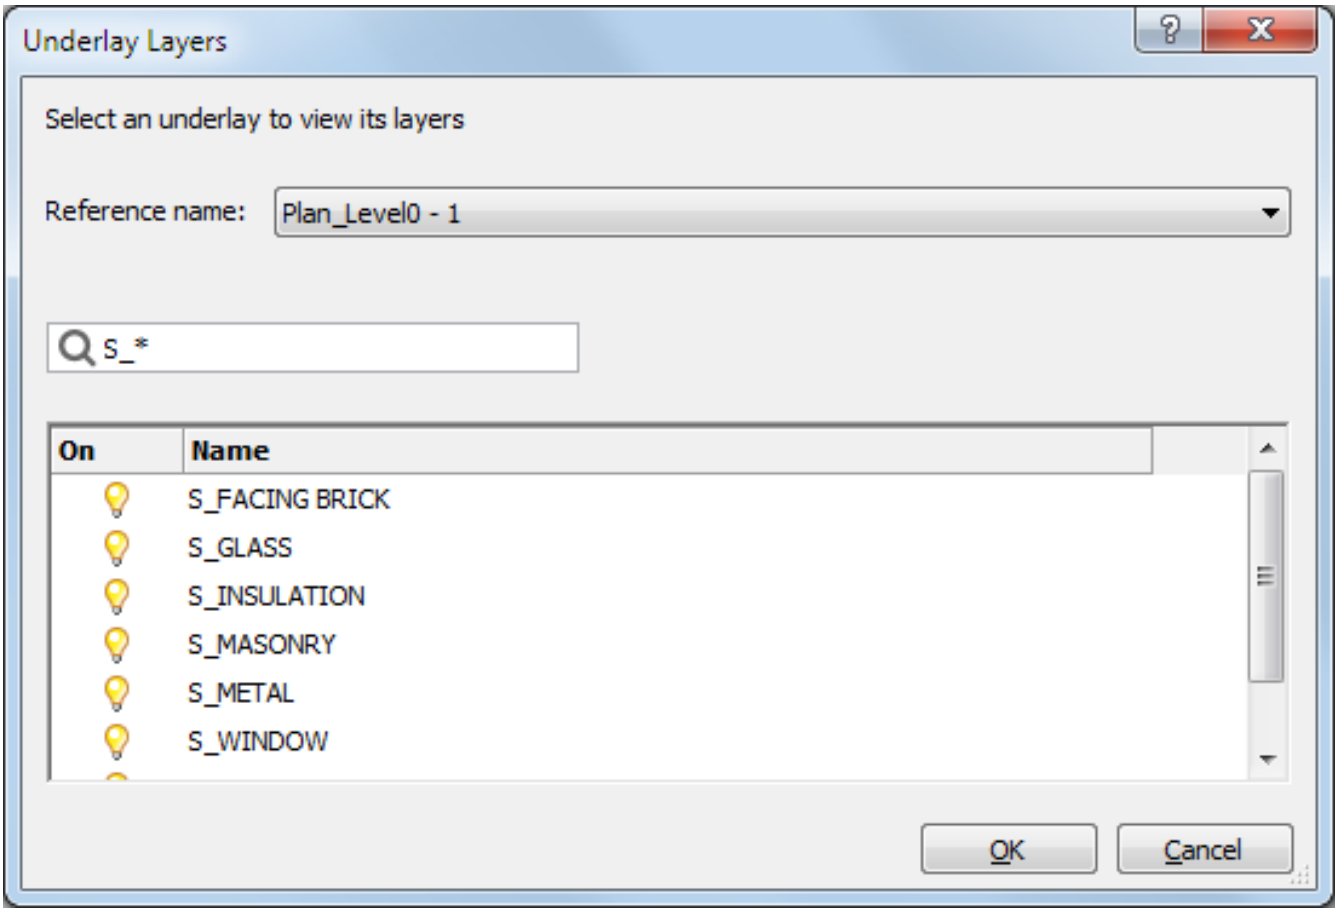


To clip a PDF underlay

1. Type **pdfclip** in the command bar, then press Enter. You are prompted: Select PDF underlay:
2. Click the frame of the PDF underlay. The frame of the selected PDF highlights. You are prompted: Enter PDF clipping option [ON/OFF/Delete/New] <New>: A prompt menu displays: (1.1179 on the facing page)
3. Do one of the following:
   - Choose **New boundary** in the prompt menu.
   - Press Enter to accept the **New** default command option.

   You are prompted: Enter PDF clipping type [Polygonal/Rectangular] <Rectangular>:
4. Do one of the following:
   - Press Enter to accept the Rectangular default command option to define a rectangular clipping boundary.
   - Type P, then press Enter to define a polygonal clipping boundary.
5. Define the clipping boundary. The defining points must lie inside the frame of the PDF underlay. If you click outside the PDF underlay the point is placed on the PDF underlay frame.

Figure 1.1179



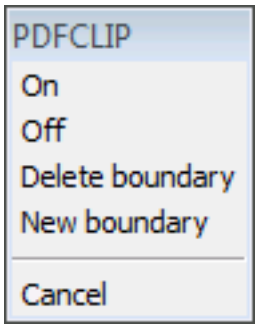
To toggle the display of the clipped part of a PDF underlay

1. Click the frame of the PDF underlay. The frame of the selected PDF highlights. The properties of the underlay display in the Properties Bar (1.15.4).
2. Under **Misc** , click **Show clipped** in the Properties Bar, then select **Yes** or **No**.

To delete a clipping boundary

1. Type **pdfclip** in the command bar, then press Enter. You are prompted: Select PDF underlay:
2. Click the frame of the PDF underlay. The frame of the selected PDF highlights. You are prompted: Enter PDF clipping option [ON/OFF/Delete/New] <New>: A prompt menu displays: (1.1180)
3. Do one of the following:
   - Choose **Delete boundary** in the prompt menu.
   - Type D in the command bar, then press Enter.

Figure 1.1180



The clipping boundary is deleted and the complete PDF underlay displays.

To adjust the display settings of a PDF underlay

The PDFADJUST (6.24.17) command allows to adjust the **Fade** , **Contrast** and **Monochrome** settings of a PDF-underlay in the command bar. Select the PDF underlay, then adjust the display settings under **Underlay Adjust** the Properties Bar (1.15.4): (1.1181)

Figure 1.1181

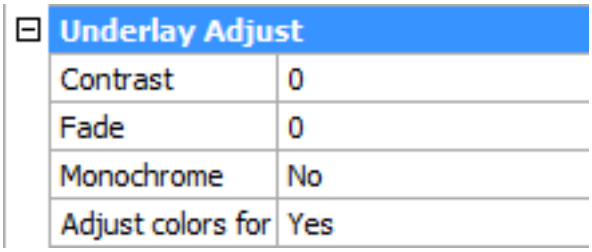


Figure 1.1182

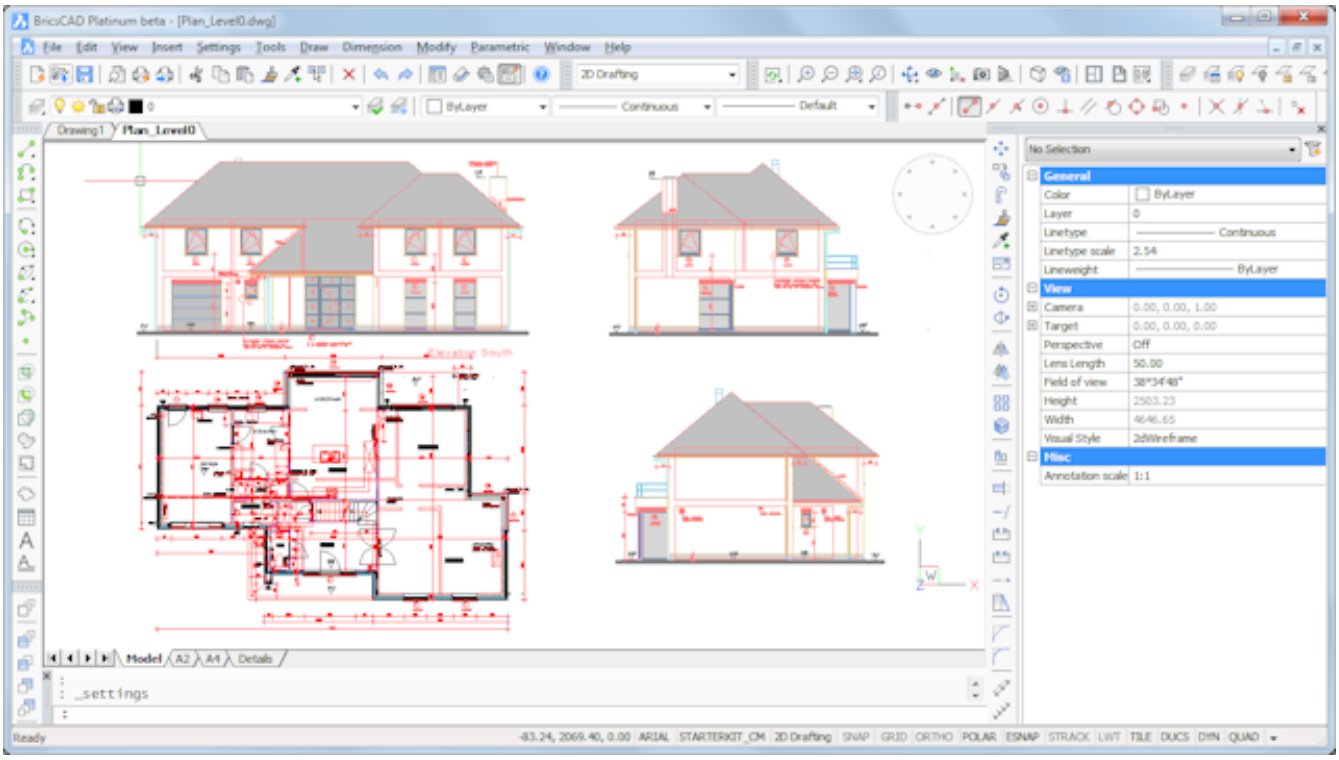
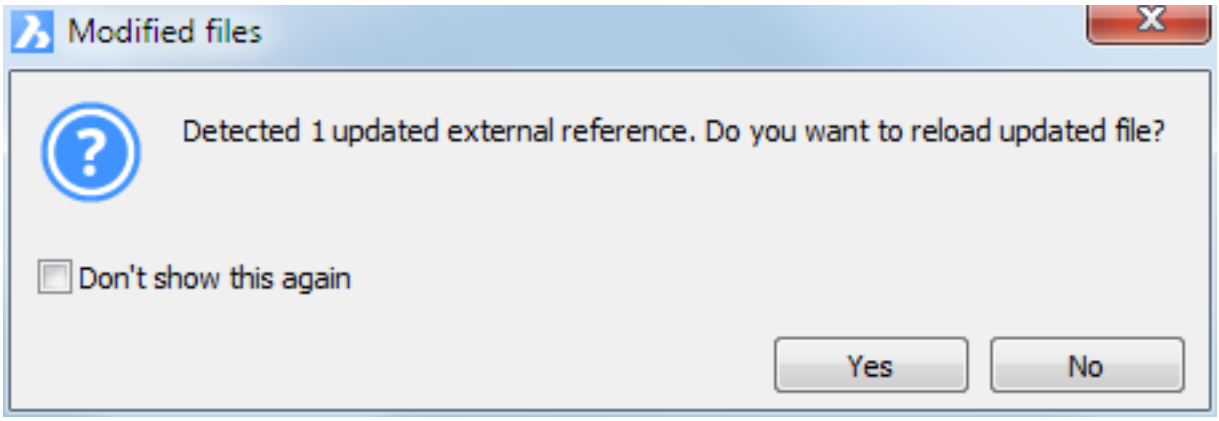


1.30.24 Working with external references

You can link entire drawings to the current drawing as external references. Unlike inserting a drawing as a block, in which you add all the entities from the separate drawing into the current drawing, external references attach a pointer to the external file. The entities in the external reference appear in the current drawing, but the entities themselves are not added to the drawing. Thus, attaching an external reference does not significantly increase the size of the current drawing file. External references provide additional capabilities not available when you insert a drawing as a block. When you insert a drawing as a block, the entities are stored in the drawing. Any changes you make to the original drawing are not reflected in the drawing in which you inserted it. When you attach an external reference, however, any changes you make to the original drawing file are reflected in the drawings that reference it. These changes appear automatically each time you open the drawing containing the external reference. If you know that the original drawing was modified, you can reload the external reference anytime you're working on the drawing. External references are useful for assembling master drawings from component drawings. Use external references to coordinate your work with others in a group. External references help reduce drawing file size and ensure that you are always working with the most recent version of a drawing. Commands: XREF (6.13.23), -XREF (6.34.8), XATTACH (6.34.1) and XCLIP (6.34.2) The **Xref** command attaches DWG files to the current drawing through the Drawing Explorer (1.19.2) (short for "external reference"). The **-Xref** command attaches DWG files to the current drawing through the command bar. The **Xattach** command attaches externally-referenced drawings through a dialog box (short for "external attach"). The **Xclip** command clips externally-referenced drawings, and adjust front and rear clipping planes (short for "xref clip"). The **XDWGFADECTL** system variable controls the fading of external references. Values between 0 (no fading) and 90 are accepted. The fading factor affects the screen display only, not the printing. (1.1182) External References (elevations) display faded: XDWGFADECTL + 50 The **XNOTIFYTIME** system variable defines the frequency to check for modified externally referenced resources: xrefs, images and pdf attachments if **XREFNOTIFY, IMAGENOTIFY** and/or **PDFNOTIFY** is ON. (1.1183 on the facing page) The **XREFNOTIFY** system variable controls whether warnings for missing or modified xrefs are issued.

Figure 1.1183



1.30.25 Components and Component Inserts

A component is a named group of entities, that can be inserted in a drawing with the BmInsert (6.8.16) command. Components can be parametric: e.g. windows and doors (5.3.10), in a BricsCAD BIM and standard mechanical components (3.7.4) in BricsCAD Mechanical. Any .dwg file can be used as a component. The same component can be inserted once or several times into one or more other components. When the component is modified, all inserts of the component will reflect these changes automatically. Components cannot self-reference. A component insert is a named entity. The default name of a component insert is composed of the name of the component and the serial number of the insert. Internally a component insert is represented either as a reference to an anonymous block or as an external reference (1.30.25). Properties of inserted components, including their parameters, can be edited in the Mechanical Browser (3.3.2) and Properties (6.24.54) panel.

External and local components

Components can be either local or external. A local component is stored in the .dwg file with the assembly as an anonymous block. An external component is defined in a separate .dwg file and represented by an Xref or as a local copy stored as an anonymous block. When the corresponding .dwg file is modified all inserts of external components can be updated using the BMUPDATE (6.8.29) command or the Mechanical Browser context menu. If you use external components in your assembly, always remember to transfer all related files when you want to share your model. Use the ETRANSMIT (**??**) command to create a package of a drawing file and all its dependencies, such as external references, images, font files, plot configuration files, plot style tables and font map files. You can always convert a local component to an external one and vice versa. To edit a local component, it first needs to be converted to an external component using the BMEXTERNALIZE (6.8.11) command. Alternatively, you can use the BMOPENCOPY (6.8.22) command to open a copy of a component, edit and save it. Then use the BmReplace (6.8.31) command to replace the original with the copy. You can choose the default insertion type for your component: **Local** or **External.** To change the type, select the root node in the Mechanical Browser (3.3.2) and select **Local** or **External** from **Insert as** properties: (1.1184) Dependant on the value of BMAUTOUPDATE (1.17.10), inserts of external components are updated automatically on opening the assembly document or manually with the BmUpdate (6.8.29) command. You can change this value in the Settings dialog (1.17.10): (1.1185 on the facing page)

Figure 1.1184

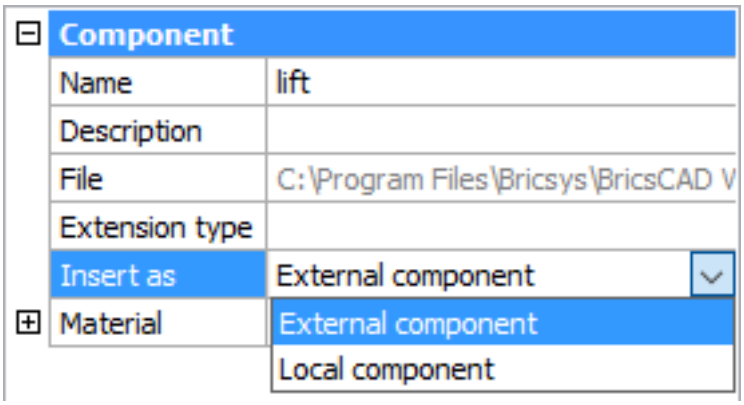


Figure 1.1185

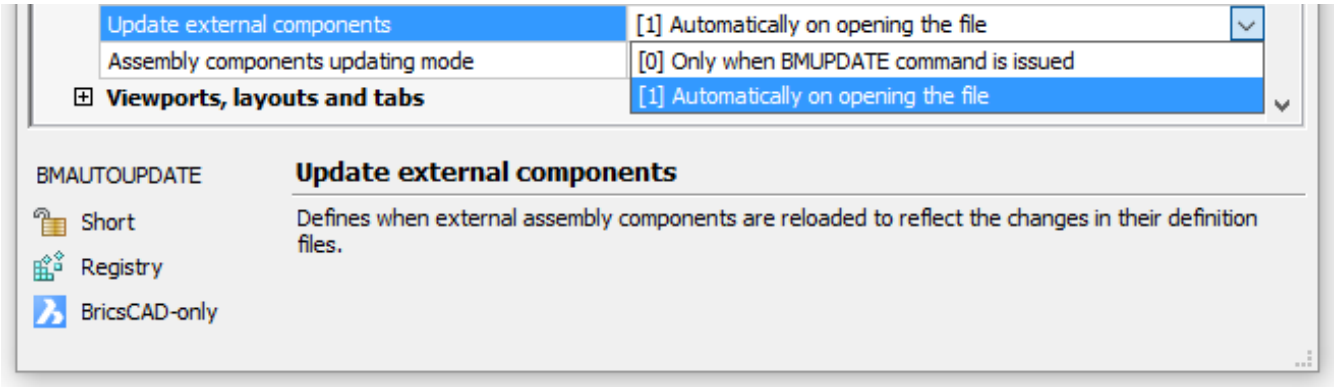


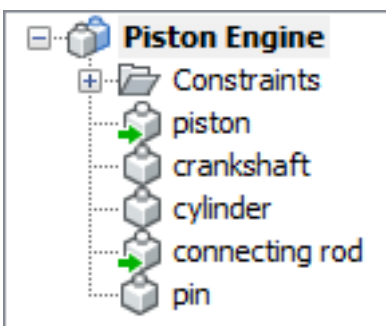
Convert components

Do one of the following:

- Click **Switch Component to External** () or **Switch Component to Local** on the **Assembly** ribbon tab. The tools are also available from the Assembly toolbar and in the Assembly menu.
- Right-click on the component insert in the Mechanical Browser (3.3.2) and select **Switch to External** or **Switch to Local** in the context menu.
- Hover your mouse cursor over a component insert in a drawing window and select **Switch to External** () or **Switch to Local** in the **Assembly Modeling** command group in the Quad (2.3.3).
- Type **BmExternalize** or **BmLocalize** in the command bar.

When you convert an external component to a local one, the .dwg file with the component definition is not deleted but future changes will not affect your assembly. You can always distinguish between inserts of local components () and inserts of external components () by their icons in the Mechanical Browser (3.3.2): (1.1186)

Figure 1.1186



Parametric Components

You can make parametric changes of inserted components at the assembly level. A component is considered parametric if it contains at least one 2D (1.21.7) or 3D (1.27.3) dimensional constraint or an associative array with an expression. (1.1187 on the facing page)

NOTES

- BricsCAD automatically maintains associativity between the definition of a parametric component and its inserts. So, you can open the parametric component for editing, modify its geometry and save it. To see the result, execute the BmUpdate (6.8.29) command to update the mechanical structure of your assembly.
- If you need to go back to the default value of a component's parameter, just edit the **Expression** field and delete its content.

You can control if a particular component parameter will be available for edit in a drawing that contains the inserts of these components (at the assembly level). To do that, select a parameter in the Mechanical Browser (3.3.2) and change the value of the **Exposed** field in the properties grid of the parameter: (1.1188 on the next page) The options are:

- **Off**: Hides the parameters at the assembly.
- **On**: Makes the parameter visible at the assembly level.
- **Auto**: Hides all parameters with values controlled by expressions and exposes all other parameters.

You can associate units with a parameter. If you assign a value, directly or via an expression, to a component parameter at the assembly level, it automatically converts from drawing units of the assembly drawing to the units of the parameter. Values assigned to unitless parameters are not converted. (1.1189 on page 1302) By default, all parameters are unitless except parameters of dimensional constraints and parameters, which are used as expressions for dimensional constraints. BricsCAD automatically assigns drawing units to such parameters.

Figure 1.1187

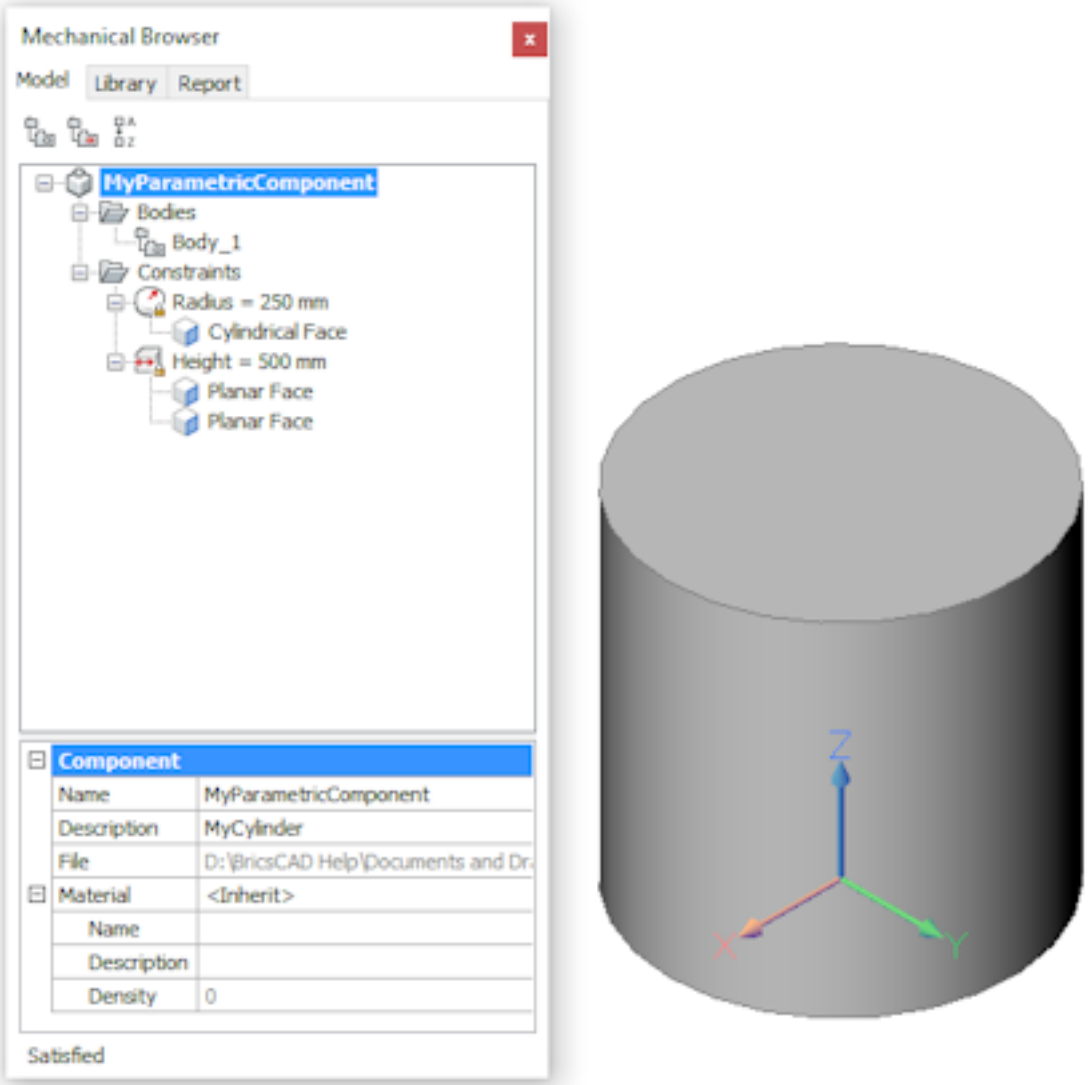


Figure 1.1188

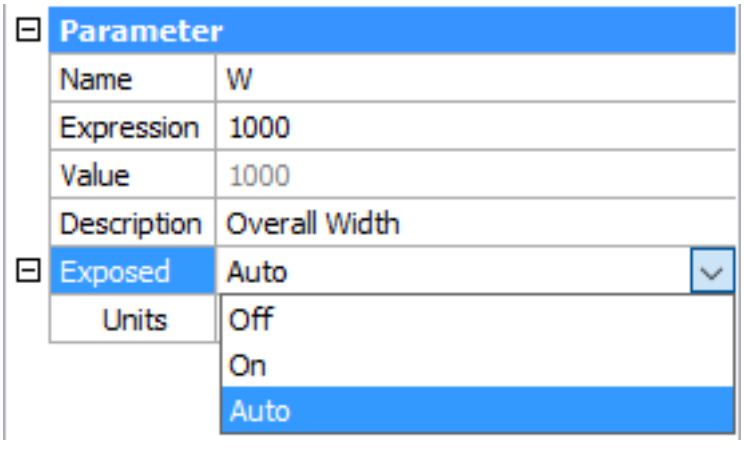

Figure 1.1189

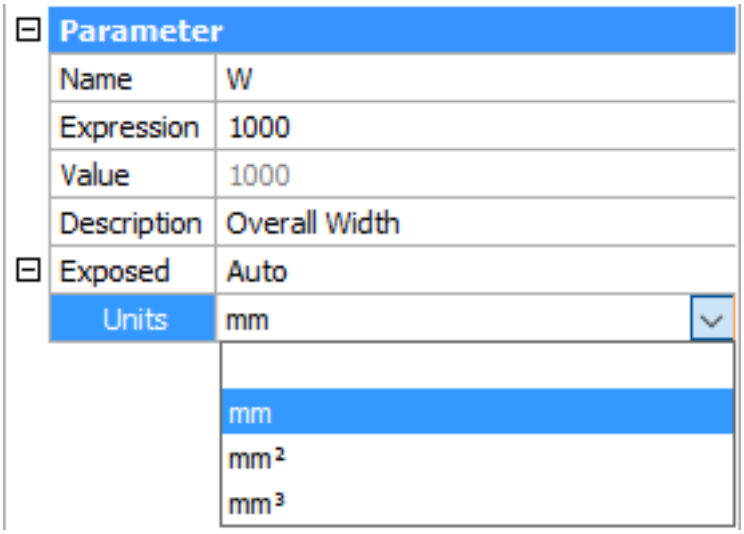
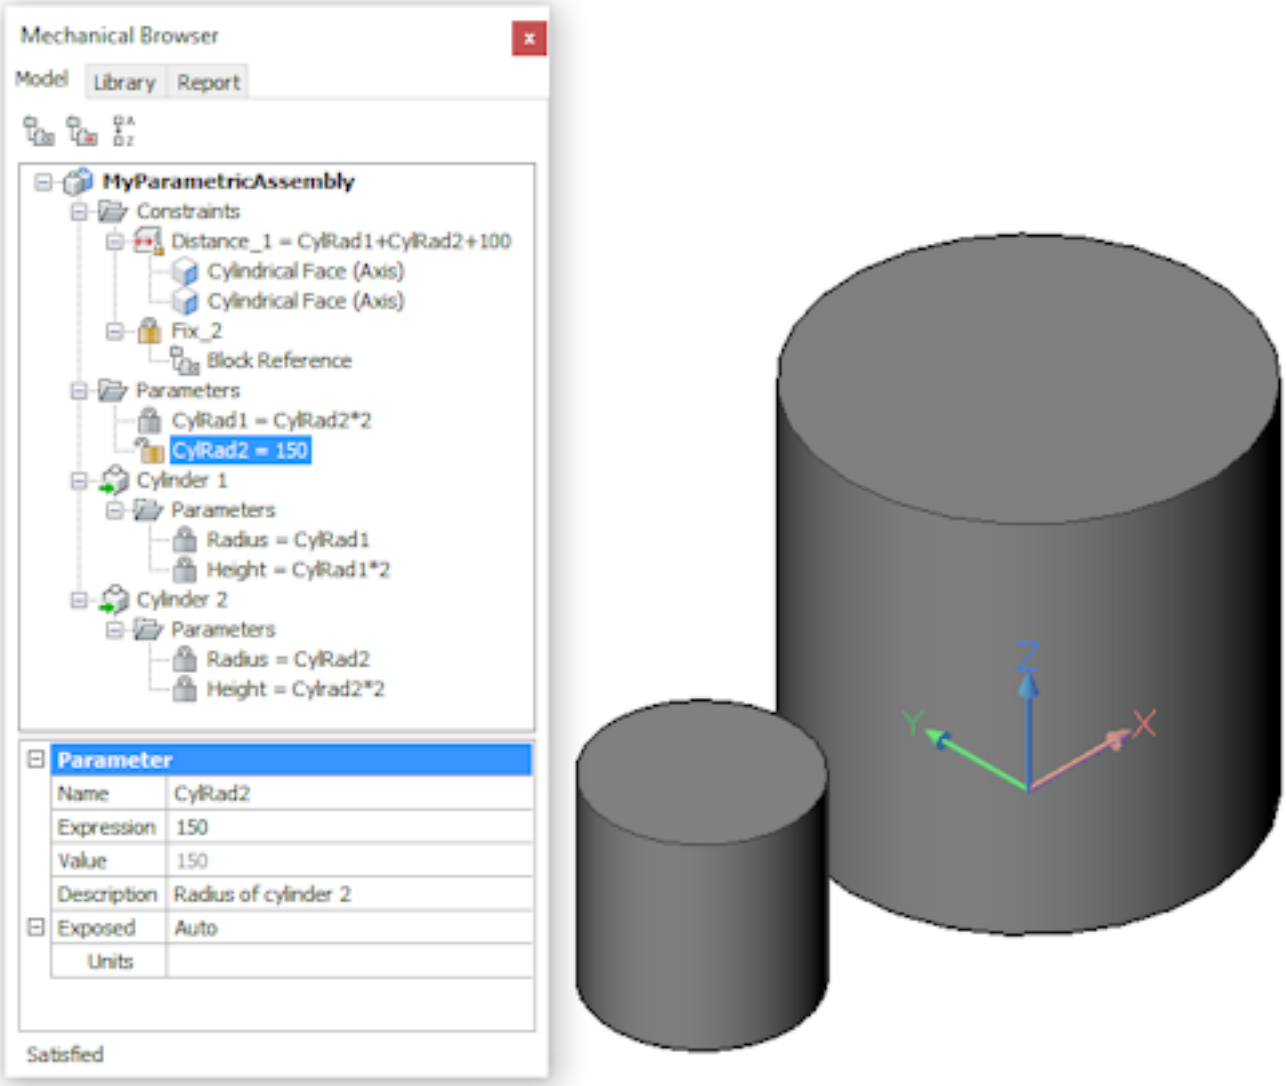


To edit the parameters of a parametric component insert

When a parametric component is inserted in a model, you can edit the parameters either in the Mechanical Browser (3.3.2) or in the Properties Bar (1.15.4). The component insert immediately updates according to the new value of a parameter. Please note that this does not modify the definition of the parametric component, which is a separate drawing file. As a result, multiple inserts of the same parametric component can exist in the same model, with different values for each of their parameters: (1.1190 on the next page)

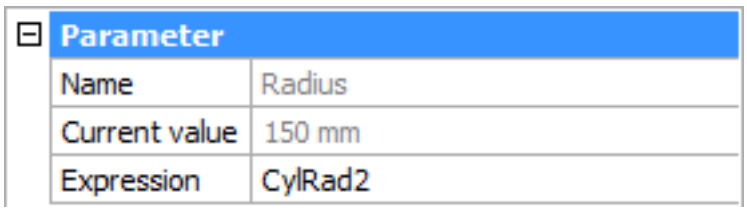
Figure 1.1190



To edit a parameter in the Mechanical Browser

1. Expand the **Parameters** node of the component.
2. Select the parameter.
3. In the **Parameter** section, type a new value in the **Expression** field. (1.1191)

Figure 1.1191



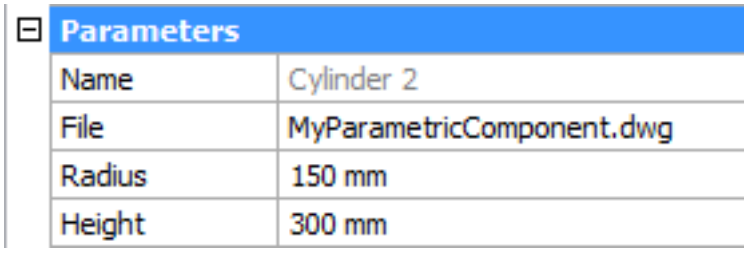
To edit a parameter in the Properties Bar

1. Select the component in the drawing.
2. Expand the **Parameters** settings group.
3. Type a new value for one of the available parameters. (1.1192)

NOTES

- In the Properties Bar (1.15.4) the current value displays. In case this value is controlled through an expression, the expression will be overwritten by the newly entered value.
- If multiple parametric components are selected, the shared parameters can be edited simultaneously. The settings fields of parameters that currently have different values reads: *Varies*. (1.1194 on page 1308)

Figure 1.1192



Replace Components

To replace component inserts with another component, use the BmReplace (6.8.31) command. Only top-level inserts can be replaced.

1. Do one of the following:

   - Click **Replace Component** tool () on the **Assembly** ribbon tab. The tool is available on the Assembly toolbar and in the Assembly menu.
   - Right-click on the component insert in the Mechanical Browser (3.3.2) and select **Replace...** or **Replace all inserts...** in the context menu.
   - Hover over a component insert in a drawing window and select the **Replace** tool () in the Quad (2.3.3).
   - Type **BmReplace** in the command bar. The File open, dialog displays.

2. Select a .dwg file for the replacement component and press the **Open** button. **You are prompted: Replace file for all similar inserts [Yes/No] <Yes>:**

3. Do one of the following:

   - **Yes**: Replace all inserts of the same name.
   - **No**: Replace the selected insert only.

Note: Parameter values that are shared between the replacement component and the replaced component are copied automatically.

Components, blocks or external references?

Components are based on blocks and external references (xrefs) but the behavior of components is different. An external component is linked to a file, much like an Xref, but an external component can be represented by either an Xref (BMINSERT (6.8.16) acts like XATTACH (6.34.1)) or by a local anonymous block (BMINSERT (6.8.16) acts like INSERT (6.17.13)). Components can be either parts or assemblies:

- **Part**: composed of entities only; no inserts of subcomponents.
- **Assembly**: composed of entities and subcomponent inserts. Even when the subcomponents are removed, the assembly status is kept.

When an external component is a part and its parameters are not modified, the component is inserted as an Xref. This is listed in the External References section of the Drawing Explorer (1.19.2) dialog. Xref layers have a 'file_name' prefix. When an external component is an assembly, it is inserted as a local anonymous block. All its layers are merged with the layers of the main document and no prefix is added to the layer name.

Convert blocks and external references

Drawings with blocks and external references can be converted to mechanical assemblies: block references are converted to inserts of local components and external references are converted to inserts of external components.

1. Do one of the following:

   - Click the **Initialize Mechanical Structure** tool () in the ribbon tab. The tool is also available in the **Assembly** toolbar and in the Assembly menu.
   - Type **BmMech** in the command bar.

2. **You are prompted: Name for new mechanical component <test>:** Type a name for the mechanical component or hit **Enter** to accept the current name or the default **Component_1** name.

3. **You are prompted: Convert blocks and external references to mechanical components? [No/Yes] <Yes>:** Hit **Enter** to convert blocks and external references to mechanical components.

Mechanical components can be converted back to blocks and external references.

1. Do one of the following:

- Click **Remove Structure** tool () on the Assembly tab of the Ribbon. This tool is also available in the Assembly toolbar and in the Assembly menu.
- Type **BmUnmech** in the command bar.

2. You are prompted: **Warning: this command removes all mechanical structure from the current document. Proceed? No/<Yes>:** Hit **Enter** to:
   - Convert external components to External References (Xrefs).
   - Convert local components to blocks.

Component-based features

A feature is a physical constituent of a part with engineering significance. Examples of features are holes, ribs, slots, pockets, forms. If applied to a 3D solid, a feature removes and/or adds geometry. To create your own features use the BricsCAD component extension technology. An extended component has **BC_SUBTRACT** and/or **BC_UNITE** layers. When you use the BmInsert (6.8.16) command to insert such a component on the face of a 3D solid the target solid is modified as follows:

- All 3D solids on the **BC_SUBTRACT** layer of the component are subtracted from the target 3D solid.
- All 3D solids on the **BC_UNITE** layer of the component are united with the target 3D solid.

All faces created after Boolean operations form a component-based feature. They are updated when you move the component insert or when you modify any parameters. When the insert is deleted, the target solid is healed. Adjust the target 3D solids with the BmLink (6.8.15) command. Some examples of parametric component-based features are included with BricsCAD. You can use them as samples to create your own features.

Assign physical materials to components

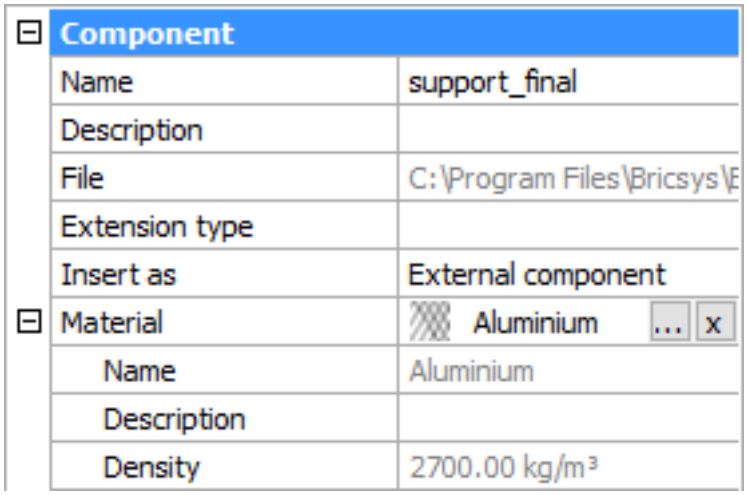
You can assign a physical material (2.7.17) to a mechanical component. If a mechanical component does not have an assigned material, it will inherit the material from its parental component. If the parental component does not have an assigned material, the material of the nearest component, will be used. As a result, the same material can be assigned to all components that have a common parent.

1. Select the root component in the Mechanical Browser (3.3.2).
2. Select the **Material** property and press the **Browse** button (...). (1.1193)
3. In the **Physical Materials (6.7.58)** dialog select a material from either the **In Project** or the **In Library** list. Materials that are chosen from the **In Library** are copied to the **In Project** database automatically.
4. Click the **OK** button to assign the selected material to the component.

To remove the material from the component:

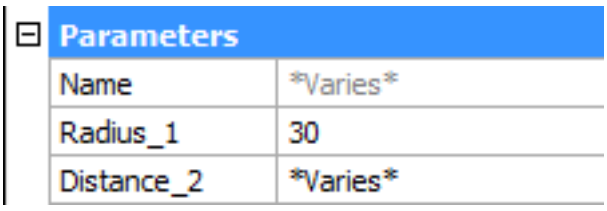
1. Select the root component in the Mechanical Browser (3.3.2).
2. Select the **Material** property and press the **Clear** button (X).

Figure 1.1193



Insert a component with a physical material When you insert a mechanical component in a model, all its materials are copied to the material library of the model. If a material with the same name already exists in the target model, this material will be used instead. As a result, the properties of the material in the target model are used. This replaces the properties of the material from the inserted component. **Note:** Materials that are copied to the document material library will not be erased in Undo operations.

Figure 1.1194



1.31 Managing Images

1.31.1 Exploring Images

Commands: IMAGE (6.13.13), IMAGEADJUST (6.17.3), IMAGEATTACH (6.17.6), IMAGECLIP (6.17.7), IMAGEFRAME (6.17.9), IMAGEQUALITY (6.17.8) The **Image** command Inserts images in drawings through the Images Explorer. The **Imageadjust** command adjusts the properties of images through the Properties bar (1.15.4). The **Imageattach** command attaches raster images to the drawing. The **Imageclip** command clips images. The **Imageframe** command toggles the display of the frame around images. The **Imagequality** command toggles the display quality of images between draft and high. The **IMAGENOTIFY** system variable controls whether warnings for missing or modified image files are issued. The **XREFNOTIFYTIME** system variable defines the frequency to check for modified externally referenced resources: xrefs, images and pdf attachments if **XREFNOTIFY, IMAGENOTIFY** and/or **PDFNOTIFY** is ON.

Open the Images Explorer

To open the **Images Explorer** do one of the following:

- Choose **Drawing Explorer > Images** in the **Tools** menu.
- Click the **Image Management** tool button ( ) in the **Images** toolbar.
- Type **image** in the command bar, then press Enter.
- Select **Images** in the **Open Drawings** sub-window of the Drawing Explorer (1.19.2).

In the **Images Explorer** you can:

- See a preview of the attached images
- Place images ( ) or ( )
- Load / Unload inserted images
- Detach images ( )

Images Explorer display options

You can choose between **Detail View** (list), **Icon View** and **Tree View** to see the images in the current drawing.

Open the Detail View of the Images Explorer Click the **Detail View** button ( ) in the **Drawing Explorer** toolbar. The **Detail View** button is now pressed, indicating the image details are displayed. The selected image displays in the **Preview** sub-window of the **Drawing Explorer** .

(1.1198 on page 1315)
Detail View of the images in the current drawing

Open the Icon View of the Images Explorer

Click the **Icon View** button ( ) in the **Drawing Explorer** toolbar. The **Icon View** button is now pressed, indicating the image icons are displayed. The selected image displays in the **Preview** sub-window of the **Drawing Explorer** .

(1.1199 on page 1315)
Icon View of the images in the current drawing

Open the Tree View of the Images Explorer

Click the **Tree View** button ( ) in the **Drawing Explorer** toolbar. The **Tree View** button is now pressed, indicating the image tree is displayed. The selected image displays in the **Preview** sub-window of the **Drawing Explorer** .

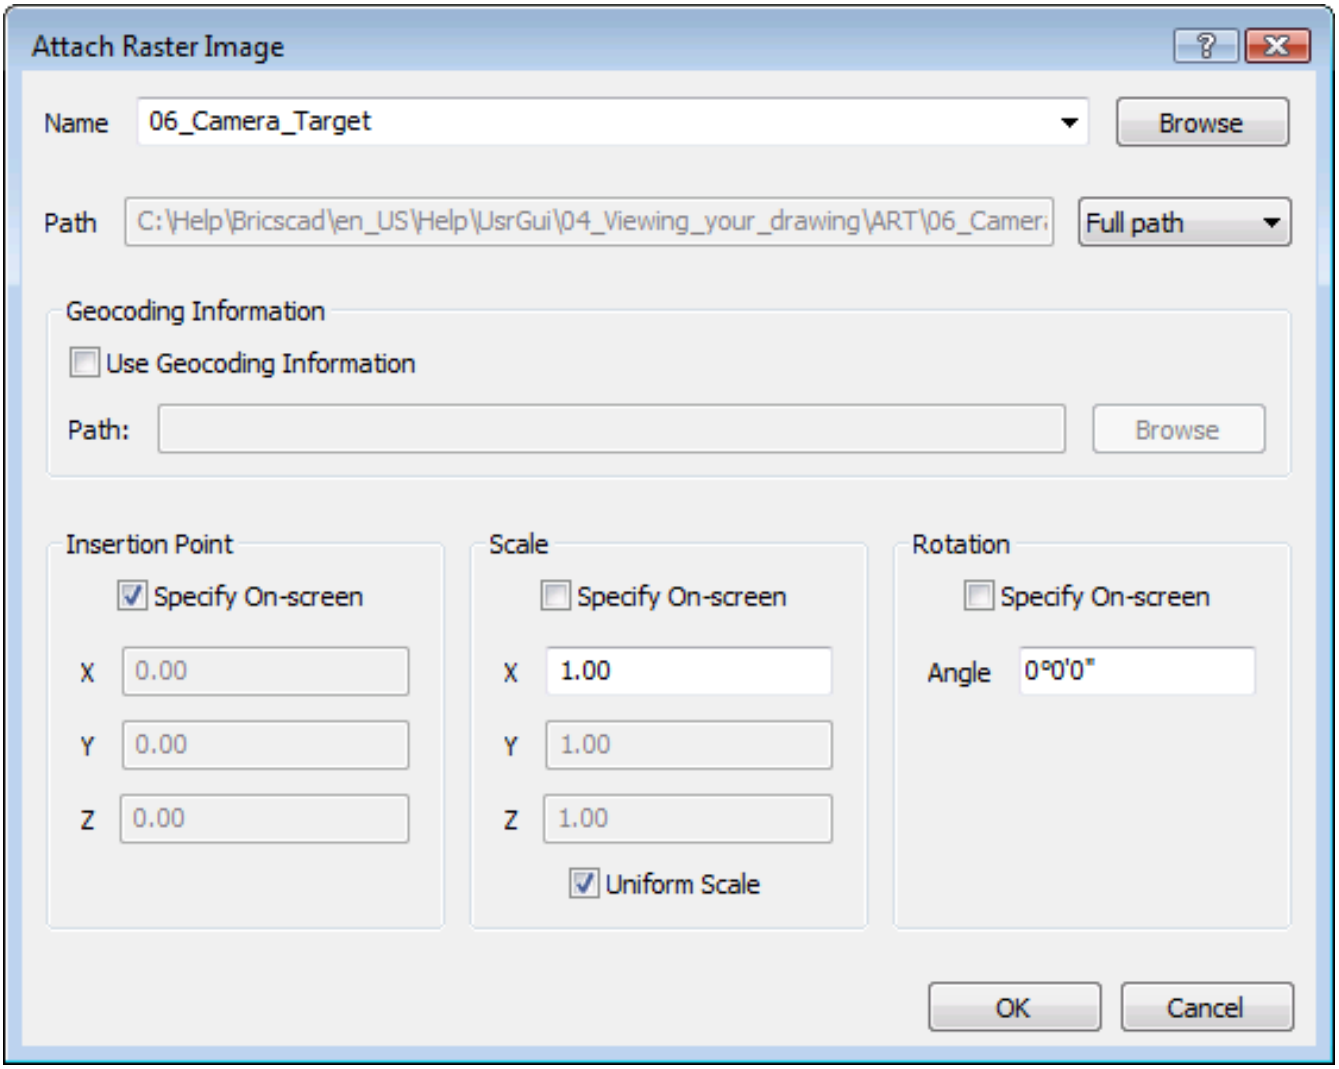
(1.1200 on page 1316)
Tree View of the images in the current drawing

Placing images in a drawing

1. Do one of the following:
   - Launch the **Image Explorer** , then click the **New** tool button ( ) in the **Drawing Explorer - Images** toolbar.
   - Launch the **Image Explorer** , select a raster image file in the list, then click the **Insert** tool button ( ) in the **Drawing Explorer - Images** toolbar.
   - Click the **Attach Raster Image** tool button ( ) in the **Insert** toolbar.

   The **Attach Raster Image** dialog opens. (1.1195 on the next page)
2. Do one of the following:
   - Accept the currently selected image file.
   - Click the down arrow button in the **Name** field to select a different raster image file in the list. Raster images which are already attached are listed.
   - Click the **Browse** button to select a new raster image file in the **Select Raster Image** dialog.
3. (option) Check the **Use Geocoding Information** option, then click the **Browse** button to open an appropriate world file to be used with the selected raster image. If the **Use Geocoding Information** option is checked, the **Insertion Point** , **Scale** and **Rotation** settings fields are not available.
4. (option) Do the following:
   - Specify an **insertion point** or select the **Specify on-screen** check box.
   - Specify **scale** or select the **Specify on-screen** check box.
   - Specify **rotation** angle or select the **Specify on-screen** check box.
5. Click the **OK** button.
6. If none of the **Specify on-screen** options is selected, the image is inserted at the desired insertion point, scale and rotation angle; else **You are prompted** to specify the insertion point, scale and/or rotation angle on-screen.

Figure 1.1195



Load / Unload images

When an image is attached and then inserted in the drawing, you can unload the image to temporarily remove it. Unloaded images are still inserted in the drawing, but they no longer display. If the **Imageframe** setting is ON, the frame around the image still displays though.

Load / Unload a single image

1. Launch the **Image Explorer**.
2. For the image you want to load or unload, click the check box in the **Loaded** column. (1.1196 on the facing page)
3. If the **Regen On/Off** button ( ) is not pressed, click the **Regen** tool ( ) in the **Images Explorer** toolbar.

NOTE	It is not necessary to select the image first in step 2.

Figure 1.1196

	Name	Loaded	Size In Pixels	Refere
1	Chartres_France	☑	128,116	1

Removing images

Since an image is first attached, then inserted in the drawing, you can delete an image, without detaching it.

Detach images

1. Launch the **Image Explorer**.
2. Select the image(s) that you want to detach.
3. Do one of the following
4. Click the **Delete** tool button (✕) in the **Images Explorer** toolbar.
5. Right click and select **Delete** in the context menu.

NOTE Press and hold the Ctrl key to select multiple images.

Figure 1.1198

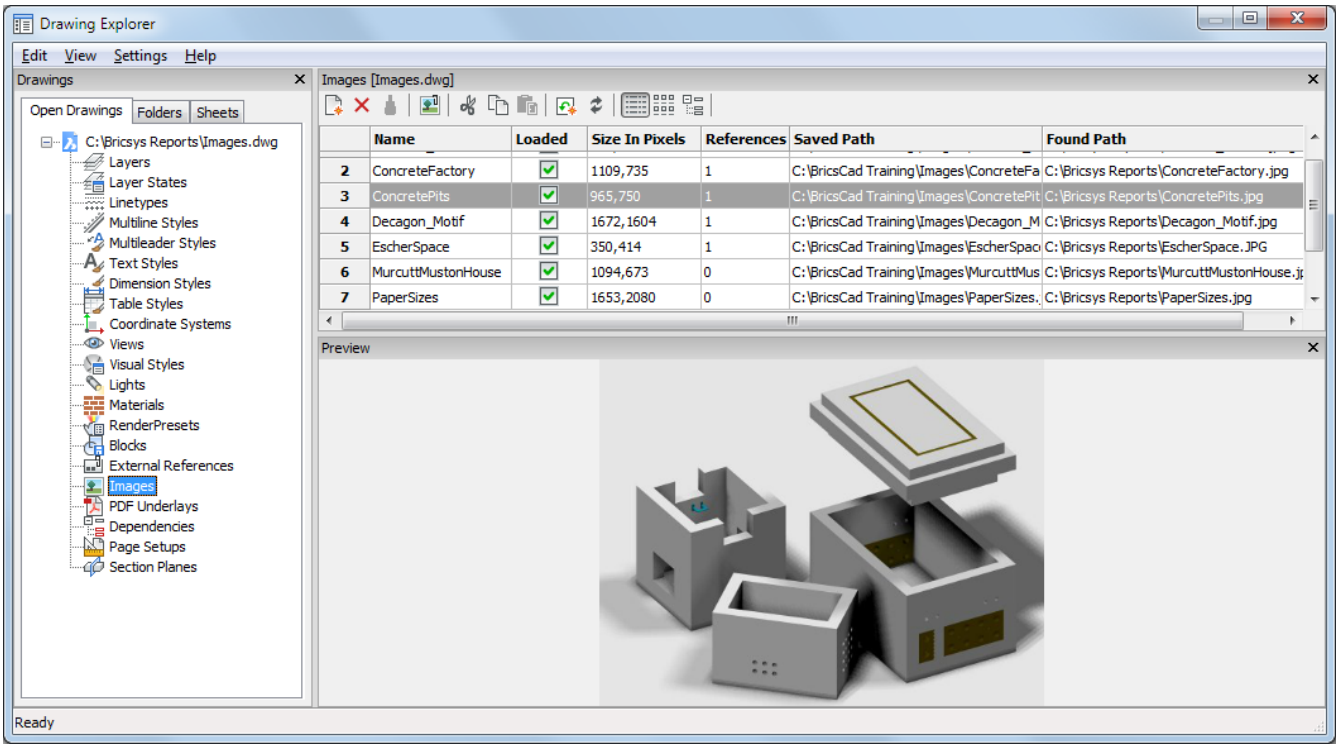

Figure 1.1199

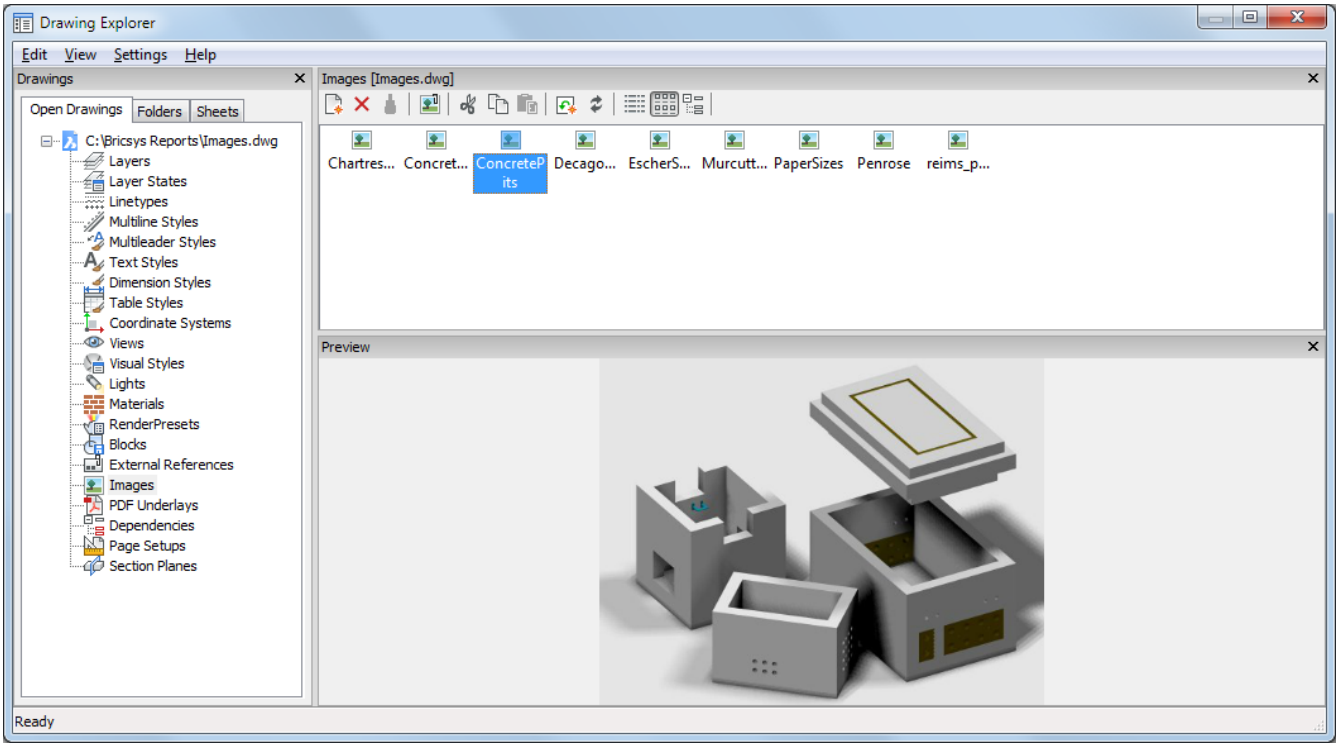

Figure 1.1200

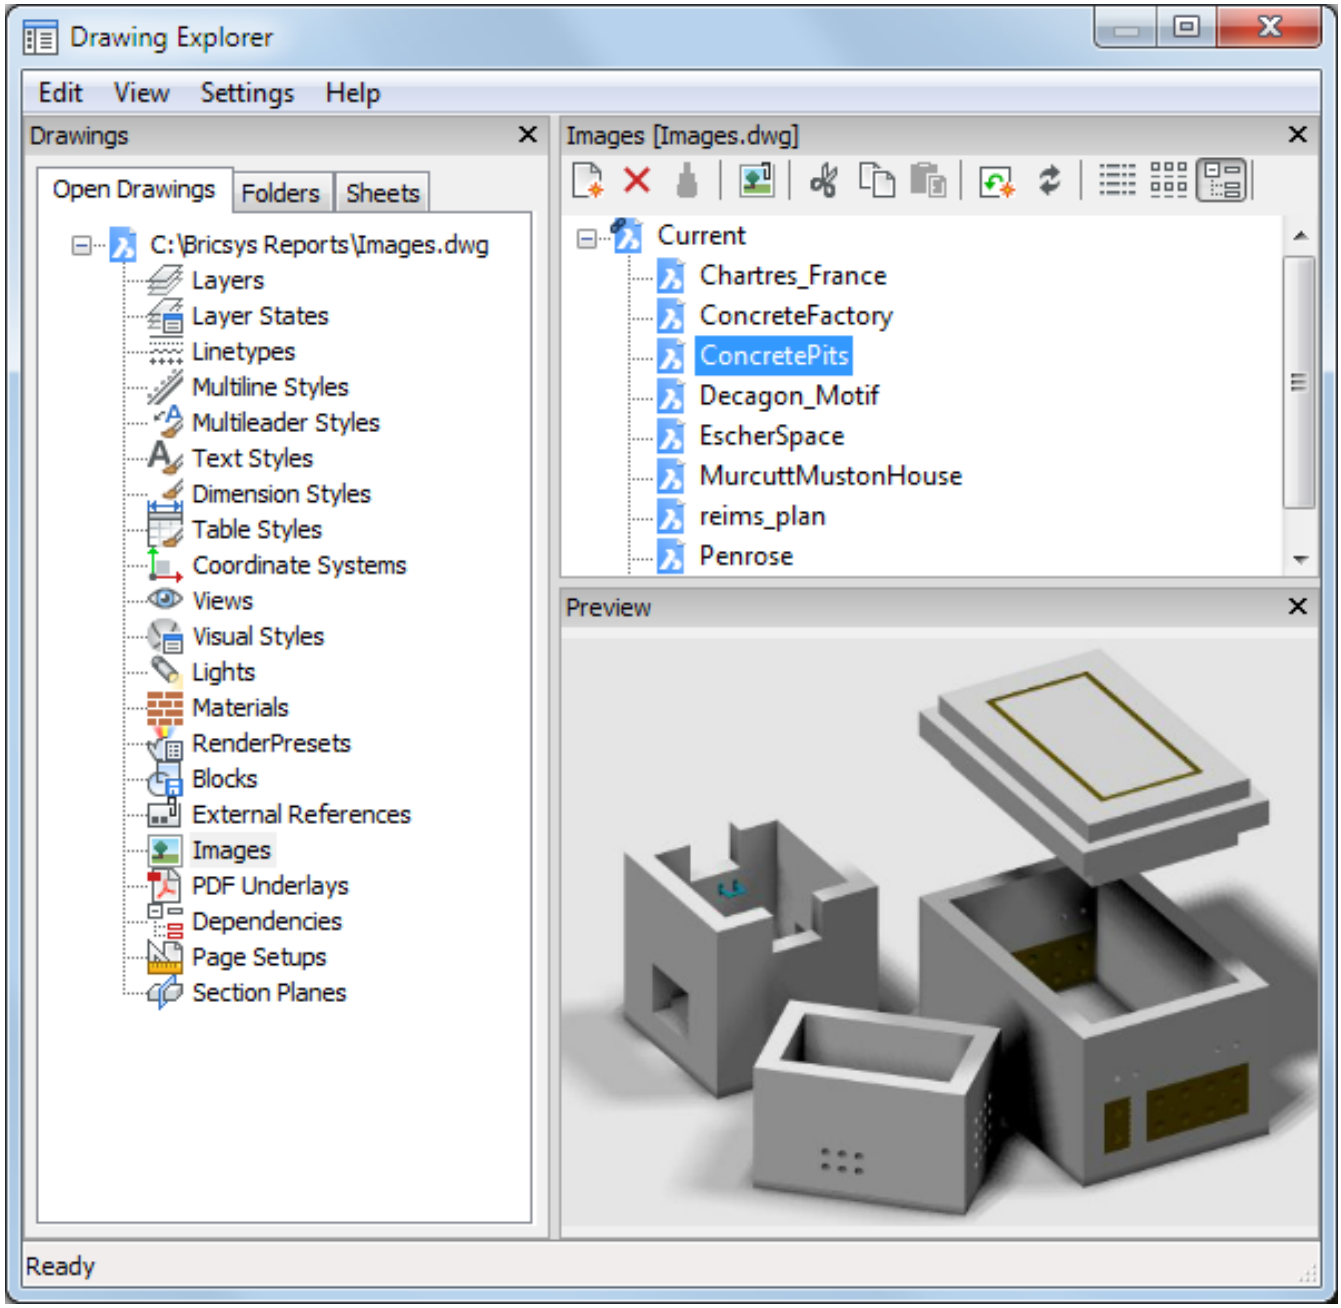


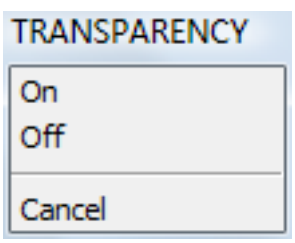
1.31.2 Image Utilities

To set the image transparency

1. Do one of the following:
   - Click the **Image Transparency** tool button ( ) on the **Images** toolbar.
   - Choose **Image Transparency** in the **Images** menu.
   - Type **transparency** in the command bar, then press Enter. **You are prompted:** Select images.
2. Select (1.32.7) the images you want to set the **Transparency** property of. **You are prompted:** Enter transparency mode [ON/OFF]<current mode>: A prompt menu displays. (1.1201)
3. Do one of the following:
   - Press Enter to accept the current mode.
   - Choose **On** in the prompt menu or type **ON** in the command bar, then press Enter to switch the **Transparency** property of the selected images on.
   - Choose **Off** in the prompt menu or type **OFF** in the command bar, then press Enter to switch the **Transparency** property of the selected images off.

(1.1202 on page 1319)
Transparency OFF (left) and Transparency ON (right)

Figure 1.1201



Modify the Image Frame setting

Using the Image Frame tool:

1. Click the **Image Frame** tool () in the **Images** toolbar. **You are prompted:** Enter image frame setting <1>:
2. Do one of the following:
   - Type 0 + Enter to hide image frames.
   - Type 1 + Enter to display and plot image frames.
   - Type 2 + Enter to display but not print image frames.

Editing the Image Frame system variable:

1. Open the **Settings** dialog.
2. Go to **Drawing / Underlays**.
3. Set the **Frame** system variable = **3**: Use individual settings.
4. Select the **Image Frame** system variable. The options are:
   - 0: Hide image frames.
   - 1: Display and plot image frames
   - 2: Display but do not plot image frames.

To clip an image

1. Make sure image frames display.
2. Do one of the following:
   - Click the **Clip Image** tool button () on the **Image** toolbar.
   - Type **imageclip** in the command bar, then press Enter. **You are prompted:** Select image:
3. Click the image frame. **You are prompted:** Enter image clipping option [ON/OFF/Delete/New] <New>:
4. Press Enter to accept the **New Boundary** default option. **You are prompted:** Enter image clipping type [Polygonal/Rectangular] <Rectangular>:
5. Press Enter to accept the **Rectangular** default option. **You are prompted:** Specify first corner.
6. Click a point to define the first corner of the clipping rectangle. The clipping rectangle displays dynamically. **You are prompted:** Specify opposite corner:
7. Click a point to define the clipping rectangle. The image is clipped.

To toggle the clipping boundary of an image

1. Make sure image frames display.
2. Click the image frame. The properties of the image display in the Properties Bar (1.15.4).
3. Under **Misc / Show clipped** choose **Yes** or **No**.

Figure 1.1202

1.32 Modifying Entities

1.32.1 Modifying Commands Overview

All entity modification tools can be found either on the **Modify** toolbar or in the **Modify** menu.

Icon	Tool name	Command	Description
	Manipulator (1.32.10)	MANIPULATE (6.21.3)	Launches the Manipulator widget; rotates, moves, mirrors and scales entities. Keep the Ctrl-key pressed while starting an action to manipulate a copy of the selected entities.
	Move (1.32.11)	MOVE (6.21.29)	Moves entities to another location in the same drawing or into another drawing.
	Copy (1.32.17)	COPY (6.9.35)	Draws a duplicate or multiple duplicates of the selected entities.
	Offset (1.32.20)	OFFSET (6.23.3)	Creates a parallel or offset copy of curves and lines.
	Scale (1.32.25)	SCALE (6.27.6)	Changes the scale of existing entities, either enlarging them or reducing them proportionately in x, y, and z directions.
	Rotate (1.32.12)	ROTATE (6.26.29)	Rotates entities around a specified point.
	3D Rotate (1.32.12)	ROTATE3D (6.26.31)	Rotates entities around a three-dimensional axis.
	Mirror (1.32.13)	MIRROR (6.21.17)	Moves or copies the reflected image of entities about a line.
	3D Mirror (1.32.13)	MIRROR3D (6.21.20)	Moves or copies the reflected image of entities about a plane.
	Array (1.32.19)	ARRAY (6.4.19)	Creates multiple copies of entities in one of two symmetrical patterns: rectangular (rows and columns) or polar (circular).

	3D Array (1.32.19)	3DARRAY (6.3.2)	Creates multiple copies of entities in three dimensions. Entities are arrayed in a three-dimensional rectangular (rows, columns and levels) pattern or a two-dimensional polar (circular) pattern in three-dimensional space.
	Break (1.32.32)	BREAK (6.6.21)	Splits an entity into two entities.
	Join (1.32.26)	JOIN (6.18.1)	Joins two entities (two or more lines or two or more arcs) into one entity.
	Trim (1.32.21)	TRIM (6.29.35)	Erases the portions of selected entities that cross a specified boundary.
	Align (1.32.14)	ALIGN (6.4.7)	Aligns selected entities with other entities in three-dimensional space.
	Extend (1.32.22)	EXTEND (6.13.21)	Lengthens lines, arcs, polylines or rays to meet another entity.
	Edit Length (1.32.23)	LENGTHEN (6.20.24)	Changes the length of a line, polyline, freehand entity or arc.
	Stretch (1.32.24)	STRETCH (6.27.52)	Moves a portion of a drawing while retaining connections to other parts of the drawing.
	Chamfer (1.32.27)	CHAMFER (6.9.9)	Creates a chamfer, or a beveled edge, at the intersection of two 3D solids, lines, rays, or infinite lines.
	Fillet (1.32.28)	FILLET (6.14.6)	Creates a fillet, or rounded corner, at the intersection of 3D solids, two lines, rays, or infinite lines.

	Measure (1.32.38)	MEASURE (6.21.11)	Divides a selected entity into segments by placing markers (points or blocks) at specified intervals along its length or circumference.
	Divide (1.32.41)	DIVIDE (6.10.39)	Places markers (points or blocks) along a selected entity. The markers evenly divide the entity into the specified number of equal parts.
	Hatch Edit (1.25.29)	HATCHEDIT (6.16.2)	Edits hatches and gradient fills in a dialog box
	Edit Polyline (1.32.35)	PEDIT (6.24.24)	Edits a two-dimensional or three-dimensional polyline, or a polygon mesh.
	Spline Edit	SPLINEDIT (6.27.46)	Edits a two-dimensional or three-dimensional spline.
	Flatten	FLATTEN (6.14.12)	Projects 2D and 3D entities onto the XY-plane of the current view.
	Explode (1.32.36)	EXPLODE (6.13.16)	Ungroups a block, polyline, polyface mesh, solid, or hatch, creating separate entities for each element.
	Change (1.32.16)	CHANGE (6.9.10)	Changes the location, size, color, elevation, layer, linetype, linetype scale, lineweight, and three-dimensional thickness of entities.
	Properties (1.15.4)	PROPERTIES (6.24.54)	Opens the BricsCAD Properties Bar (if not already open).

1.32.2 Entity Modification Settings

Entity modification settings are found in the **Entity modification** settings group of the **Drawing** settings category in the Settings (1.17.10) dialog. (1.1203 on the following page)

Figure 1.1203

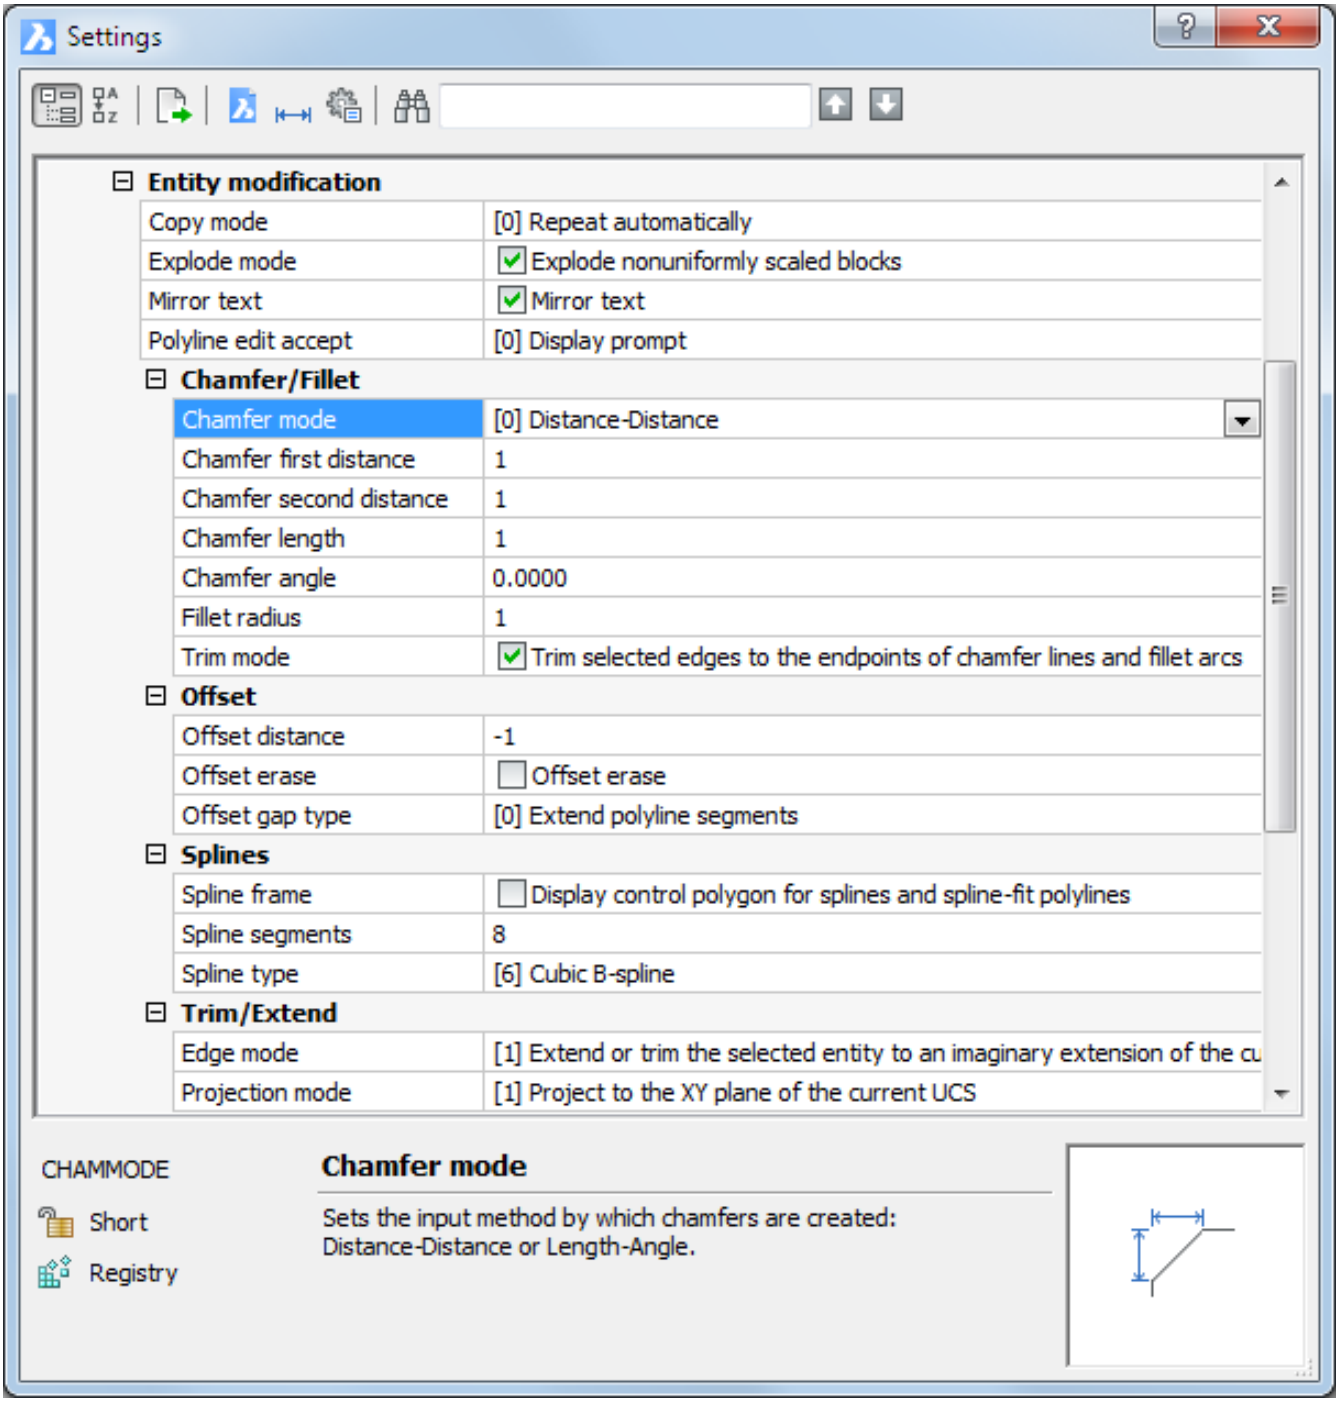


Figure 1.1204

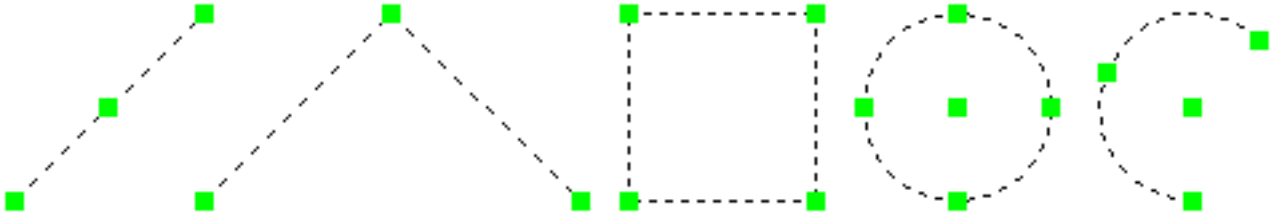

Figure 1.1205

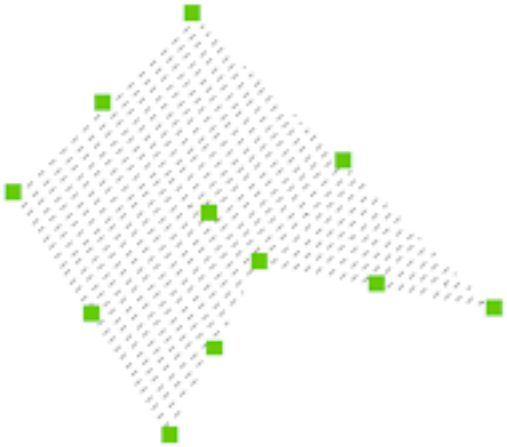


1.32.3 Grips editing

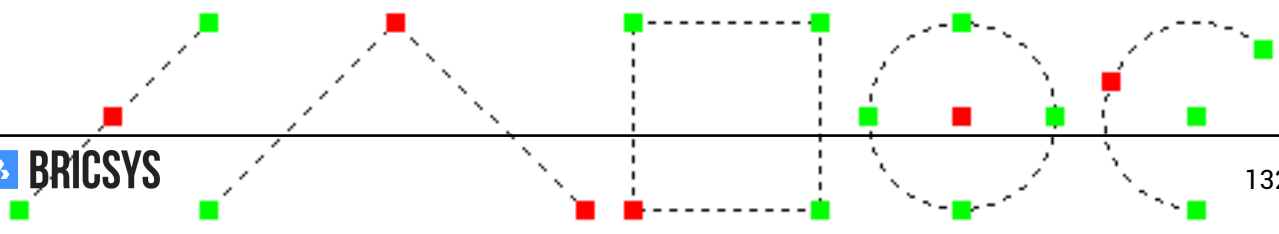
Grips display as small colored squares at key-points on selected entities. (1.1204) (1.1205) Whether grips display or not and the appearance of grips is controlled through a series of grips settings (1.32.4). When the display of grips is turned on, grips can be dragged using the mouse in order to stretch (1.32.3), move (1.32.3), mirror (1.32.3), rotate (1.32.3) or scale entities (1.32.3). When the GEOMRELATIONS (1.17.10) system variable is set, the geometric relation (perpendicular or tangent) of the entity being edited with crossing or nearby other lines, polylines, arcs or circles is indicated (see Geometric Relations (1.21.15)). The **Copy** option of the grips editing commands allows to create multiple copies of the entities being edited. To select a grip, move the mouse over it, then click. Selected grips display in a different color, which is defined by the **HOTGRIP** system variable. A selected grip is called a hot grip. By default hot grips display in red. The **midpoint** grip on lines (1.25.10) and infinite (1.25.13) lines, the **startpoint** grip on rays (1.25.11), the **center** grip on circles (1.25.14), arcs (1.25.15), ellipses (1.25.21) and elliptical arcs (1.25.16), the grip on points (1.25.33) and the **insertion point** grip of texts (1.29.20), mtexts (1.29.20), blocks (1.30.6) and Xrefs (6.13.23) can be used to quickly move such entities.

NOTE	When DRAGSNAP (1.21.15) is ON, dragged entities display at the current entity snap location.

Selecting multiple grips

1. Select all entities you want to edit.
2. Press and hold the Shift key, then click the first grip. The selected grip displays in red.
3. Keep the Shift key pressed, then click more grips. All selected grips display in red. (1.1206)
4. Release the Shift key, then click the hot grip you want to use as the base point. The hot grips move simultaneously.

Figure 1.1206



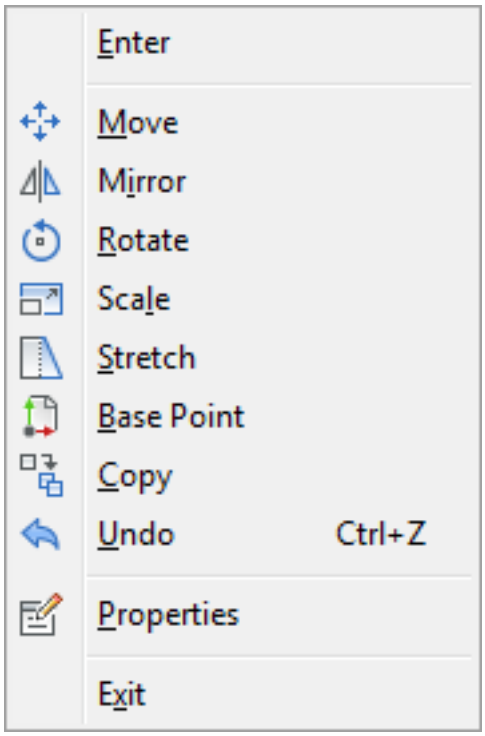
Keyboard	Prompt Box	Description
B	Base Point	Prompts you to specify a new base point, other than the selected grip.
C	Copy	Copies the selected entities and keeps the originals. By default, multiple copies can be created. Press Enter to stop making copies.
U	Undo	If the **Copy** option is chosen, deletes the latest copy.
R	Reference	(Applies to **Grip Rotate** only) Allows to specify a reference angle. Type the angle in the command bar or specify two points.
X	Exit	Aborts the grip edit command.

The grips editing context menu

The grips editing commands can either be chosen by repeatedly hitting the space bar or the Enter key or in a context menu. To display the context menu, do the following:

1. Select the entities you want to manipulate, then drag one of the grips.
2. Right click. (1.1207 on the facing page)

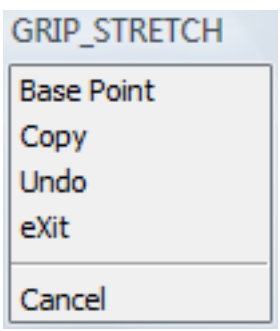
Figure 1.1207



To stretch entities using grips

1. Select the entity or entities.
2. Select the grip or grips (1.32.3) you want to manipulate.
3. Click the grip you want to use as the base point. All selected grips move simultaneously. The **GRIP_STRETCH** prompt box displays: (1.1208) **You are prompted:** Enter new point: Base point/Copy/Undo/eXit:
4. Do one of the following to define the displacement point:
   - Click in the drawing.
   - Enter the coordinates (1.21.11), then press Enter.
   - Key-in (1.21.4) the distance, then press Enter. Use ORTHO (1.21.2) or Polar Tracking (1.21.18) to control the angle.

Figure 1.1208

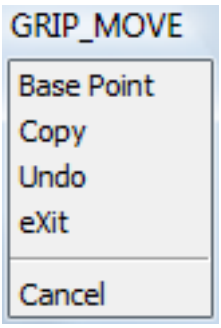


To move entities using grips

1. Select the entity or entities.
2. Select the grip or grips (1.32.3) you want to manipulate.
3. Click the grip you want to use as the base point for the move. The **Grip Stretch** command is launched.
4. Do one of the following:
   - Right click, then select **Move** in the context menu.
   - Hit the **Space bar** or **Enter** key to cycle through the **Grips Editing** commands until **Move** is active.

   The **GRIP_MOVE** prompt box displays: (1.1210 on the facing page) **You are prompted:** Enter move point: Base point/Copy/Undo/eXit:
5. Do one of the following to define the displacement point:
   - Click in the drawing.
   - Enter the coordinates (1.21.11), then press Enter.
   - Key-in (1.21.4) the distance, then press Enter. Use ORTHO (1.21.2) or Polar Tracking (1.21.18) to control the angle.

Figure 1.1209

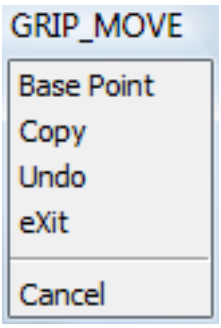


To copy entities using grips

1. Select the entity or entities.
2. Select the grip or grips (1.32.3) you want to manipulate.
3. Click the grip you want to use as the base point for the move. The **Grip Stretch** command is launched.
4. Do one of the following:
   - Right click, then select **Move** in the context menu.
   - Hit the **Space bar** or **Enter** key to cycle through the **Grips Editing** commands until **Move** is active.

   The **GRIP_MOVE** prompt box displays: (1.1210) **You are prompted:** Enter move point: Base point/Copy/Undo/eXit:
5. Do one of the following
   - Choose **Copy** in the context menu.
   - Type **C** , then hit the **Space bar** or **Enter** key.
6. Do one of the following to define the displacement point:
   - Click in the drawing.
   - Enter the coordinates (1.21.11), then press Enter.
   - Key-in (1.21.4) the distance, then press Enter. Use ORTHO (1.21.2) or Polar Tracking (1.21.18) to control the angle.
7. Repeat the previous step to create more copies or press the Space bar or Enter key to stop.

Figure 1.1210

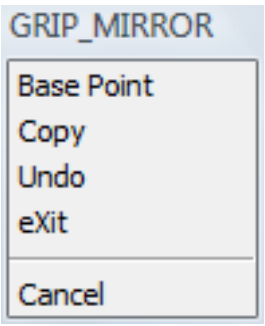


To mirror entities using grips

1. Select the entity or entities.
2. Select the grip or grips (1.32.3) you want to manipulate.
3. Click the grip you want to use as the base point for the mirroring. The **Grip Stretch** command is launched.
4. Do one of the following:
   - Right click, then select **Mirror** in the context menu.
   - Repeatedly hit the **Space bar** or **Enter** key to cycle through the **Grips Editing** commands until **Mirror** is active.

   The **GRIP_MIRROR** prompt box displays. (1.1211) **You are prompted:** Enter second point: Base point/Copy/Undo/eXit.
5. Specify a second point to define the mirror axis. The selection is mirrored.

Figure 1.1211

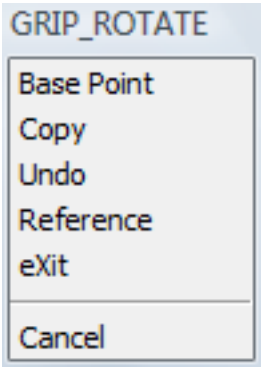


To rotate entities using grips

1. Select the entity or entities.
2. Select the grip or grips (1.32.3) you want to manipulate.
3. Click the grip you want to use as the base point for the rotation. The **Grip Stretch** command is launched.
4. Do one of the following:
   - Right click, then select **Rotate** in the context menu.
   - Repeatedly hit the **Space bar** or **Enter** key to cycle through the **Grips Editing** commands until **Rotate** is active.

   The **GRIP_ROTATE** prompt box displays. (1.1212) **You are prompted:** Enter rotation angle: Base point/Copy/Undo/eXit.
5. Do one of the following to rotate the selection:
   - Specify a point to define the rotation angle.
   - Type the rotation angle in the command bar, then press Enter

Figure 1.1212



To scale entities using grips

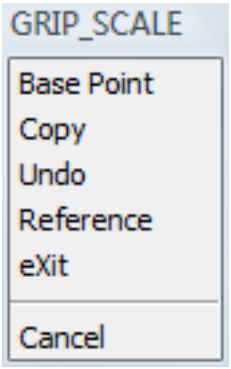
1. Select the entity or entities.
2. Select the grip or grips (1.32.3) you want to manipulate.
3. Click the grip you want to use as the base point for the scaling. The **Grip Stretch** command is launched.
4. Do one of the following:
   - Right click, then select **Scale** in the context menu.
   - Repeatedly hit the **Space bar** or **Enter** key to cycle through the **Grips Editing** commands until **Scale** is active.

   The **GRIP_SCALE** prompt box displays. (1.1213)

   You are prompted: Enter scale factor: Base point/Copy/Undo/eXit.
5. Type the scale factor in the command bar, then press Enter to scale the selection.

Tutorial: Grips Editing in BricsCAD Click here (1.14.5) to watch

Figure 1.1213



1.32.4 Selection and grip settings

When you select entities in a drawing, the selection method and the display of selected entities, e.g. whether grips display or not, is controlled by a number of settings.

Selection settings

Selection settings sit in the **Selection** settings group of the **Program Options** settings category in the Settings (1.17.10) dialog. (1.1214 on page 1337)

Name	System Variable	Description
Highlight	HIGHLIGHT	Determines wether or not entities highlight on screen when selected.
Image highlight	IMAGEHLT	Determines whether the entire raster image highlights or only the raster image frame when selected.
Pick add	PICKADD	Controls whether subsequent selections replace the current selection set or add to it. **ON** : The selection set is extended if you select additional entities. Press and hold the Shift key to remove entities from the selection set. **OFF** : You cannot add entities to a selection set. The newly selected entity or entities replace the existing selection set. However, if you press and hold the **Shift** key, you can add entities. If you select an entity that was already selected while pressing the **Shift** key, this entity is removed from the selection set.
Pick automatic	PICKAUTO	Controls automatic window selection (inside or crossing) when selecting entities. The value is stored as a bitcode using the sum of the selected options. • negative: Disables window selection, saving current value. • 1 = draws a selection window if the mouse is over a blank area of the drawing when clicked. • 2 = draws a selection window if the mouse is over an entity when dragged.
Pick box	PICKBOX	Defines the size of the small square at the end of the selection cursor ( ) . If you select an entity by clicking the **Pick Box** must touch or overlap the entity. The default size of the **Pick Box** is 3.

Pick drag	PICKDRAG	Controls the method of drawing a selection window. **ON** : Allows to define a selection window by dragging:press and hold the left mouse button to define the first corner of the rectangle, then move the mouse to define the size of the selection window and release the mouse button to define the opposite corner. **OFF** : Define the selection window by clicking two opposite corners.
Pick first	PICKFIRST	Controls whether you select objects before or after you issue a modification command. **ON** : Allows to first compose a selection set, then launch a modification command. **OFF** : You must first start the command, then compose the select entities.
Pick style	PICKSTYLE	Controls the selection of groups and associative hatches. • 0 = No group selection, nor associative hatch selection. • 1 = Group selection: if a member of a selectable group is selected, all members of the group are selected. • 2 = Associative hatch selection: the hatch and its boundary are selected, no matter what is picked: the hatch or the boundary (not supported yet). • 3 = Group selection and Associative hatch selection.
Match options for SELECTSIMILAR	SELECTSIMILARMODE	Controls which properties must match for an entity of the same type to be selected with the SELECTSIMILAR (6.27.23) command. (1.1216 on page 1339)
Selection area	SELECTIONAREA	Controls the display of selection area effects.
Selection area opacity	SELECTIONAREAOPACITY	Controls the transparency of the selection area: the higher the value the more opaque the selection area.
Crossing area color	CROSSINGAREACOLOR	Specifies the color for crossing selection areas.
Window area color	WINDOWAREACOLOR	Specifies the color for window selection areas.

Selection preview display	SELECTIONPREVIEW	Controls when entities highlight when the cursor hovers over them: • 0 = never; • 1 = when no commands are active; • 2 = when a command prompts for entity selection; • 3 = both, when no commands are active and when a command prompts for entity selection. When the QUAD (1.15.5) cursor menu is active, SELECTIONPREVIEW is neglected, unless a command prompts for entity selection.
Selection preview effect	PREVIEWEFFECT	Controls the appearance of highlighted entities: 0=dashed lines; 1=thickened lines; 2=dashed and thickened lines (not yet supported).
Selection preview filter	PREVIEWFILTER	Controls which entity types are excluded from selection previewing. The options are: • Entities on locked layers • Entites in Xrefs • Tables • Mtext entities • Hatches • Groups
GL Selection Highlight Style	HIGHLIGHTEFFECT	Specifies the highlight method: • 0=dashed lines • 1=use different color • 2=use thickened line • 3=use different color and thickened line.
Selection Highlight color	HIGHLIGHTCOLOR	Specifies the highlight color to be used when HIGHLIGHTEFFECT is 1 or 3.

Selection Modes	SELECTIONMODES	Defines which subentities should highlight in selection preview. The variable is stored as a bitcode using the sum of the values of all selected options. Click the buttons on the **Selection Modes** toolbar to set the value of SELECTIONMODES. A pressed button indicates the option is selected. (1.1217 on page 1339) (1.1218 on page 1339) • 1 = Enable detection of 3D solid edges () • 2 = Enable detection of 3D solid faces ()* • 4 = Enable boundary detection (). Controls whether closed boundaries in XY-plane of the current coordinate system or on the face of 3D solids highlight when no commands are active. The BOUNDARYCOLOR system variable specifies the color for highlighting detected boundaries. * Hold down the Ctrl-key to invert the status of the **Select Faces** option: if ON allows to select 3D solids, if OFF allows to select solid faces. Repeatedly pressing the TAB key, while keeping the cursor at the same position, highlights all included subentity types one by one. See also window selection (1.32.7).
Constraint Bar Display	CONSTRAINTBARDISPLAY	Controls the visibility of a geometric constraint at its creation or selection.
Dynamic Constraint Mode	DYNCONSTRAINTMODE	Controls the visibility of hidden dimensional constraints when the constrained entity is selected. When the cursor is over an entity with a dimensional constraint, the blue constraint glyph displays.
	User Preference	
Preview selection delay	PreviewDelay	Specifies how many milliseconds to wait before highlighting the (sub)entities under the cursor.

Figure 1.1214

Selection	
Pick add	☑ Add selected entities to current selection set
Pick automatic	0x0003 (3)
negative	☐ Disables window selection, saving earlier value

8	☐ Exclude multiline text entities
16	☐ Exclude hatch entities
32	☐ Exclude entities in groups
Selection modes	0x0000 (0)
1	☐ Select edges
2	☐ Select faces
4	☐ Select detected boundaries
Delay to preview selection	30
Constraint Bar Display	0x0003 (3)
1	☑ Displays constraint bars when geometrical constraints are added.
2	☑ Displays hidden constraint bars when constrained entities are selected.
Dynamic Constraint Mode	☐ Display hidden dimensional constraints when the constrained entities are selected.

Grips settings

If the **Grips** system variable is different from zero, grips display on selected entities. **Grips** settings sit under **Display/Viewing** in the **Drafting** settings group of the **Drawing** settings category in the Settings (1.17.10) dialog. Grips can be used to manipulate entities (see Grips Editing (1.32.3)) (1.1215 on the next page)

Name	System Variable	Description
Grips	GRIPS	The value of GRIPS can be 0, 1 or 2 • 0 : No grips. • 1 : Display grips. Polyline endpoint and midpoint grips. • 2 : Display grips. No midpoint grips on polyline segments.
Grips in blocks	GRIPBLOCK	Toggles the display of grips on entities in blocks on/off.
Grip color	GRIPCOLOR	Sets the color of unselected grips. Default value is green (index color no. 72).
Selected grip color	GRIPHOT	Sets the color of selected grips, so called 'hot grips'. Default value is red (index color no. 240).
Hover grip color	GRIPHOVER	Sets the color of an unselected grip when the cursor pauses over it. Default value is blue (index color no. 150).
Grip size	GRIPSIZE	Sets the size of the grip box, expressed in pixels. Default value = 4.
Grip object limit	GRIPOBJLIMIT	Suppresses the display of grips if the number of selected objects exceeds the value of GRIPOBJLIMIT. If set to 0 (zero) grips always display.
Grip tips	GRIPTIPS	(Not supported yet) Determines whether grip tips display when the cursor hovers hover grips on custom entities or dynamic blocks that support grip tips.
Grips attraction	EnableAttraction (*)	Toggles the magnetism of grips on/off.
Grips attraction distance	AttractionDistance (*)	Sets the grips attraction distance: if the cursor is within this distance the cursor is attracted by the grip and jumps to it.

(*) User Preference

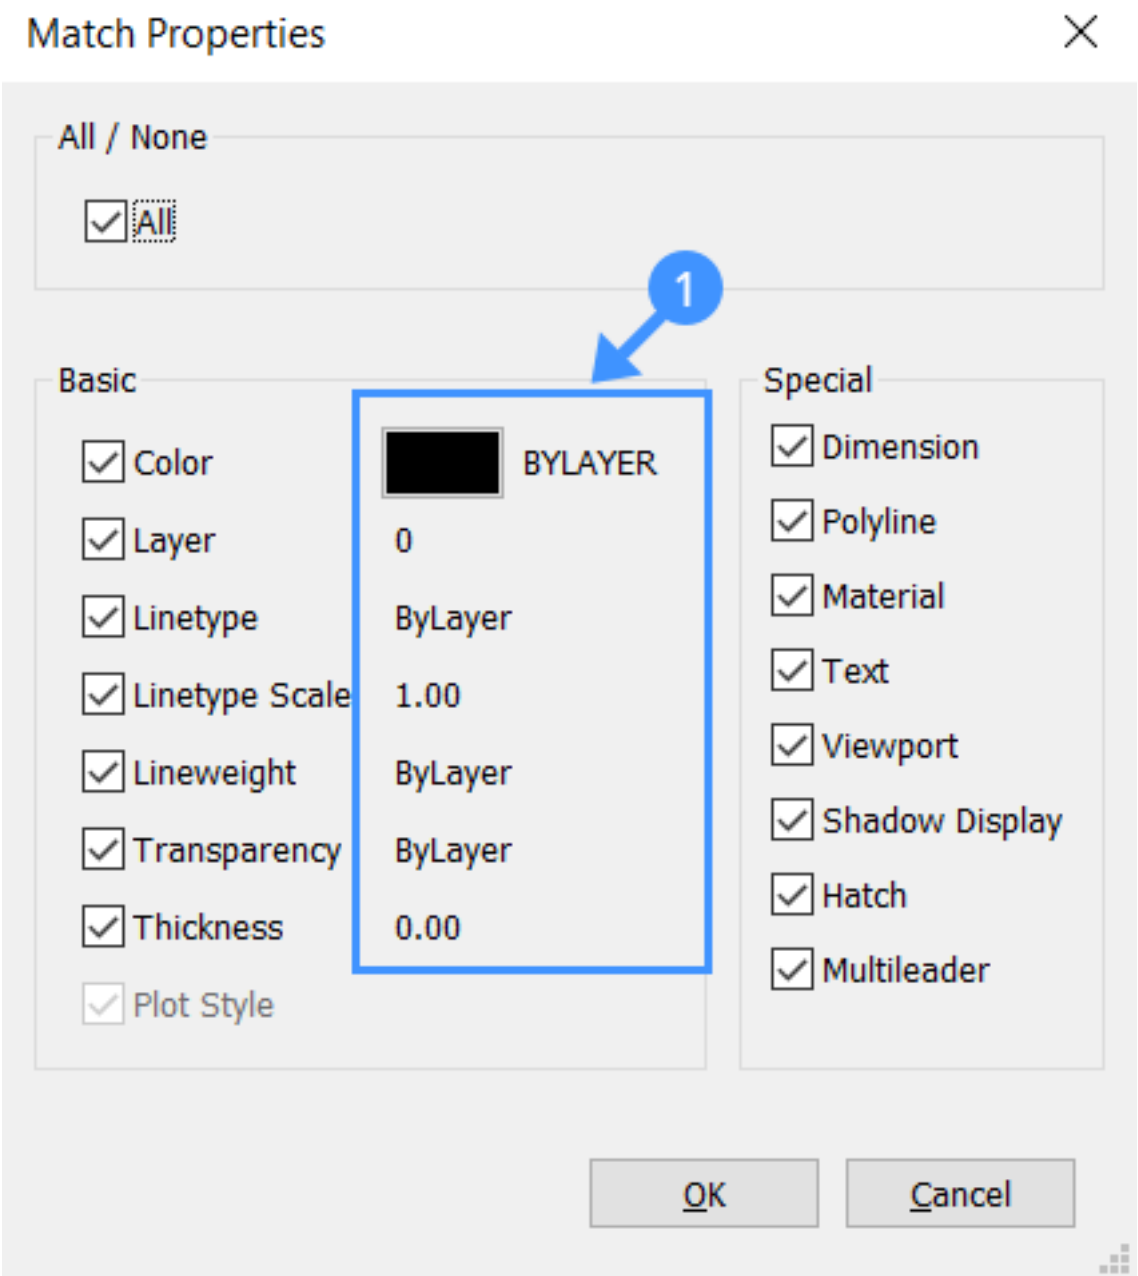
1.32.5 Match Properties

Command: MatchProp (6.21.18) The **Matchprop** command (short for "match properties") assigns the properties of one entity to other entities.

To copy properties between entities

1. Launch the MatchProp (6.21.18) command. **You are prompted:** Select entity to copy properties from:
2. Select the source entity. **You are promted:** Active Settings: 'Color' 'Layer' 'Linetype' 'Linetype Scale' 'Lineweight' 'Thickness' 'Plot Style' 'Dimension' 'Polyline' 'Material' 'Text' 'Shadow Display' 'Hatch' 'Multileader' Select entities to copy properties to or [Settings]:
3. **Optional** Type **S** , then press Enter. The **Match Properties** dialog box is displayed: (1.1219 on the facing page) The entity properties you are about to copy display in the Match Properties dialog (1).
4. Adjust the settings, then click the **OK** button.
5. Select the target entities. **You are prompted:** Select entities to copy properties to or [Settings]:
6. Do one of the following:
   - Repeat step 3 to adjust the settings, then select more target entities.
   - Right-click, or press Enter, to stop.

Figure 1.1219



Copy properties between entities with BIM data

Whether the **Matchprop** command copies BIM data depends on the value of the BimMatchProp (1.17.10) user preference. **BimMatchProp = 0:** Match standard properties Only standard properties will be copied, according to the currently selected options (see above). **BimMatchProp = 1:** Match standard and BIM properties BIM data, including IFC properties and user defined properties (6.7.38) are copied, except:

- BIM Type*
- Composition/Profile
- GUID
- Quantities

Note: When using MatchProp between a BIM classified entity and an entity without any BIM data, the unclassified entity will be assigned the same BIM type and the corresponding BIM properties will be copied along, except Composition/Profile, GUID and Quantities.

1.32.6 Quick Select

Use smart filters to compose a selection set Using **Quick Select** you can specify filters, such as entity type, color, linetype or any other entity property, to compose a selection set. After composing the filter criteria you can choose to add the matching entities to a new selection set, add the entities to the current selection set or remove them from the current selection. **Quick Select** applies to the entire drawing or to a previously created selection.

Tutorial: Use Quick Select Click here (1.14.8) to watch

To create a selection set

1. Click the **Quick Select** tool button ( ) on the Properties bar (1.15.4). The **Properties bar** mode is set to **Quick Select** . (1.1220 on the next page) The **Apply to current selection set** option is checked if a selection set exists. (1.1221 on the following page)
2. Click the **Selection List** button, to see a list of all entity types in the current drawing or current selection set (see previous step). A list of all entities in the drawing and the number of entities of each type displays. (1.1222 on page 1345)
3. Select an entity type in the list, e.g. **Line** . Line properties show in the **Properties** Bar. (1.1223 on page 1346)
4. Specify the property filters, e.g. **Color** , **Layer** and **Linetype** . (1.1224 on page 1347)
5. (option) Specify a different selection operator for each entity property: Click the = sign, then select an operator in the list. (1.1225 on page 1348)
6. Do one of the following:
   - Click the **Add to new selection set** button ( ). The entities that match the selected criteria are selected. (1.1226 on page 1349)
   - Click the **Add to the current selection set** button ( ). The entities that match the selected criteria are added to the current selection.
   - Click the **Remove from current selection** set button ( ). The entities that match the selected criteria are removed from the current selection.
7. (option) Repeat the above procedure to further refine the selection set.

Figure 1.1220

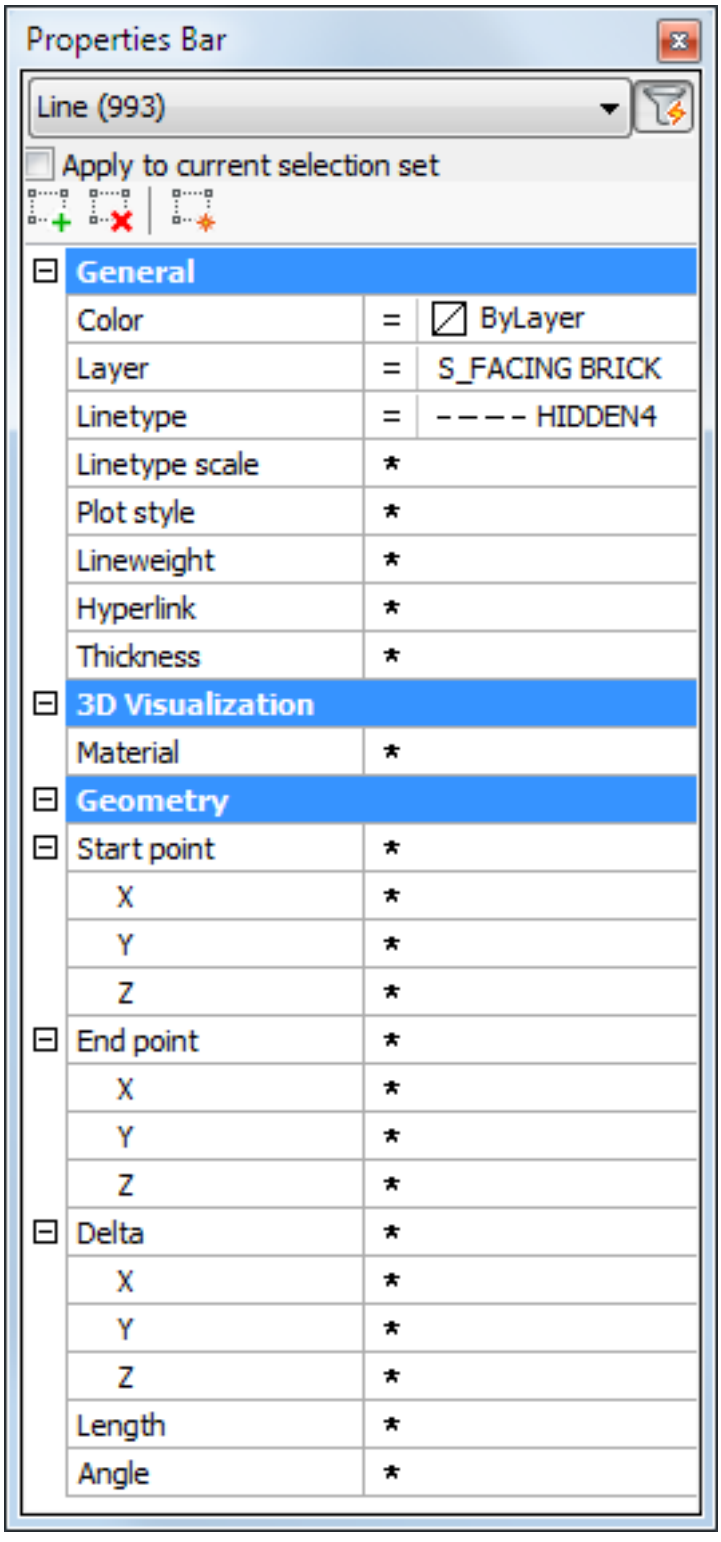

Figure 1.1225

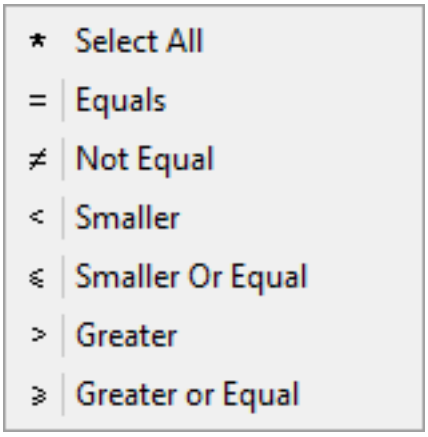

Figure 1.1226

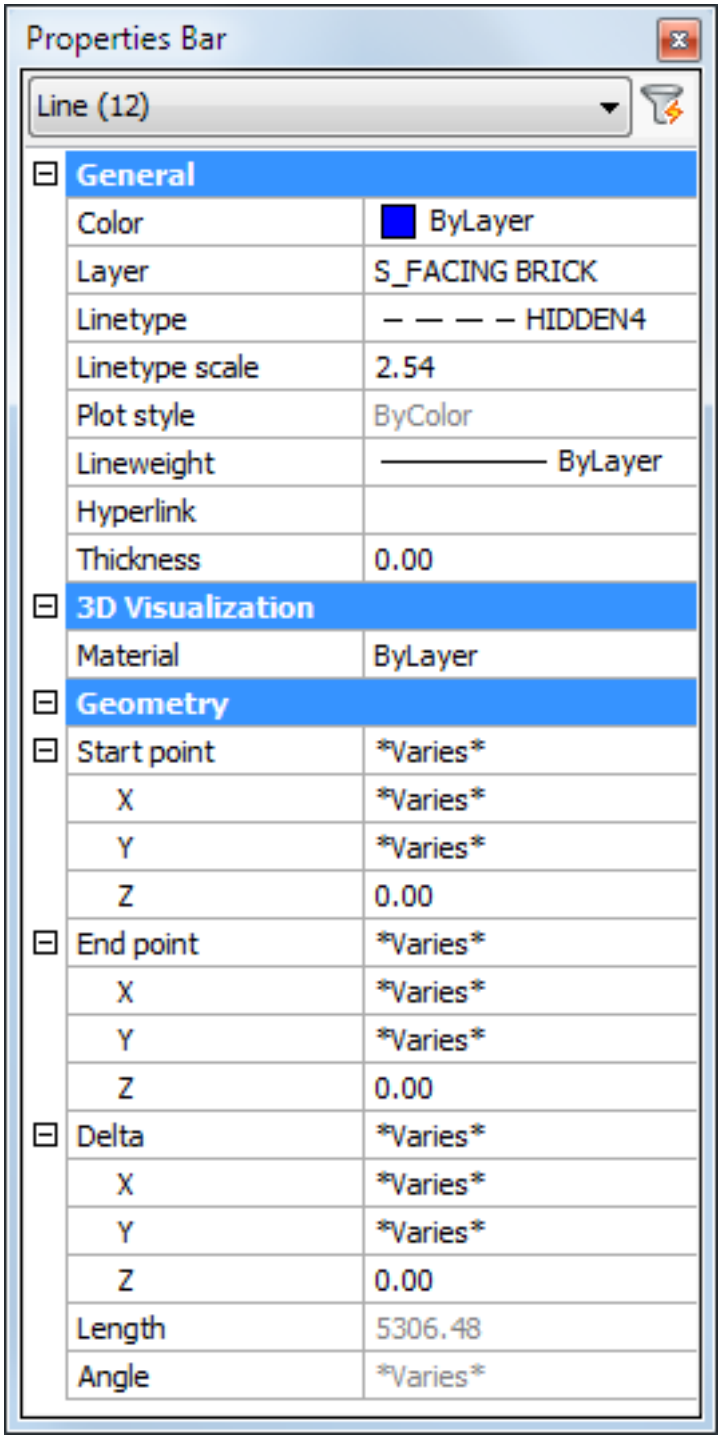


1.32.7 Selection Methods

https://www.youtube-nocookie.com/embed/0RgInrXDIVU Before you start to use modification commands, you need to know how to compose a selection set. If the **PICKFIRST** variable is **ON** you can build the selection set before starting the command, else you are prompted to select the entities after you launched the modification command. Using QUICK SELECT (1.32.6) you can specify filters, such as entity type, color, linetype or any other entity property, to compose a selection set. The SELECTIONPREVIEW (1.32.4) and PREVIEWEFFECT (1.32.4) system variables facilitate the selection procedure.

Composing a selection set before (pre-pick)

To compose a selection set before launching a modification command do one or more of the following:

- Click entities. Selected entity highlight and grips show.
- Window selection:
  - Click to define the first corner of a selection window. Move the mouse to the left to define a **Crossing Window**:  All entities which overlap the window or are completely inside the window are added to the selection set. The selection window displays in dashed lines with a green background.
  - Click to define the first corner of a selection window. Move the mouse to the right to define a **Window-Inside**:  All entities which are completely inside the window are added to the selection set. The selection window displays in continuous lines with a blue background.
  - Pressing the Ctrl key during window selection allows to select faces or edges of 3D solids and surfaces. The icon next to the cursor indicates the selection mode:  : Solids (Default)  : Faces  : Edges

  Depending on the value of the TIPS (1.17.10) system variable, the Hotkey Assistant widget (1.15.2) displays to indicate the current selection mode: (1.1227)
- Press an hold the **Shift** key, then use one of the above methods to **remove** entities from the selection set.

NOTE

- If the **PICKADD** system variable is **OFF** , you cannot add entities to a selection set.
- Press and hold the left mouse button to start window selection when the entity under the cursor highlights. This method is especially helpful for window selection in rendered 3D models.

Figure 1.1227

Composing a selection set afterwards (post-pick)

Command: SELECT (6.27.16) If you launch a modification command when no selection set is active, **you are prompted** to select entities. BricsCAD provides a range of selection methods to let you compose your selection set easily. The various selection methods are:

- **Add to set**: Selected entities are added to the selection set.
- **Subtract from set**: Selected entities are removed from the selection set.
- **Picking**: Place the pickbox over a part of the object and click.
- **Select all entities**: Select all entities in the entire drawing, including entities which are on hidden layers. Entities on frozen layers are not selected.
- **Previous selection**: Re-use the previous selection set.
- **Last entity in drawing**: Select the most recent entity.
- **Window**: All entities which are inside, overlap or are completely outside a window are selected. You can choose between a **rectangle**, **polygon** or a **circle**.
- **Fence**: All entities that cross a multi-segment line are selected.
- **Point**: Click a point to select all closed entities which enclose this point.
- **Select by Properties**: Displays the **Select by Properties** context menu to select entities by **Color**, **Layer**, **Linetype**, **Name**, **Thickness**, **Type**, **Value**, **Width** or **Handle**.
- **Undo**: Undoes the last selection action.
- **Location**: Displays the **Select Location** context menu.

(1.1228 on the next page) (1.1229 on page 1353)
Select Location and Select By Properties context menus

Selecting overlapping entities

When entities are close together or lie on top of each other it is difficult or sometimes impossible to select the entities needed. Cycling through the overlapping entities, highlighting each entity one by one, helps you to select such entities. Make sure SELECTIONPREVIEW (1.32.4) is ON and/or the Quad cursor menu (1.15.5) is active.

1. Place the cursor over the overlapping entities. One of the entities highlights.
2. Repeatedly hit the TAB key. The overlapping entities highlight one by one.
3. Click when the desired entity highlights.
4. Repeat the previous steps to select more entities.

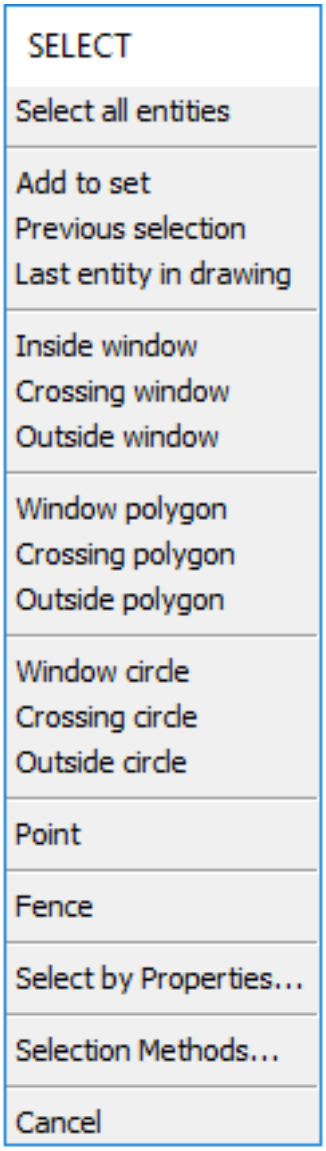
NOTES

- Do not move the mouse while hitting the TAB key, because this will restart the highlight order.
- Hold down the Shift key to cycle the overlapping entities in reverse order.

Selecting subentities

By default the entire entity is selected. To select subentities of compound entities, such as polylines, 3D polylines, regions, 3D solids, etc.. The following subentities can be selected: polyline segments, vertices and segments of 3D polylines, vertices, edges and faces of regions, surfaces, meshes and 3D solids. Do the following:

Figure 1.1228

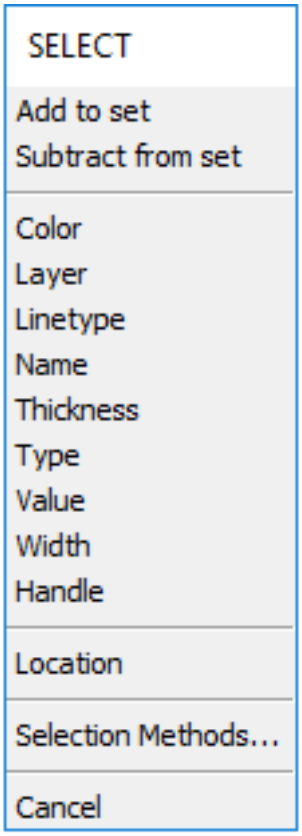


1. Place the cursor over the subentity.
2. When the entire entity highlights*, hold down the Ctrl key.
3. Click when the subentity highlights.
4. Repeat the previous steps to select more subentities.

*When a subentity is already selected, the entire entity does not highlight anymore.

NOTE The properties of the selected subentity show in the Properties panel (1.15.4).

Figure 1.1229



1.32.8 Adjusting the Draw Order

Commands: DRAWORDER (6.10.40), HATCHTOBACK (6.16.6), TEXTTOFRONT (6.29.13) If new entities overlap existing entities, they will display and print on top of the previously drawn entities. The **Draw Order** tool can change the order in which overlapping entities are displayed and printed. You can move entities to the front or the back, or above or under another entity.

Using Draw Order

1. Do one of the following:
   - Click the **Draw Order** tool button ( ) on the **Draw Order** toolbar.
   - Choose **Draw Order** in the **Tools** menu.
   - Type **draworder** in the command bar.

   You are prompted: Select entities to change the draw order:
2. Select the entities (1.32.7), then right click or press enter. **You are prompted:** Change draw order: Above/Under/Clear/Fro
3. Choose the appropriate draw order tool option.
4. Depending on your choice:
   - If you have chosen **Above** or **Under** , the command bar reads: Select reference entity: Identify the reference entity. The display of the selection set is changed with respect to the reference entity.
   - If you have chosen **Front** or **Back** , the display of the selection set is changed accordingly.

Using Draw Order tools

1. Select the entities (1.32.7) you want to change the draw order of.
2. Do one of the following:
   - Click the appropriate tool button on the **Draw Order** toolbar.
   - Right click, then choose **Draw Order** in the context menu and select the appropriate tool. (1.1230)

Tool Button	Tool Name	Description
	Bring To Front	Places the selection set on top.
	Bring Above	Places the selection set above the reference entity. (*)
	Send Under	Places the selection set under the reference entity. (*)

Figure 1.1230

	Send to Back	Moves the selection set to the back.
	Hatch to Back	Sends all hatch entities to the back.
	Text and Dimensions to Front	Brings all texts and/or dimension entities to front. Options: **Text / Dimensions / Both** can be chosen either in the command bar or in the prompt menu. The default option is **Both** .

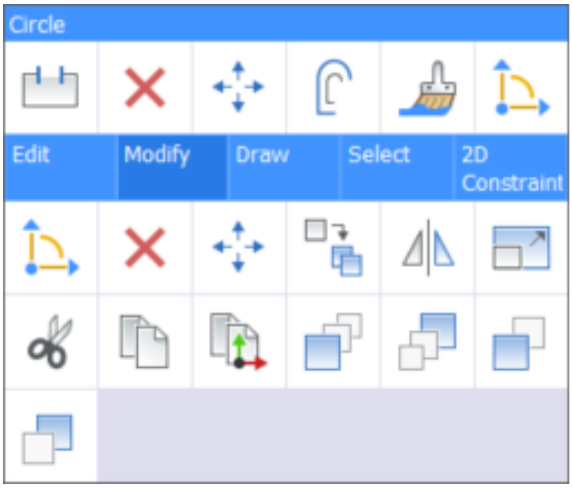
(*) **You are prompted** to select the reference entity.

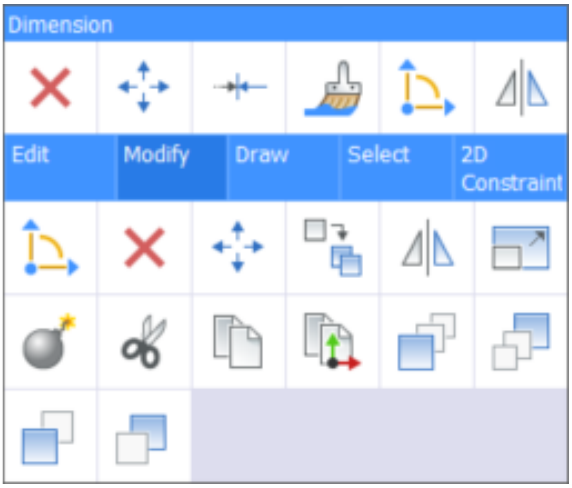
1.32.9 Entity Manipulation

Traditional Manipulation Tools

You can access most of the manipulation tools using typical methods such as the command line. They're also available on the Modify tab of the Quad when you select or hover over an entity. Unlike Edit tools which can vary significantly for different entities, the Modify tools are relatively consistent. For example, they include Erase, Move, Copy and tools to specify draw order. Some entities such as dimensions, hatches, and blocks, also include the Explode tool. Since you're probably familiar with all the traditional modify tools from your AutoCAD® experience, I'll focus on the one that's unique to BricsCAD, the Manipulator! (1.1231)

Figure 1.1231





Manipulator

The Manipulator is somewhat like the 3D Gizmos in AutoCAD (not available in AutoCAD LT). In BricsCAD the Manipulator is useful for both 2D and 3D entity manipulation. Therefore, it's available in all BricsCAD editions including Classic. You can access the Manipulator from the Quad when objects are selected. It's also accessible via other methods including the MANIPULATE command. (1.1232) With this single Manipulator tool, you can move, rotate, scale, copy and even mirror the selected entities. And, you can easily do so while constraining them along a specific axis or plane. Right-click on the Manipulator to access additional controls including a toggle to switch the Arrowhead behavior between Mirror and Scale. (1.1233 on the following page)

Figure 1.1232

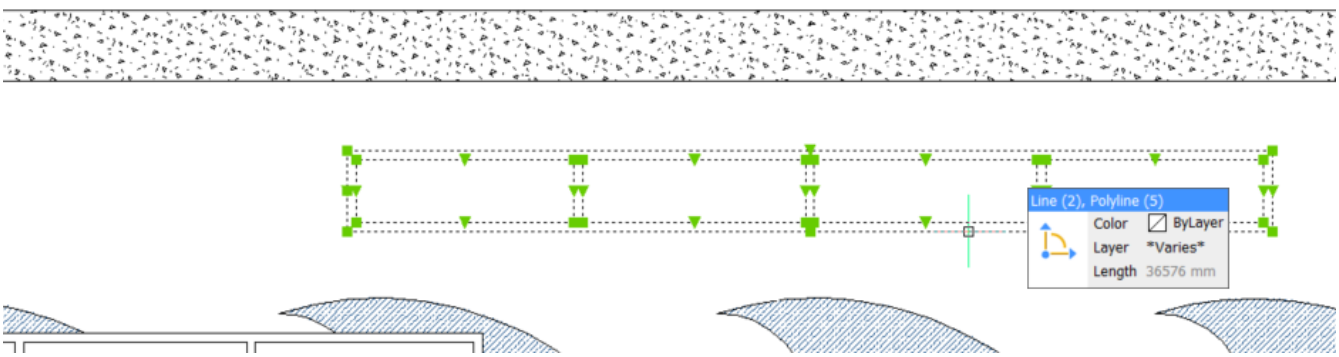


Figure 1.1233

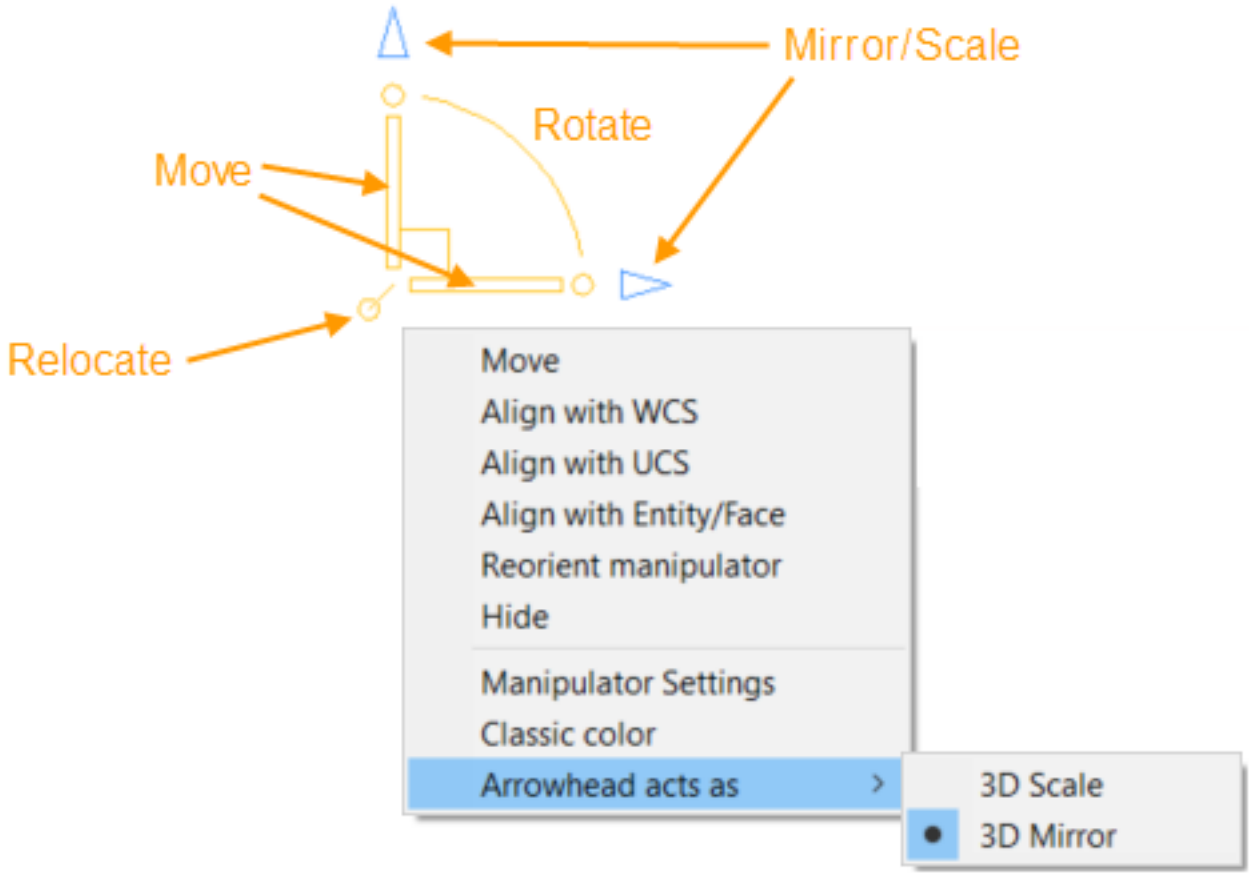


Reorient the Manipulator By default, the Manipulator displays at the center of the selection set. To move it, you can select the relocate grip and pick a new base point for the manipulation. As you move it across the drawing, it can automatically align with geometry enabling you to manipulate along any relevant axis. The default alignment is with the current UCS. Options on the right-click menu offer additional controls to reorient and align the Manipulator. (1.1234)

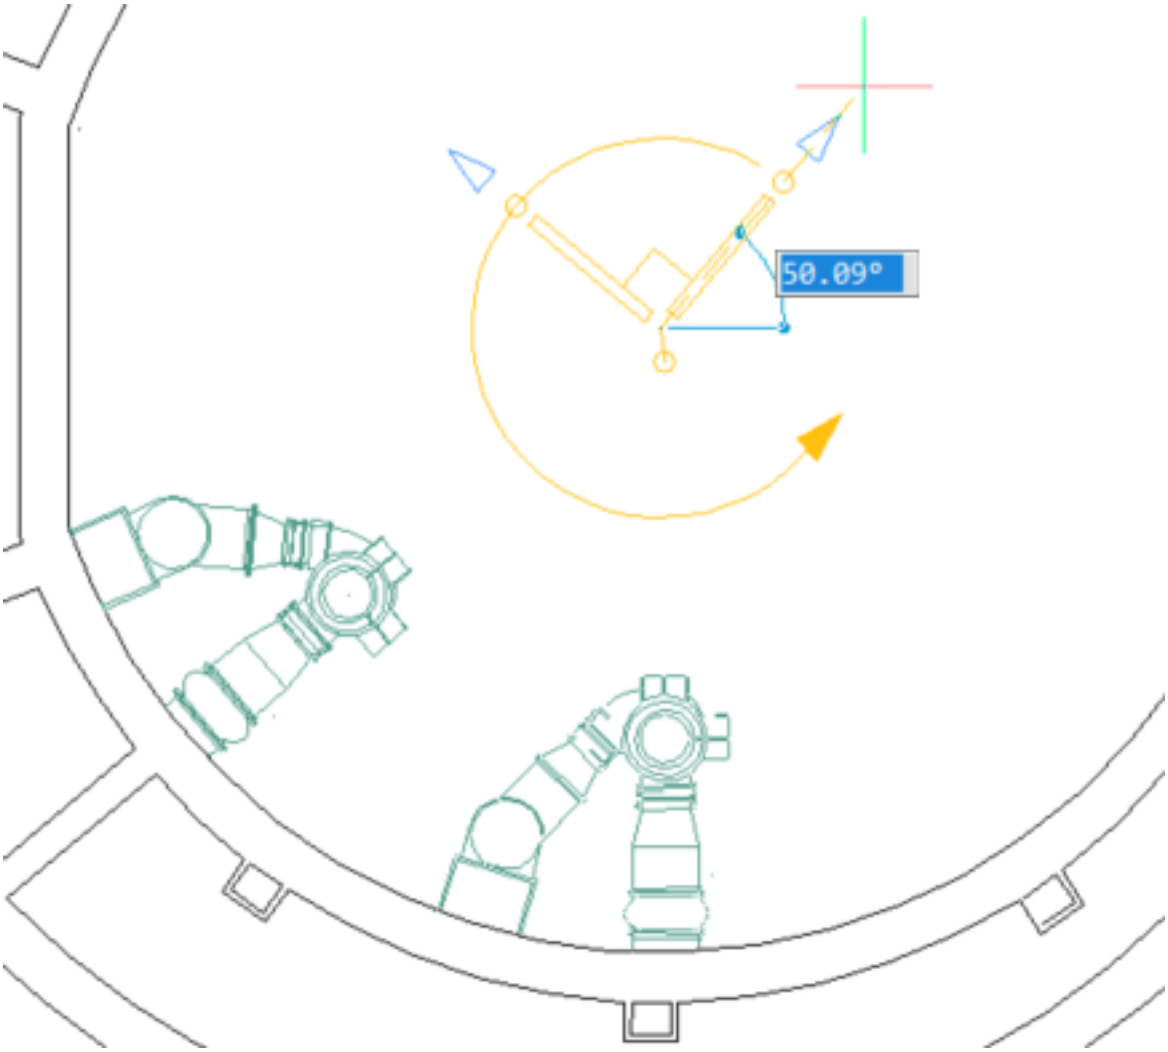
Figure 1.1234

Move With the Manipulator properly oriented, you can click an axis or plane to move the selected entities. Their movement is automatically constrained to the specified axis or plane as you pick the second point. (1.1235)

Figure 1.1235

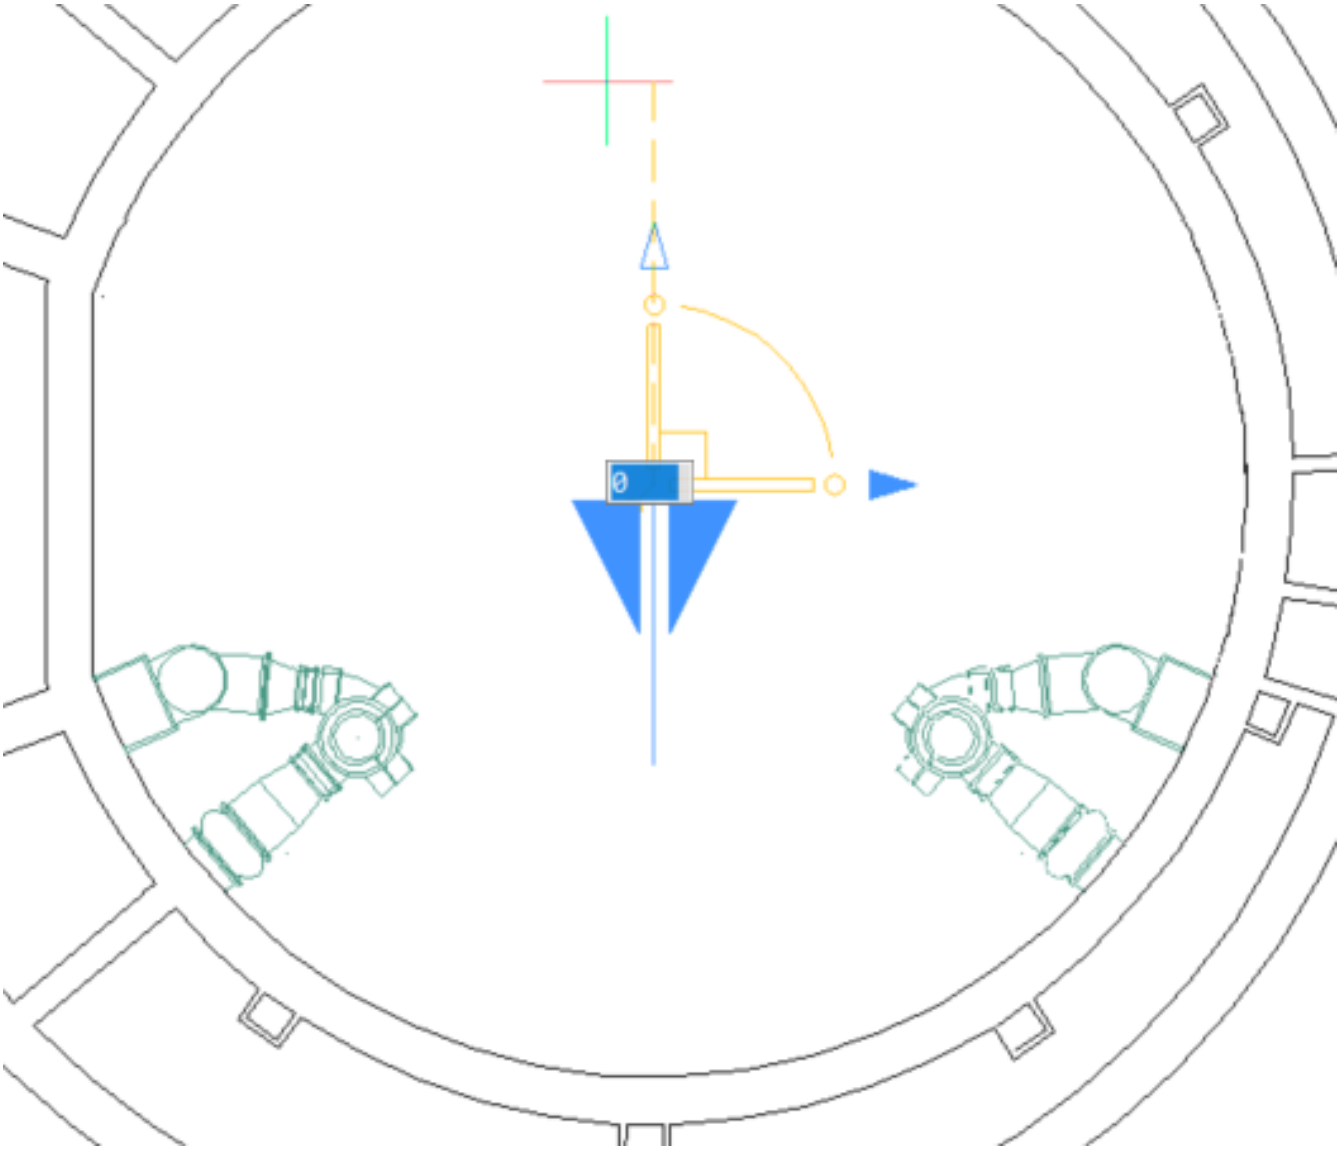
Rotate To rotate the entities around the basepoint of the manipulator, select the rotation arc. (1.1236 on the next page)

Figure 1.1236



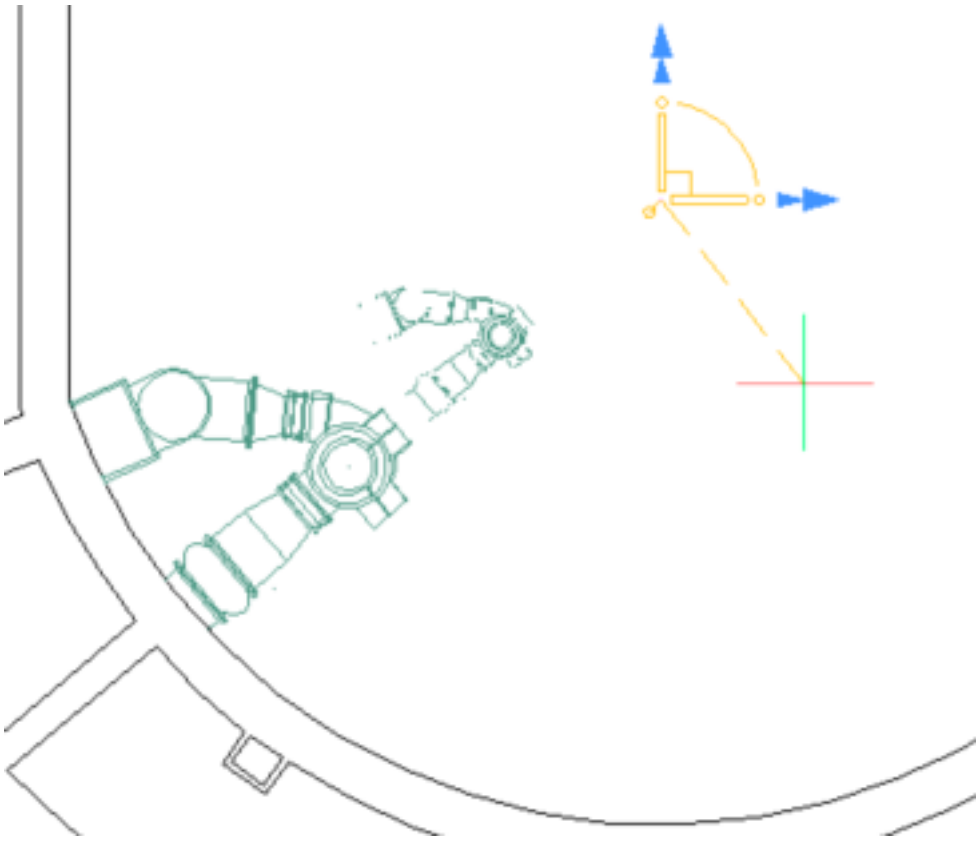
Mirror Select one of the arrowheads to mirror the entities along either axis. Mirror is the default behavior for the arrowheads. You can change their behavior to Scale using the right-click menu. (1.1237 on the facing page)

Figure 1.1237



Scale With the arrowhead behavior set to Scale, you can select either arrow to scale the selected entities from the manipulator basepoint. (1.1238 on the next page)

Figure 1.1238



Copy As you perform any of the four operations using the Manipulator (Move, Rotate, Mirror, Scale), you can create a copy of the selected entities. Simply press the Ctrl key as you select the operation.

1.32.10 Manipulator

Command: MANIPULATE (6.21.3) The manipulator is a versatile grip tool to swiftly move (6.21.3), rotate (6.21.3), scale (6.21.3) and mirror (6.21.3) selected entities. Holding down the Ctrl-key when starting the action keeps the original entities, thus creating copies. Upon selecting an entity, the manipulator is displayed at a user-controlled location and orientation. The location and orientation are controlled in a similar way as for a dynamic UCS. When multiple entities are selected simultaneously, the manipulator initially is placed at their geometric center. When a selection is built up step by step, the initial location of the manipulator is preserved. The manipulator can easily and directly be moved to any desired location or orientation using its handles. Depending on the operation type and if dynamic dimensions (1.21.9) are active, a dynamic entry field is available to set the distance, angle or scale factor.

Adaptive Snap Step

The snap step size automatically adapts to the current screen zoom factor if SNAPTYPE= 2. The AdaptiveGrid-StepSize SETTING controls the smallest available step size. The adaptive step size is used by Manipulator Ruler, which enables to quickly modify entities using precise values, without having to key in numbers.

The manipulator settings

To display the manipulator settings in the Settings (1.17.10) dialog:

1. Right click the manipulator.
   (a) Choose **Manipulator Settings** in the context menu. (1.1239 on the facing page) (1.1240 on the next page)

Name	Title
MANIPULATOR	Manipulator
MANIPULATORDURATION	Manipulator duration
ManipulatorSize	Size of manipulator
ManipulatorHandle	Manipulator Handle
ManipulatorColorTheme	Manipulator Color Theme
AdaptiveGridStepSize	Adaptive grid step size

Figure 1.1239

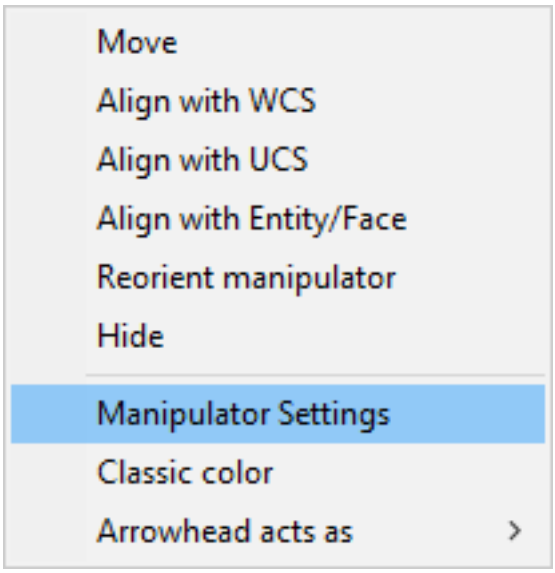


Figure 1.1240

Manipulator

Manipulator	[2] Display Manipulator if left mouse button was pressed longer than MANIPULATORDURATION.
Manipulator duration	250
Size of Manipulator	1
Manipulator handle	[0] Handle moves the Manipulator itself
Color theme of Manipulator	[0] Monochrome color theme
Adaptive grid step size	4

The manipulator layout

Check the **Classic Color** option in the manipulator context menu for the classic layout. Uncheck the option for the default layout.

(1.1244 on page 1370)	(1.1243 on page 1370)
Default	Classic

4 handles

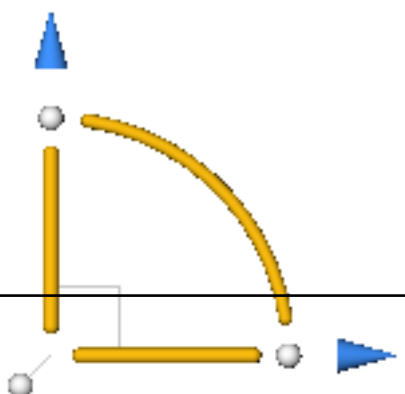
- **1**: manipulator handle
- **2**: axis handle

12 command trigger zones:

- **3**: axis
- **4**: arrowhead
- **5**: plane swatch
- **6**: rotation arc

When the current view is parallel to one of the main axes of the coordinate system, as in a plan view, the manipulator is simplified to a 2D version. (1.1241)

Figure 1.1241



The location and orientation of the manipulator

The initial location and orientation of the 3D manipulator tripod depends on:

- The entity type.
- The point you click on the entity.

Entity Type Selection point Manipulator Anchor point Orientation Line Near endpoint At endpoint X-axis through the other endpoint Near midpoint At midpoint X-axis through the nearest endpoint Polyline Line Segment Near vertex At vertex X-axis through the other vertex of the selected line segment Near segment midpoint At the segment midpoint X-axis through the nearest vertex Polyline Arc Segment On the arc segment At the arc center X-axis through the nearest vertex Arc Random At the arc center X-axis through the nearest endpoint Circle Random At the circle center X-axis Parallel with the X-axis of the current coordinate system Spline Random At the nearest endpoint Through the other endpoint Region On a line segment At the nearest endpoint of the line segment X-axis through the other endpoint On a arc segment At the center of the arc segment X-axis through the nearest endpoint of the arc segment Text, MText Block, Xref Random At the origin of the entity X-axis at the rotation angle of the entity. 3D Solid* 3D Solid Face* On a face of the solid At the nearest vertex X-axis along the nearest edge XY-plane in the selected face. Multiple Entities Random At the geometric center of the selection set** Parallel with the axes of the current coordinate system * See Selection Modes (1.32.4) to learn how to select a 3D solid face or the entire solid. ** The position of the manipulator does not change when more entities are added to the selection set.

To display the manipulator when multiple entities are selected

Do one of the following:

- Select the entities one by one or use window selection, then click to select the last entity
- Set the value of the MANIPULATOR (1.32.10) system variable to 1: **Display the manipulator whenever entities are selected**.
- Compose the selection set, then launch the MANIPULATE (6.21.3) command.

To relocate the manipulator

(1.1244 on page 1370)

To move the manipulator Do one of the following:

- Long-click anywhere on the manipulator and move it to a new location*.
- MANIPULATORHANDLE = 0: Click the manipulator handle (1) and move it to a new location*. The anchor handle stands out to avoid overlap with entity grips.
- MANIPULATORHANDLE = 1: Long click the manipulator handle (1) and move it to a new location*.
- Place the cursor over the manipulator then right click and choose **Move** in the context menu and move it to a new location*.

* Specify the new location using entity snaps.

To rotate the manipulator Select one of its axis handles (2) to rotate the manipulator. Pick a point or type a value in the dynamic entry field to specify the rotation angle. Press the SHIFT key to rotate the Manipulator 90 degrees about its normal axis (Z-axis).

To reorient the manipulator

1. Place the cursor over the manipulator, then right click and choose **Reorient** in the context menu. **You are prompted:** Specify origin of manipulator:
2. Pick a point. The anchor point of the manipulator is placed at the specified point. **You are prompted:** Point on X-axis or <Accept>:
3. Pick a point. The manipulator rotates about its X-axis. **You are prompted:** Point on the XY-plane with positive Y value or <Accept>:
4. Pick a point to define new position of the manipulator.

To align the manipulator with a coordinate system Move the cursor over the manipulator, then right click and select an option in the context menu:

- **Align with WCS** : the manipulator axes are forced parallel with the corresponding axes of the World Coordinate System.
- **Align with UCS** : if a UCS is currently the active coordinate system, the manipulator axes are forced parallel with the corresponding axes of the UCS.

To align the manipulator with the face of a solid Dynamic UCS (1.21.21) (DUCS) must be ON for this operation to succeed.

1. Place the cursor over the manipulator then right click and choose **Move** in the context menu.
2. Hover over the face of a solid. The XY-plane of the manipulator aligns with the solid face under the cursor.
3. Do one of the following:
   - Snap to a point on the selected face or on one of its edges.
   - Hit the Shift-key to lock the XY-plane to the selected face, then snap to a point outside the face.

Figure 1.1242

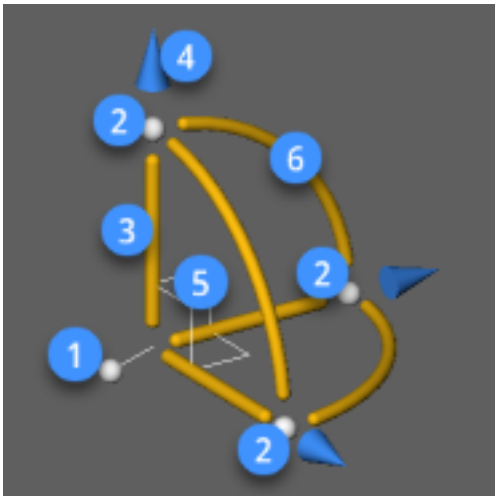


Figure 1.1243

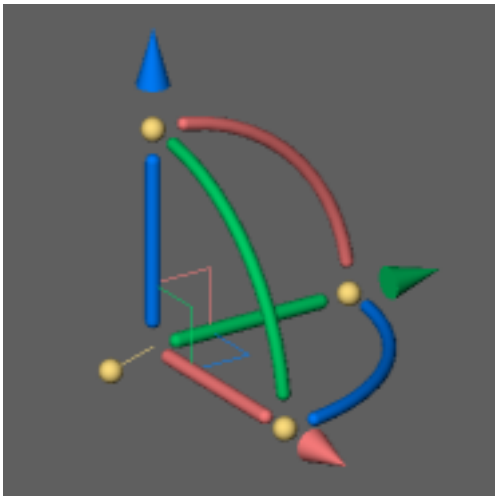

Figure 1.1244

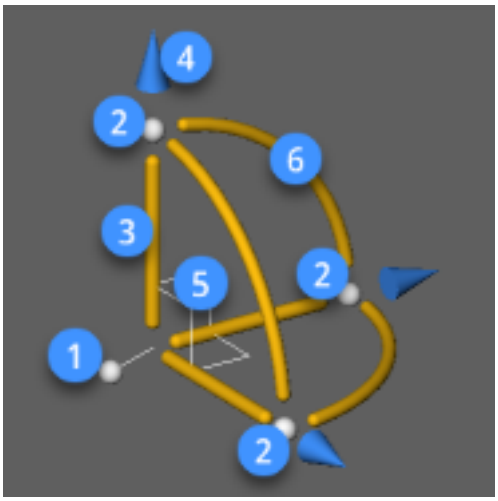


1.32.11 Moving Entities

Commands: MOVE (6.21.29), CUTCLIP (6.9.48), PASTECLIP (6.24.13), PASTEORIG (6.24.12) and PASTEBLOCK (6.24.11) The **Move** command moves entities in the drawing. The **Cutclip** command copies entities to the **Clipboard** , and then erases them from the drawing. The **Pasteclip** command pastes entities from the **Clipboard** into the current drawing (short for "paste clipboard"). The **Pasteorig** command pastes entities from the **Clipboard** into another drawing, using the coordinates of the source drawing. The **Pasteblock** command pastes entities from the **Clipboard** as a block into the current drawing. Use **Cutclip** then either **Pasteclip, Pasteorig** or **Pasteblock** to move entities to another drawing. The Copy option (1.32.3) of the Grips Editing (1.32.3) commands allows to create multiple copies of the entities being stretched, moved, rotated, mirrored or scaled.

NOTE	When DRAGSNAP (1.21.15) is ON, dragged entities display at the current entity snap location.

Moving entities in a drawing

The default method is to create a selection set and then specify a starting point (base point0 and an endpoint (displacement point) to define the relocation of the entities. You can also move the entities using a direction vector. Some entities can be moved using grips. The grip you select depends on the type of entity. For example, to move a line entity, select the midpoint grip. To move a curved entity, such as an arc, circle, or ellipse, select the center point grip. Not all entities can be moved using grips.

Using the Move command

1. Do one of the following:

   - Click the **Move** tool button () on the **Modify** toolbar.
   - Choose **Move** in the **Modify** menu.
   - Type **move** or **M** in the command bar.

   You are prompted: Select entities to move:

2. Select the entities (1.32.7), then right click or press Enter. **You are prompted:** Vector/<Base point>:

3. Specify the base point. The selection set is now attached to the cross hairs. **You are prompted:** Displacement point.

4. Do one of the following to specify the displacement point.

   - Click the displacement point.
   - Use Direct Distance Entry (1.21.4): type the displacement distance, then press Enter. The distance is measured in the cursor direction. Use ORTHO (1.21.2) or POLAR TRACKING (1.21.18) to constrain the movement of the cross hairs.

The selection set is moved.

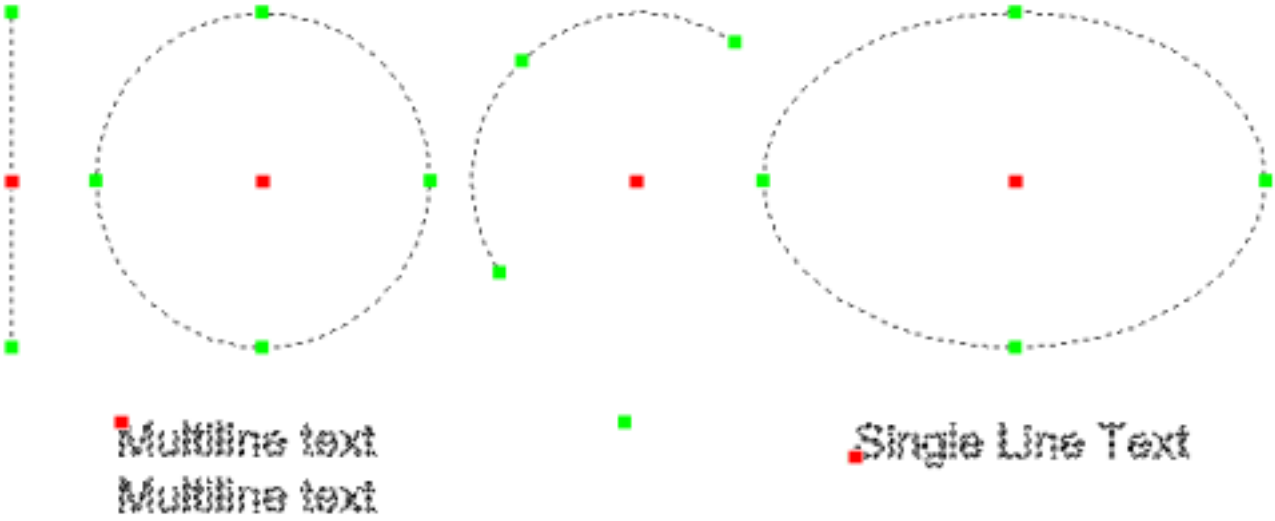
Moving entities using grips

1. Select the entity.

2. Click the grip. The selected grip displays in the **Selected Grip Color** (defined by the **GRIPHOT** system variable, default = RED). The entity moves with the cross hairs. (1.1245 on the following page)

3. Click to relocate the entity.

Figure 1.1245



NOTE

The following entities can be moved using grips:

- lines, infinite lines and rays
- circles and circular arcs
- ellipses and elliptical arcs
- 3D solids
- text and multi-line text
- blocks

Moving entities between drawings

Entities can be moved between drawings in one of three ways: Use **CUTCLIP** to cut the entities from the source drawing, then either **PASTECLIP, PASTEORIG** or **PASTEBLOCK** to paste the entities into the target drawing.

NOTE

Use Ctrl + Tab (press and hold the Ctrl key, then press the Tab key) to cycle between open drawings.

Using Cut and Paste to move entities between drawings

1. In the source drawing, select the entities (1.32.7) you want to move.
2. Do one of the following:
   - Right click, then choose **Cut** in the context menu.
   - Choose **Cut** in the **Edit** menu.
   - Press **Ctrl + X** (press and hold the Ctrl key, then press X).

   The entities are deleted in the source drawing and copied to the Clipboard.
3. Switch to the target drawing.
4. Do one of the following:
   - Right click, then choose **Paste** in the context menu.
   - Choose **Paste** in the **Edit** menu.
   - Press **Ctrl + V** (press and hold the Ctrl key, then press V).

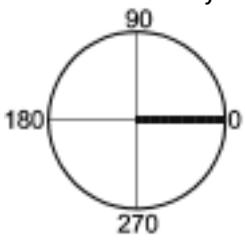
   The bottom left corner of the bounding rectangle of the selection is attached to the cross hairs in the target drawing.
5. Do one of the following:

The entities are deleted in the source drawing and copied to the Clipboard.

3. (option) Switch to the target drawing.
4. Choose **Paste as a Block** in the **Edit** menu or press Ctrl+Shfit+V. The bottom left corner of the bounding rectangle of the selection is attached to the cross hairs in the target drawing.
5. Specify the insertion point.

1.32.12 Rotating Entities

Commands: ROTATE (6.26.29) and ROTATE3D (6.26.31) You can rotate entities about a specified point at a specified rotation angle or by an angle referenced to a base angle. The default method rotates the entities using a relative rotation angle from their current orientation. By default, angles start at 3 o'clock and increase in a counter-clockwise direction. If you want to rotate in a clockwise direction you can enter a negative angle by using a minus sign.



NOTES

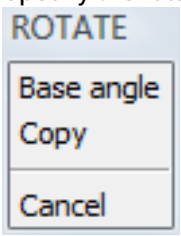
- The **Angular Base** is controlled by the **ANGBASE** system variable, which in turn refers to the current UCS.
- The **Angle Direction** is controlled by the **ANGDIR** system variable, which sets the positive angle direction from angle 0 with respect to the current UCS.

The Copy option (1.32.3) of the Grips Editing (1.32.3) commands allows to create multiple copies of the entities being stretched, moved, rotated, mirrored or scaled.

Rotating a selection set

1. Do one of the following:
   - Click the **Rotate** tool button ( ) on the **Modify** toolbar.
   - Choose **Rotate** in the **Modify** menu.
   - Type **rotate** or **RO** in the command bar.

   You are prompted: Select entities to rotate:
2. Select the entities (1.32.7), then right click or press Enter. **You are prompted:** Rotation point:
3. Specify the rotation point. **You are prompted:** Copy/Base angle/<Rotation angle>: A prompt menu displays:



4. (option) Choose **Copy** in the prompt menu or type **C** , then press Enter to create a rotated copy of the selection set.
5. Specify the rotation angle. The selection set is rotated.

NOTE Use the **Center** option of the Array (1.32.19) command if you want to keep the original entities.

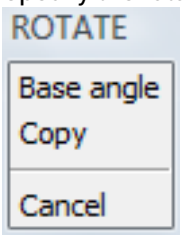
Rotating a selection set in reference to a base angle

1. Do one of the following:
   - Click the **Rotate** tool button (on the **Modify** toolbar.

- Choose **Rotate** in the **Modify** menu.
- Type **rotate** or **RO** in the command bar.

You are prompted: Select entities to rotate:

2. Select the entities (1.32.7), then right click or press Enter. **You are prompted:** Rotation point:
3. Specify the rotation point. **You are prompted:** Copy/Base angle/<Rotation angle>: A prompt menu displays:



4. (option) Choose **Copy** in the prompt menu or type **C**, then press Enter to create a rotated copy of the selection set.
5. Do one of the following:

- Choose **Base angle** in the prompt menu.
- Type **B** in the command bar, then press Enter.

You are prompted: Base angle <0>:

6. To specify the base angle do one of the following:

- Type the base angle in the command bar.
- Click the rotation point again, then click a second point.

You are prompted: New Angle.

7. Do one of the following:

- Type the new angle in the command bar.
- Click a point to define the new angle.

Rotating in 3D

1. Do one of the following.

- Click the **3D Rotate** tool button ( ) on the **Modify** toolbar.
- Choose **3D Rotate** in the **Modify** menu.
- Type **rotate3d** in the command bar.

You are prompted: Select entities to rotate:

2. Select the entities (1.32.7), then right click or press Enter. **You are prompted:** Select axis by [Entity/Last/View/Xaxis/Yaxi
<2points>:
3. Press Enter to define the rotation axis by specifying two points.
4. Specify the first rotation axis point.
5. Specify the second rotation axis point. **You are prompted:** Rotation angle or [Base angle/Copy]:
6. Specify the rotation angle. The selection set is rotated clockwise, looking in the rotation axis direction.

1.32.13 Mirroring Entities

Commands: MIRROR (6.21.17) and MIRROR3D (6.21.20) The **Mirror** command creates a mirror image of a selection set. The selection is mirrored about a mirror line, which you define by specifying two points. You can choose to either delete or retain the original entities. The **Mirror3d** commands creates a mirror image of selected entities in three-dimensional space. In this case the selection is mirrored about a mirror plan, which can be defined by either specifying three points, selecting an existing two-dimensional planar entity, aligning the plane parallel to the xy, yz, or xz plane of the current UCS or aligning the plane with the current view. You can choose to either delete or retain the original entities. The Copy option (1.32.3) of the Grips Editing (1.32.3) commands allows to create multiple copies of the entities being stretched, moved, rotated, mirrored or scaled.

NOTE	Whether text is mirrored or not by the **Mirror** command is controlled by the **Mirror Text** (**MIRRTEXT**) system variable.

Mirroring entities about a line

1. Do one of the following:

   - Click the **Mirror** tool button ( ) on the **Modify** toolbar.
   - Choose **Mirror** in the **Modify** menu.
   - Type **mirror** or **MI** in the command bar.

   You are prompted: Select entities to mirror:

2. Select the entities (1.32.7) then right click or press Enter. **You are prompted:** Start of mirror line.
3. Specify the start point of the mirror line.
4. Specify the endpoint of the mirror line. **You are prompted:** Delete the original entities? <N>
5. Do one of the following:

   - Press Enter to keep the original entities.
   - Type **Y** , then press Enter to delete the original entities.
   - Choose **Yes-Delete entities** in the context menu.

Mirroring entities about a plane

1. Do one of the following:

   - Click the **3D Mirror** tool button ( ) on the **Modify** toolbar.
   - Choose **3D Mirror** in the **Modify** menu.
   - Type **mirror3d** in the command bar.

   You are prompted: Select entities:

2. Select the entities (1.32.7) then right click or press Enter. **You are prompted:** Define mirror plane by: Entity/Last/View/Zaxis/XY/YZ/ZX/<3points>:
3. Specify the first point of the mirror plane.
4. Specify the second point of the mirror plane.
5. Specify the third point of the mirror plane. **You are prompted:** Delete the original entities? <N>
6. Do one of the following:

   - Press Enter to keep the original entities.
   - Type **Y**, then press Enter to delete the original entities.
   - Choose **Yes-Delete entities** in the context menu.

1.32.14 Aligning Entities

Command: ALIGN (6.4.7) The **Align** command lets you reposition a selection set with respect to an existing entity in the drawing. The selection set is moved and rotated in a single action. If necessary you can even scale the selection to fit in its new location. The command can be used both in a 2D and 3D environment.

Tutorial: How to Align Entities Click here (1.14.7) to watch

Aligning an entity in 2D

1. Do one of the following:

   - Click the **Align** tool button ( ) on the **Modify** toolbar.
   - Choose **Align** in the **Modify** menu.
   - Type **align** in the command bar, then press Enter.

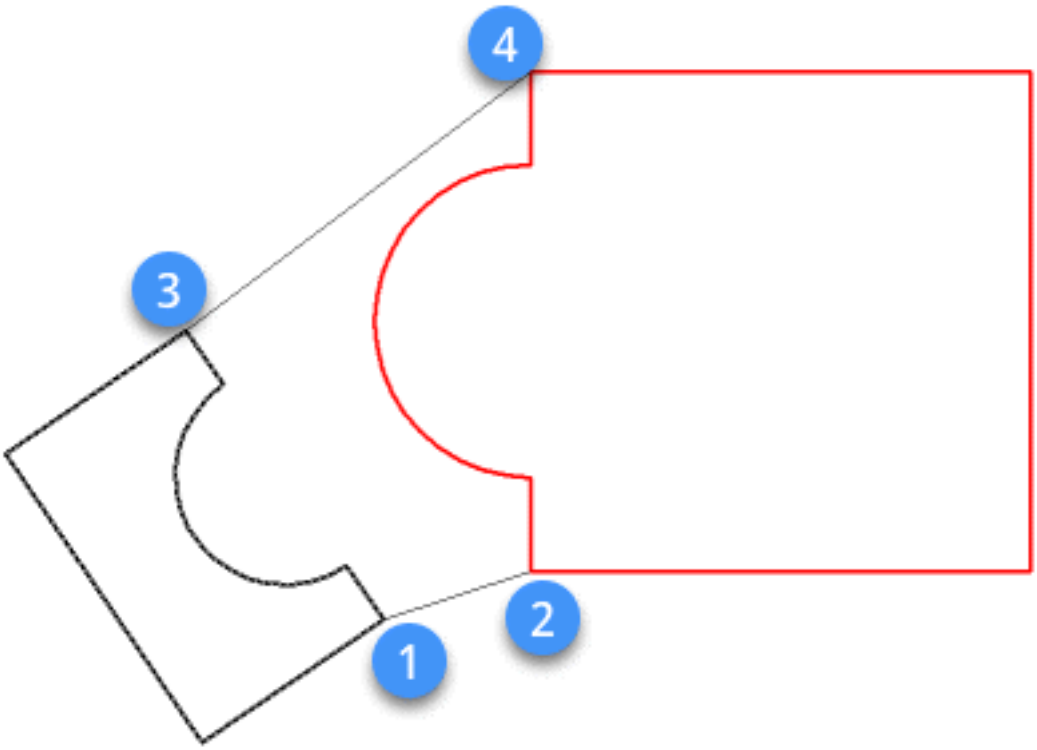
   You are prompted: Select entities:

2. Select the entities (1.32.7), then right click or press Enter. **You are prompted:** Specify first source point:
3. Snap to the first source point in the selection set (1). **You are prompted:** Specify first destination point:
4. Snap to the first destination point on the reference entity (2). A witness line is drawn between the source point and the target point. **You are prompted:** Specify the second source point: (1.1246 on the next page)
5. Snap to the second source point in the selection set (3). **You are prompted:** Specify second destination point:
6. Snap to the second destination point on the reference entity (4). A witness line is drawn between the source point and the target point. **You are prompted:** Specify the third source point:
7. Right click to skip the third source point. **You are prompted:** Scale objects based on alignment points [Yes/No] <No>:
8. Do one of the following:

   - Press Enter if you don't want to scale the selection set.
   - Type Y and press Enter to scale the selection set.

(1.1249 on page 1380)
Result of the Align procedure with scaled selection set.

Figure 1.1246



Aligning an entity in 3D

1. Do one of the following:

   - Click the **Align** tool button ( ) on the **Modify** toolbar.
   - Choose **Align** in the **Modify** menu.
   - Type **align** in the command bar, then press Enter.

   You are prompted: Select entities:

2. Select the entities (1.32.7), then right click or press Enter. **You are prompted:** Specify first source point:
3. Snap to the first source point in the selection set (1). **You are prompted:** Specify first destination point:
4. Snap to the first destination point on the reference entity (2). A witness line is drawn between the source point and the target point. **You are prompted:** Specify the second source point: (1.1247 on the next page)
5. Snap to the second source point in the selection set (3). **You are prompted:** Specify second destination point:
6. Snap to the second destination point on the reference entity (4). A witness line is drawn between the source point and the target point. **You are prompted:** Specify the third source point:
7. Snap to the third source point in the selection set (5). **You are prompted:** Specify third destination point:
8. Snap to the third destination point on the reference entity (6). A witness line is drawn between the source point and the target point. The entity is moved. (1.1248 on the facing page)

Figure 1.1247

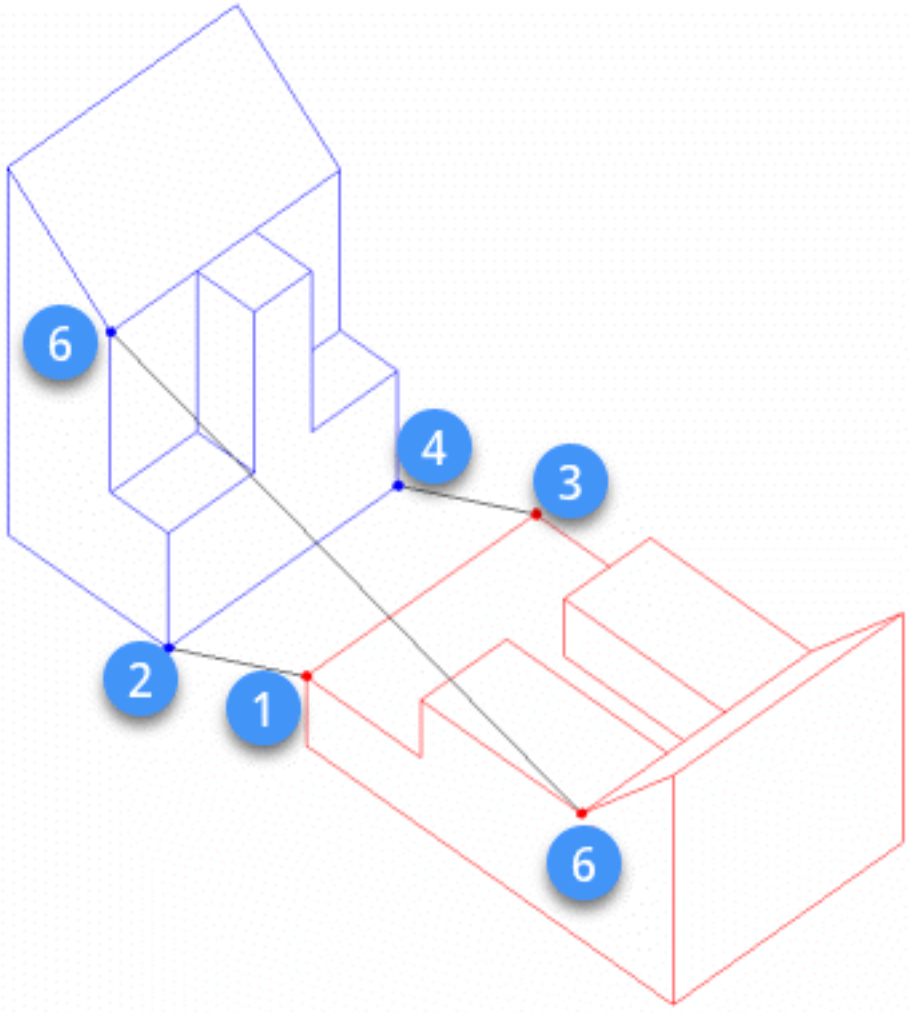


Figure 1.1248

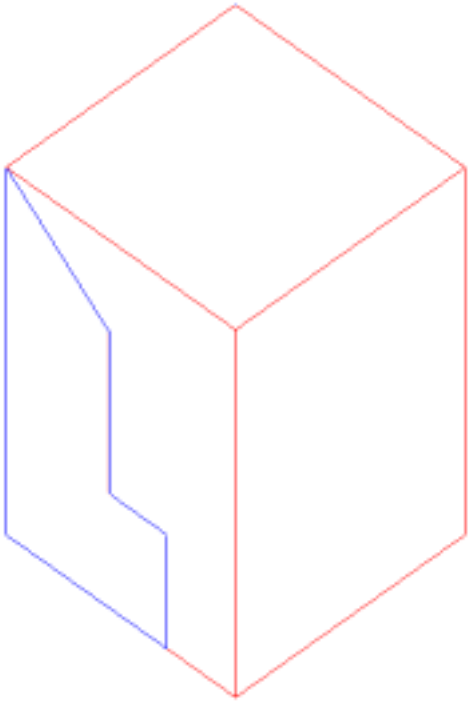

Figure 1.1249

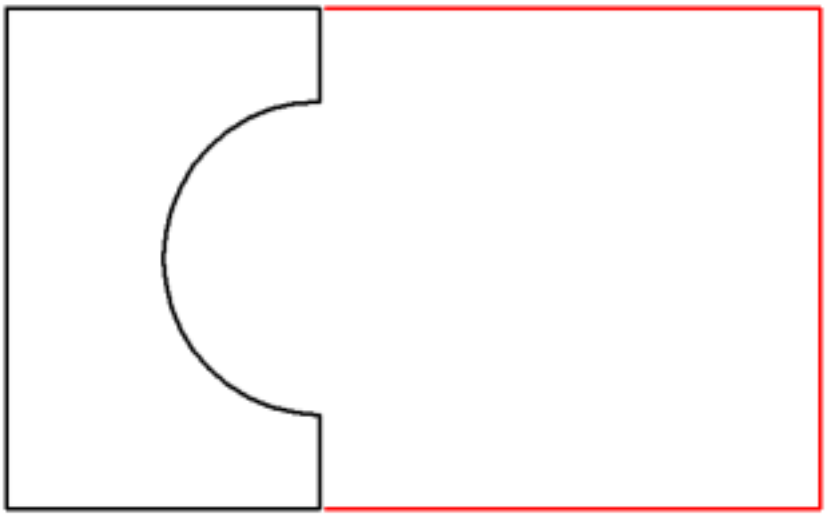

1.32.15 The Structure Panel

The dockable (1.15.7) **Structure** panel displays a structured tree view of the drawing content. This structured view is fully configurable and configurations can easily be saved and recalled. The *.cst configuration files are stored in the Support folder (1.17.2) by default. Entities selected in the structure tree can optionally be simultaneously highlighted and selected in the drawing, and vice versa, when selecting entities in the drawing they optionally can become selected and highlighted in the structure tree.

To open the Structure panel

1. To open the **Structure** panel do one of the following:
   - Place the cursor over a toolbar or ribbon panel, then right click and choose **Panels > Structure** in the context menu.
   - Type **STRUCTUREPANEL**in the command bar, then press Enter.
2. Click the down-arrow button and load a configuration file in the list; e.g. **bim**. (1.1250) The BIM model is organized in a tree-structure: (1.1251 on the following page)
3. Do the following:
   - Click the expand/collapse icon of a node to expand or collapse the node.
   - Right click a node then choose **Expand All** or **Collaspe All** in the context menu to expand or collapse all branches. If you do this on the drawing name the whole tree structure expands or collapses.
   - Select an entity in the tree. Depending on the selected option in the current configuration file, entities are either selected or highlighted in the model. e.g. if you click a story, all entities on that story are selected. You can then use IsolateObjects (6.17.22) ( ) or HideObjects (6.16.10) ( ) to isolate or hide the selected story in the model.
   - Right click an entity, then choose **Zoom** in the context menu, to zoom onto the entities.
   - Select an entity in the model: the entity is selected in the tree.

Figure 1.1250

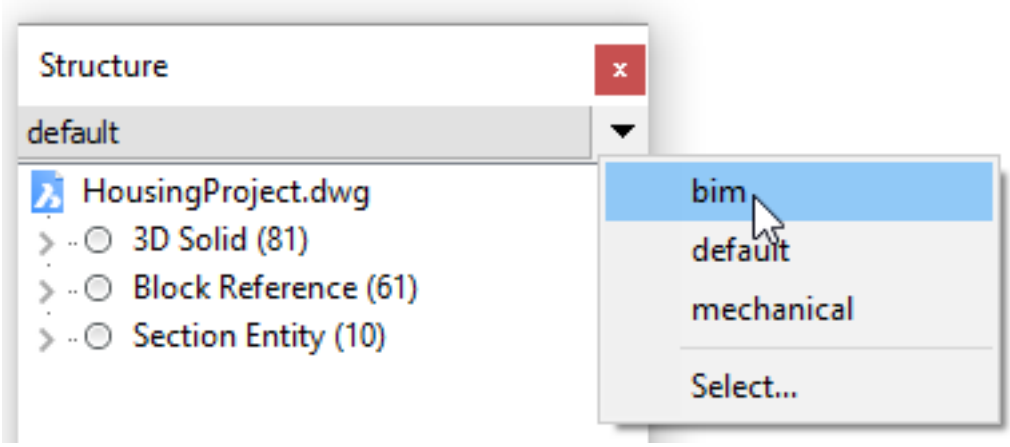

Figure 1.1251

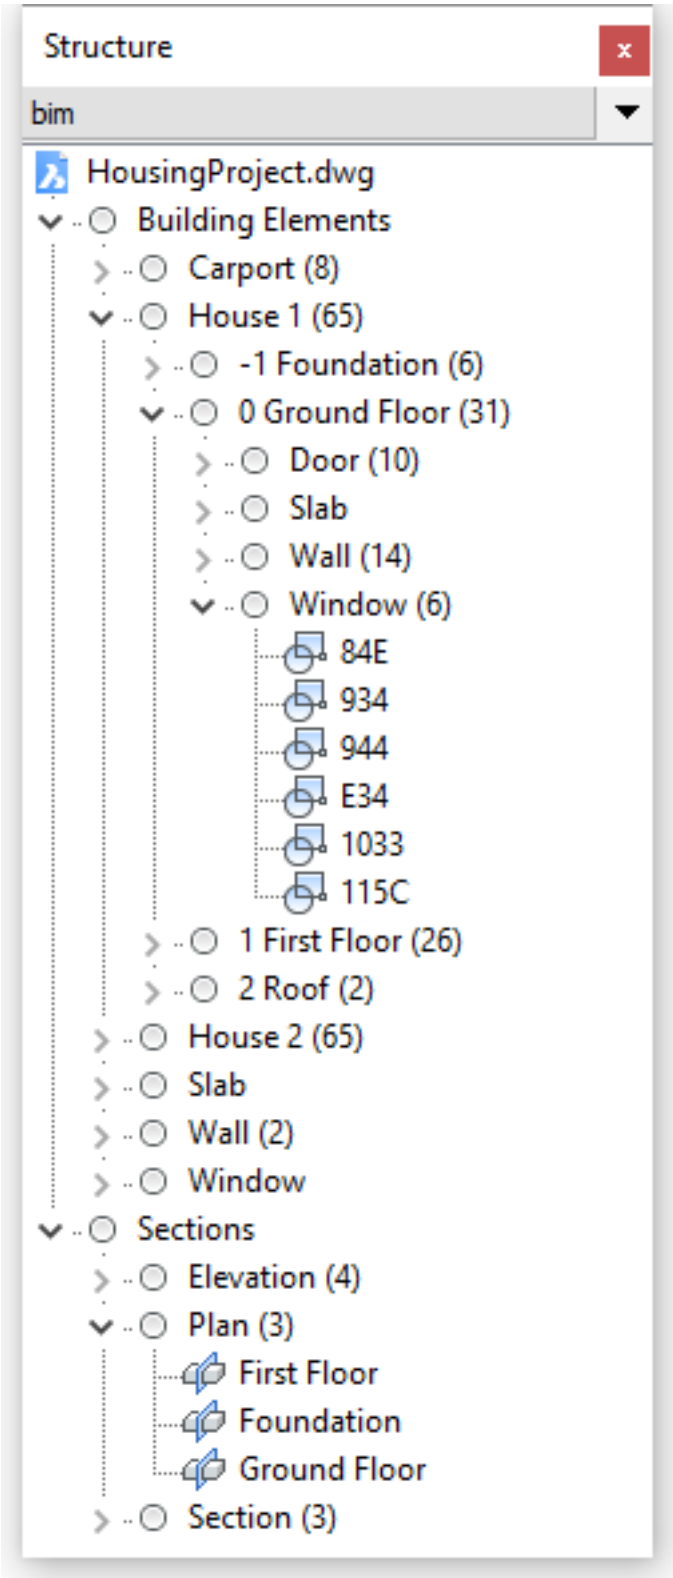

To configure the tree-structure on the Structure panel

The tree structure on the **Structure** panel is a hierarchical set of rules. Each rule has a **grouping property** and a **sorting property**. The structure configurations are saved to *.cst files. By default *.cst files are saved in the **Support** subfolder of the Roamable Root (1.17.2) folder (e.g. **C:\Users\<UserName>\AppData\Roaming\Bricsys\BricsCAD\V17x64\en**). The name of the *. cst configuration file is saved in the drawing through the StructureTreeConfig (1.17.10) user preference. BricsCAD searches for *.cst configuration files in the folders defined by the SRCHPATH (1.17.10) configuration variable.

1. Right click a node, then choose **Configure** in the context menu. The **Configure Structure Tree** dialog box opens: (1.1252 on the next page)
2. To add a rule, do the following:
   - Select an existing rule, then click the **Add** icon () or right click and choose**Add Rule** in the context menu. The new rule is added below the selected rule.
   - Select the newly created group, then click the name or right click and choose **Rename** in the context menu and type a new name for the rule.
   - Select the **Group** node of the rule, then click the **Add** icon () or right click and choose **Add Grouping Property** in the context menu. The **Select Property** dialog box displays. (1.1253 on page 1385)
   - Select a property, then double click or click the **OK** button. Optionally, type a search string in the **Search** field, then click the **Up** () or **Down** () arrow buttons to look up the properties containing the search string.
   - Repeat the previous step to add more grouping properties.
   - Select the Sort node, then click the **Add** icon () or right click and choose **Add sorting property** in the context menu. The **Select Property** dialog box displays.
   - Select a property, then double click or click the **OK** button. Optionally, type a search string in the **Search** field, then click the **Up** () or **Down** () arrow buttons to look up the properties containing the search string.
   - Repeat the previous step to add more grouping properties.
3. Click the **Show/Skip** tab: (1.1254 on page 1386) Select an option and the select the entity types to show or to exclude.
4. Click the **Options** tab: (1.1255 on page 1387)
   - Choose what happens in the model when entities are selected in the structure tree: (1.1256 on page 1387)
   - Select what happens in the structure tree when an entity is selected/deselected in the model: (1.1257 on page 1387)
5. (option) To move an item in the tree: select the item, then click the **Move Up** ( ) or **Move Down** ( ) button.
6. Do one of the following:
   - Click the **OK** button to save the configuration and close the dialog box.
   - Click the **File** menu on the dialog box and choose an option: (1.1258 on page 1387) Open...: opens a file dialog to select another *.cst configuration file. Save : save the current configuration and keep the file dialog open. Save As... : save the current configuration under a different name and keep the file dialog open.

Figure 1.1252

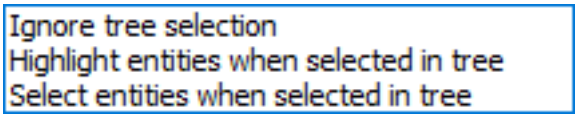

Figure 1.1257

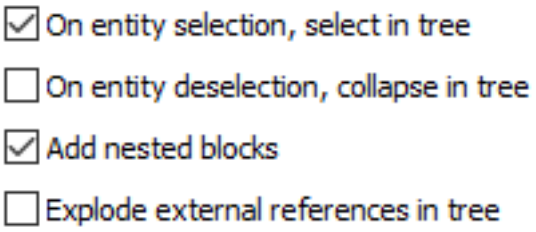

Figure 1.1258

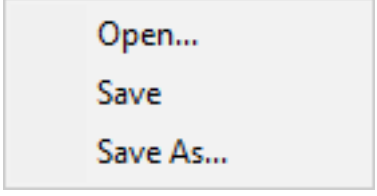


1.32.16 Changing Entities

Command: CHANGE (6.9.10) The **Change** command lets you change the insertion point and orientation of texts and block inserts. The **Properties** option of the command can also change the layer, line type, line type scale, line weight, etc. but the BricsCAD Properties bar (1.15.4) is much more versatile to do such things.

To change text entities

1. Type **change** in the command bar, then press Enter. **You are prompted:** Select entities to change:
2. Select the text entities (1.32.7), then right click or press Enter. **You are prompted:** Change: Entities/Properties/<Change point>:
3. Right click or press Enter to accept the default option. **You are prompted:** New point for text, or Enter for no change: The first text entity is attached to the cursor.
4. Specify the new insertion point for the text or right click to accept the current location. **You are prompted:** New text style <current style>:
5. Type a new text style and press Enter or right click to keep the current style. **You are prompted:** New height <current height>:
6. Type a new height and press Enter or right click to keep the current height. **You are prompted:** New rotation angle <current angle>:
7. Type a new angle and press Enter or right click to keep the current angle. **You are prompted:** New text <current text>:
8. Type the new text and press Enter or right click to keep the current text.
9. (option) If multiple text entities were selected in step 2, steps 3 through 8 are repeated for each text.

NOTE	The **Change** command cannot change Multi-Line text (Mtext) entities.

To relocate blocks

1. Type **change** in the command bar, then press Enter. **You are prompted:** Select entities to change:
2. Select the blocks (1.32.7), then right click or press Enter. **You are prompted:** Change: Entities/Properties/<Change point>:
3. Right click or press Enter to accept the default option. **You are prompted:** New point for block, or Enter for no change: The first block is attached to the cursor.
4. Specify the new insertion point or right click to accept the current orientation. **You are prompted:** New rotation angle <current angle>:
5. Do one of the following:
   - Right click to accept the current rotation angle.
   - Type a new rotation angle in the command bar, then press Enter.
   - Click to specify the new rotation angle graphically.
6. (option) If multiple blocs were selected in step 2, steps 3 through 5 are repeated for each block.

1.32.17 Copying Entities in a Drawing

Commands: COPY (6.9.35), COPYCLIP (6.9.36), COPYBASE (6.9.58), PASTECLIP (6.24.13) and PASTEBLOCK (6.24.11)
You can duplicate entities within the current drawing using the **Copy** command. The default method is to create a selection set and then specify a starting point (base point) and an endpoint (second point) for the copy. You can also specify the displacement as a direction vector (X,Y,Z). Depending on the **COPYMODE** system variable you can create multiple copies of the selection set or just one. **Copybase** and **Pasteblock** pastes the selection as a block. The Copy option (1.32.3) of the Grips Editing (1.32.3) commands allows to create multiple copies of the entities being stretched, moved, rotated, mirrored or scaled.

Tutorial: Copying between drawings Click here (1.14.11) to watch

To copy a selection set

1. Do one of the following:

   - Click the **Copy** tool button ( ) on the **Modify** toolbar.
   - Choose **Copy** in the **Modify** menu.
   - Type **copy** or **CO** in the command bar.

   You are prompted: Select entities to copy:

2. Select the entities (1.32.7), then right click or press Enter. If **Copy Mode** is **Multiple** : **You are prompted:** Enter base point: mOde/<Displacement>: If **Copy Mode** is **Single** : **You are prompted:** Enter base point: mOde/Multiple/<Displacement>:

3. Specify the base point. The selection set is now attached to the cross hairs. **You are prompted:** Enter second point: <Enter to use the base point as displacement>:

4. Do one of the following:

   - Click the second point.
   - Use Direct Distance Entry (1.21.4): type the displacement distance, then press Enter. The distance is measured in the cursor direction. Use ORTHO (1.21.2) or POLAR TRACKING (1.21.18) to constrain the movement of the cross hairs.
   - Press <Enter>: the first point is interpreted as a relative X,Y,Z displacement. E.g. if the coordinates of the base point are 2,3,0, the selection set is copied 2 units in the X direction and 3 units in the Y direction from their current position.

The selection set is copied. If **Copy Mode** is **Single** , the copy command is completed. If **Copy Mode** is **Multiple** , **you are prompted** to create the next copy. See To make multiple copies.

To make multiple copies

1. Do one of the following:

   - Click the **Copy** tool button ( ) on the **Modify** toolbar.
   - Choose **Copy** in the **Modify** menu.
   - Type **copy** or **CO** in the command bar.

   You are prompted: Select entities to copy:

2. Select the entities (1.32.7), then right click or press Enter. If **Copy Mode** is **Multiple** : **You are prompted:** Enter base point: mOde/<Displacement>: If **Copy Mode** is **Single** : **You are prompted:** Enter base point: mOde/Multiple/<Displacement>:

3. (Option) If **Copy Mode** is **Single** , do one of the following:

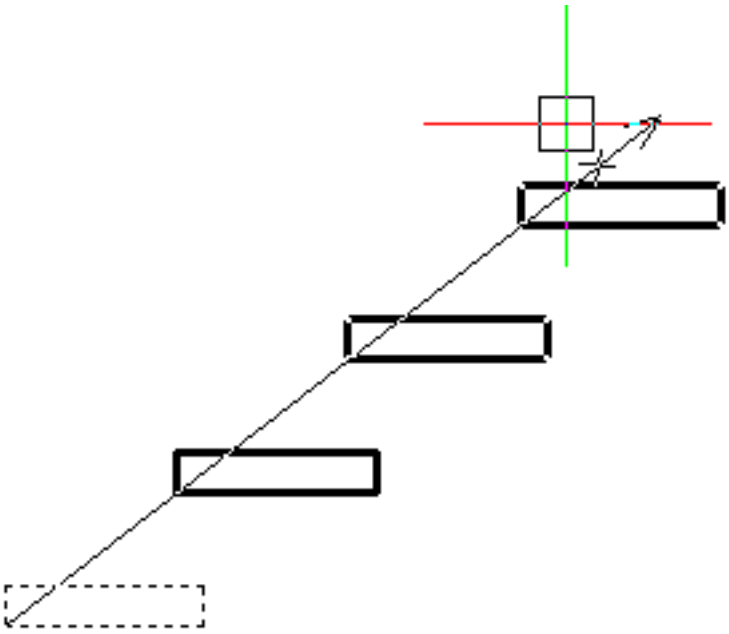
   - Choose **Multiple** in the prompt menu
   - Type **M** , then press Enter

   You are prompted: Enter base point: mOde/<Displacement>:

4. Specify the base point. The selection set is now attached to the cross hairs. **You are prompted:** Enter second point: <Enter to use the base point as displacement>:

5. Do one of the following to specify the second point.

Figure 1.1259



- Click the second point.
- Type the displacement distance, then press Enter. The distance is measured in the cursor direction. Use ORTHO (1.21.2) or POLAR TRACKING (1.21.18) to constrain the movement of the cross hairs.

The first copy of the selection set is created. **You are prompted:** Enter second point: Undo/Repeat/Exit:

6. (option) Repeat step 5 to create additional copies. Right click or press Enter to conclude the command.
7. (option) Choose the **Repeat** option. **You are prompted:** Select end point (<ENTER> to key in number of repeats) The number of repeats increases when you move the cursor away from the source selection set. (1.1259)
8. Do one of the following:
   - Click when the desired number of copies displays.
   - Press Enter or right click, then type the desired number of copies.

To paste a selection set as a block

1. Do one of the following:
   - Choose **Copy with Base Point** in the **Edit** menu.
   - Type **copybase** in the command bar, then press Enter.
   - Press and hold the **Ctrl** and **Shift** keys, then press **C** .

   You are prompted: Select base point:
2. Specify the base point (origin point). **You are prompted:** Select entities to copy to the clipboard:
3. Select the entities.
4. Press Enter to conclude the selection of entities.
5. Do one of the following:
   - Choose **Paste as Block** in the **Edit** menu.
   - Type **pasteblock** in the command bar, then press Enter.
   - Press and hold the **Ctrl** and **Shift** keys, then press **V** .

   The selection set is attached to the cursor. The command window reads: Select insertion point.
6. Specify the insertion point. The selection is pasted as a block.
7. (option) Repeat steps 5 and 6 to paste another copy as a block.

NOTE	If you paste multiple copies of the same selection set, each block is named differently.

1.32.18 Copying Entities Between Drawings

Commands: COPYCLIP (6.9.36), COPYBASE (6.9.58), PASTECLIP (6.24.13), PASTEORIG (6.24.12) and PASTEBLOCK (6.24.11) Entities can be copied between drawings in several ways:

- **Copyclip** and **Pasteclip** pastes the selection using a default base point.
- **Copyclip** and **Pasteorig** pastes the selection using the coordinates of the source drawing.
- **Copybase** and **Pasteclip** pastes the selection using a user-defined base point.
- **Copybase** and **Pasteblock** : pastes the selection as a block in the target drawing.

NOTE	Use Ctrl + Tab (press and hold the Ctrl key, then press the Tab key) to cycle between open drawings.

Using Copy and Paste to copy entities between drawings

1. In the source drawing, select the entities (1.32.7) you want to Copy.
2. Do one of the following:
   - Right click, then choose **Copy** in the context menu.
   - Choose **Copy** in the **Edit** menu.
   - Press **Ctrl + C** (press and hold the Ctrl key, then press C).

   The entities are copied to the Clipboard.
3. Switch to the target drawing.
4. Do one of the following:
   - Right click, then choose **Paste** in the context menu.
   - Choose **Paste** in the **Edit** menu.
   - Press **Ctrl + V** (press and hold the Ctrl key, then press V).

   The bottom left corner of the bounding rectangle of the selection is attached to the cross hairs in the target drawing.
5. Do one of the following:
   - Specify the displacement point.
   - Press Enter to paste the selection set using the coordinates of the source drawing.

Using Copy and Pasteorig to copy entities between drawings

1. In the source drawing, select the entities (1.32.7) you want to Copy.
2. Do one of the following:
   - Right click, then choose **Copy** in the context menu.
   - Choose **Copy** in the **Edit** menu.
   - Press **Ctrl + C** (press and hold the Ctrl key, then press C).

   The entities are copied to the Clipboard.
3. Switch to the target drawing.
4. Do one of the following:
   - Choose **Paste to Original Coordinates** in the Edit menu.
   - Type **pasteorig** in the command bar, then press Enter.

   The selection is pasted using the coordinates of the source drawing.

Using Copybase and Paste to copy entities between drawings

1. In the source drawing do one of the following:

   - Choose **Copy with Base Point** in the **Edit** menu.
   - Type **copybase** in the command bar, then press Enter.
   - Press and hold the **Ctrl** en **Shift** keys, then press **C** .

   You are prompted: Select base point:

2. Specify the base point (origin point). **You are prompted:** Select entities to copy to the clipboard:
3. Select the entities.
4. Press Enter to conclude the selection of entities.
5. Switch to the target drawing.
6. Do one of the following:

   - Choose **Paste** in the **Edit** menu.
   - Press **Ctrl + V** (press and hold the Ctrl key, then press V).

   The selection set is attached to the cursor. **You are prompted:** Select insertion point:

7. Specify the insertion point to paste the selection set.
8. (option) Repeat step 7 to create more copies of the selection set.

Tutorial: Copying between drawings Click here (1.14.11) to watch

Paste a selection as a block in the target drawing

1. In the source drawing do one of the following:

   - Choose **Copy with Base Point** in the **Edit** menu.
   - Type **copybase** in the command bar, then press Enter.
   - Press and hold the **Ctrl** en **Shift** keys, then press **C** .

   You are prompted: Select base point:

2. Specify the base point (origin point). **You are prompted:** Select entities to copy to the clipboard:
3. Select the entities.
4. Press Enter to conclude the selection of entities.
5. Switch to the target drawing.
6. Do one of the following:

   - Choose **Paste as Block** in the **Edit** menu.
   - Type **pasteblock** in the command bar, then press Enter.
   - Press and hold the **Ctrl** and **Shift** keys, then press **V** .

   The selection set is attached to the cursor. The command window reads: Select insertion point.

7. Specify the insertion point. The selection is pasted as a block.
8. (option) Repeat steps 5 and 6 to paste another copy as a block.

NOTE	If you paste multiple copies of the same selection set, each block is named differently.

1.32.19 Arraying Entities

Commands: ARRAY (6.4.19) , -ARRAY (6.4.20), ARRAYCLASSIC (6.4.22), ARRAYRECT (6.4.28), ARRAYPATH (6.4.26), ARRAYPOLAR (6.4.41), ARRAYEDIT (6.4.25), 3DARRAY (6.3.2) The **Array** commands copy a selection set in a rectangular or polar (circular) pattern or along a linear entity. For a rectangular array you must specify the number of rows and columns and also the spacing between subsequent rows and columns. To create a polar array you will be prompted to specify the center point of the array, the rotation step and the number of items in the array or the angle to fill. You can choose to rotate the selection set about the center point or to keep its original orientation. The **ArrayClassic** command creates a static polar or rectangular array of entities through a dialog box. The **-Array** command creates a static polar or rectangular array of entities. The **3DArray** command constructs static 3D rectangular arrays and rotated polar arrays The **Array** command distributes entity copies in an evenly spaced associative rectangular, polar or path array. The **ArrayRect** command associatively distributes entity copies into any number of rows, columns, and levels. The **ArrayPolar** command associatively distributes entity copies evenly in a circular pattern about a center point or axis of rotation, using multiple rows, and levels. The **ArrayPath** command associatively distributes entity copies evenly along a path into multiple rows, and levels. The **ArrayEdit** command allows editing associative arrays and their source entities.

Creating a static rectangular array

1. Type **arrayclassic** in the command bar, then press Enter. A dialog box displays: (1.1260 on the next page)
2. Under **Array Type** choose **Rectangular**.
3. Click the **Select Entities** button ( ). The **Array** dialog box closes temporarily to let you select entities.
4. Select the entities (1.32.7), then right click or press Enter. The **Array** dialog box reopens.
5. Fill out the **Settings** fields or press the **Pick Points** buttons ( ) to define the settings graphically. The **Array** dialog box closes temporarily to let you pick point in the drawing. (1.1261 on page 1396) **Row offset (A) and column offset (B) can be defined by the spacing rectangle (red).**
6. Click the OK button to create the array.

NOTE	Positive values in steps 4 and 5 are measured along the positive X- and Y-axis of the current UCS. Negative values are measured in the opposite direction.

Figure 1.1260

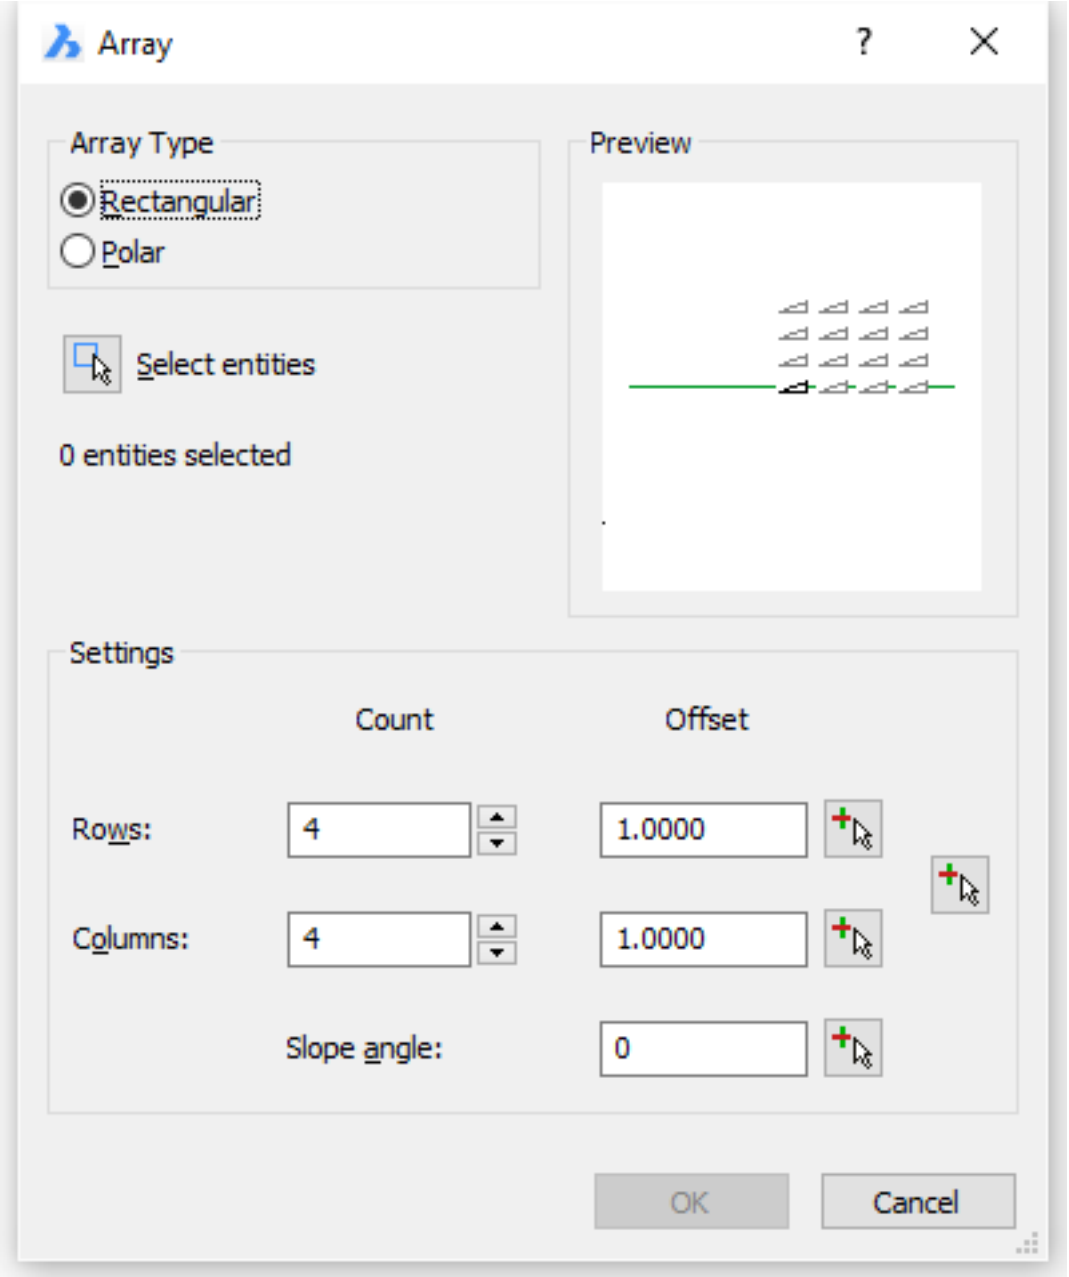


Figure 1.1261

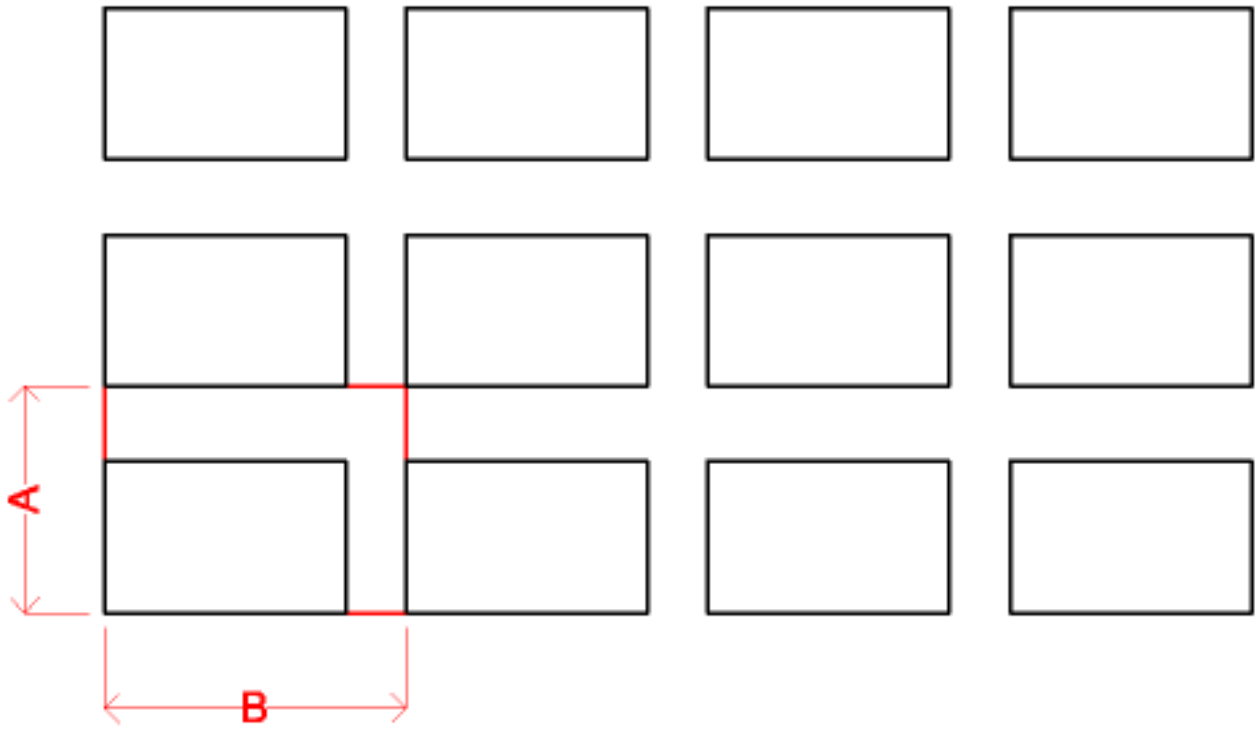

Creating a static polar array

1. Type **arrayclassic** in the command bar, then press Enter. A dialog box displays: (1.1262 on the next page)
2. Under **Array Type** choose **Polar** .
3. Click the **Select Entities** button (===ERROR WITH DOWNLOADED IMAGE===). The **Array** dialog box closes temporarily to let you select entities.
4. Select the entities (1.32.7), then right click or press Enter. The **Array** dialog box reopens.
5. Choose a **Calculate** option: **Angle between**, **Angle to fil** l or **Number of items**. The settings field of the selected option is dimmed.
6. Fill out the **Settings** fields or press the **Pick Points** buttons ( ) to define the settings graphically. The **Array** dialog box closes temporarily to let you pick point in the drawing.
7. (option) Check the **Rotate items as copied** option. (1.1263 on page 1398) **Entities rotated (left) or not (right) about the center point of the array.**
8. (option) Define an **Entity base point**. (1.1264 on page 1398) **Polar array with base point (dot) and center point (cross).**

Figure 1.1262

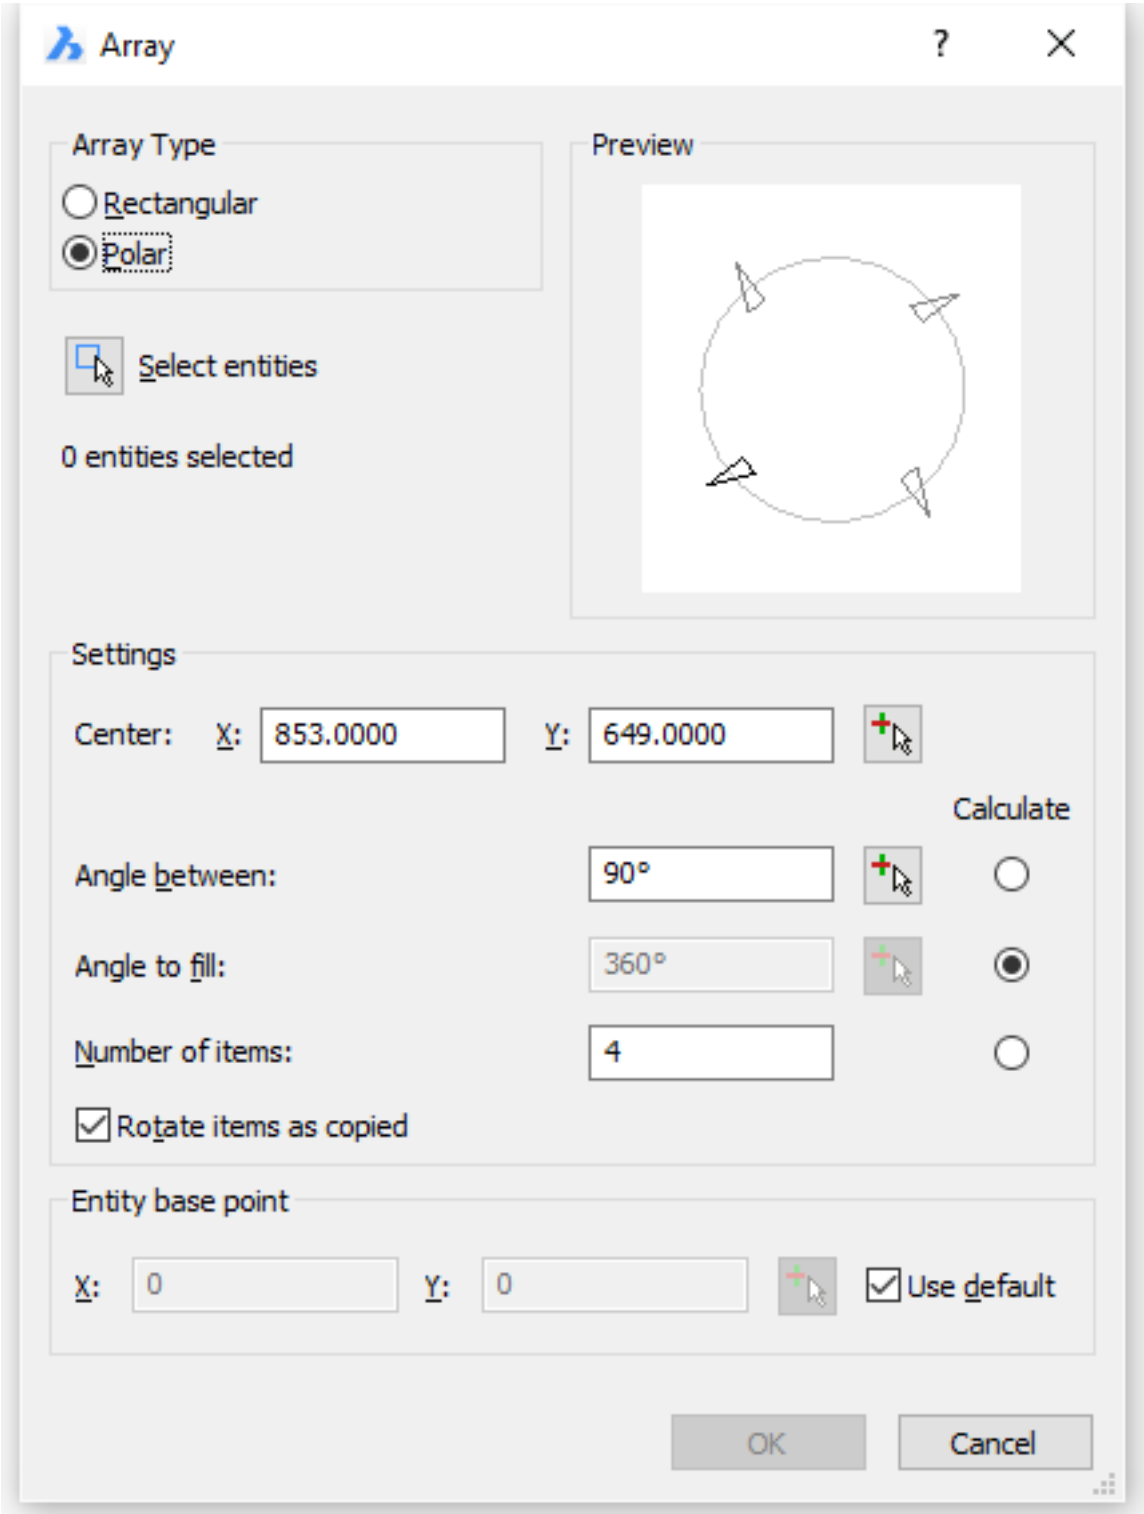

Figure 1.1263

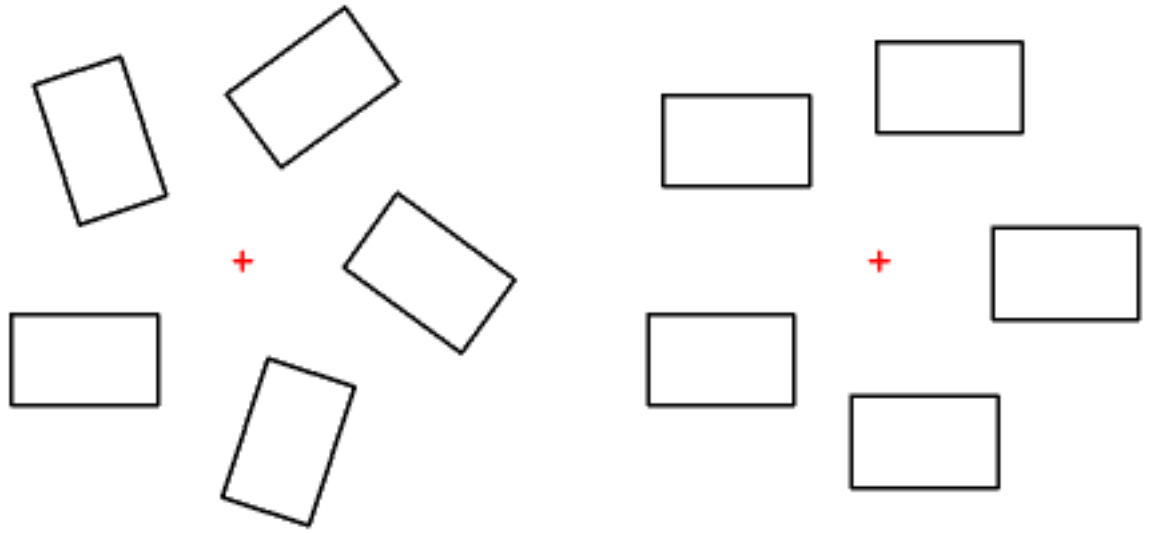

Figure 1.1264

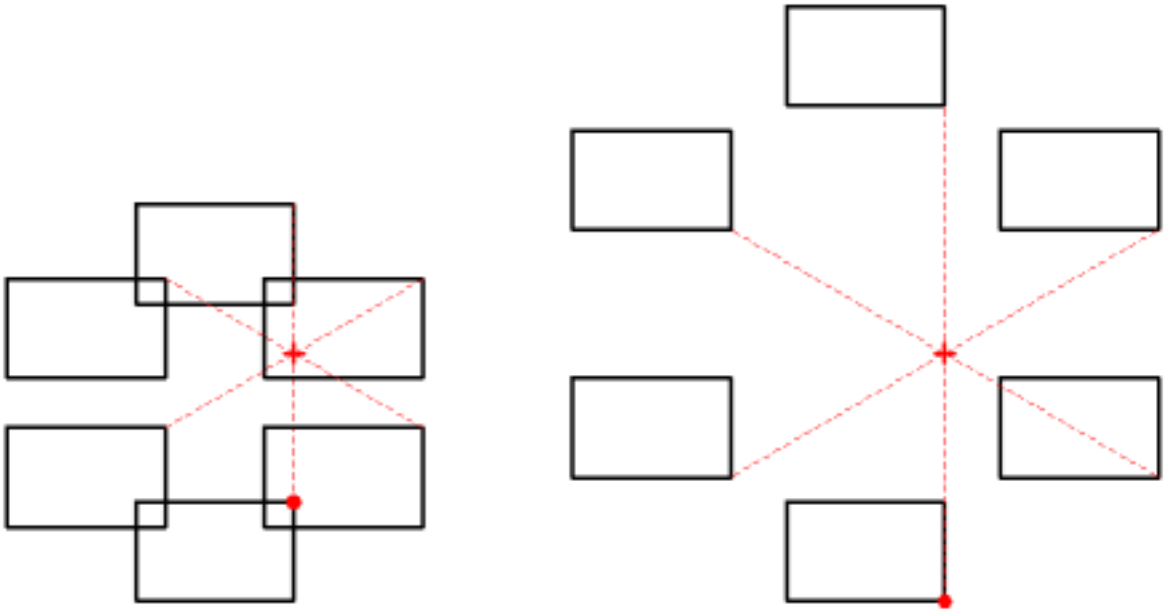


Creating a static 3D rectangular array

1. Do one of the following:

   - Click the **3D Array** tool button ( ) on the **Modify** toolbar.
   - Choose **3D Array** in the **Modify** menu.
   - Type **3darray** in the command bar, then press Enter.

   You are prompted: Select entities to array:

2. Select the entities (1.32.7), then right click or press Enter. **You are prompted:** Type of array: Polar/<Rectangular>:
3. Choose **Rectangular** in the prompt menu or type **R** in the command bar and press Enter. **You are prompted:** Number of rows in the array <1>:
4. Type the number of rows in the command bar, then press Enter. **You are prompted:** Number of columns <1>:
5. Type the number of columns in the command bar, then press Enter. **You are prompted:** Number of levels <1>:
6. Type the number of levels in de command bar, then press Enter. **You are prompted:** Vertical distance between rows:
7. To define the distance between rows of the array, do one of the following:

   - Type the distance in the command bar and press Enter.
   - Specify the distance by clicking two points.

   You are prompted: Horizontal distance between columns:

8. To define the distance between the columns of the array, do one of the following:

   - Type the distance in the command bar and press Enter.
   - Specify the distance by clicking two points.

   You are prompted: Depth between levels:

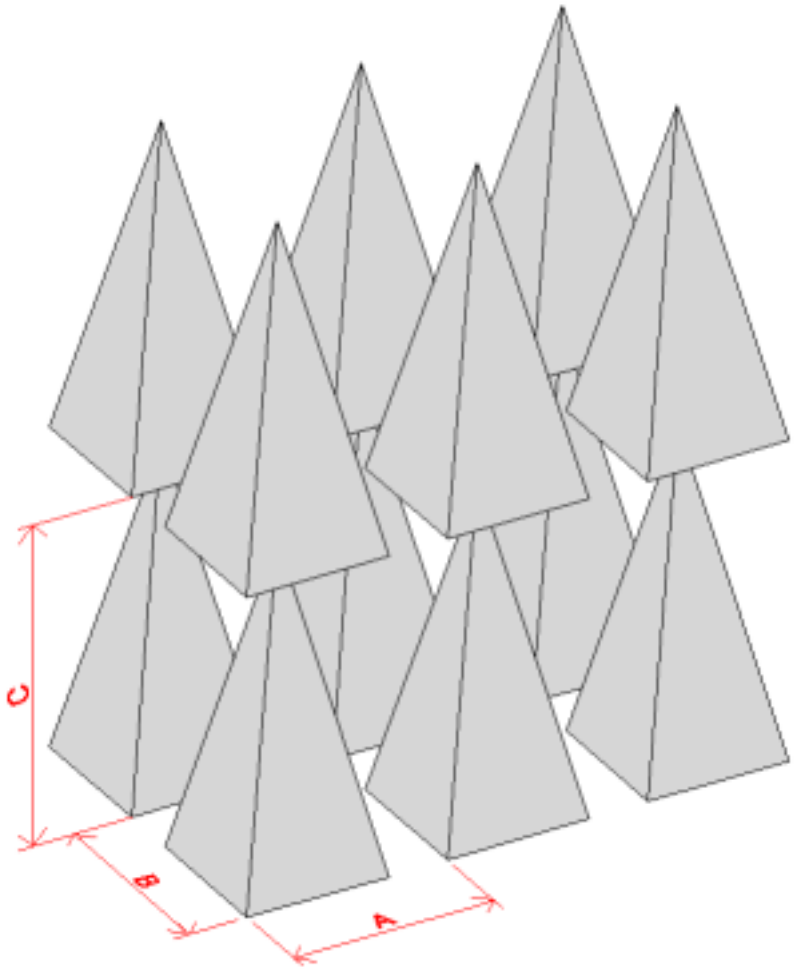
9. To define the distance between the levels of the array, do one of the following:

   - Type the distance in the command bar and press Enter.
   - Specify the distance by clicking two points.

The array is created. (1.1265 on the following page) **Rectangular 3D Array:row spacing A, column spacing B, level spacing C**

NOTE	Positive values in steps 7, 8 and 9 are measured along the positive X-, Y- and Z-axis of the current UCS. Negative values are measured in the opposite direction.

Figure 1.1265



Creating a static 3D polar array

1. Do one of the following:

   - Click the **3D Array** tool button ( ) on the **Modify** toolbar.
   - Choose **3D Array** in the **Modify** menu.
   - Type **3darray** in the command bar, then press Enter.

   You are prompted: Select entities to array:

2. Select the entities (1.32.7), then right click or press Enter. **You are prompted:** Type of array: Polar/<Rectangular>:
3. Choose **Polar** in the prompt menu or type **P** in the command bar and press Enter. **You are prompted:** ENTER to specify angle between items/<Number of items to array>:
4. Type the number of items you want in the array, then press Enter. **You are prompted:** Angle to array (+ for ccw, - for cw) <360>:
5. Do one of the following:

   - Type the angle to array, then press Enter.
   - Press Enter to create a 360° array.

   You are prompted: Rotate entities around the array? No/<Yes>

6. Do one of the following:

   - Press Enter to rotate the entities about the array axis.
   - Type N and press Enter to keep the original orientation of the entities.

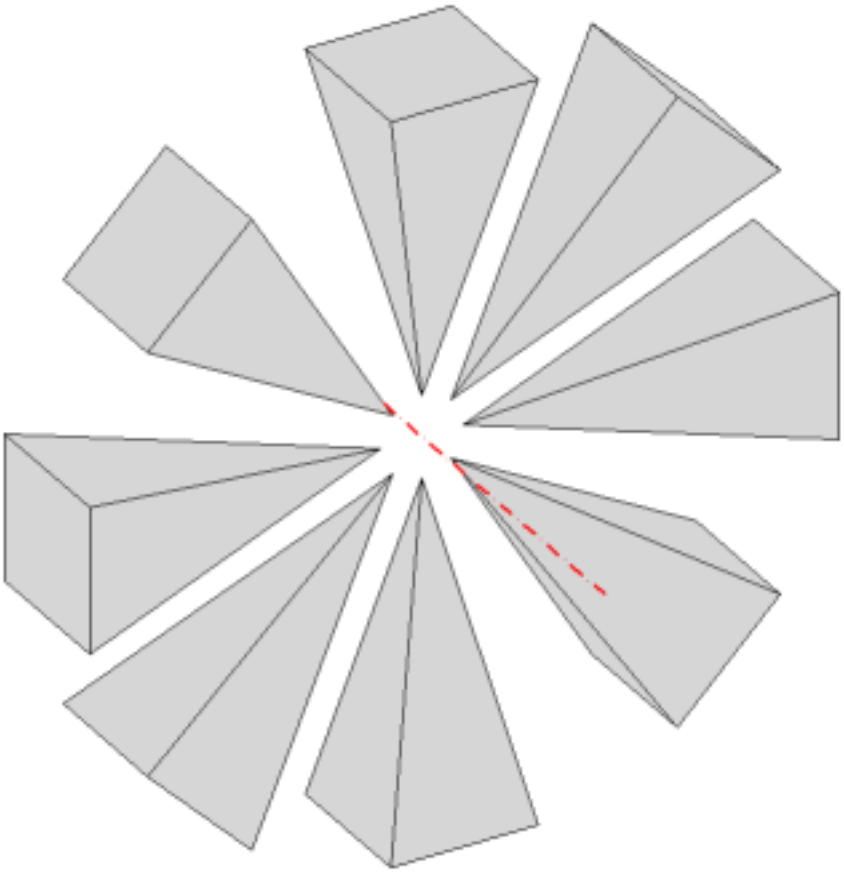
   You are prompted: Center of polar array.

7. Specify the first point of the array axis. **You are prompted:** Specify second point along central axis of array:
8. Specify the second point of the array axis.

The array is created. (1.1266 on the next page) **Polar 3D array about a horizontal axis (red).**

Tutorial: Creating and Editing Associative Arrays Click here (1.16.4) to watch

Figure 1.1266



1.32.20 Making Parallel Copies

Command: OFFSET (6.23.3) The **Offset** command creates a copy of linear entities and aligns them parallel to the original entities at a specified distance. You can make parallel copies of arcs, circles, ellipses, elliptical arcs, lines, two-dimensional polylines, rays and infinite lines. Depending on the selected options in the **Selection Modes** toolbar, the **Offset** command allows to create a parallel copy of:

- an edge of a 3D solid if the **Select Edges** option ( ) is set.
- the edges of a 3D solid face if the **Select Faces** option ( ) is set.
- detected boundaries if the **Select Detected Boundaries** option ( ) is set.

Making parallel copies of curved entities creates larger or smaller curves, depending on which side of the original entity you place the copy. For example, placing a parallel copy of a circle outside the circle creates a larger concentric circle; positioning the copy inside the circle creates a smaller concentric circle.

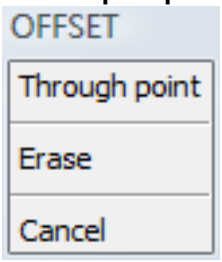
NOTE	The **OFFSETGAPTYPE** settings variable controls how potential gaps between segments are treated when closed polylines are offset.

Making a parallel copy at a specified distance

1. Do one of the following:

   - Click the **Offset** tool button ( ) on the **Modify** toolbar.
   - Choose **Offset** in the **Modify** menu.
   - Type **offset** in the command bar.

   You are prompted: Offset: Through point/Erase/<Distance> <current distance>: A prompt menu displays:

2. (Option) Choose **Erase** in the prompt menu or type **E**, then press Enter. Respond **Yes** at the command prompt to erase the source entity.
3. Do one of the following:

   - Press Enter to accept the current distance.
   - Type a new distance in the command bar.
   - Define a new distance by specifying two points.

   You are prompted: Select Entity.

4. Select the entity. **You are prompted:** Both sides/<Side for parallel copy>:
5. Click the side for the parallel copy. The parallel copy is created. **You are prompted:** Select Entity.
6. Do one of the following:

   - Repeat steps 4 and 5 to create more parallel copies.
   - Right click or press Enter to stop.

Making a parallel copy through a point

1. one of the following:

   - Click the **Offset** tool button ( ) on the **Modify** toolbar.
   - Choose **Offset** in the **Modify** menu.

- Type **offset** in the command bar.

You are prompted: Offset: Through point/<Distance> <current distance>:

2. Choose **Through point** in the context menu or type **T**, then press Enter. **You are prompted:** Select entity:
3. Select the entity. **You are prompted:** Through point:
4. Specify the point to create the parallel copy through. The parallel copy is created. **You are prompted:** Select entity:
5. Do one of the following.
   - Repeat steps 3 and 4 to create more parallel copies.
   - Right click or press Enter to stop.

Making a parallel copy of a 3D solid edge

Make sure the Quad (1.15.5) is active and the **Select edges** button ( ) in the **Selection Modes** toolbar is pressed.

1. Move the cursor over the edge of the solid. When the edge highlights, choose **Parallel** ( ) in either the **2D Editing** or the **Direct Modeling** command group in the **Quad** . The parallel copy is created dynamically.
2. Do one of the following:
   - Type a distance in the dynamic entry field.
   - Snap to a point.

Making a parallel copy a 3D solid face

Make sure the Quad (1.15.5) is active and the **Select Faces** button ( ) in the **Selection Modes** toolbar is pressed.

1. Move the cursor over the face of the solid. When the face highlights, choose **Parallel** ( ) in either the **2D Editing** or the **Direct Modeling** command group in the **Quad** . The parallel copy is created dynamically.
2. Do one of the following:
   - Type a distance in the dynamic entry field.
   - Snap to a point.

Making a parallel copy of a detected boundary

Make sure the Quad (1.15.5) is active and the **Select Detected Boundaries** button ( ) in the **Selection Modes** toolbar is pressed.

1. Move the cursor inside the boundary. When the boundary highlights, choose **Parallel** ( ) in either the **2D Editing** or the **Direct Modeling** command group in the **Quad** . The parallel copy is created dynamically.
2. Do one of the following:
   - Type a distance in the dynamic entry field.
   - Snap to a point.

1.32.21 Trimming Entities

Command: TRIM (6.29.35) and EXTEND (6.13.21) The Trim command lets you clip or trim entities by cutting entities. If the **Edge Mode** (**EDGEMODE**) system variable is **On** , you can trim entities by an implied edge of the cutting entities. If the cutting entity is not in the same plane as the entity you want to trim, the **Projection Mode** (**PROJMODE**) system variablele defines how the intersection is to be calculated. The options are:

- Project to the XY plane of the current UCS
- Project to the current view plane
- True 3D mode (No projection).

When trimming entities, you first select the cutting edges, and then specify the entities to trim, selecting them either one by one or using the fence selection method. The following entities can be trimmed: lines, two- and three dimensional polylines, arcs, circles, ellipses, elliptical arcs, splines, rays and infinite lines. Cutting entities can be: lines, splines, polylines, arcs, circles, elliptical arcs, ellipses, rays, infinite lines, layout viewports. Entities in a block can be selected as cutting entities.

To trim entities

1. Do one of the following:

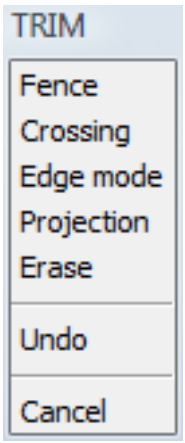
   - Click the **Trim** tool button ( ) on the **Modify** toolbar.
   - Choose **Trim** in the **Modify** menu.
   - Type **trim** or **TR** in the command bar, then press Enter.

   You are prompted: Select cutting entities for trim <ENTER to select all>:

2. Select the cutting entities, then press Enter or right click. **You are prompted:** Fence/Crossing/Edge mode/Projection/eRa entity to trim or shift-select to extend>: A prompt menu displays. (1.1267)
3. Click the entity you want to trim, the part of the entity that you click will be removed. The entity is trimmed. **Or** Press and hold the shift key to extend (1.32.22) the entity.
4. Repeat step 3 to trim more entities.
5. Right click to conclude the **Trim** command.

NOTES	Entities which are selected when you launch the **Trim** command will be used as cutting entities.

Figure 1.1267



1.32.22 Extending Entities

Command: EXTEND (6.13.21) and TRIM (6.29.35) The **Extend** command lets you extend entities to a boundary, which is defined by one or more other entities. If the **Edge Mode** setting (**EDGEMODE**) is **On** , you can extend entities to an implied edge of the boundary entities. If the boundary entity is not in the same plane as the entity you want to extend, the **Projection Mode** setting (**PROJMODE**) lets you choose how the intersection is to be calculated. The options are:

- Project to the XY plane of the current UCS
- Project to the current view plane
- True 3D mode (No projection).

When extending entities, first select the boundary edges, and then specify the entities to extend, selecting them either one by one or using the fence selection method. The following entities can be extended: arcs, lines, two-dimensional polylines, rays. Boundary entities can be: arcs, circles, ellipses, lines, splines, polylines, rays, infinite lines, layout viewports.

To extend entities

1. Do one of the following:

   - Click the **Extend** tool button ( ) on the **Extend/Stretch** flyout of **Modify** toolbar.
   - Choose **Extend** in the **Modify** menu.
   - Type **extend** or **EX** in the command bar, then press Enter.

   You are prompted: Select boundary entities for extend <ENTER to select all>:

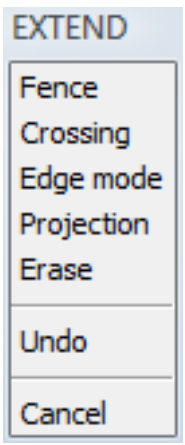
2. Select the boundary entities, then press Enter or right click. **You are prompted:** Fence/Crossing/Edge mode/Projection/e entity to extend or shift-select to trim>: A prompt menu displays. (1.1268)

3. Click the entity you want to extend near the end that can make the extension. The entity is extended. **Or** Press and hold the shift key to trim (1.32.21) the entity.

4. Repeat step 3 to extend more entities.

5. Right click or press Enter to conclude the **Extend** command.

Figure 1.1268



NOTES

- Entities which are selected when you launch the **Extend** command will be used as boundary entities.
- If you select an entity near the end that cannot make an extension to one of the boundary entities, the **Extend** command is aborted.

1.32.23 Changing the length of an entity

Command: LENGTHEN (6.20.24) The **Lengthen** command lets you change the length of lines, open polylines and arcs. You can also modify the included angle of arcs.

Change the length of an entity dynamically

1. Do one of the following:

   - Click the **Lengthen** tool button ( ) on the **Modify** toolbar.
   - Choose **Lengthen** in the **Modify** menu.
   - Type **lengthen** in the command bar, then press Enter.

   You are prompted: Edit length: DYnamic/Increment/Percent/Total/<Select entity to list length>: A prompt menu displays: (1.1269)

2. (option) Click an entity. The current length of the selected entity displays in the command bar. In case an arc is selected, the current length and the included angle display in the command bar.

3. Do one of the following:

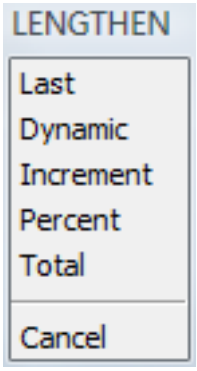
   - Choose **Dynamic** in the prompt box.
   - Type **DY** in the command bar, then press Enter.

   You are prompted: Mode/<Select entity to change>:

4. Click the entity near the end you want to change. The length of the entity changes dynamically.

5. Click to define the new length.

Figure 1.1269



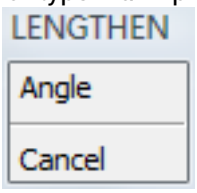
Modify the included angle of an arc

1. Do one of the following:

   - Click the **Edit Length** tool button ( ) on the **Modify** toolbar.
   - Choose **Edit Length** in the **Modify** menu.
   - Type **editlen** in the command bar, then press Enter.

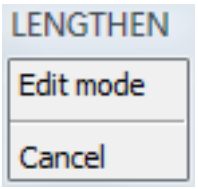
   You are prompted: Edit length: DYnamic/Increment/Percent/Total/<Select entity to list length>:

2. Choose **Total** in the prompt menu or type **T** and press Enter. **You are prompted:** Angle/<Enter total Length (0.00)>: A prompt menu displays:

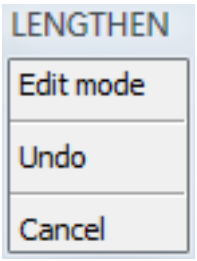


3. Choose **Angle** in the prompt menu or type **A** and press Enter. **You are prompted:** Enter total angle <00° 0′ 0″>:

4. Type the new angle in the command bar and press Enter. **You are prompted:** Mode/<Select entity to change>: A prompt menu displays:



5. Click the arc at the end you want to lengthen or shorten. The arc is modified. **You are prompted:** Mode/Undo/<Select entity to change>: A prompt menu displays:



6. Do one of the following:

   - Select another arc.
   - Choose **Undo** in the prompt menu or type **U** and press Enter to undo the previous action.
   - Choose **Edit mode** in the prompt menu or type **M** and press Enter to choose a different **Edit Length** command option.
   - Choose **Cancel** in the prompt menu to conclude the **Edit Length** command.

NOTE	In the Properties bar (1.25.15) you can edit the **start angle** , **end angle** and**radius** of an arc.

1.32.24 Stretching Entities

Command: STRETCH (6.27.52) The size and shape of entities can be changed by stretching them. You select an area in your drawing using either a rectangular window or a polygon, then you specify a base point and a displacement point. All points and nodes inside the selected area will be moved over the specified distance. As a result, entities that cross the window or polygon boundary are stretched; those completely within the window or polygon are simply moved. The Copy option (1.32.3) of the Grips Editing (1.32.3) commands allows to create multiple copies of the entities being stretched, moved, rotated, mirrored or scaled.

To stretch entities

1. Do one of the following:

   - Click the **Stretch** tool button ( ) on the **Extend/Stretch** flyout of the **Modify** toolbar.
   - Choose **Stretch** in the **Modify** menu.
   - Type s**tretch** or **S** in the command bar and press Enter.

   You are prompted: Select entities to stretch by crossing-window or crossing-polygon: A prompt menu displays: (1.1270)

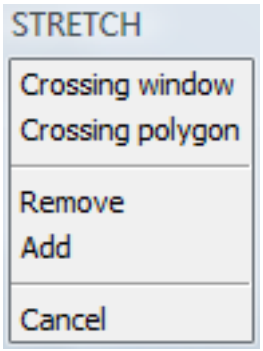
2. (option) Choose **Crossing window** in the **Stretch** prompt menu, then define the stretch area by a rectangular window.
3. (option) Choose **Crossing polygon** in the **Stretch** prompt menu, then define the stretch area by a polygon.
4. (option) Repeat steps 2 and 3 to expand the stretch area.
5. (option) Choose **Remove** in the **Stretch** prompt menu to select entities in the stretch area that must not be stretched.
6. (option) Choose **Add** in the **Stretch** prompt menu to add previously remove entities to the selection of entities that must be stretched.
7. Right click to conclude the selection of entities. **You are prompted:** Base point of displacement.
8. Specify the base point. The selection stretches dynamically. **You are prompted:** Second point of displacement.
9. Do one of the following to specify the second displacement point.

   - Click the displacement point.
   - Use Direct Distance Entry (1.21.4): type the displacement distance, then press Enter. The distance is measured in the cursor direction. Use ORTHO (1.21.2) or POLAR TRACKING (1.21.18) to constrain the movement of the cross hairs.

The selection is stretched.

NOTE	To add or remove entities from the selection set in steps 5 and 6 you can use any selection method: picking, window inside or crossing window.

Figure 1.1270



Stretching entities using grips

1. Click the entity you want to stretch. The entity grips display.
2. Click a grip to activate it. The grip is attached to the drawing cursor.
3. Press and hold the Shift key to select multiple grips, then release the Shift key and move one of the selected grips.
4. Click to relocate the grip. The grip is released from the drawing cursor.

NOTES

- Use Ortho Mode (1.21.2), Polar Tracking (1.21.18) or Snap Tracking (1.21.17) to constrain the movement of the drawing cursor.
- If you select two (or more) entities with coinciding grips, the shared grips move simultaneously.

1.32.25 Scaling Entities

Command: SCALE (6.27.6) The **Scale** command resizes a selection set in relation to a base point. You can specify the scale factor by selecting a base point and a length or by typing an explicit scale factor in the command bar. The scale factor can also be defined with respect to a base scale factor. E.g. when the base scale factor is 2 and the new scale is 3, the new size is 3/2 of the original. The base scale and the new scale can also be defined graphically in the drawing. The Copy option (1.32.3) of the Grips Editing (1.32.3) commands allows to create multiple copies of the entities being stretched, moved, rotated, mirrored or scaled.

To scale a selection set

1. Do one of the following:

   - Click the **Scale** tool button () on the **Modify** toolbar
   - Choose **Scale** in the **Modify** menu.
   - Type **scale** or **SC** in the command bar.

   You are prompted: Select entities to scale:

2. Select the entities (1.32.7), then right click or press Enter. **You are prompted:** Base point:
3. Specify the base point for the scaling. The selection set scales dynamically. **You are prompted:** Base scale/<Scale Factor>:
4. Type the scale factor in the command bar and press Enter. The selection set is scaled.

NOTE	The length of the vector between the base point and the current cursor position is used as the dynamic scale factor in step 3.

Scaling an entity using a base or reference scale

1. Select the entity.
2. Do one of the following:

   - Click the **Scale** tool button () on the **Modify** toolbar
   - Choose **Scale** in the **Modify** menu.
   - Type **scale** or **SC** in the command bar.

   You are prompted: Base point:

3. Specify the base point (1). **You are prompted:** Base Scale/<Scale Factor>: (1.1271 on the facing page)
4. Choose **Base** in the prompt menu of type **B** or **R** and press Enter. **You are prompted:** Base scale <1>:
5. Click point 1, then point 2 to define the base scale. The pentagon scales dynamically.
6. Click point 3. The edge of the pentagon now equals the side of the square. (1.1272 on the next page)

Figure 1.1271

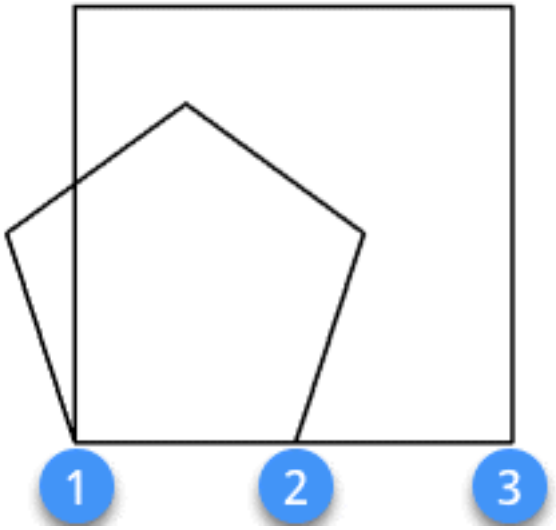


Figure 1.1272

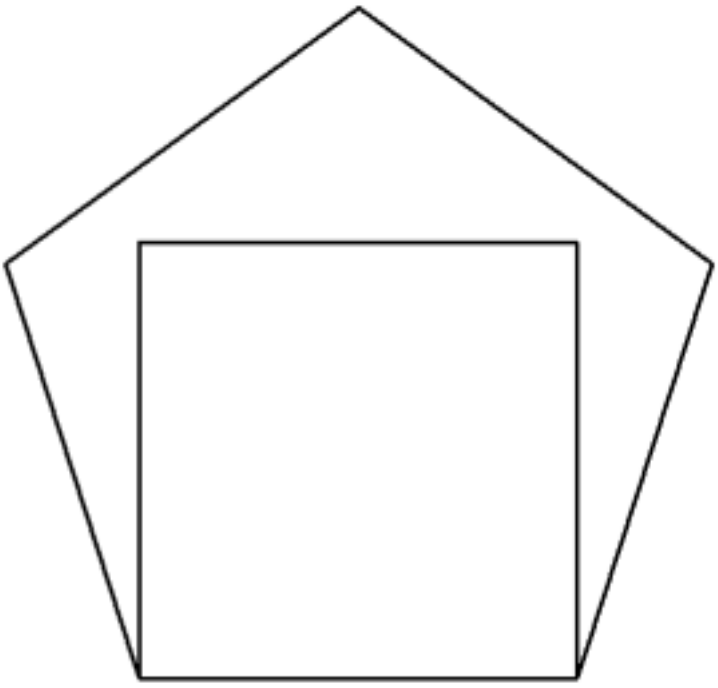


1.32.26 Joining Entities

Command: JOIN (6.18.1) The **Join** command joins lines, LW polylines, 2D polylines, 3D polylines, circular arcs, elliptical arcs, splines and helixes at their common endpoints. The type of the resulting entity depends on the types of the input entities and on their coplanarity.

Tutorial: Joining Multiple Entities into One Click here (1.12.19) to watch

To join colinear lines

When you join colinear lines, the farthest endpoints remain at their existing locations; BricsCAD draws a new line between these points.

1. Do one of the following:

   - Click the **Join** tool button ( ) on the **Modify** toolbar.
   - Choose **Join** in the **Modify** menu.
   - Type **join** in the command bar, then press Enter.

   You are prompted: Select source entity or multiple entities to join at once:

2. Select the lines. **You are prompted:** Select entities to join:

3. Right click or press Enter. The lines are joined.

To join two arcs

Coplanar arcs, sharing midpoint and radius, are joined counterclockwise, therefore the result depends on the selecting order.

1. Do one of the following:

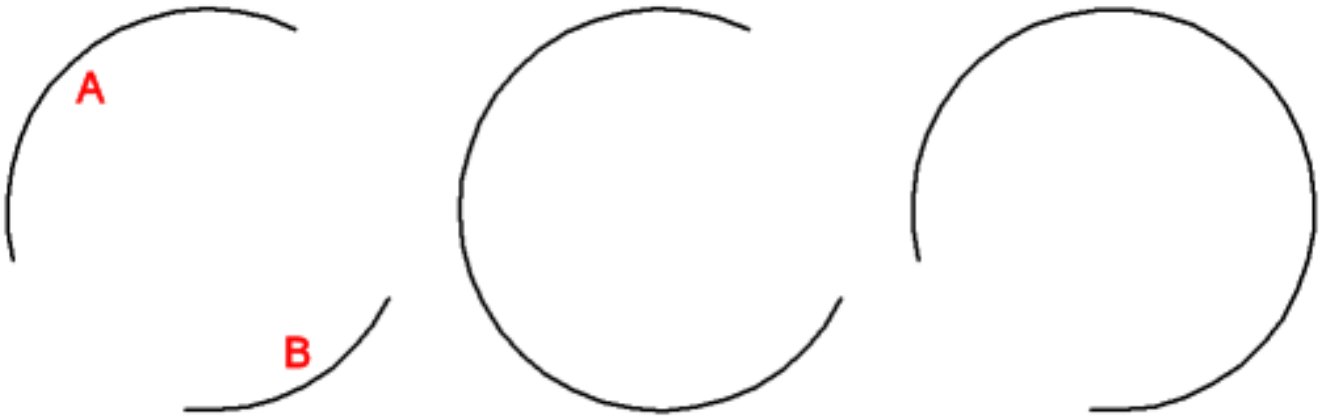
   - Click the **Join** tool button ( ) on the **Modify** toolbar.
   - Choose **Join** in the **Modify** menu.
   - Type **join** in the command bar, then press Enter.

   You are prompted: Select source entity or multiple entities to join at once:

2. Select the first arc. **You are prompted:** Select entities to join:

3. Select the second arc and press Enter. **You are prompted:** 2 entities joined into 1 arc. (1.1273) **Joining two arcs: start situation (left) and result when selecting A first (middle) or B first (right).**

Figure 1.1273



NOTE	If more arcs share the same center point and radius, you can select them in step 3. Press Enter after selecting the last arc.

1.32.27 Chamfering Entities

Command: CHAMFER (6.9.9) The **Chamfer** command connects two non-parallel entities by extending or trimming them and then joining them with a line to create a beveled edge. In BricsCAD you can choose between two chamfer methods:

- **distance-distance** : specify how far to trim the entities back from their intersection
- **distance-angle** : specify the length of the chamfer and the angle it forms along the first entity.

The following entities can be chamfered: lines, polylines, rays and infinite lines. When chamfering a polyline, you can create a chamfer between two polyline segments or you can chamfer the entire polyline.

Chamfering using the distance-distance method

1. Do one of the following:

   - Click the **Chamfer** tool button ( ) on the **Chamfer/Fillet** flyout of the **Modify** toolbar.
   - Choose **Chamfer** in the **Modify** menu.
   - Type **chamfer** or **CHA** in the command bar, then press Enter.

   You are prompted: Chamfer (<current chamfer settings>): Settings/Polyline/Angle/Distance/mEthod/Trim/Undo/Multi first entity>: A prompt menu displays: (1.1277 on page 1420)

2. (option) Choose **Chamfer Settings ...** in the prompt menu or type **S** and press Enter. In the **Settings** dialog window:

   - Specify the **Chamfer first distance**.
   - Set the **Chamfer second distance**.
   - Set the **Chamfer mode** to **Distance-Distance.**

   (1.1275 on the facing page) Close the **Settings** dialog window. **You are prompted:** Chamfer (<current chamfer settings>): Settings/Polyline/Angle/Distance/mEthod/Trim/Undo/Multiple/<Select first entity>:

3. Select the first entity or polyline segment. The command window reads: Select second entity.

4. Select the second entity or polyline segment. The chamfer is created.

Figure 1.1274

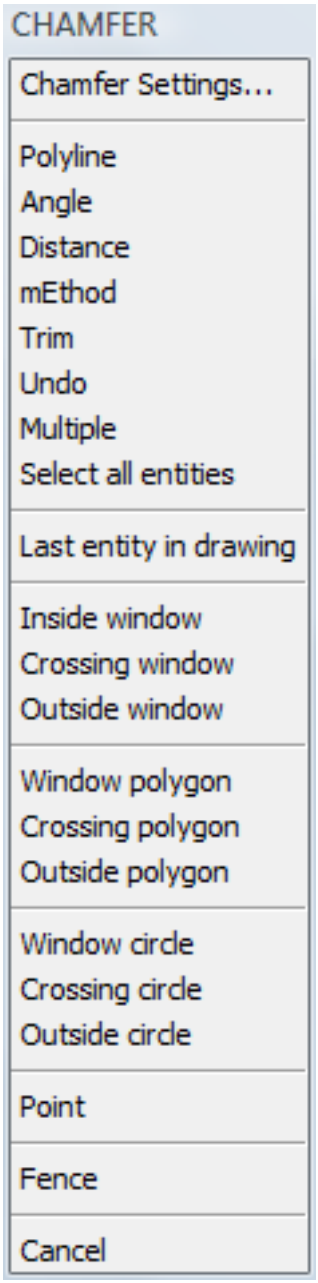


Figure 1.1275

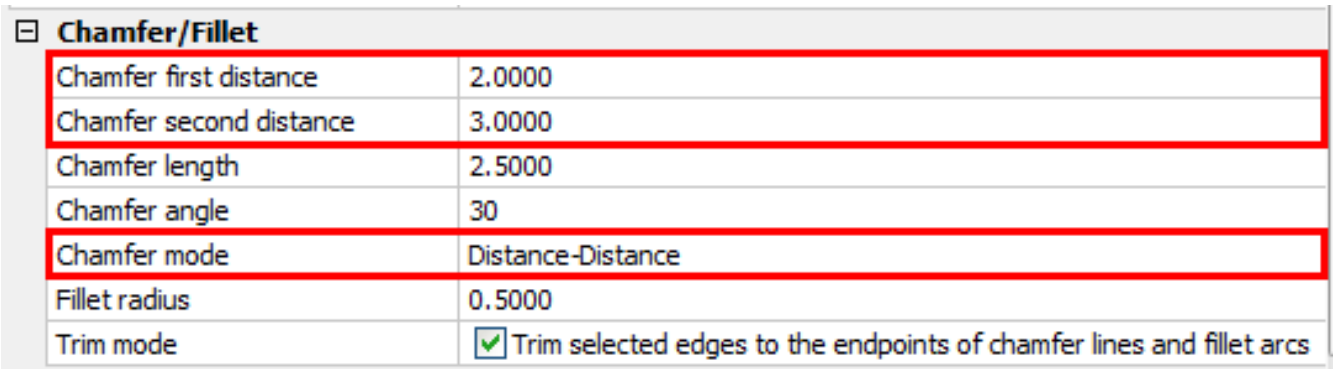


Chamfering using the length-angle method

1. Do one of the following:

   - Click the **Chamfer** tool button ( ) on the **Chamfer/Fillet** flyout of the **Modify** toolbar.
   - Choose **Chamfer** in the **Modify** menu.
   - Type **chamfer** or **CHA** in the command bar, then press Enter.

   You are prompted: Chamfer (<current chamfer settings>): Settings/Polyline/<Select first entity>: A prompt menu displays.

2. Choose **Chamfer Settings ...** in the prompt menu or type **S** and press Enter.

3. In the **Settings** dialog window:

   - Specify the **Chamfer length**.
   - Set the **Chamfer angle**.
   - Set the **Chamfer mode** to **Length-Angle.**

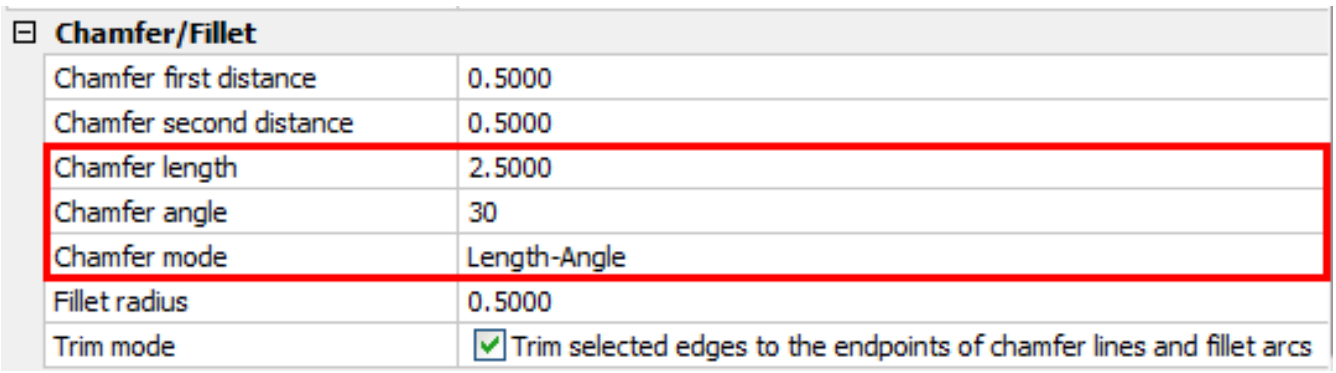
   (1.1276)

4. Close the Settings dialog window. **You are prompted:** Chamfer (<current chamfer settings>): Settings/Polyline/<Select first entity>:

5. Select the first entity or polyline segment. The command window reads: Select second entity.

6. Select the second entity or polyline segment. The chamfer is created.

Figure 1.1276



Chamfering all vertices of a polyline

1. Do one of the following:

   - Click the **Chamfer** tool button ( ) on the **Chamfer/Fillet** flyout of the **Modify** toolbar.
   - Choose **Chamfer** in the **Modify** menu.
   - Type **chamfer** or **CHA** in the command bar, then press Enter.

   You are prompted: Chamfer (<current chamfer settings>): Settings/Polyline/<Select first entity>: A prompt menu displays: (1.1277 on the following page)

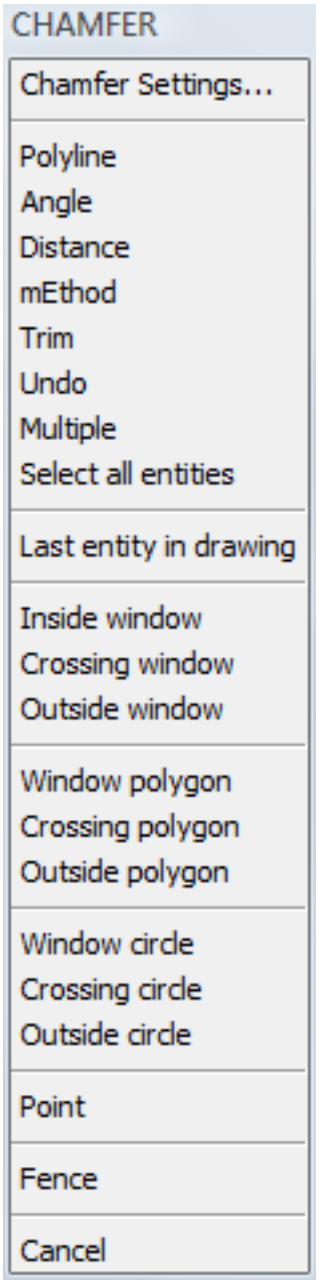
2. (option) Adjust the **Chamfer Settings**.

3. Choose **Polyline** in the prompt menu or type **P** and press Enter. **You are prompted:** Select 2D polyline to chamfer:

4. Select a polyline. All vertices of the selected polyline are chamfered.

NOTE	When the chamfer method is **distance-angle** , the direction of the polyline defines which is the first entity of a vertex. See drawing rectangles (1.25.18) for more information about the direction of closed polylines.

Figure 1.1277



1.32.28 Filleting Entities

Command: FILLET (6.14.6) The **Fillet** command connects two entities with an arc of a specified radius to create a rounded edge. You can fillet pairs of line segments, straight polyline segments, arcs, circles, rays, and infinite lines. You can also fillet parallel lines, rays, and infinite lines. When filleting a polyline, you can fillet multiple segments between two selected segments or you can fillet the entire polyline.

Filleting two entities or polyline segments

1. Do one of the following:

   - Click the **Fillet** tool button ( ) on the **Chamfer/Fillet** flyout of the **Modify** toolbar.
   - Choose **Fillet** in the **Modify** menu.
   - Type **fillet** or **F** in the command bar, then press Enter.

   You are prompted: Fillet (<current fillet settings>): Settings/Polyline/Radius/Trim/Undo/Multiple/<Select first entity>: A prompt menu displays: (1.1280 on page 1424)

2. (option) Choose **Fillet Settings ...** in the prompt menu or type **S** and press Enter. Specify the **Fillet radius** in the **Settings** dialog window: (1.1279 on the following page) Close the Settings dialog window. **You are prompted:** Fillet (<current fillet settings>): Settings/Polyline/Radius/Trim/Undo/Multiple/<Select first entity>:

3. Select the first entity or polyline segment. The command window reads: Select second entity.

4. Select the second entity or polyline segment. The fillet is created.

Figure 1.1278

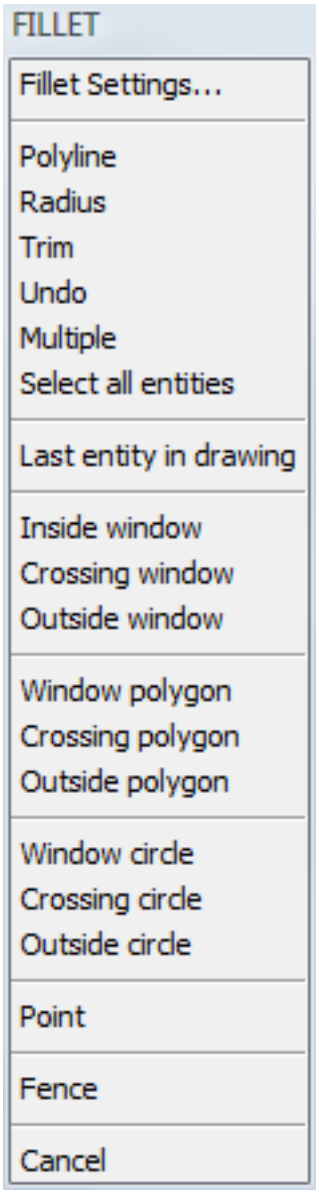


Figure 1.1279

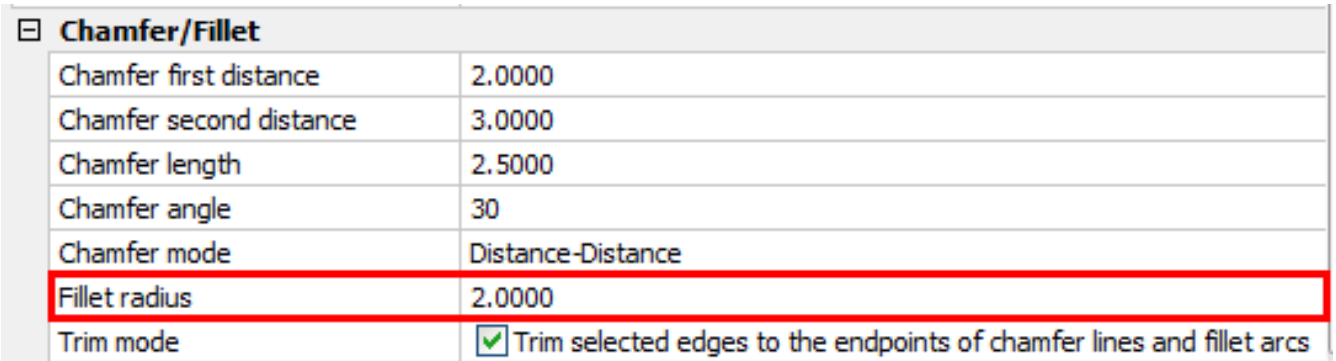


Filleting all vertices of a polyline

1. Do one of the following:

   - Click the **Fillet** tool button ( ) on the **Chamfer/Fillet** flyout of the **Modify** toolbar.
   - Choose **Fillet** in the **Modify** menu.
   - Type **fillet** or **F** in the command bar, then press Enter.

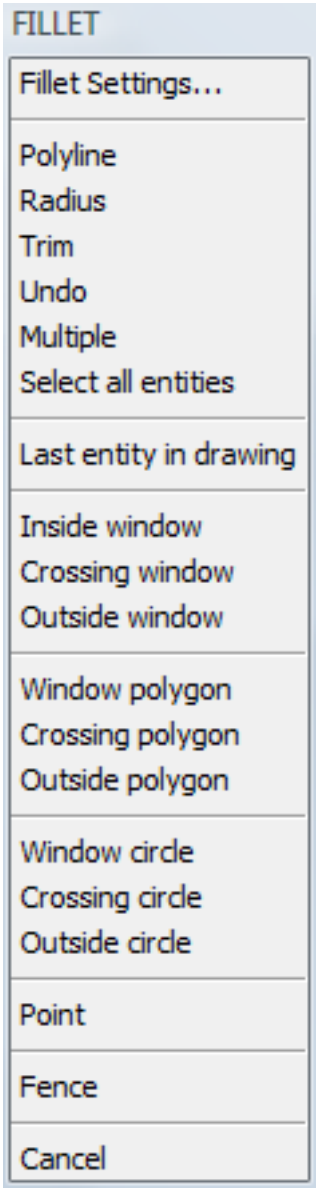
   You are prompted: Fillet (<current fillet settings>): Settings/Polyline/<Select first entity>: Pompt menu displays: (1.1280 on the next page)

2. (option) Adjust the **Fillet Settings**.

3. Choose **Polyline** in the prompt menu or type **P** and press Enter. **You are prompted:** Select 2D polyline to chamfer:

4. Select a polyline. All vertices of the selected polyline are filleted.

Figure 1.1280



Filleting two parallel lines

1. Do one of the following:

   - Click the **Fillet** tool button ( ) on the **Chamfer/Fillet** flyout of the **Modify** toolbar.
   - Choose **Fillet** in the **Modify** menu.
   - Type **fillet** or **F** in the command bar, then press Enter.

   You are prompted: Fillet (<current fillet settings>): Settings/Polyline/Radius/Trim/Undo/Multiple/<Select first entity>:

2. Select the first entity (line or ray). The command window reads: Select second entity:

3. Select the second entity (line, ray or infinite line). The fillet is executed at the endpoint closest to the point were the first entity is selected. The length of the second entity is adjusted.

1.32.29 Converting an entity into a polyline

Command: PEDIT (6.24.24) Lines and arcs can be converted into single-segment polyline.

Converting an entity into a polyline

1. Do one of the following:

   - Click the **Edit Polyline** tool button ( ) on the **Modify** toolbar.
   - Choose **Edit Polyline** in the **Modify** menu.
   - Type **editpline** or **pedit** in the command window, then press Enter.

   You are prompted: Select polyline to edit. Select a line or arc. **You are prompted:** The entity selected is not a polyline. Turn it into one? <Y> A prompt menu displays: (1.1281)

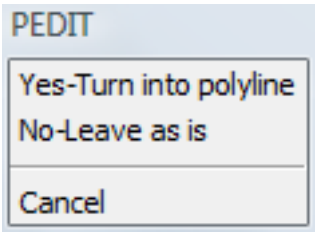
2. Do one of the following:

   - Press Enter to accept the default option.
   - Choose **Yes-Turn into polyline** in the prompt menu.

3. Press Enter to conclude the **Edit Polyline** command.

NOTE	The **Explode** tool turns a single segment polyline back into a line or arc.

Figure 1.1281



1.32.30 Opening and closing polylines

Command: PEDIT (6.24.24) When you close a polyline, a straight polyline segment is drawn from the last vertex of the polyline to the first vertex. Opening a polyline removes the closing segment. When you select a polyline for editing, the prompt menu displays either the **Open** or **Close** option, depending on whether the polyline you select is closed or open. The following entities are created as closed polylines:

- rectangles (1.25.18)
- polygons (1.25.20)
- donuts (1.25.28)
- revision clouds (1.25.24)

You can open or close a polyline using the **Edit Polyline** tool or in the BricsCAD Properties bar (1.15.4).

To close or open a polyline

1. Do one of the following:

   - Click the **Edit Polyline** tool button ( ) on the **Modify** toolbar.
   - Choose **Edit Polyline** in the **Modify** menu.
   - Type **editpline** or **pedit** in the command window, then press Enter.

   You are prompted: Select polyline to edit.

2. Click the polyline you want to close or open. **You are prompted:** Edit polyline: Edit vertices/Close (or Open)/Decurve/Fit/Join/Linetype-Mode/Reverse/Spline/Taper/Width/Undo/<eXit>: A prompt menu displays.

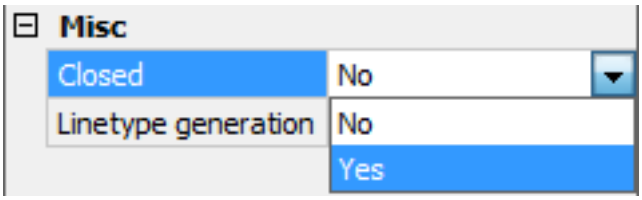
3. To close (or open) a polyline do one of the following:

   - Type **C** (or **O**) in the command bar, then press Enter.
   - Choose **Close** (or **Open**) in the prompt menu.

Opening and closing a polyline using the BricsCAD Properties bar

1. Select the polyline. The current properties of the selected polyline display in the BricsCAD Properties bar (1.15.4).
2. Select **Closed** in the **Misc** settings category in the **BricsCAD Properties** bar.
3. Click the down arrow and select **Yes** (or **No**). (1.1282)

Figure 1.1282



1.32.31 Joining Polylines

Commands: PEDIT (6.24.24) and JOIN (6.18.1) Using the **Join** option of the **Edit Polyline** tool you can add an arc, a line or a polyline entity to an existing open polyline, forming one continuous polyline entity. To join an entity to a polyline, that entity must already share an endpoint with an end vertex of the selected polyline. When you join an entity to a polyline, the **width** of the new polyline segment depends on the width of the original polyline and the type of entity you are joining to it:

- A line or an arc inherits the width from the polyline segment to which it is joined.
- A polyline joined to a tapered polyline retains its own width values.
- A polyline joined to a uniform-width polyline inherits the width from the polyline to which it is joined.

The **Join** command joins lines, LW polylines, 2D polylines, 3D polylines, circular arcs, elliptical arcs, splines and helixes at their common endpoints. The type of the resulting entity depends on the types of the input entities and on their coplanarity.

To join an arc, line, or polyline to an existing polyline

1. Do one of the following:

   - Click the **Edit Polyline** tool button ( ) on the **Modify** toolbar.
   - Choose **Edit Polyline** in the **Modify** menu.
   - Type **editpline** or **pedit** in the command window, then press Enter.

   You are prompted: Select polyline to edit.

2. Select the parent polyline. **You are prompted:** Edit polyline: Edit vertices/Close (or Open)/Decurve/Fit/Join/Linetype-Mode/Reverse/Spline/Taper/Width/Undo/<eXit>: A prompt menu displays.
3. Choose **Join** in the prompt menu or type **J** and press Enter. **You are prompted:** Select entities to join:
4. Select the entities to join. The number of already selected entities displays in the command bar.
5. Right click or press Enter to stop selecting entities and add the selection to the polyline.
6. Do one of the following:

   - Continue editing the selected polyline.
   - Choose **Exit** in the prompt menu or press Enter to conclude the **Edit Polyline** tool.

NOTE	You can select multiple entities in step 3 on condition they form one chain with the parent polyline.

1.32.32 Breaking Entities

Command: BREAK (6.6.21) The **Break** command remove a portion of an entity, thus breaking it into two parts. You can break arcs, circles, ellipses, lines, polylines, rays and infinite lines. Breaking a circle converts it to an arc. A ray is broken into a ray and a line, an infinite line is broken into two rays. When breaking entities, you must specify two points for the break. By default, the point you use to select the entity becomes the first break point; however, you can use the First option to select a break point different from the one that selects the entity.

To break an entity

1. Do one of the following:

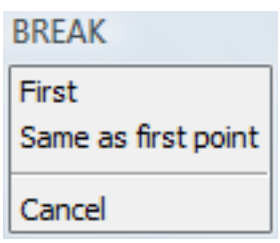
   - Click the **Break** tool button ( ) on the **Modify** toolbar.
   - Choose **Break** in the **Modify** menu.
   - Type **Break** or **BR** in the command bar, then press Enter.

   You are prompted: Select entity to break:

2. Click the entity you want to break. **You are prompted:** First break point/<Second break point>: A prompt menu displays: (1.1283)

3. Click a second point on the entity. The entity is broken. The portion between the two break points is removed.

Figure 1.1283



1.32.33 Editing polyline vertices

Commands: PEDIT (6.24.24) and PEDITEXT (6.24.21) The Edit vertices option of the Pedit command modifies individual polyline vertices. When you select this option, the program switches into a special vertex editing mode and places an X on the first vertex. The X indicates the vertex you are editing. The Next and Previous options move the X to the next or previous vertex. You can edit only one vertex at a time. When editing vertices, you can modify the polyline in the following ways:

- Convert a straight polyline segment into a curve (1.32.33).
- Break a polyline into two separate polylines (1.32.33).
- Insert a new vertex in a polyline (1.32.33).
- Move a vertex in a polyline (1.32.33).
- Delete vertices in a polyline (1.32.33).
- Change the width of a polyline segment (1.32.33).

The Peditext command is used in 2D Editing command group of the Quad (1.15.5) cursor menu

Editing a polyline segment using the Quad

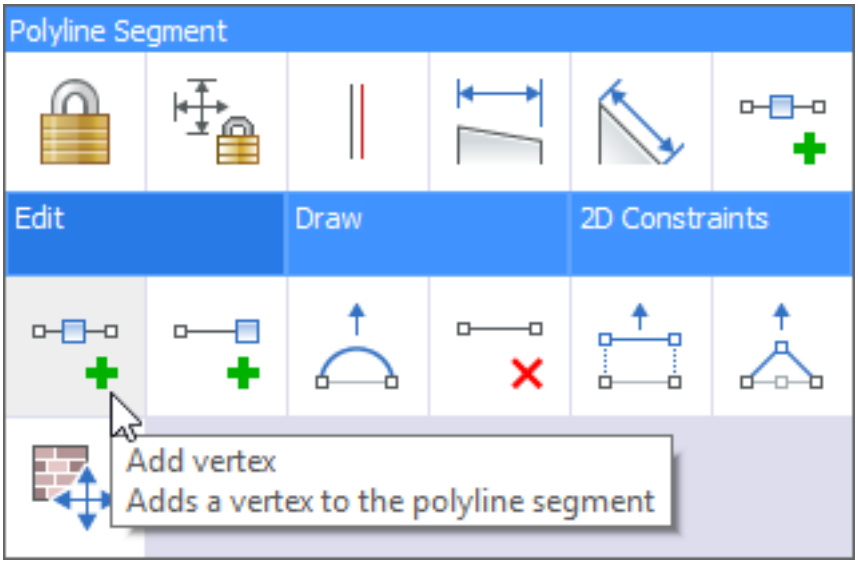
1. Move the cursor over the polyline. If currently ON, the TIPS widget displays: (1.1284) The available commands in the Quad apply to the entire polyline.
2. Press the Ctrl-key to switch to segment mode. (1.1285 on the facing page) The available commands in the Quad apply to the segment under the cursor.
3. When the Quad cursor menu (1.15.5) displays, do one of the following:
   - Right click to execute the default Quad command.
   - Move the cursor to the Quad and move to the Edit command group.

   (1.1286 on the next page)
4. Select a command:
   - Add vertex: adds a vertex to the segment under the cursor.
   - Add vertex at end: adds as a new vertex at the end of the polyline. This option is only available if the cursor is on one of the endpoints of a polyline.
   - Adjust Bulge (1.32.35): Modifies the bulge factor of the segment under the cursor.
   - Delete segment: deletes the segment under the cursor.
   - Stretch segment: moves the segment under the cursor.
   - Stretch vertex: moves the vertex closest to the cursor.

Figure 1.1284

Figure 1.1285

Figure 1.1286



Starting the polyline vertex editing mode

1. Do one of the following:

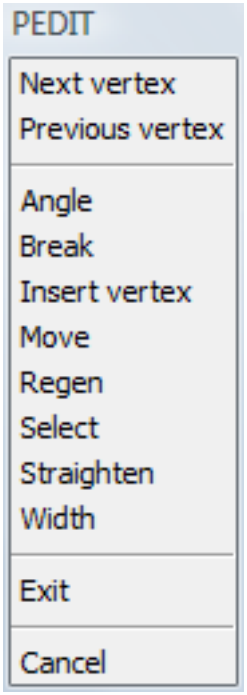
   - Click the Edit Polyline tool button ( ) on the Modify toolbar.
   - Choose Edit Polyline in the Modify menu.
   - Type editpline or pedit in the command window, then press Enter.

   You are prompted: Select polyline to edit.

2. Select the polyline. **You are prompted:** Edit polyline: Edit vertices/Close (or Open)/Decurve/Fit/Join/Linetype-Mode/Reverse/Spline/Taper/Width/Undo/<eXit>: A prompt menu displays.

3. Choose Edit vertices in the prompt menu or type E and press Enter. **You are prompted:** Next/Previous/Angle/Break/Inser The Editpline prompt menu changes: (1.1287 on the following page) A triangle indicates the start point of the polyline. The first vertex of the polyline is selected.

Figure 1.1287



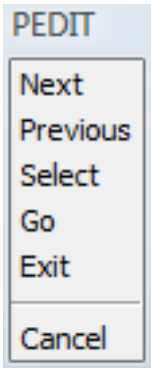
Convert a straight polyline segment into an arc

1. Start the polyline vertex editing mode (1.32.33).
2. Select the start vertex of the segment you want to convert. **Choose Next vertex / Previous vertex** in the prompt menu to select a vertex. The X indicates the currently selected vertex.
3. Choose Angle in the prompt menu or type A and press Enter. The prompt menu closes. **You are prompted:** Included angle for segment (>0 is ccw, 0 is straight, <0 is cw) <current angle>:
4. Type a new included angle for the segment and press Enter. The direction of an arc segment is as follows:
   - positive angles: counter clockwise
   - negative angle: clockwise direction
   - 0° for straight segments
5. Choose **Exit** in the prompt menu or type **X** and press Enter to leave the Polyline vertex editing mode.
6. Do one of the following:
   - Continue editing the selected polyline.
   - Choose Exit in the prompt menu or press Enter to conclude the Edit Polyline tool.

Break a polyline into two separate polylines

1. Start the polyline vertex editing mode (1.32.33).
2. Select the start vertex where you want to break the polyline. **Choose Next vertex / Previous vertex** in the prompt menu to select a vertex. The X indicates the currently selected vertex.
3. Choose Break in the prompt menu or type B and press Enter. **You are prompted:** Next/Previous/Select/Go/eXit/<Next>: The prompt menu changes: (1.1288 on the next page)
4. (option) Do one of the following to select a second vertex:
   - **Choose Next vertex / Previous vertex** in the prompt menu.
   - Choose **Select** in the prompt menu or type **S** and press Enter. **You are prompted** to select a vertex.
5. Choose </p> in the prompt menu or type **G** and press Enter. The polyline is broken into two polylines. If a second point is selected in step 4 the segment(s) between the selected vertices is (are) deleted.
6. Choose **Exit** in the prompt menu or type **X** and press Enter to leave the Polyline vertex editing mode.

Figure 1.1288



7. Do one of the following:
   - Continue editing the selected polyline.
   - Choose **Exit** in the prompt menu or press Enter to conclude the Edit Polyline tool.

Insert a new vertex in a polyline

1. Start the polyline vertex editing mode (1.32.33).
2. Select the start vertex of the segment where you want to insert a vertex. **Choose Next vertex / Previous vertex** in the prompt menu to select a vertex. The X indicates the currently selected vertex.
3. Choose **Insert** vertex in the prompt menu or type **I** and press Enter. **You are prompted:** Location for new vertex:
4. Specify the location for the new vertex. The new vertex is inserted.
5. Choose **Exit** in the prompt menu or type **X** and press Enter to leave the Polyline vertex editing mode.
6. Do one of the following:
   - Continue editing the selected polyline.
   - Choose **Exit** in the prompt menu or press Enter to conclude the Edit Polyline tool.

Move a vertex in a polyline

1. Start the polyline vertex editing mode (1.32.33).
2. Select the vertex you want to move. **Choose Next vertex / Previous vertex** in the prompt menu to select a vertex. The X indicates the currently selected vertex.
3. Choose **Move** in the prompt menu or type **M** and press Enter. **You are prompted:** New location for vertex.
4. Specify the new location for the selected vertex. The vertex is moved.
5. Choose **Exit** in the prompt menu or type **X** and press Enter to leave the Polyline vertex editing mode.
6. Do one of the following:
   - Continue editing the selected polyline.
   - Choose **Exit** in the prompt menu or press Enter to conclude the Edit Polyline tool.

Delete vertices in a polyline

1. Start the polyline vertex editing mode (1.32.33).
2. Select the vertex before the first vertex you want to delete. **Choose Next vertex / Previous vertex** in the prompt menu to select a vertex. The X indicates the currently selected vertex.
3. Choose **Straighten** in the prompt menu or type **S** and press Enter. **You are prompted:** Straighten: Next/Previous/Select/G
4. Do one of the following to select the vertex after the last vertex you want to delete:

- **Choose Next vertex / Previous vertex** in the prompt menu.
- Choose **Select** in the prompt menu or type **S** and press Enter. **You are prompted** to select a vertex.

5. Choose **Go** in the prompt menu or type **G** and press Enter. The vertices between the selected vertices are removed. A straight segment is drawn between the selected vertices.
6. Choose **Exit** in the prompt menu or type **X** and press Enter to leave the Polyline vertex editing mode.
7. Do one of the following:
   - Continue editing the selected polyline.
   - Choose **Exit** in the prompt menu or press Enter to conclude the Edit Polyline tool.

Change the width of a polyline segment

1. Start the polyline vertex editing mode (1.32.33).
2. Select the start vertex of the segment you want to change the width of. **Choose Next vertex / Previous vertex** in the prompt menu to select a vertex. The **X** indicates the currently selected vertex.
3. Enter starting width <current width>:
4. Do one of the following:
   - Type the new width in the command bar and press Enter.
   - Click to define the width graphically.

   You are prompted: Enter ending width <current width>:
5. Do one of the following:
   - Type the new width in the command bar and press Enter.
   - Click to define the width graphically.
6. Choose **Exit** in the prompt menu or type **X** and press Enter to leave the Polyline vertex editing mode.
7. Do one of the following:
   - Continue editing the selected polyline.
   - Choose **Exit** in the prompt menu or press Enter to conclude the Edit Polyline tool.

NOTE	The new width is applied when you conclude the Edit Polyline tool in step 6.

1.32.34 Changing the polyline width

Command: PEDIT (6.24.24) The **Width** option of the **Edit Polyline** tool applies a uniform width to the entire entity, while the **Taper** option tapers the polyline uniformly along its entire length.

To apply a uniform width to a polyline

1. Do one of the following:

   - Click the **Edit Polyline** tool button ( ) on the **Modify** toolbar.
   - Choose **Edit Polyline** in the **Modify** menu.
   - Type **Editpline** or **Pedit** in the command window, then press Enter.

   You are prompted: Select polyline to edit.

2. Select the polyline. **You are prompted:** Edit polyline: Edit vertices/Close (or Open)/Decurve/Fit/Join/Linetype-Mode/Reverse/Spline/Taper/Width/Undo/<eXit>: A prompt menu displays.

3. Choose **Width** in the prompt menu or type **W** and press Enter. **You are prompted:** Enter new width for all segments:

4. Type a new width in the command bar and press Enter. The new width is applied to the entire polyline.

5. Do one of the following:

   - Continue editing the selected polyline.
   - Choose **Cancel** in the prompt menu or press Enter or right click to conclude the **Edit Polyline** tool.

To taper a polyline uniformly along its length

1. Do one of the following:

   - Click the **Edit Polyline** tool button ( ) on the **Modify** toolbar.
   - Choose **Edit Polyline** in the **Modify** menu.
   - Type **Editpline** or **Pedit** in the command window, then press Enter.

   You are prompted: Select polyline to edit.

2. Select the polyline. **You are prompted:** Edit polyline: Edit vertices/Close (or Open)/Decurve/Fit/Join/Linetype-Mode/Reverse/Spline/Taper/Width/Undo/<eXit>: A prompt menu displays.

3. Choose **Taper** in the prompt menu or type **T** and press Enter. **You are prompted:** Enter new starting polyline width <current starting width>:

4. Type a new starting width in the command bar and press Enter. **You are prompted:** Enter new ending polyline width <current ending width>:

5. Type a new ending width in the command bar and press Enter. The polyline is tapered uniformly along its length.

6. Do one of the following:

   - Continue editing the selected polyline.
   - Choose **Cancel** in the prompt menu or press Enter or right click to conclude the **Edit Polyline** tool.

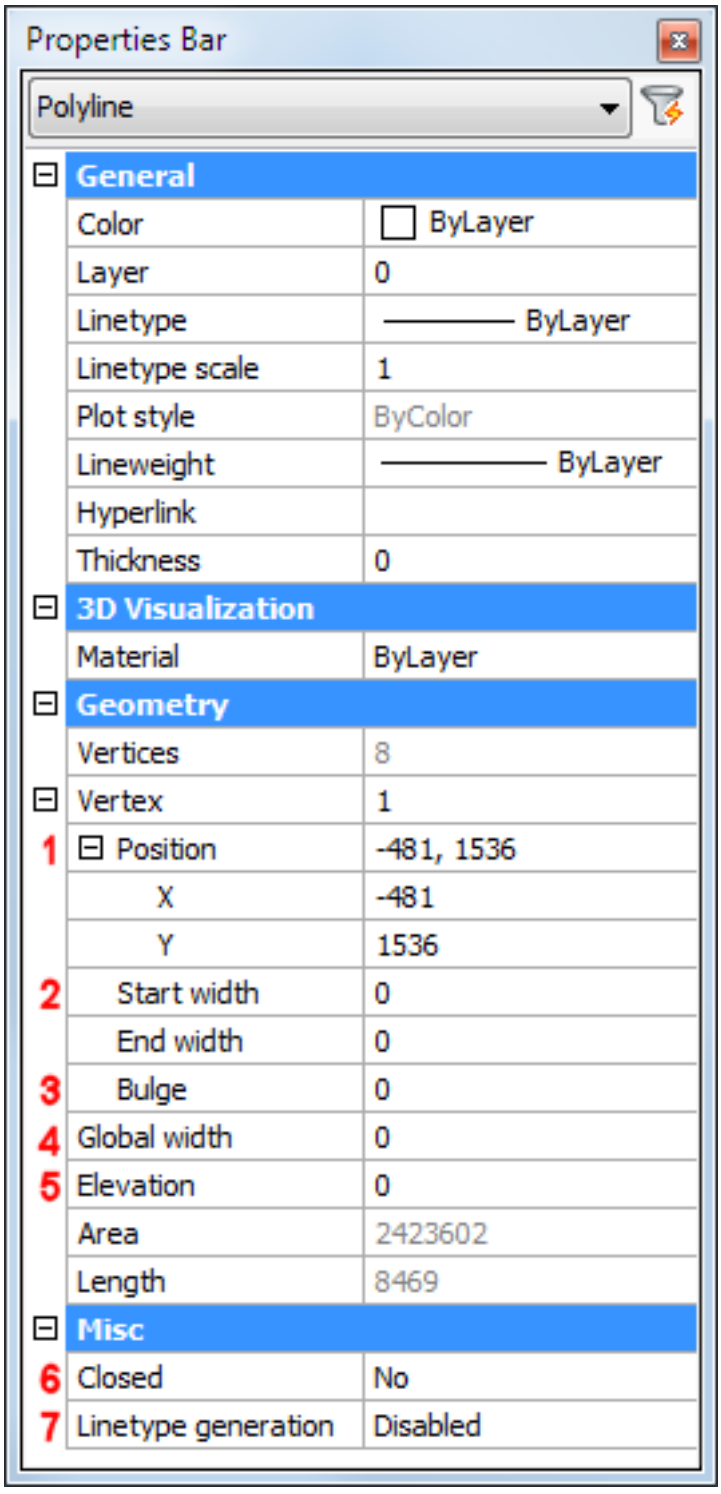
1.32.35 Editing polylines in the Properties bar

When you select polyline, its current properties display in the BricsCAD Properties bar (1.15.4). In the **BricsCAD Properties bar** the following polyline properties can be edited:

- Move vertices (1)
- Change the width of polyline segments (2)
- Convert straight segments into a curve (3)
- Change the global width (4)
- Change the Elevation (5)
- Open / close the polyline (6)
- Change the Linetype generation mode (7)

(1.1289 on the facing page)

Figure 1.1289



To move polyline vertices

1. Select the polyline.
2. Click the **Vertex** field in the **Properties bar**, then press the arrow buttons to select the vertex you want to move. A **X** indicates the currently selected vertex in the drawing. (1.1293 on page 1440)
3. Do one of the following:
   - Adjust the **X-** and/or **Y-field** and press Enter.
   - Click the **Vertex Position** field and press the **Position** button to move the vertex in the drawing.

   (1.1291 on the facing page)
4. Continue editing the polyline or press the Esc key to stop.

Figure 1.1290

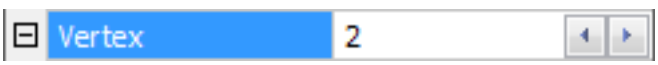


Figure 1.1291

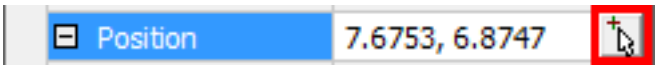
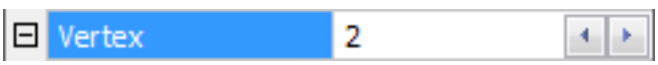


To change the width of polyline segments

1. Select the polyline.
2. Click the **Vertex** field in the **Properties bar**, then press the arrow buttons to select the start vertex of the segment you want to modify. A **X** indicates the currently selected vertex in the drawing. (1.1293 on the next page)
3. Type a new width in the **Start width** field and press Enter.
4. Type a new width in the **End width** field and press Enter.
5. Continue editing the polyline or press the Esc key to stop.

Figure 1.1292



To convert straight segments into a curve

1. Select the polyline.
2. Click the **Vertex** field in the **Properties bar**, then press the arrow buttons to select the start vertex of the segment you want to modify. A **X** indicates the currently selected vertex in the drawing. (1.1293)
3. Type a new value in the Bulge field and press Enter. (1.1294 on the next page)
4. Continue editing the polyline or press the Esc key to stop.

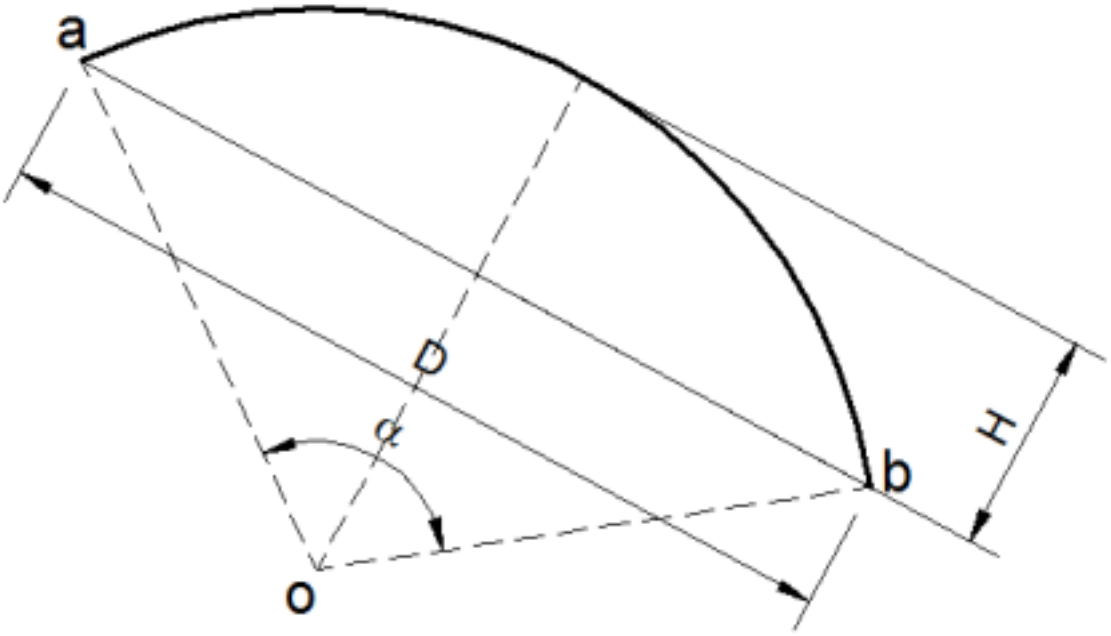
NOTE

The bulge is the tangent of one fourth the included angle for an arc segment. A positive bulge creates a counter clockwise arc, while a negative bulge creates an arc with a clockwise direction. Straight segments have a zero bulge. (1.1295 on the facing page) Bulge = 2H/D Bulge = tg α / 4

Figure 1.1293

Figure 1.1294

Figure 1.1295



1.32.36 Exploding entities

Commands: EXPLODE (6.13.16) and TXTEXP (6.29.36) The **Explode** command converts complex entities, such as blocks, polylines, solids or dimensions into their component parts. Exploding a polyline or dimension reduces it to a collection of individual line and arc entities that you can then modify individually. Blocks are converted to the individual entities, possibly including other, nested blocks that composed the original entity. Multiline texts explode into single line text entities. In general exploding entities will have no visible effect in the drawing, except for:

- If the original polyline had a width, the width information is lost when you explode it. The resulting lines and arcs follow the centerline of the original polyline.
- If you explode a block containing attributes, the attributes are lost, but the original attribute definitions remain. Colors and linetypes assigned **BYBLOCK** may appear different after exploding an entity, because they will adopt the default color and linetype.

The **TxtExp** command explodes text into polylines (short for "text explode").

To explode entities

1. Do one of the following:

   - Click the **Explode** tool button () on the **Modify** toolbar.
   - Choose **Explode** in the **Modify** menu.
   - Type **Explode** in the command bar, then press Enter.

   The command window reads: Select entities to explode.

2. Select the entities (1.32.7), then right click or press Enter.

NOTE	If you select the entities first, then launch the **Explode** tool, the selected entities are exploded immediately.

1.32.37 Creating Regions

Command: REGION (6.26.18) The **Region** command converts closed entities into a solid entity. You can create regions from closed entities, such as polylines, polygons, circles, ellipses, closed splines and donuts. Creating regions typically has no visible effect on a drawing. However, if the original entity had a width or lineweight, that information is lost when you create the region.

To create regions

1. Do one of the following:

   - Click the **Region** tool button ( ) in the **Draw** toolbar.
   - Choose **Region** in the **Draw** menu.
   - Type **Region** in the command bar, then press Enter.

   You are prompted: Select objects:

2. Select the entities (1.32.7), then right click or press Enter. The command bar displays how many regions have been created.

1.32.38 Measuring Entities

Command: MEASURE (6.21.11) The **Measure** command places markers - points or blocks - at a specified interval along the length or circumference of an entity. The Measure tool starts placing markers at the closes endpoint to where you select the entity. You can measure lines, polylines, arcs, circles, ellipses, elliptical arcs and splines. You cannot measure rays and infinite lines. You measure a circle along its circumference starting from the **Angle Base** value as defined in the **Settings** dialog. If **Angle Base** is set to zero, a circle is measured starting at 3 o'clock (east).

To measure an entity using points

1. Do one of the following:

   - Click the **Measure** tool button ( ) on the **Modify** toolbar.
   - Choose **Measure** in the **Modify** menu.
   - Type **measure** in the command bar, then press Enter.

   You are prompted: Select entity to measure:

2. Click the entity you want to measure. **You are prompted:** Block/<Segment length>:

3. To define the measurement interval, do one of the following:

   - Type the measurement interval and press Enter.
   - Specify two points in the drawing.

   Points are placed along the selected entity at the specified interval.

NOTE	It might be necessary to adjust the Point display mode (1.25.33) settings to display the points correctly.

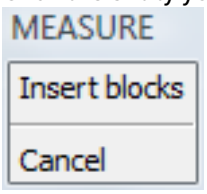
To place blocks a specified interval along an entity

1. Do one of the following:

   - Click the **Measure** tool button ( ) on the **Modify** toolbar.
   - Choose **Measure** in the **Modify** menu.
   - Type **measure** in the command bar, then press Enter.

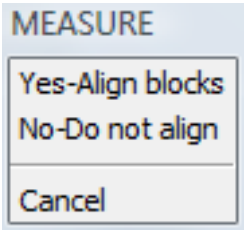
   You are prompted: Select entity to measure:

2. Click the entity you want to measure. **You are prompted:** Block/<Segment length>: A prompt menu displays:



3. Choose **Insert blocks** in the prompt menu or type B and press Enter. **You are prompted:** Name of block to insert:

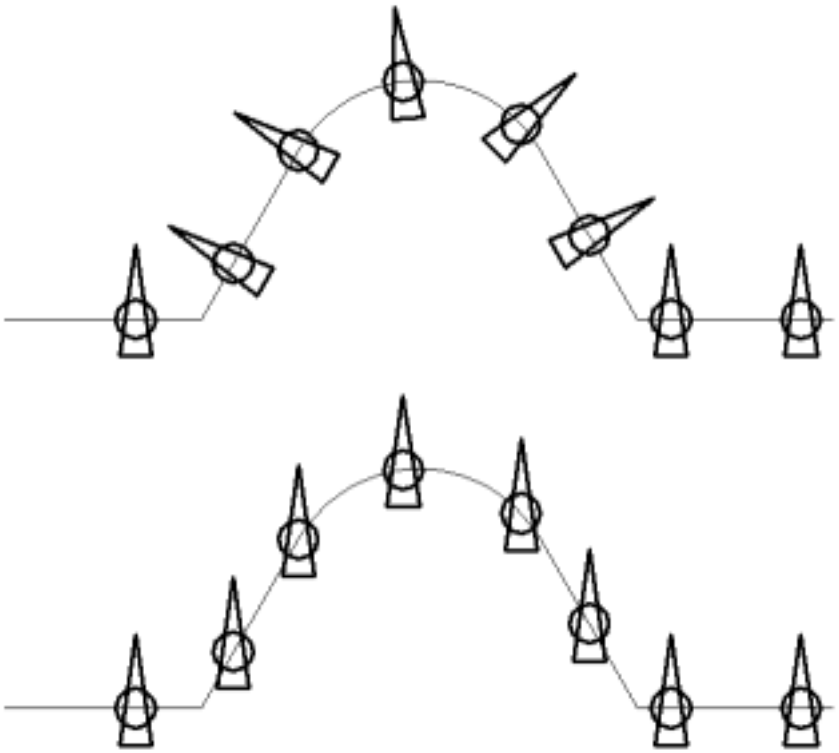
4. Type the name of the block in the command bar and press Enter. **You are prompted:** Align blocks with entity? <Y>: A prompt menu displays:



5. Do one of the following:

   - Choose **Yes-Align blocks** in the prompt menu or press Enter to align the blocks with the selected entity.
   - Choose **No-Do not align** in the prompt menu or type N and press Enter to place the blocks not rotated.

Figure 1.1296



You are prompted: Segment length:

6. To define the measurement interval, do one of the following:

   - Type the measurement interval and press Enter.
   - Specify two points in the drawing.

   The blocks are placed along the selected entity at the specified interval. (1.1296) **Blocks aligned (top) or not aligned (bottom)**

1.32.39 Setting the Linetype generation mode

Command: PEDIT (6.24.24) The **Linetype mode** option of the **Edit Polyline** tool lets you change the way how a dashed linetype is applied to a multi-segment polyline.

To set the Linetype mode

1. Do one of the following:

   - Click the **Edit Polyline** tool button ( ) on the **Modify** toolbar.
   - Choose **Edit Polyline** in the **Modify** menu.
   - Type **editpline** or **pedit** in the command window, then press Enter.

   You are prompted: Select polyline to edit.

2. Select the polyline. **You are prompted:** Edit polyline: Edit vertices/Close (or Open)/Decurve/Fit/Join/Linetype-Mode/Reverse/Spline/Taper/Width/Undo/<eXit>: A prompt menu displays.

3. Choose **Linetype** mode in the prompt menu or type **L** and press Enter. **You are prompted:** Linetype continuous along polyline: ON/OFF <current setting>: The **Editpline** prompt menu changes:

4. Do one of the following:

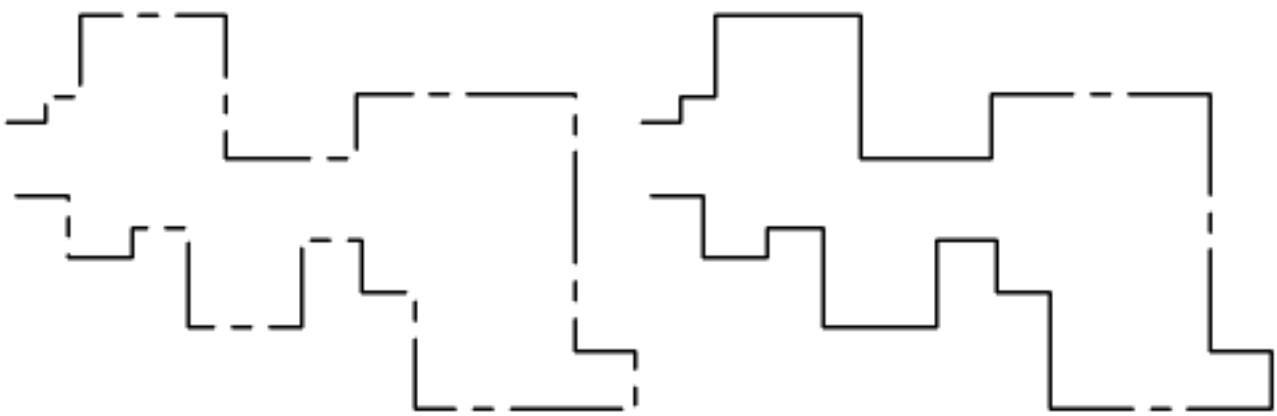
   - Choose **Continuous on** or **Continuous off** in the prompt box.
   - Type **ON** or **OF** in the command bar, then press Enter.

   (1.1297) **The same polyline with Continuous On (left) and Continuous Off (right)**

5. Do one of the following:

   - Continue editing the selected polyline.
   - Choose **Cancel** in the prompt menu or press Enter or right click to conclude the **Edit Polyline** tool.

Figure 1.1297



1.32.40 Curving and decurving polylines

Command: PEDIT (6.24.24) The **Fit** or **Spline** options of the **Edit Polyline** tool convert a multi-segment polyline into a smooth curve. The **Fit** option creates a smooth curve connecting all the vertices. The **Spline** option computes a smooth curve that is pulled toward the vertices but passes through only the first and last vertices. The **Decurve** option removes **Fit** or **Spline** curves and arcs, leaving straight segments between the vertices.

To fit a curve to a polyline

1. Do one of the following:

   - Click the **Edit Polyline** tool button ( ) on the **Modify** toolbar.
   - Choose **Edit Polyline** in the **Modify** menu.
   - Type **editpline** or **pedit** in the command window, then press Enter.

   You are prompted: Select polyline to edit.

2. Select the polyline. **You are prompted:** Edit polyline: Edit vertices/Close (or Open)/Decurve/Fit/Join/Linetype-Mode/Reverse/Spline/Taper/Width/Undo/<eXit>: A prompt menu displays.

3. Do one of the following:

   - Choose **Fit** in the prompt menu of type **F** and press Enter.
   - Choose **Spline** in the prompt menu or type **S** and press Enter.

(1.1298 on the next page)	(1.1299 on the following page)	(1.1300 on the next page)
Original polyline	After applying Fit	After applying Spline

4. Do one of the following:

   - Continue editing the selected polyline.
   - Choose **Done** in the prompt menu or press Enter to conclude the **Edit Polyline** tool.

NOTES

- Use the **Decurve** option in step 3 of the above procedure to restore the original polyline.
- The **SPLINESEGS** (Spline Segments) settings variable controls the number of segments (lines or arcs) to be generated for spline-fit polylines.

Figure 1.1298

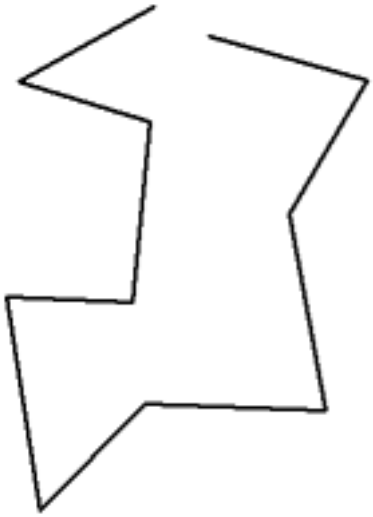


Figure 1.1299

Figure 1.1300

1.32.41 Dividing Entities

Command: DIVIDE (6.10.39) The **Divide** command places markers - points or blocks - along a selected entity. The markers evenly divide the entity into the specified number of equal parts. You can divide lines, polylines, arcs, circles, ellipses, elliptical arcs and splines.

To divide an entity using points

1. Do one of the following:

   - Click the **Divide** tool button ( ) on the **Modify** toolbar.
   - Choose **Divide** in the **Modify** menu.
   - Type **divide** in the command bar, then press Enter.

   You are prompted: Select entity to divide:

2. Click the entity you want to divide. **You are prompted:** Blocks/<Number of Segments>:

3. Type the number of segments in the command bar and press Enter. Points are placed along the selected entity to divide the entity.

NOTE	It might be necessary to adjust the Point display mode (1.25.33) settings to display the points correctly.

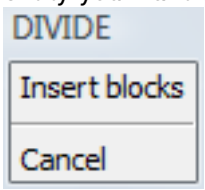
To divide an entity using blocks

1. Do one of the following:

   - Click the **Divide** tool button ( ) on the **Modify** toolbar.
   - Choose **Divide** in the **Modify** menu.
   - Type **divide** in the command bar, then press Enter.

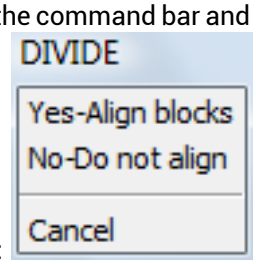
   You are prompted: Select entity to divide:

2. Click the entity you want to divide. **You are prompted:** Blocks/<Number of Segments>: A prompt menu displays:



3. Choose **Insert blocks** in the prompt menu or type B and press Enter. **You are prompted:** Name of block to insert:

4. Type the name of the block in the command bar and press Enter. **You are prompted:** Align blocks with entity? <Y>: A prompt menu displays:

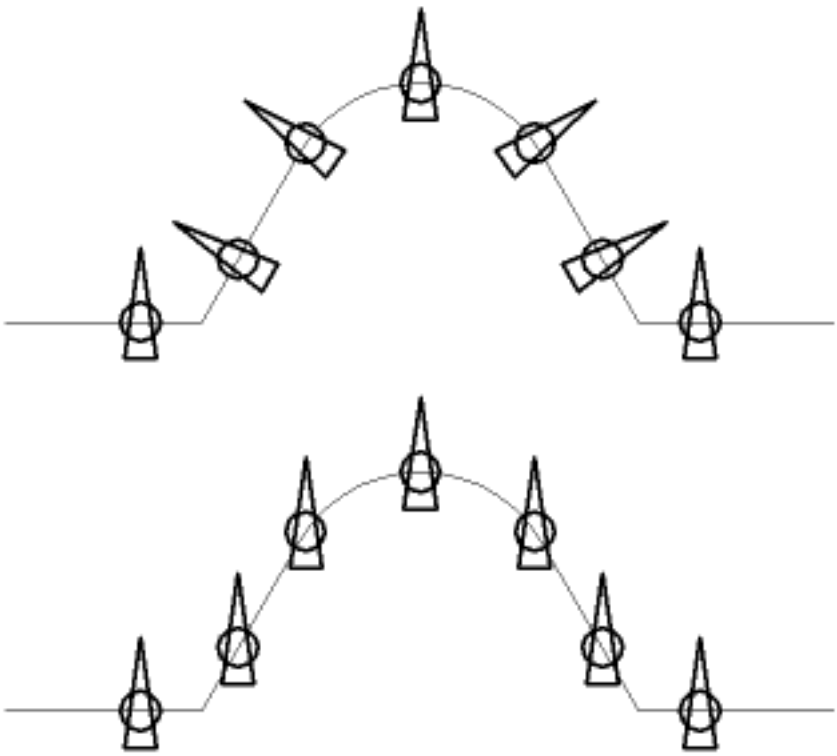


5. Do one of the following:

   - Choose **Yes-Align blocks** in the prompt menu or press Enter to align the blocks with the selected entity.
   - Choose **No-Do not align** in the prompt menu or type N and press Enter to place the blocks not rotated.

   The blocks are placed along the selected entity to divide the entity. (1.1301 on the following page) **Blocks aligned (top) or not aligned (bottom)**

Figure 1.1301



1.33 Printing and Plotting

1.33.1 General procedure for printing

Commands: PLOT (6.24.42), PRINT (6.24.51), QPRINT (6.25.2), PAGESETUP (6.24.2), PUBLISH, (6.24.68) PLOTSTAMP (6.24.44)

- The **Plot** command plots drawings to printers and to files, through prompts at the command bar; this command is meant for scripts and routines.
- The **Print** command prints drawings to plotters and files through a dialog box.
- The **Qprint** command prints the drawing with the default plot configuration, without displaying the Print dialog box (short for "quick print").
- The **PageSetup** command creates and edits page setups for plotting drawings in the Drawing Explorer.

Youtube Youtube A standard print procedure consists of the following steps:

- Choose either a Layout (1.23.13) tab or the Model (1.23.11) tab.
- Open the Print dialog. (1.33.1)
- Select a Page Setup name (6.24.2). (1)

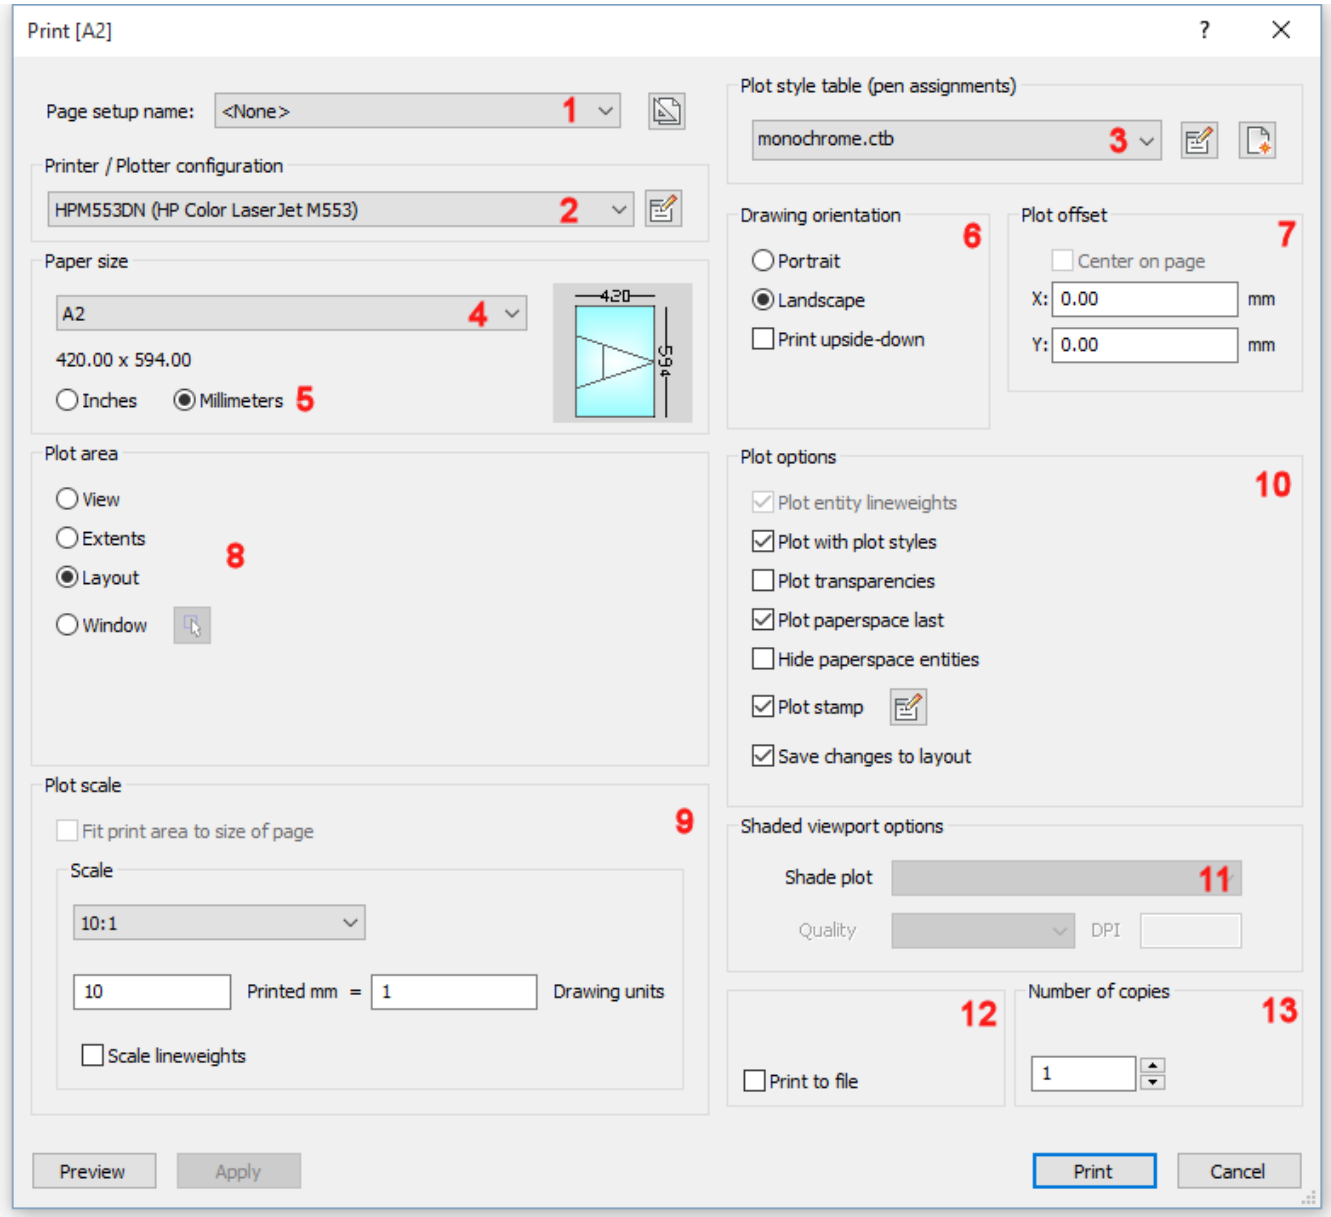
The following steps are optional and only necessary if you want to use overrides on the selected page setup definition.

- Choose a Printer or Plotter Configuration (1.33.2). (2)
- Choose a Plot style table (1.33.4). (3)
- Choose a Paper Size. (4) The image reflects the position and orientation of the drawing on the selected paper size.
- Choose the Paper Units. (5)
- Choose the Drawing Orientation.(6)
- Define the Plot offset. (7)
- Specify the Area to plot. (8)
- Define the Plot Scale. (9)
- Check the Plot Options. (10)
- When printing model space, choose a Shade Plot mode. (11) This option is disabled when printing a paper space layout.
- Check/uncheck the **Print to file** option (12)
- Specify the Number of copies. (13)
- Click the **Preview** button to see a preview of the plot output.
- When in a layout, click the **Apply** button to update the layout.
- Click the **Print** button to start printing.

NOTE	All print settings and options are saved in the **Model** and each of the **Layouts** .

(1.1302 on the next page) **Note**: On Mac or Linux, printing will always print to PDF. So a PDF document will be generated that then still needs to be sent to the printer for physical printing. On MAC and Linux there is a relevant PAGESETUP (6.24.2) command.

Figure 1.1302



To open the Print dialog

Do one of the following:

- Choose **Print...** in the File menu.
- Type **print** in the command bar, then press Enter.
- Press **Ctrl+P**
- Select the **Model** tab or a **Layout** tab, then right click and choose **Print** in the context menu.

NOTE	If you click the **Print** button in the **Standard** toolbar, the **Qprint** command is launched, which will start printing the currently selected view tab using previously saved print settings.

To choose the paper size

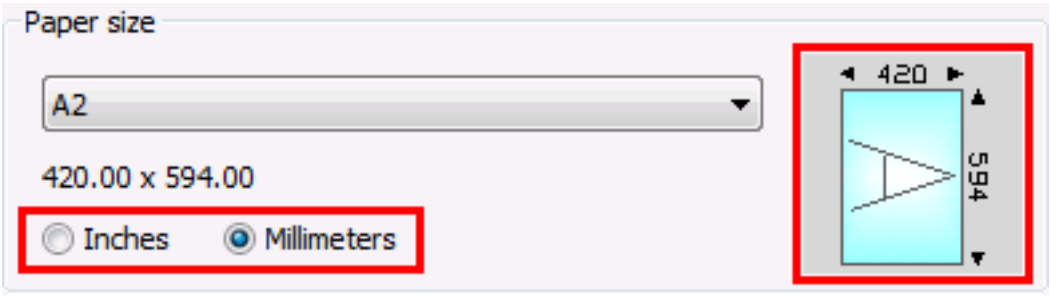
Press the down arrow, then select the paper size in the **Paper Size** list. The available sizes depend on the selected printer.

To choose the paper units

Select either **Inches** or **Millimeters** . (1.1303) The paper size image indicates the size, position and orientation of the plot area on the selected paper size.

NOTE	The **Scale** and **Plot offset** setting units are changed according to the chosen **Paper units.**

Figure 1.1303



To choose the paper orientation

Select either **Portrait** or **Landscape** .

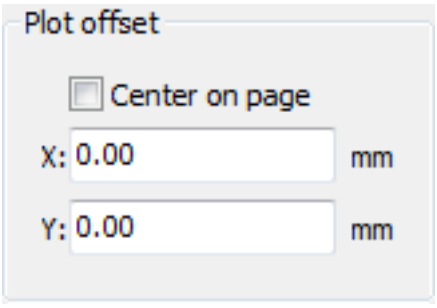
- **Portrait** : The drawing or layout x-axis is aligned with the shortest edge of the selected paper size.
- **Landscape** : The drawing or layout x-axis is aligned with the longest edge of the selected paper size.

The paper size image changes accordingly. When in a layout, click the **Apply** button to update the display.

To define the plot offset

Select either **Center on page Or** type the plot offset in the **X:** and **Y:** fields. The offset is calculated from the bottom left corner of the paper. (1.1304) When in a layout, click the **Apply** button to update the display.

Figure 1.1304



To specify the area to plot

Option	Result
View	Prints the portion of the drawing that displays in the current viewport or a saved view.
Extents	Prints all entities in the drawing.
Limits	Prints to the limits defined in the drawing. This option is only available when printing in Model space.
Layout	Prints the current layout. This option is only available when printing in Paper space.
Window	Prints the portion of the drawing contained in a user defined window, maintaining the aspect ratio of the windowed area to the drawing. Click the **Select print area** button (), then specify the two corners of the print area in the drawing. or Type the the X- and Y-coordinates of the corners of the print area in the **X:** and **Y:** fields. (1.1311 on page 1461)

To define the plot scale

NOTE	The SCALELISTEDIT (6.27.7) command allows to edit the list of available scales in the **Print** dialog and the **Standard Scale** property of a paper space viewport.

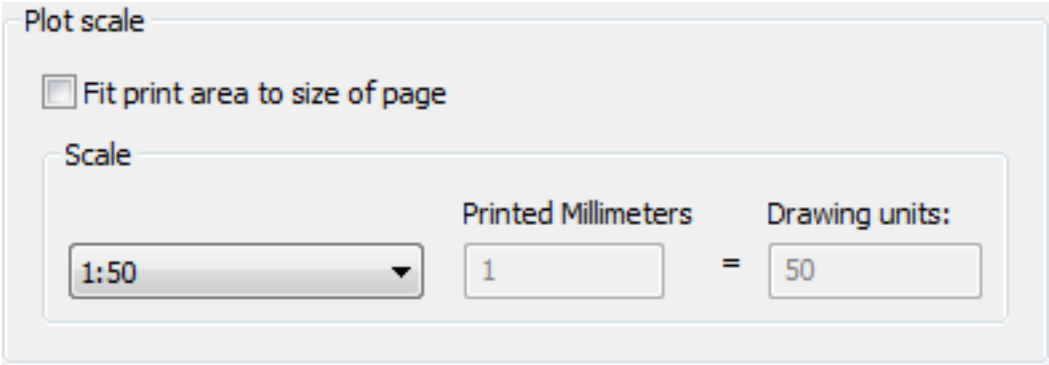
... when printing in paper space: If you print in paper space, the final scale of the plot output is the product of the viewport scale (1.23.16) and the plot scale. In order to keep control over the scale of the plot output:

- Specify the width and height of the viewports in drawing units.
- Set the scale of each viewport to the scale you want in the plot output.
- The **plot scale** reflects the relationship between paper units and drawing units. (see table below)

Paper units	Drawing units	Plot scale	Printed Millimeters or Inches	Drawing Units
mm	mm	1:1	1	1
mm	cm	10:1	10	1
mm	m	1000:1	1000	1
inches	inches	1:1	1	1
inches	feet	12:1	12	1

... when printing in model space: If you print in model space, the scale of the plot output equals the plot scale, on condition your drawing units equal the paper units. Otherwise you need to multiply the plot scale with respect to the relationship between paper units and drawing units. E.g. if you want to plot at a 1/50 scale in a drawing of which 1 DU = 1 cm, the **plot scale** = 1/5, if 1 DU = 1 m the **plot scale** = 20/1 or 1/0.05 (1.1305 on the next page)

Figure 1.1305

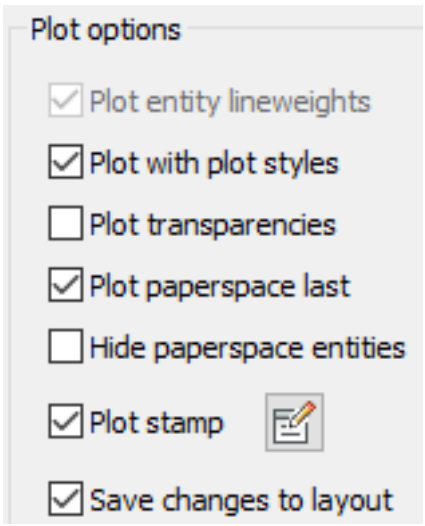


To set the plot options

Click to toggle the **plot options** On / Off. (1.1306)

Option	Result
Plot object lineweights	If **Plot with plot styles** is off, object lineweights are plotted.
Plot with plot styles	Settings of the assigned STB or CTB file are used. Note: This applies to viewports which have the 2D Wireframe or Wireframe visual style (6.31.15) only.
Plot transparencies	Plots entities using the value of the Transparency (1.25.9) property.
Plot paperspace last	Entities in Model space are plotted first, paperspace entities last.
Hide paperspace entities	Removes hidden lines from 3D entities in paper space. This option is disabled when printing model space.
Plot stamp	Adds a header and / or footer. Click the **Edit plot stamp** button ( ) to define the plot stamp.
Save changes to layout	All changes made in the **Print** dialog are saved in the layout. This option toggles the **Save changes to layout** variable

Figure 1.1306

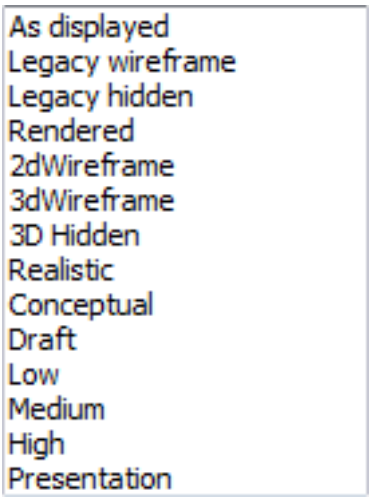


To set the shade plot mode

Under **Shade viewport options** , click the list button, then select an option: (1.1307)

NOTE	This option applies to model space printing only. The **Shade Plot** mode of a paper space viewport is defined in the Shade Plot (1.23.16) property of the viewport.

Figure 1.1307



To define the plot stamp

1. Click the **Edit plot stamp** button (). The **Plot stamp** dialog opens. (6.1949 on page 5147)
2. In the **Header** field, do one of the following:
   - Type the header text.
   - Click the down arrow button, then choose a variable in the drop down list.
   - Type one or more variable names.
   - Leave the field empty.
3. Define the X and Y offset for the header.
4. In the **Footer** field, do one of the following:
   - Type the footer text.
   - Click the down arrow button, then choose a variable in the drop down list.
   - Type one or more variable names.
   - Leave the field empty.
5. Define the X and Y offset for the footer.
6. Select a font in the **Font** list button.
7. Enter a value in the **Font Size** field
8. Set the unit type to **Millimeters** or **Inches** .
9. Click the **OK** button to confirm.

The plot stamp settings are saved to a series of user preferences in the current user profile (1.17.8), which can be edited in the Settings (1.17.10) dialog under **Program Options / Plot and Publish / Plot Stamp** : (1.1309 on the next page)

Figure 1.1308

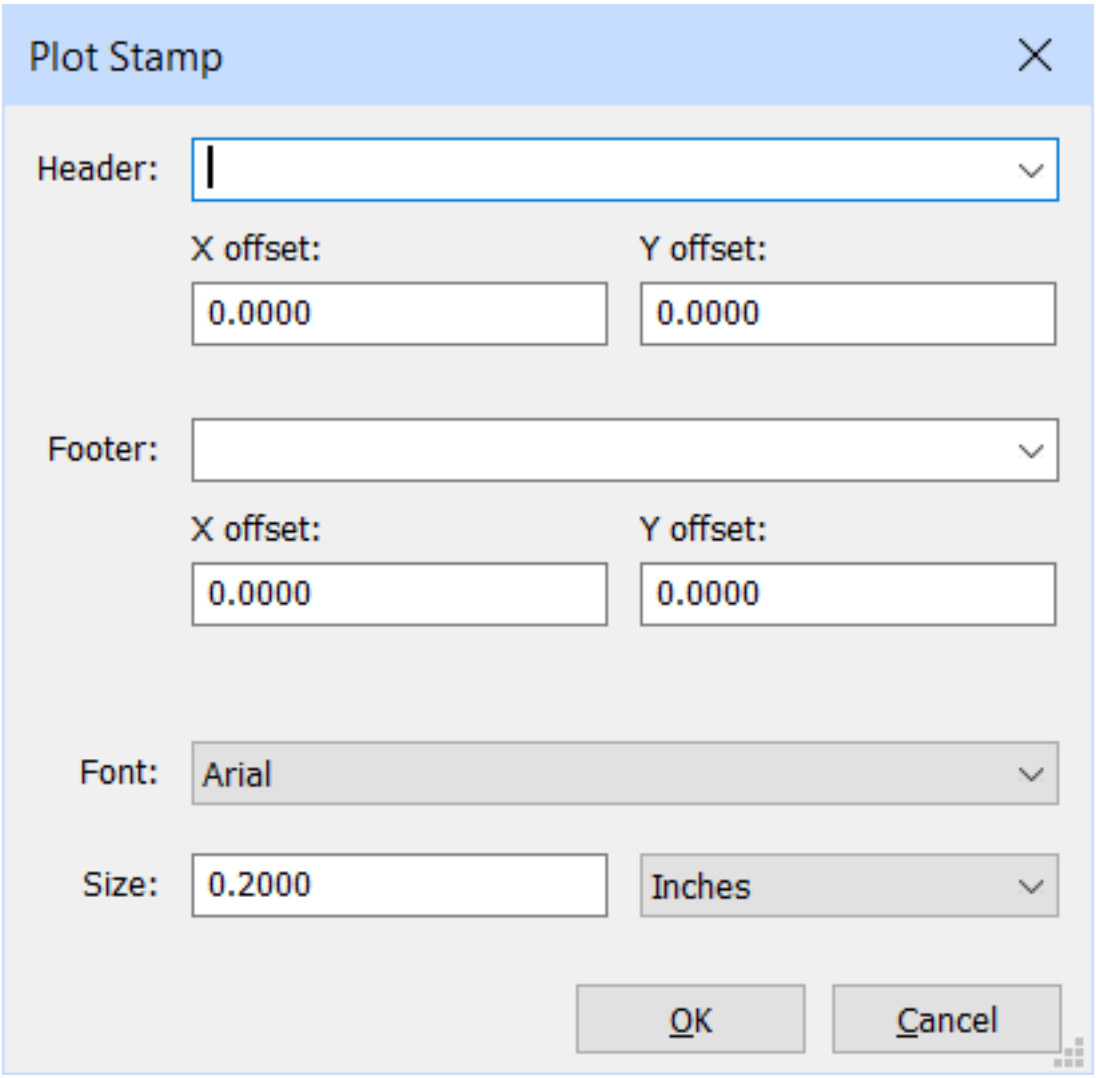


Figure 1.1309

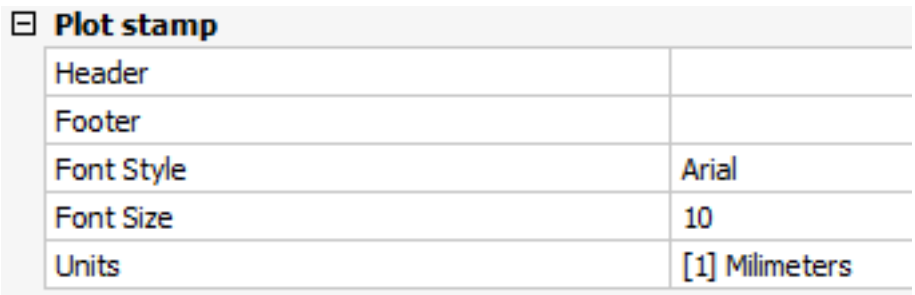

Name	Description
$Name	Adds the name of the current user, as defined in the **User Name** field of the License Information.
$Company	Adds company name of the current user, as defined in the **Company** field of the License Information.
$Date	Adds the current date.
$DateTime	Adds the current date and time.
$DwgName	Adds the file name and path of the drawing.

NOTE	The header and footer text consists of three parts (left, center and right), separated by commas. By default the header and footer text is centered. The header and footer text can be outlined left center and/or right by separating the text with commas. e.g. **$Name,$Company,$Date** places your name left, company name centered and the current date at the right. Type a space before one of the commas to leave one of the parts empty, thus outlining the header or footer left or right. • **$Company, ,** ($Company,<space>,<space>) outlines the company name left. • , ,$Company (<space>,<space>,$Company) outlines the company name right.

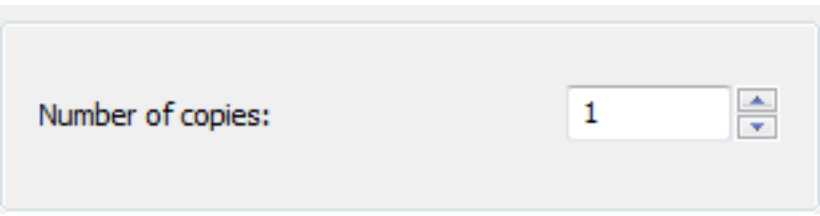
To specify the number of copies

Do one of the following:

- Type the desired number in the **Number of copies** field.
- Click the up-arrow and the down-arrow buttons to specify the number of copies.

(1.1310)

Figure 1.1310



To see a preview of the plot output

1. Do one of the following:
   - Click the **Preview** button on the **Print** or **Page Setup** dialogs.
   - Choose **Print Preview...** in the **File** menu.
   - Type **preview** in the command bar, then press Enter.
2. (option) Use the mouse scroll wheel to zoom. Double click the middle mouse button to zoom extents.
3. To close the **Print Preview** window, do one of the following:
   - Click the **Close** button to return to the drawing window.
   - Click the **Print Settings...** button to open the Print dialog.
   - Click the **Print** button to start printing.

Figure 1.1311

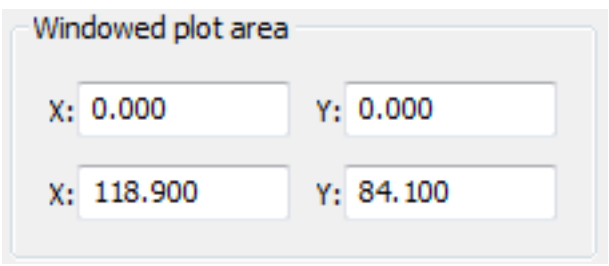


Figure 1.1312

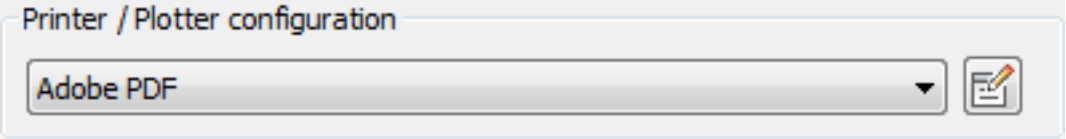

1.33.2 Plotter Configuration

Command: PLOTTERMANAGER (6.24.32) Youtube Configurations for Windows system printers are stored in plotter configuration files (.PC3 files). Unlike in AutoCAD®, PC3 plotter configuration files in BricsCAD™ apply to Windows system printers only. In a plotter configuration file, you override one or more settings of the system printers installed on your computer. You can configure BricsCAD for many plotting/printing devices and keep multiple configurations for each single device. Each plotter configuration file contains information such as:

- The device driver and model
- The output port to which the device is connected
- Various device-specific settings (not supported on the Linux platform).

PC3 files are saved in the **Plotconfig** subfolder of your Roamable root (1.17.2) folder. After creating a PC3 file, it is available in the list of plotter configuration names in the **Printer / Plotter configuration** list on the **Print** or **Page Setup** dialog boxes. (1.1312)

To configure the built-in PDF printer

1. Open the Print dialog (1.33.1).
2. Click the **Printer/Plotter configuration** list button and choose **Print As PDF.pc3** in the list. (1.1314 on the facing page)
3. Click the **Edit Plotter Configuration** button ( ). The **Plotter Configuration Editor** dialog displays withe the **Print As PDF.pc3** configuration file loaded. The default path for plotter configuration files (*.pc3) is: **C:\Users\<User_Name>\AppData\Roaming\Bricsys\BricsCAD\Vxx\en_US\PlotConfig** (1.1314 on the next page)
4. Click the **Settings** tab on the **Plotter Configuration Editor** dialog. (1.1315 on the facing page)
5. (Option) Edit the **Graphics** settings.
6. (Option) Execute the **Scale Calibration** .
7. Click the **Custom Properties** button. The **Print As PDF - Custom Properties** dialog displays. (1.1316 on page 1464)
8. (Option) Adjust the **Output quality** and **Layers suppor** t settings.
9. Click the **Manage Custom sizes ...** button. (1.1317 on page 1465)
10. To create a custom paper size do the following:
    - Click the **Add** button. A new paper size is added.
    - Double click the newly created papersize.
    - Type a name for the new paper size, then click the **OK** button. (1.1318 on page 1465)
    - Define **Width** an **Height** for the new paper size.

Figure 1.1313

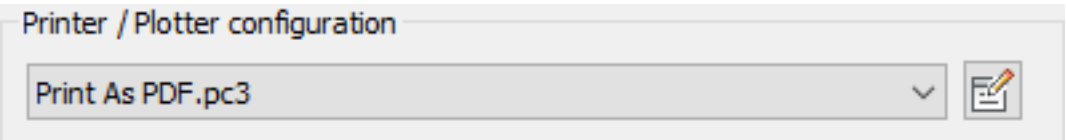

Figure 1.1314

Figure 1.1315

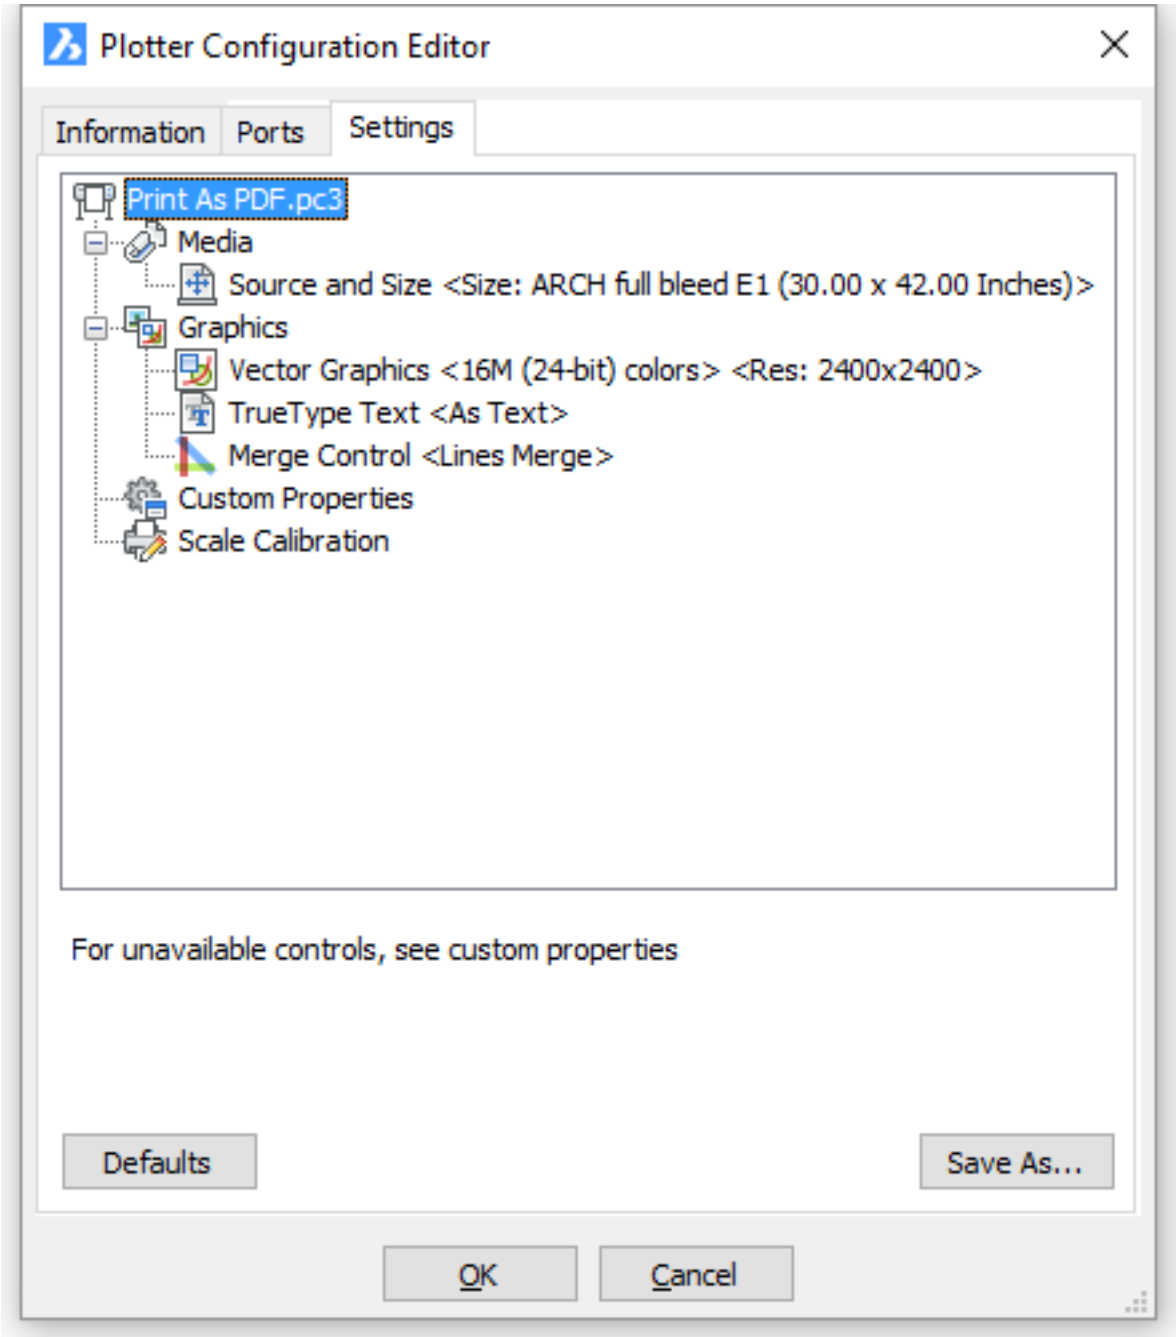

Figure 1.1316

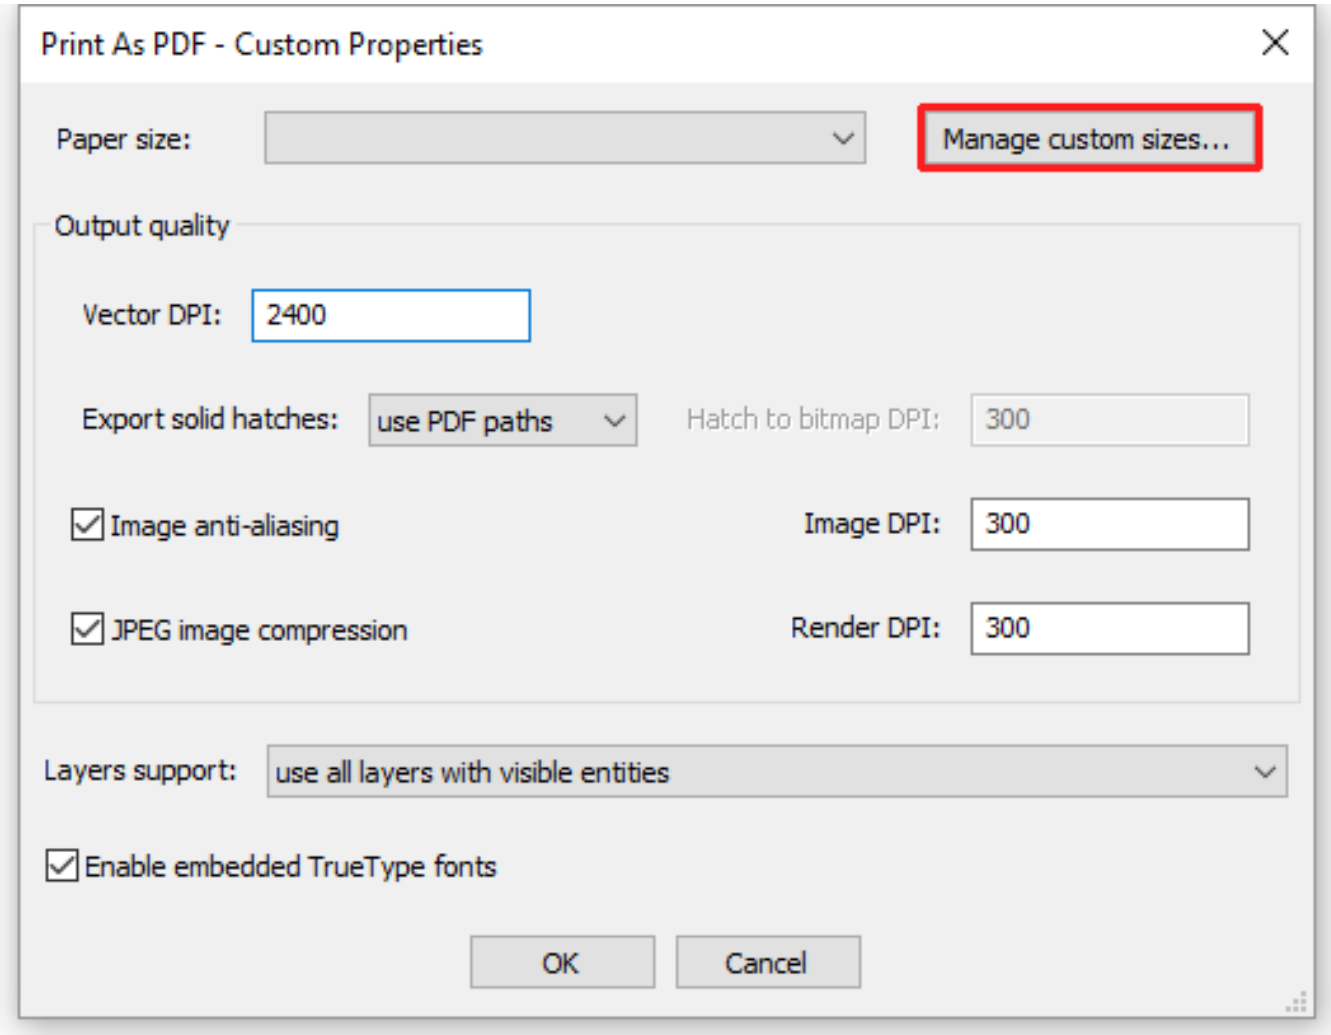

Figure 1.1317

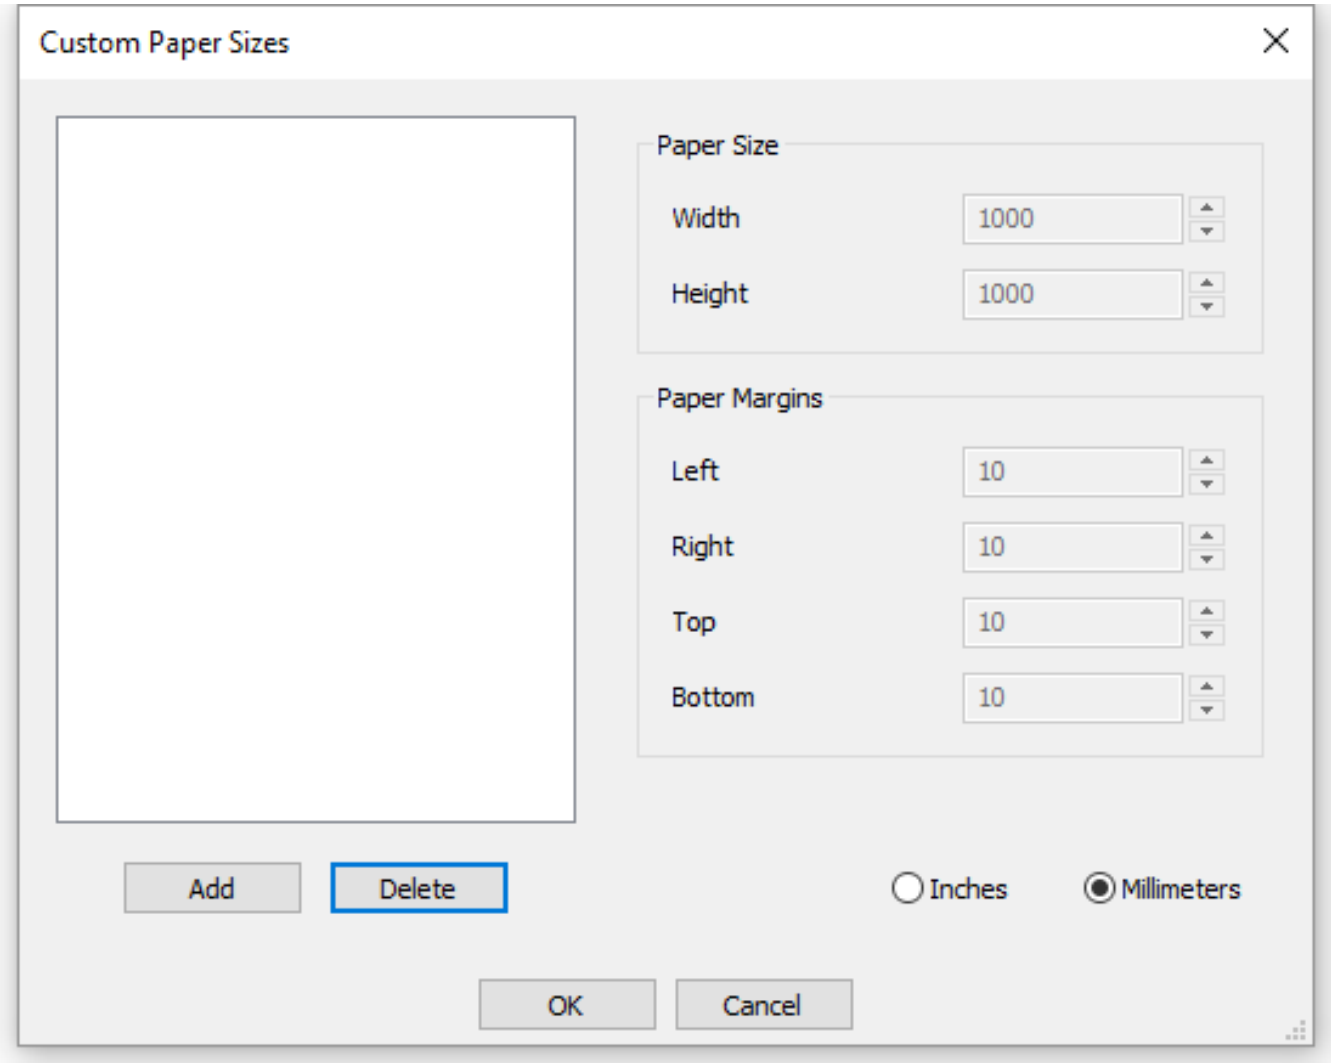

Figure 1.1318

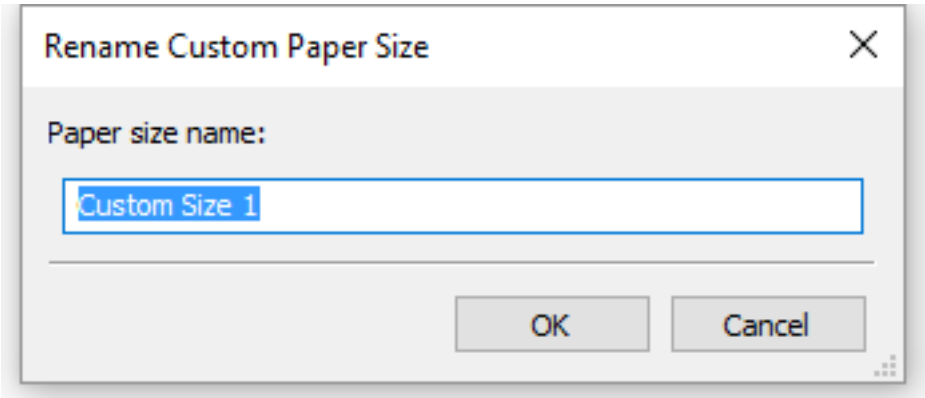

Figure 1.1319

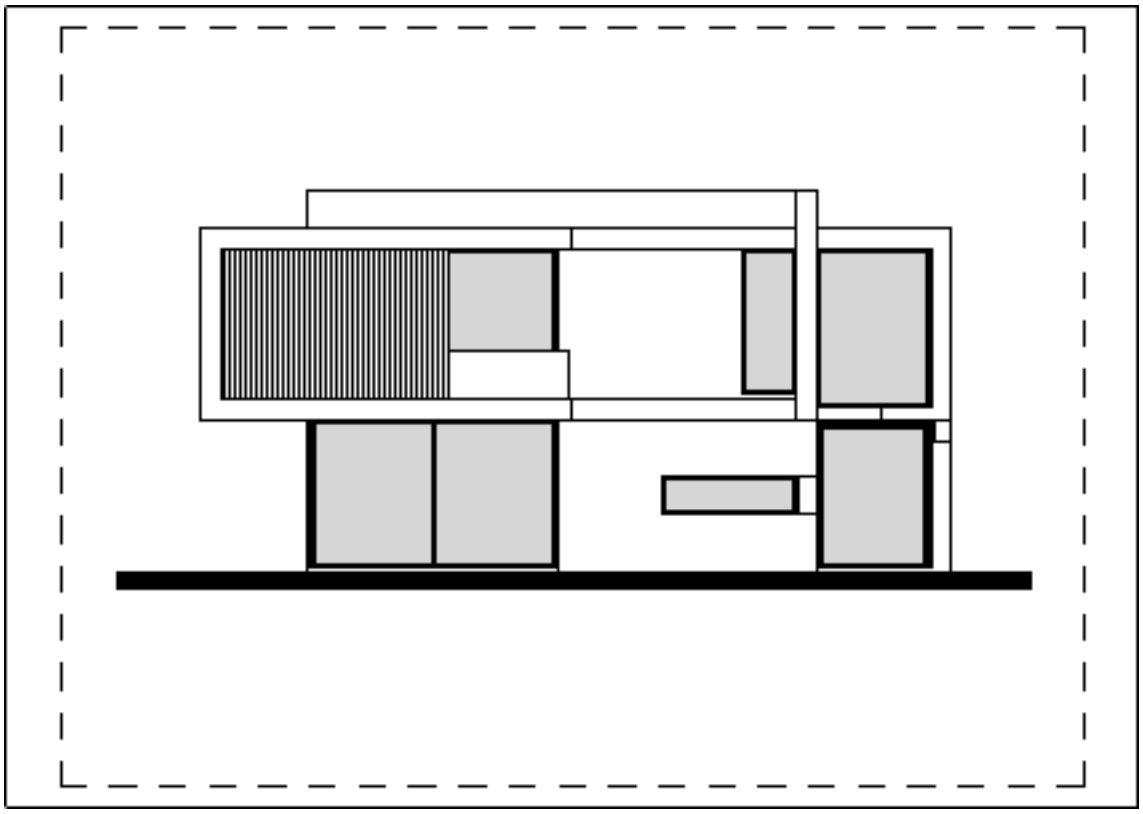

Figure 1.1320

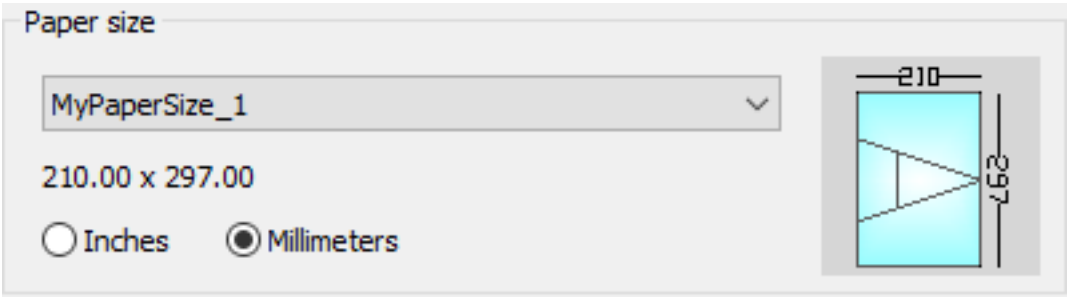

- Define the **Paper Margins** . Paper margins define the printable area of paper sheet. If the DISPPAPERMARGINS (1.17.10) system variable is **ON** , dashed lines indicate the paper margins on the paper sheet* in a layout. (1.1319) * The paper sheet background displays if the DISPPAPERBKG (1.17.10) system variable is **ON** .
- Click the **OK** button to create the custom paper size.

11. Click the **OK** button on each of the previously opened dialogs. The custom paper size(s) can now be selected in the **Paper Size** list button. (1.1320)

Tutorial: Output As Pdf Click here (1.22.1) to watch

To create a plotter configuration file

1. Choose **Plotter Manager...** in the **File** menu, then double click **Create a Plotter Configuration** shortcut. The **Plotter Configuration Editor** dialog opens. (1.1321 on the facing page)
2. In the **Printer name** list, select the printer you want to create a plotter configuration (PC3) for.
3. Click the **Settings** tab on the **Plotter Configuration Editor** dialog. (1.1322 on page 1468)
4. Click the **Custom Properties...** button. The **<Selected Printer> Properties** dialog opens. The layout of this dialog is different for each printer. Custom Properties are not supported on the Linux platform.

Figure 1.1321

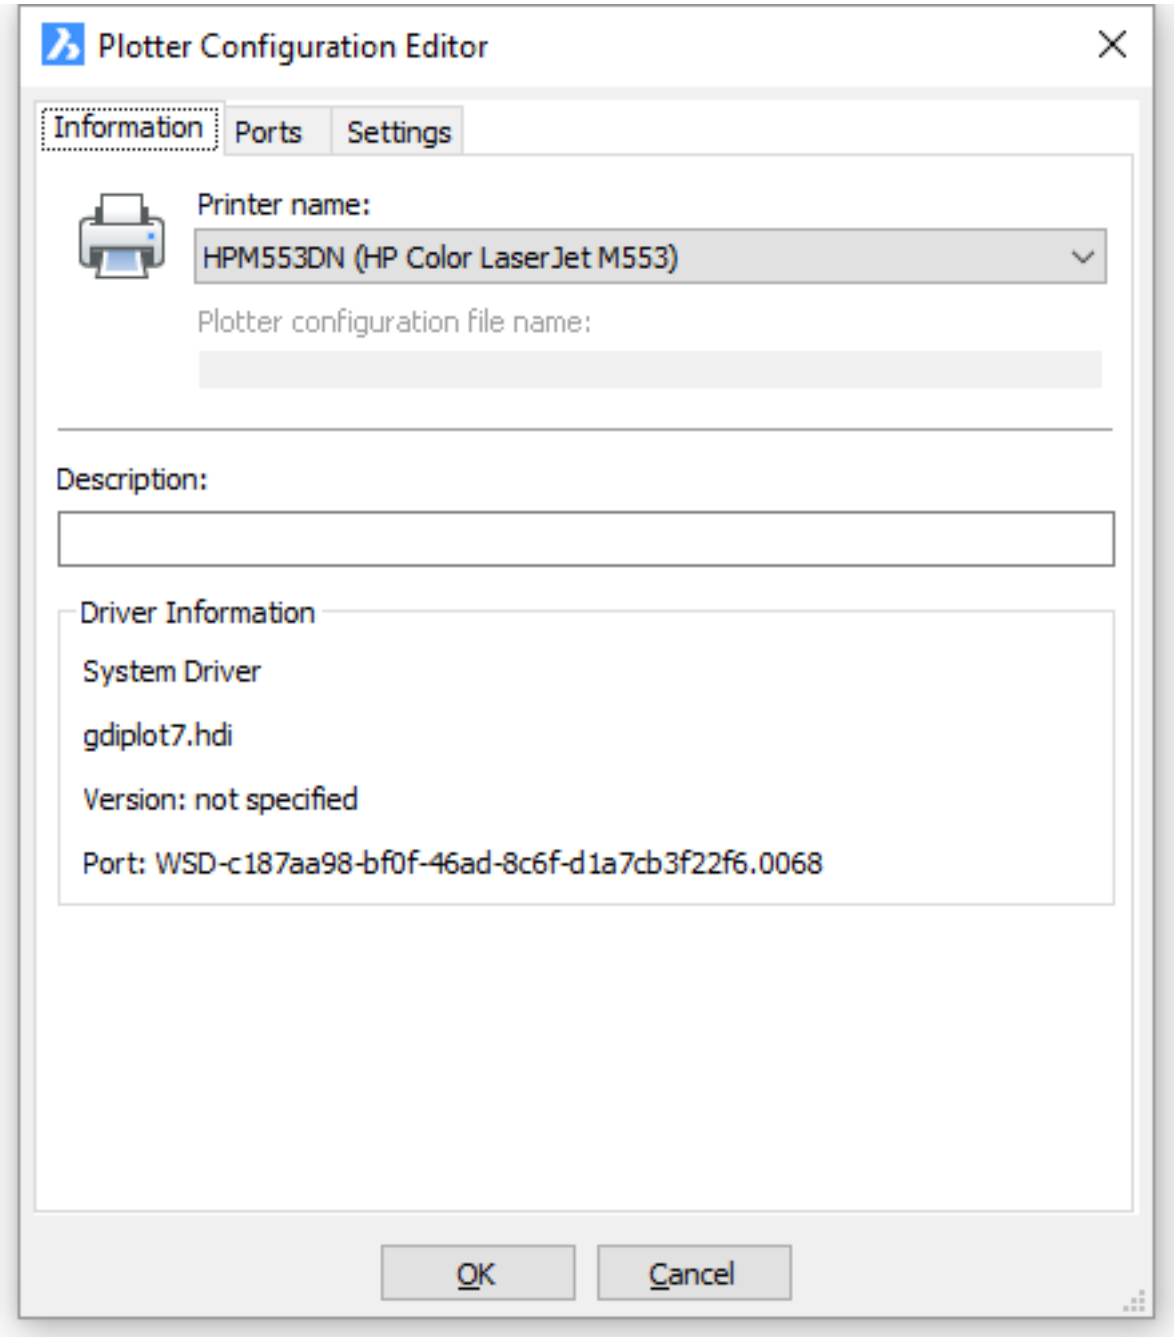

Figure 1.1322

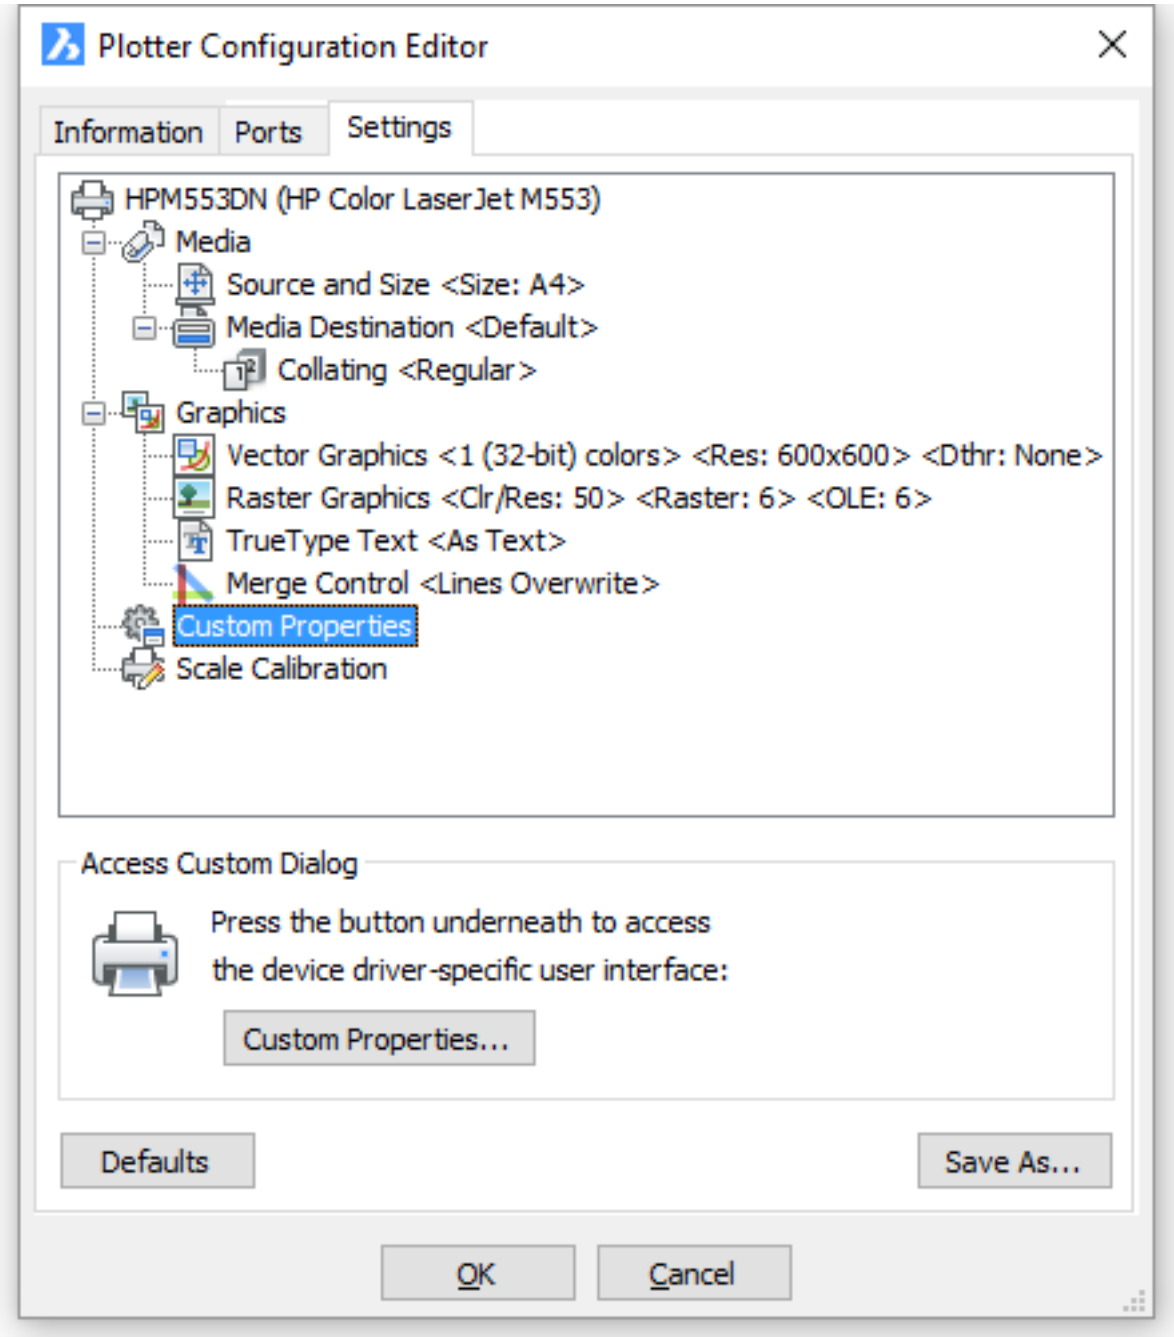

Figure 1.1323

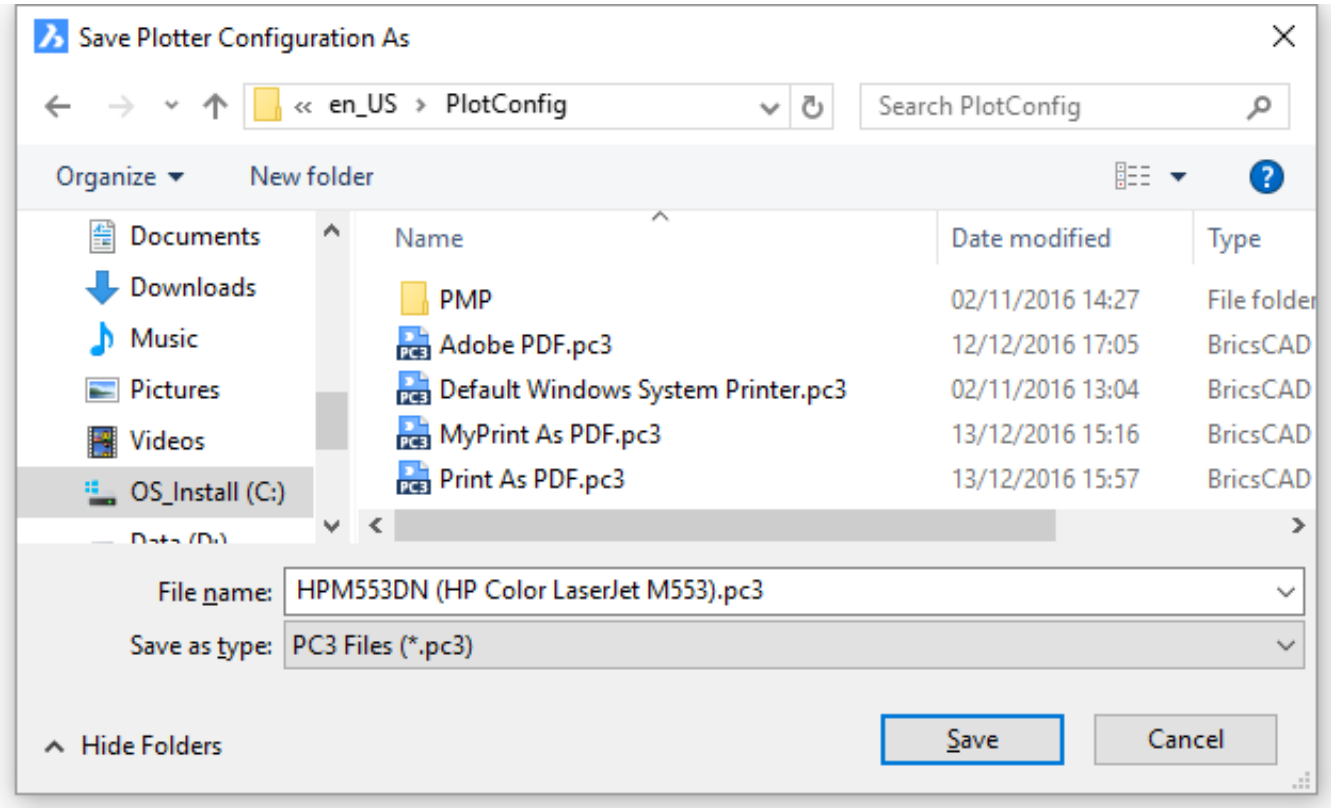


5. On the **Properties** dialog of the selected printer, adjust the printer settings, then click the **OK** button to confirm. The **<Selected Printer> Properties** dialog closes.
6. Click the **OK** button on the **Plotter Configuration Editor** dialog. The **Save Plotter Configuration As** file dialog displays. (1.1323)
7. (option) Adjust the PC3 file name. The default name is **<Selected Printer>.pc3** .
8. Click the **OK** button on the **Changes to a Printer Configuration File** dialog. The PC3 file is created.

NOTE	If you want to create multiple plotter configurations for the same printer, you must adjust the default name in step 7. If you accept the default name, the existing plotter configuration will be overwritten.

To edit a plotter configuration

1. Do one of the following:
   - Choose **Page Setup** in the **File** menu.
   - Type **pagesetup** in the command bar, then press Enter.
2. Select a plotter configuration (PC3) in the **Printer / Plotter configuration** list.
3. Click the **Edit Plotter Configuration** button ( ) on the **Print** or **Page Setup** dialogs. The **Plotter configuration editor** dialog opens.
4. Proceed in the Create a plotter configuration (1.33.2) procedure starting from step 3.

NOTE	If you select a system printer in step 2, a new plotter configuration is created for the selected printer. When you click the **Edit Plotter Configuration** button ( ) in step 3, the **Properties** dialog of the selected printer opens first. After clicking the **OK** button on the **Properties** dialog the **Plotter configuration editor** dialog opens. You can then complete the Create a

NOTE

- When BricsCAD™ cannot find the plotter configuration file assigned to the drawing, it changes the configuration file assigned to your drawing to **None** .
- The **None** printer device has its own set of paper sizes that can be stored in the drawing very much the same as for any 'real' printer. If a layout is opened and the stored printer is absent, the printer switches to **None** while the paper size is maintained. The missing printer and the previous paper size are indicated upon opening the **Print** dialog. The previous paper size can be saved in the drawing,
- PREVIOUS PAPER SIZE: drawings created by other parties are often set up for a printer that is not available in your office. In such case, BricsCAD resets the printer device to **None** , which results in using the default printer. Instead of resetting the paper size to a default, BricsCAD shows the Previous Paper size, in order to inform you about the intended paper size and allow to choose a similar size on any of the available printers.

Tutorial: Printing in BricsCAD: Plotter Configurations Click here (1.22.5) to watch

1.33.3 The Plot Style Table editor

https://www.youtube-nocookie.com/embed/DLVvwPWPhCg The **Plot Style Table Editor** can be opened, even if BricsCAD is not open.

To open the Plot Style Table editor

Do one of the following:

- Click the **Edit Plot Style** button () on the **Print** dialog.
- Choose **Plot Style Manager...** in the File menu, then double click a **CTB** or **STB** file.
- In a **Windows Explorer** window, double click a **CTB** or **STB** file.

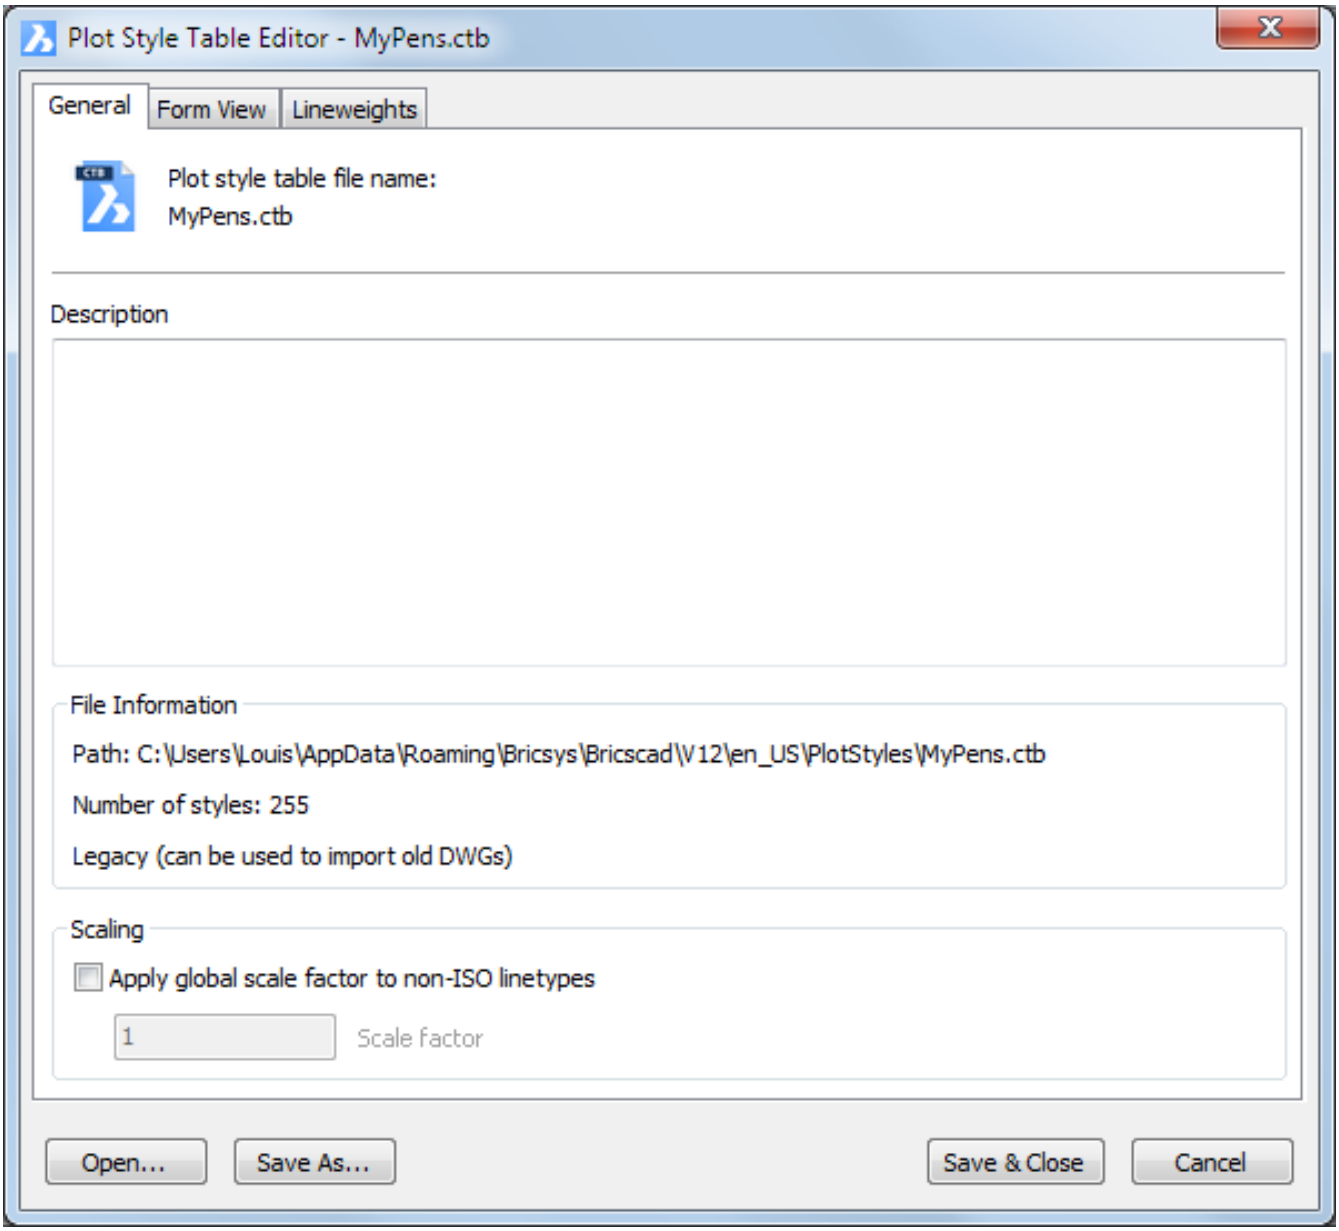
The **Plot Style Table Editor** displays the plot styles contained in the specified plot style table. The Plot Style Table Editor includes the following tabs:

- The **General** tab
- The **Form View** tab
- the **Lineweights** tab

The General tab The **General** tab lists general information about the plot style table. (1.1324 on the next page)

Name	Description
Plot style table file name	Displays the name of the plot style table file you are editing.
Description	Displays a description you want to include about the plot style table.
File Info	Displays information about path, number of plot styles and the version number of the Plot Style Table Editor. **Note:** A color-dependent plot style table always contains 255 plot styles.
Apply global scale factor to non-ISO linetypes	Specifies whether or not you want to scale all non-ISO linetypes in the plot styles of entities controlled by the plot style table.
Scale factor	Specifies the factor by which to scale non-ISO linetypes and fill patterns.

Figure 1.1324



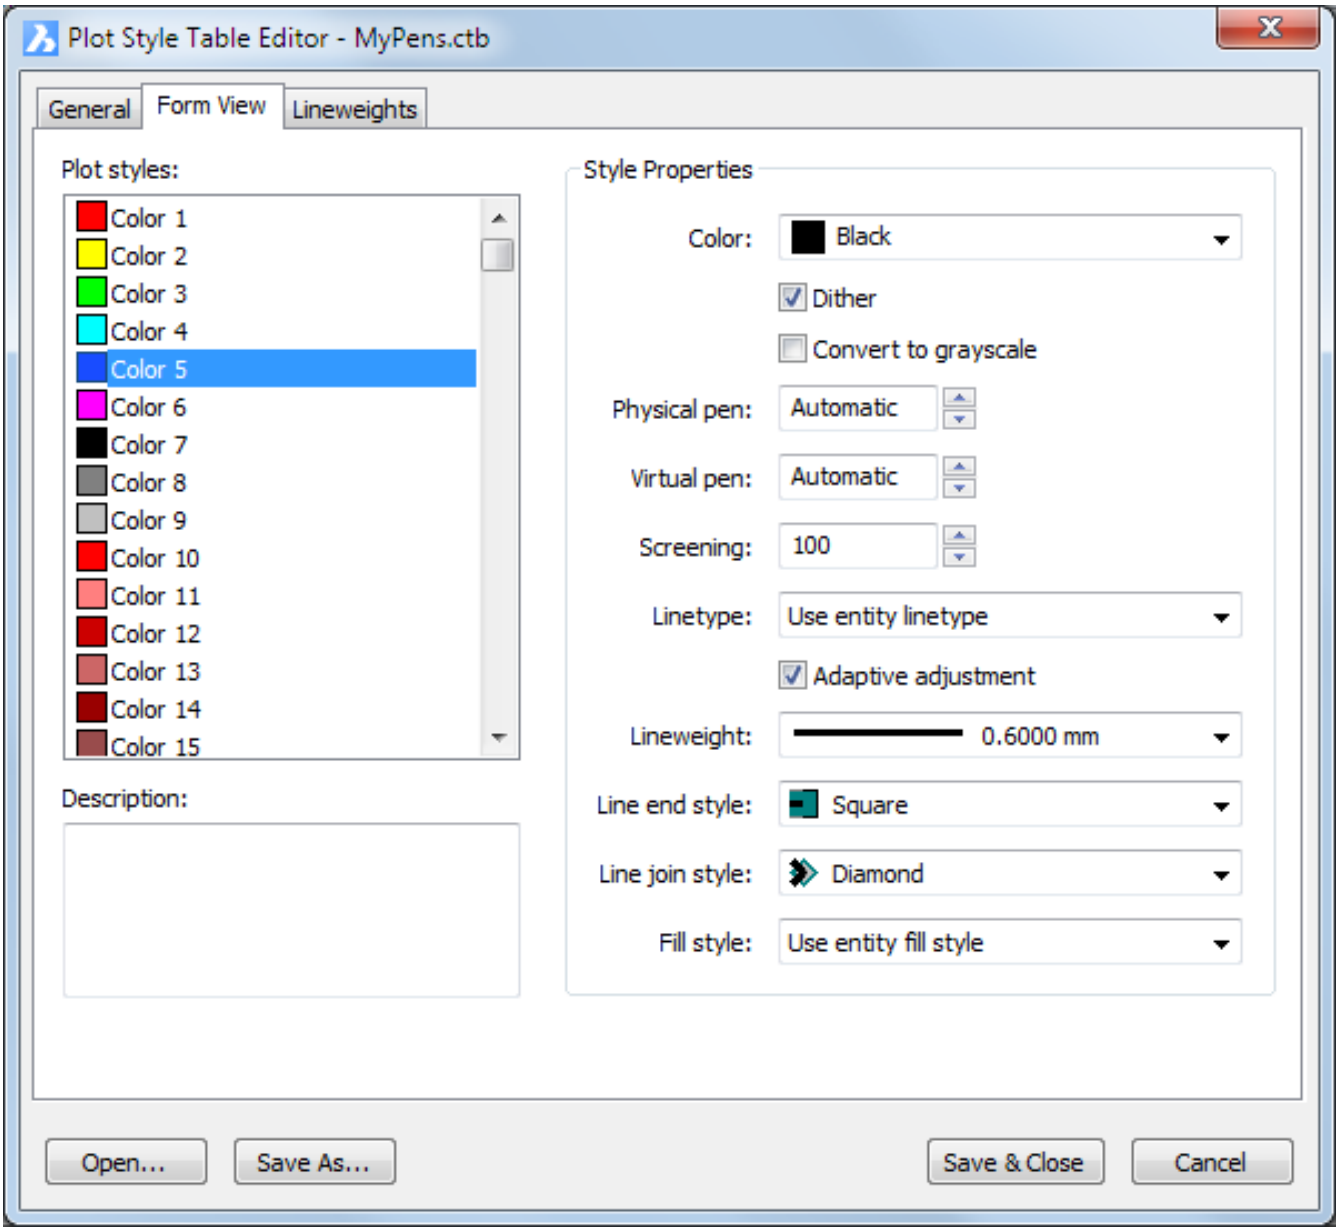
The Form View tab The **Form View** tab lists the plot styles contained in the plot style table and their settings. Plot styles are style overrides for your drawings that occur during plotting. The first plot style in a **Named Plot Style table** is **NORMAL** and represents an entity's default properties (no plot style applied). You cannot modify or delete the **NORMAL** style. (1.1325 on page 1475)

Property	Description
Plot styles	Displays the names of plot styles contained in the selected plot style table. **Color-dependent plot style table:** • Always contains 255 styles (1 for each color). • They are tied to entity color. • You cannot add nor delete a plot style. • You cannot rename a plot style. **Named plot style table:** • Contains one or more plot styles. • You can add or remove plot styles, except for the **Normal** style, which cannot be deleted. • Plot styles can be renamed, except for the **Normal** style, which cannot be renamed.
Description	Displays a description for the selected plot style.
Color	Specifies the plotted color for an entity. The default setting for plot style color is **Use Object Color** . If you assign a plot style color, the color overrides the entity's color in the plot output. • Choose **Other...** to select one of 255 colors from the **Select Color** dialog box. • Choose **True color** to select a color from the **Color** dialog box. If the plot device does not support the color you have specified, the nearest available color will be used. When you have a monochrome device, **black** will be used.
Dither	Depending on the capabilities of your plotter, dithering approximates the colors with dot patterns. When this option is not active, the colors are mapped to the nearest color, resulting in a smaller range of colors when plotting. Dithering is available only whether you select the object's color or assign a plot style color. By default, this option is active. Setting it to Off has no effect in BricsCAD.
Grayscale	Depending on the capabilities of your plotter, converts the colors to grayscale in the plot output.
Pen #	Specifies a pen to use when plotting entities that use this plot style. You can select a pen number from 1 to 32.

Virtual pen #	Specifies a virtual pen number between 1 and 255. Choose **Automatic** to specify that BricsCAD should make the virtual pen assignment from the BricsCAD Color Index. The virtual pen setting in a plot style is used only by non-pen plotters and only if they are configured for virtual pens (select **255 Virtual Pens** under **Color Depth** under **Vector Graphics** on the **Settings** tab in the **Plotter Configuration Editor**).
Screening	Specifies the color intensity of the plot on the paper. The valid range is 0 through 100. If you select 100 the drawing will plotted with its full color intensity. In order for screening to work, the **Dithering** option must be active.
Linetype	Displays a list with an example and a description of each linetype. The default setting for plot style linetype is **Use Object Linetype** . The selected linetype overrides the entity's linetype in the plot output.
Adaptive	Adjusts the scale of the linetype to complete the linetype pattern. You can activate this property if a complete linetype pattern is more important than a correct linetype scaling.
Lineweight	Displays a sample of the lineweight as well as its numeric value. You can modify an existing lineweight if the one you need is not available. The default setting for plot style lineweight is **Use Object Lineweight** . The selected lineweight overrides the entity's lineweight in the plot output.
Line end style	Displays a list of several end styles for the lines. By default, the option **Use Object End Style** is selected. If you select a line end style, the object's line end style will be overridden in the plot output.
Line join style	Displays a list of several join styles for the lines. By default, the option **Use Object Join Style** is selected. If you select a line join style, the object's line join style will be overridden in the plot output.
Fill style	Displays a list of several fill styles. By default, the option Use **Object Fill Style** is selected. If you select a fill style, the object's fill style will be overridden in the plot output.

NOTE	Objects which are created in **true color** are always plotted using their own object properties (color, lineweight, ...).

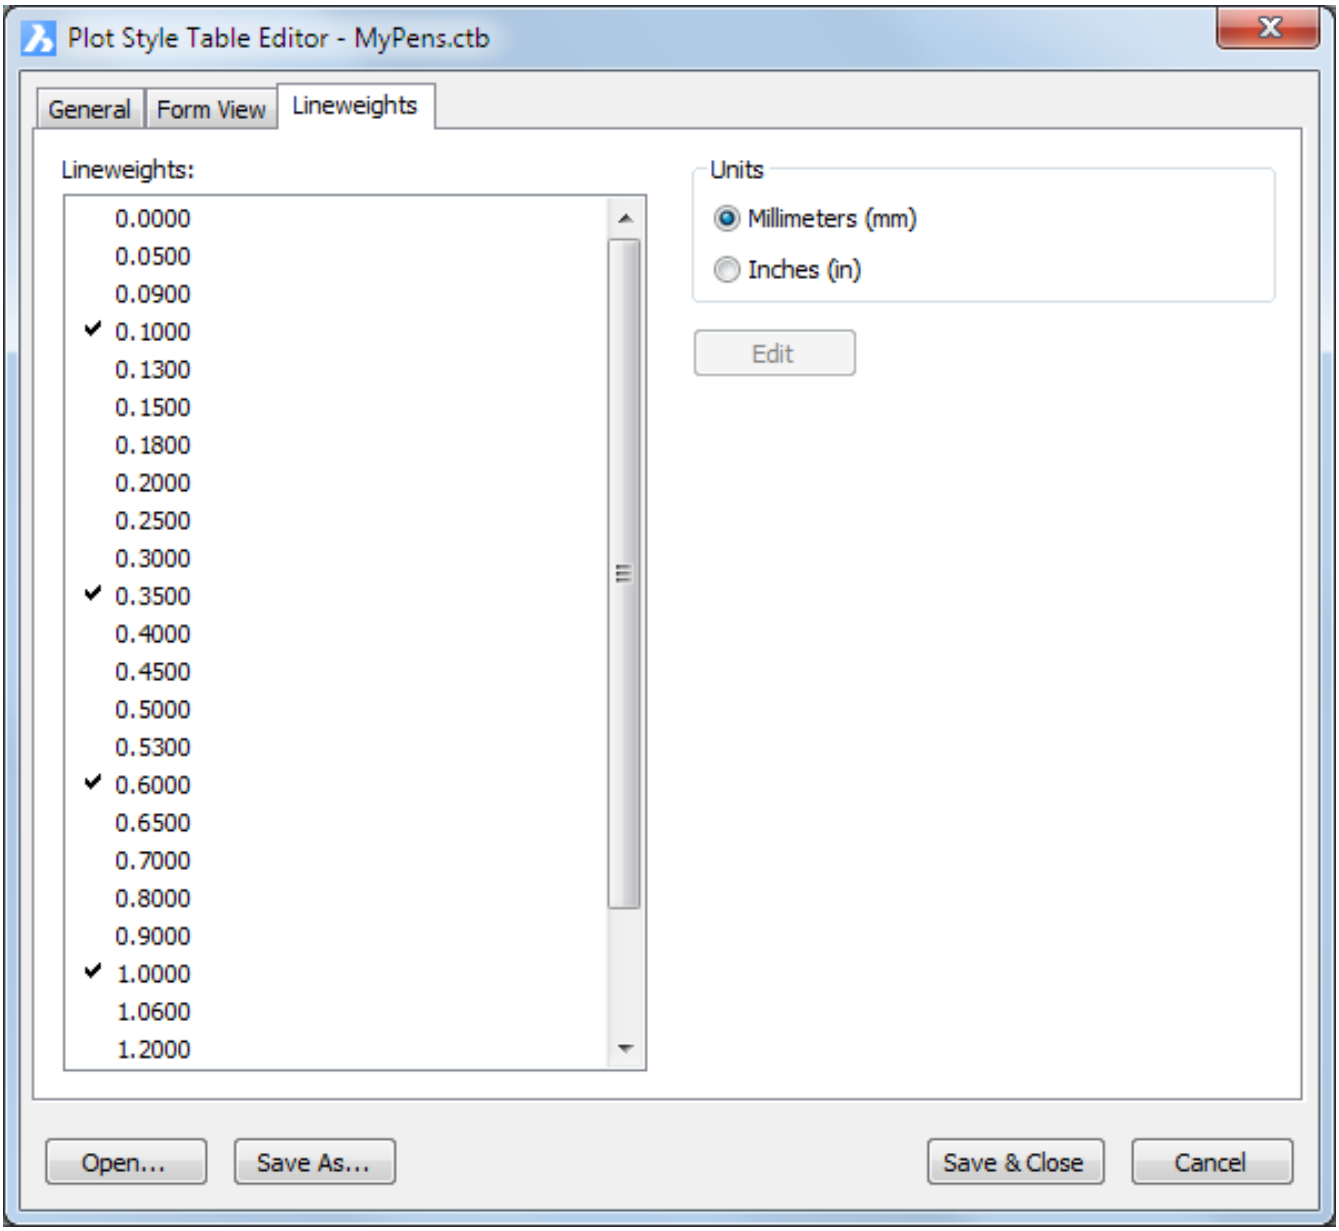
Figure 1.1325



The Lineweights tab The **Lineweights** tab lists the available lineweights. Lineweights with a tick are used in the **Lineweight** field on the **Form View** tab. To edit a lineweight, select the lineweight in the list, then click the **Edit** button. (1.1326 on the next page)

Tutorial: Printing in BricsCAD: Plot Style Tables Click here (1.22.7) to watch

Figure 1.1326



1.33.4 Assigning plot style tables

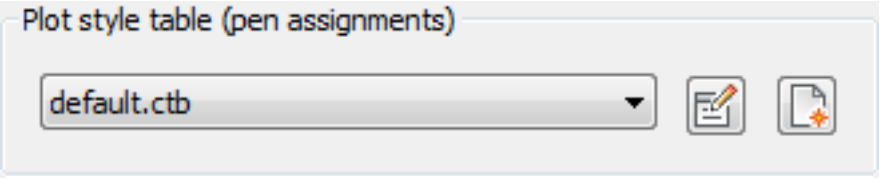
In BricsCAD you can assign plot style tables to model space and to each of the layouts in a drawing. By assigning different plot style tables to each layout in your drawing, you can control how entities in the layout are plotted. The plot style table affects both model space and paper space entities. To plot the drawing without applying plot style properties, choose 'None (use Default)' from the list of plot style tables. In STB-type drawings, each entity in the drawing either is assigned a plot style explicitly or **By Layer** .

Missing plot style table If a plot style table is not found, the text "(missing)" is added to the plot style table name. When you print the drawing, the settings of the default plot style file Default.ctb or Default.stb will be used instead.

To assign a plot style table

1. Choose **Model** or the **layout** to which you want to assign a different plot style table.
2. Do one of the following:
   - Choose **Print...** in the **File** menu.
   - Type **print** in the command bar, then press Enter.
3. Select a **Plot style table** from the list box in the **Plot Style Table (pen assignments)** section. (1.1327)
4. Click the **OK** button.

Figure 1.1327

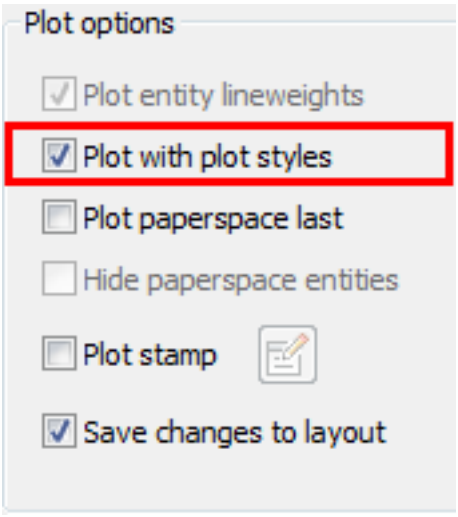


Toggling the plot style table on/off

When you turn off plot style tables, entities print according to their own properties. However, all of the plot style information is saved so you can easily turn on plot styles again. Actual plot style table files are not deleted, and for drawings that use named plot style tables, entities and layers retain their assigned plot styles.

1. Choose **Model** or the **layout** in which you want to turn the plot style table on/off.
2. Do one of the following:
   - Choose **Print...** in the **File** menu.
   - Type **print** in the command bar, then press Enter.
3. Click the **Plot with plot styles** plot option. (1.1328)

Figure 1.1328



1.33.5 The Plot Styles Manager

Commands: STYLESMANAGER (6.27.57) The **Plot Styles Manager** is a window that lists plot style table files (CTB and STB files). The Plot Styles Manager allows you to:

- Create Color-dependent Plot Style (CTB) and Named Plot Style files (STB) using the **Create a Plot Style Table** wizard.
- Edit existing Plot Style Table files.

To open the Plot Styles Manager

Do one of the following:

- Choose **Plotstyle manager...** in the **File** menu.
- Type **stylesmanager** in the command bar then press Enter.

To create a new plot style table

1. Open the Plot Styles Manager (1.33.5).
2. Double click the **Create a Plot Style Table** shortcut. (1.1329 on the facing page) The **Add Plot Style Table Editor** dialog opens. (1.1332 on page 1482)
3. Choose **Create new from scratch.** (1.1331 on page 1482)
4. Do one of the following:
   - Select either **CTB** or **STB** from the **Table type** selection button. **CTB** (C olor-dependent Plot Style T ab le) - bases plots on entity colors. Plotting parameters, such as pen thickness and linetype, are matched to the color of entities. This system is older and less flexible than named plot styles, but is the default in all new drawings. Creates a CTB file. **STB** (Named Plot S tyle T ab le) - bases plots on plot styles. Plotting parameters can be given to every entity and every layer. This system is new and more flexible, but may be incompatible with other software that reads DWG files. Creates an STB file.
   - Choose **Create from existing table** , then choose a file in the drop down list box or click the browse button to select an existing CTB or STB file.

   (1.1332 on page 1482)
5. Type a name in the **Table name** field, then click the **OK** button.

The Plot Style Table Editor (1.33.3) dialog displays.

Figure 1.1329

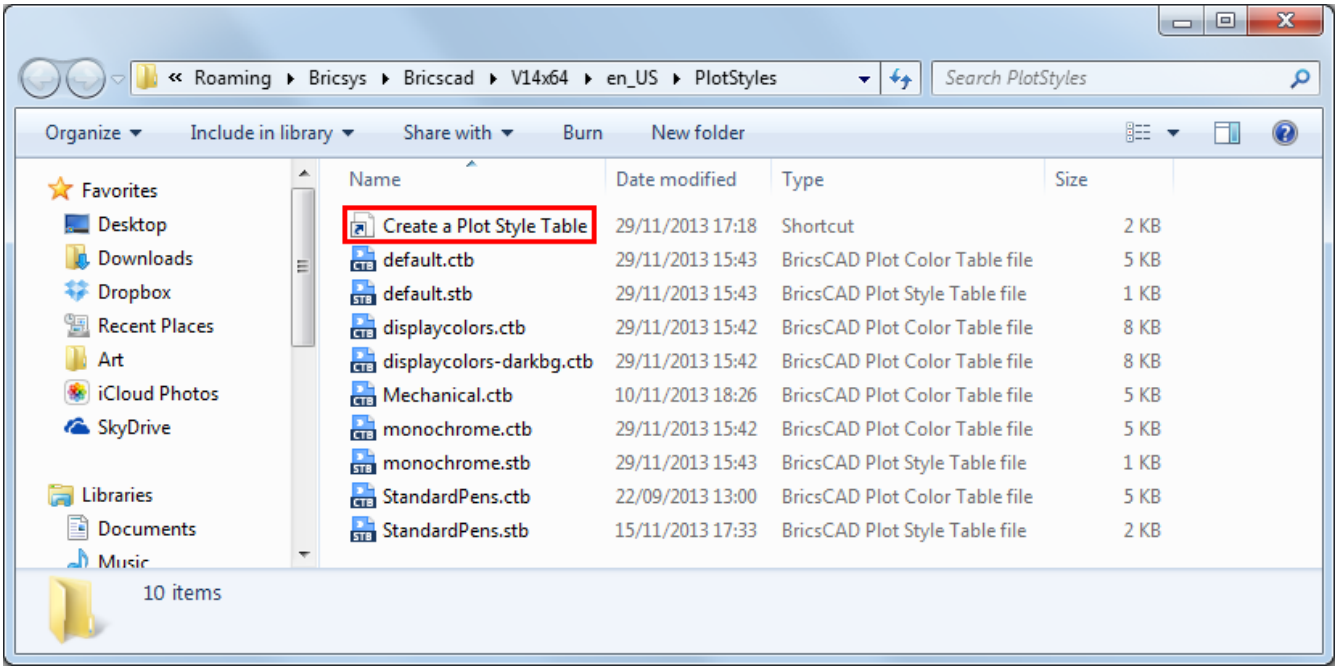


Figure 1.1330

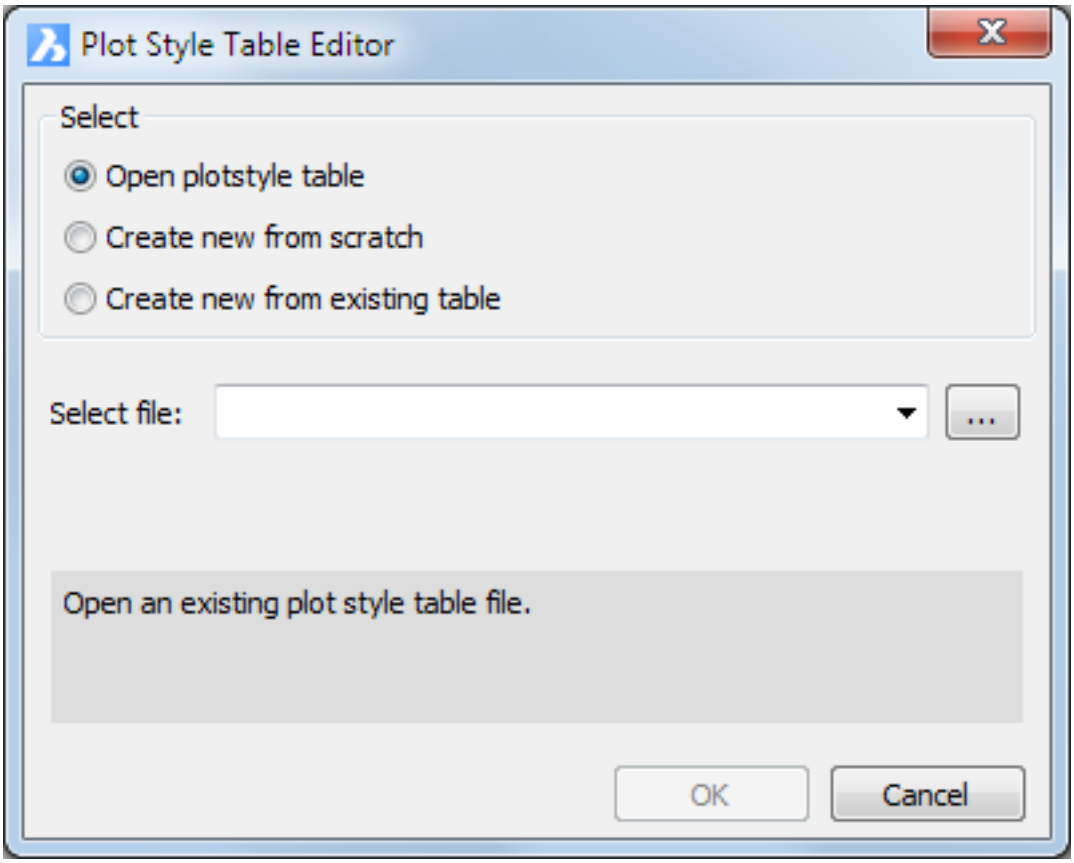

Figure 1.1331

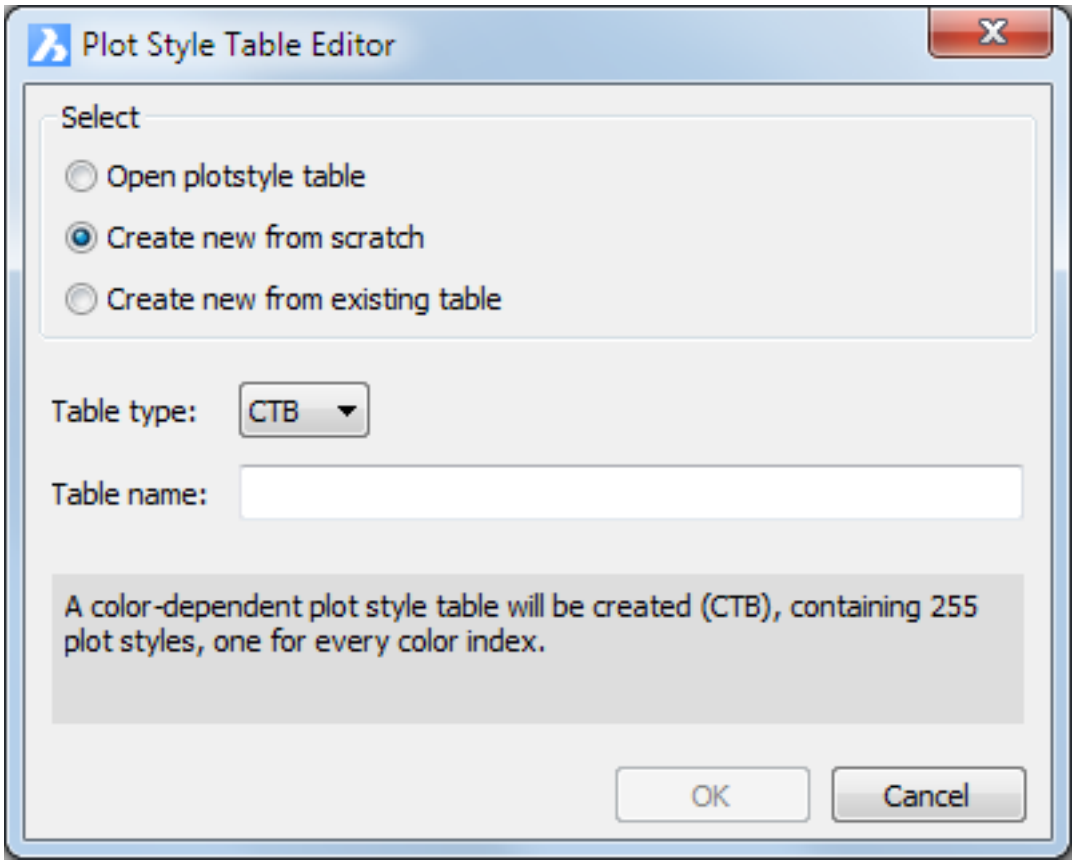

Figure 1.1332

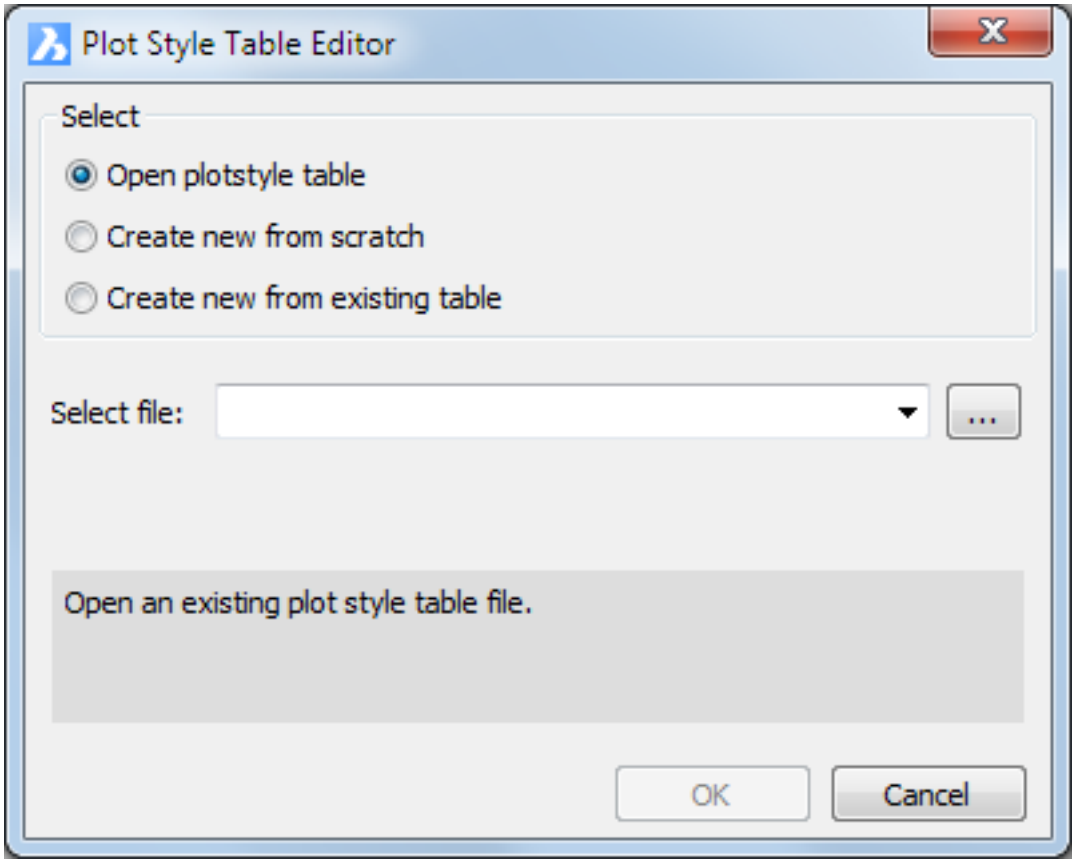
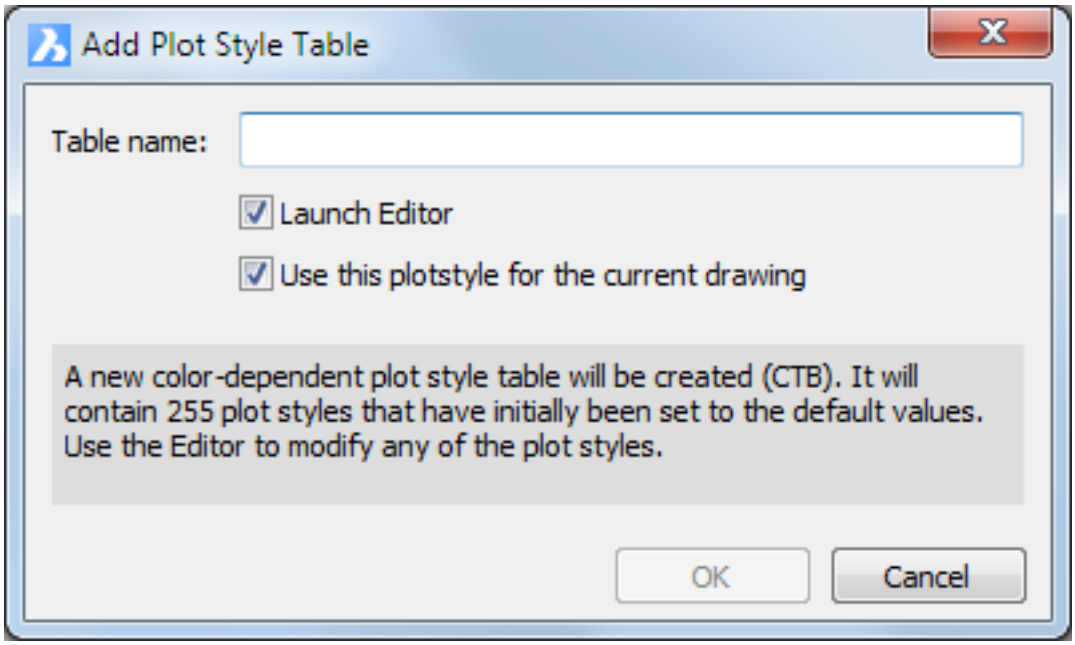


To create a new plot style table in the Print dialog

1. Open the Print dialog (1.33.1).
2. Click the **Create new plot style** button () on the **Print** dialog. The **Add Plot Style Table** dialog displays. (1.1333 on the following page)
3. Type a name in the **Table name** field, then click the **OK** button. If the Launch Editor option is chosen, the Plot Style Table Editor (1.33.3) dialog displays. If the **Use this plotstyle for the current drawing** option is chosen, the new plot style table is used in the current layout.

NOTE	The above procedure creates a CTB file in CTB-type drawing and a STB file in a STB-type drawing.

Figure 1.1333



To edit a plot style table

1. Open the Plot Styles Manager (1.33.5).
2. Double click the plot style table you want to edit.

The Plot Style Table Editor (1.33.3) dialog displays.

To edit a plot style table in the Print dialog

1. Open the Print dialog (1.33.1).
2. Select a plot style table from the **Plot Style Table** list button.
3. Click the edit **Edit plot style** button ( ).

The Plot Style Table Editor (1.33.3) dialog displays.

Tutorial: Printing in BricsCAD: Plot Style Tables Click here (1.22.7) to watch

1.33.6 Batch Plot

Commands: PUBLISH (6.24.68), -PUBLISH (6.24.62), SHEETSET (6.27.38) The **Publish** command allows to print a sheet list (= a list of model space or paper space layouts) to a printer. A sheet list can be saved to a DSD (Drawing Set Description) file. The **SheetSet** command manages sheet sets and allows to print, publish or etransmit a sheet set as a whole or a selection of sheets. A sheet set is saved to a DST file (Sheet Set Data) file.

1.34 Rendering

1.34.1 Using Twinmotion

Note: This feature is only available for BricsCAD on Windows. Twinmotion offers real-time, immersive 3D architectural visualization using the power of Unreal Engine from Epic Games. All your BricsCAD model data are exported using the Unreal Engine file type (*.udatasmith) in the EXPORT (6.13.18) command. To use Twinmotion with BricsCAD V21 you need to:

- Install the **Epics Games Launcher**.
- Download and install **Twinmotion**.
- Export your model to a ***.udatasmith** file.

Tutorial: Twinmotion webinar Click here to watch

Installing Twinmotion

From the Twinmotion Help pages:

1. Go to https://www.unrealengine.com/en-US/twinmotion.
2. Click on **Get Started Now**. (1.1334 on the next page)
3. If you do not have an Epic Games account yet, Click **Sign Up**, then fill in all required information and hit **Create Account**.
4. Click **LOG IN NOW**. (1.1335 on page 1488)
5. Once you are logged in, click on **Download the Epic Games Launcher**.
6. Once the Epic Games Launcher is downloaded, make sure to click on the **Unreal Engine** tab on the left side . You will now see the **Twinmotion** tab in the top right.
7. Click on **Install** to install Twinmotion.
8. Carefully choose your file location , it is strongly recommended to use the default location.

Figure 1.1334

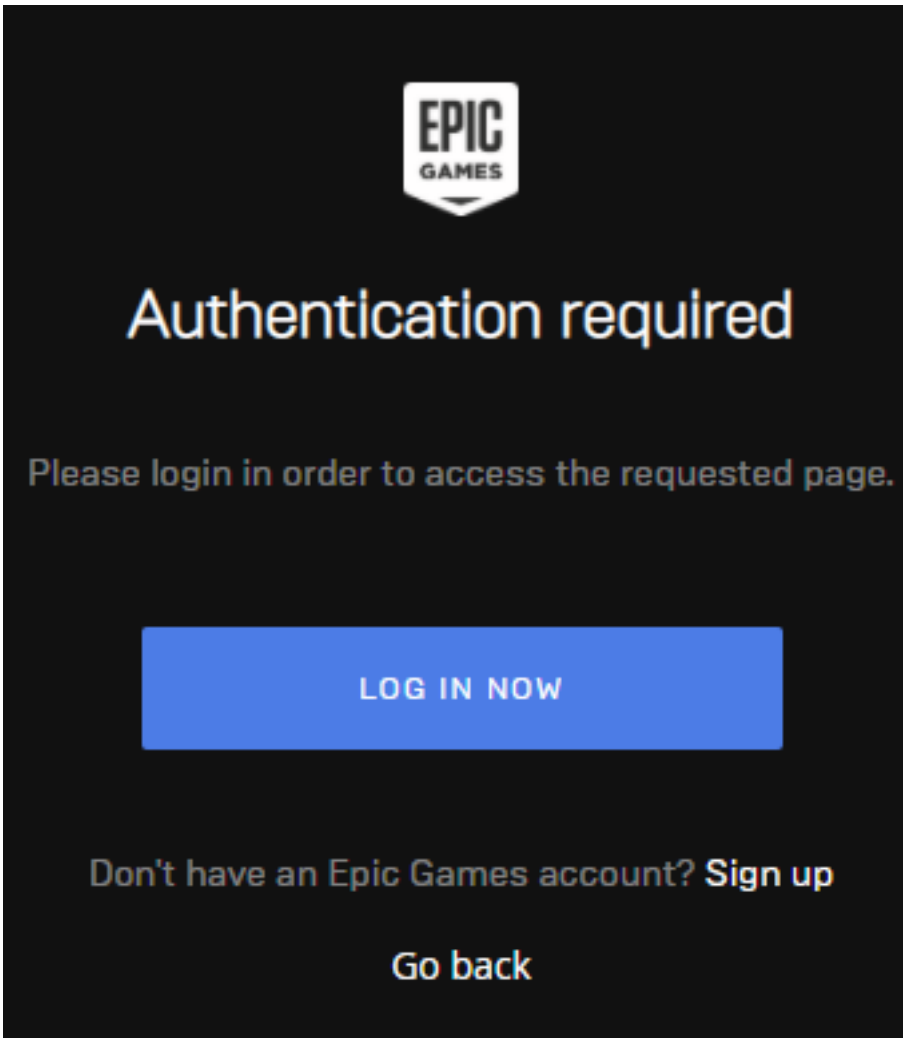


Figure 1.1335

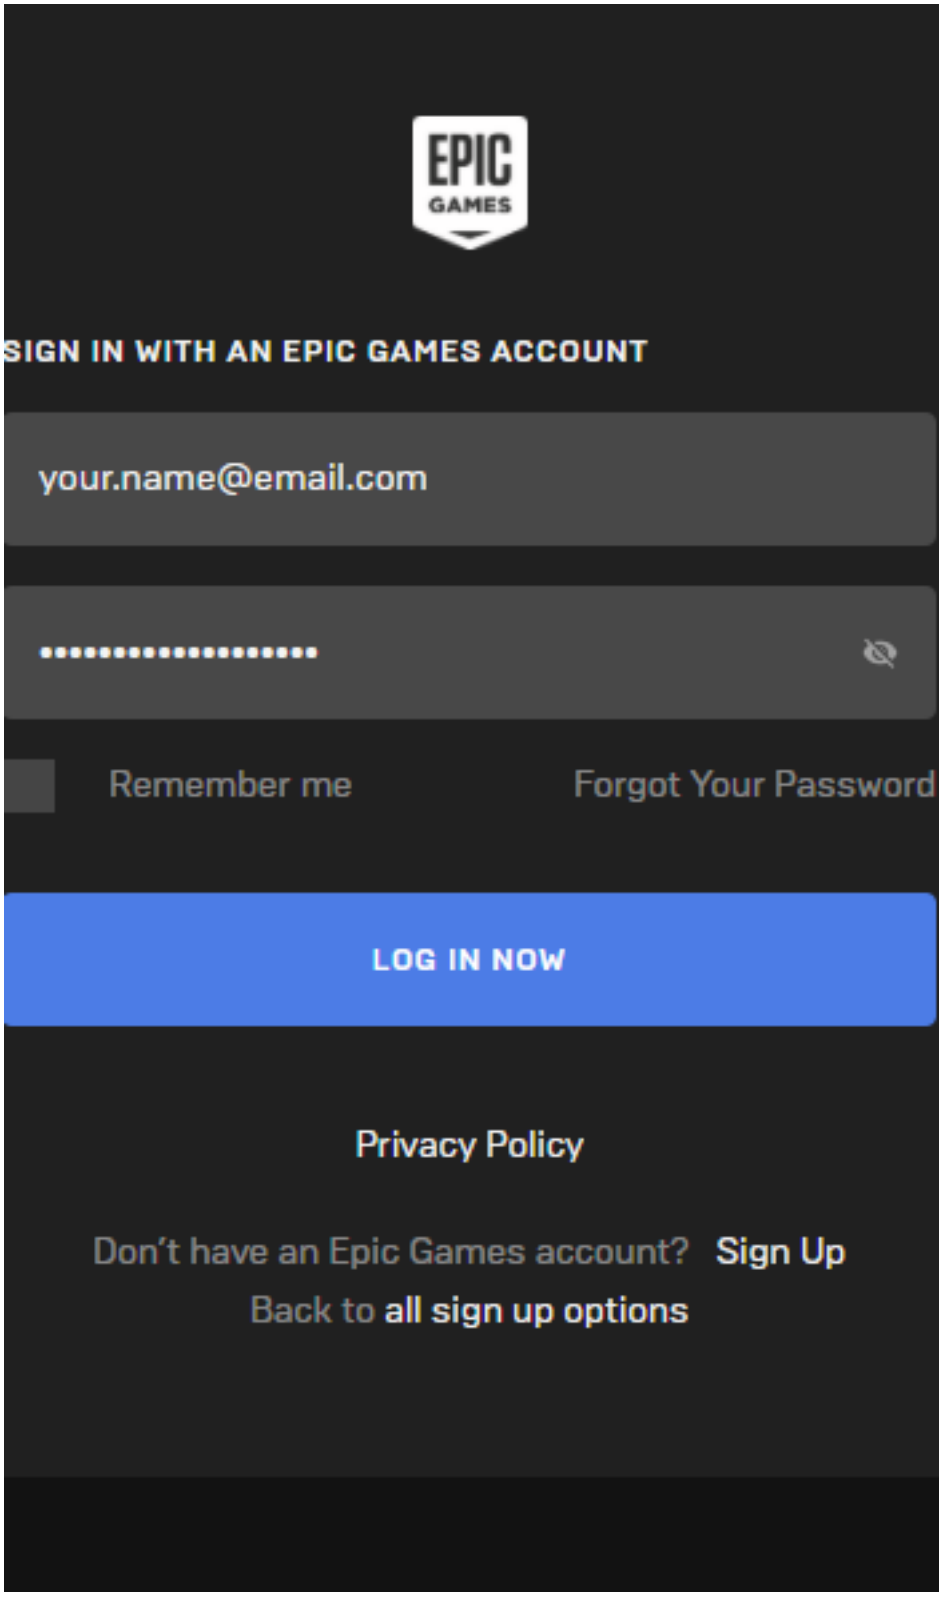

Exporting your model

1. Open your model in BricsCAD BIM.
2. Launch the DatasmithExport (6.10.3) command. The **Export drawing to** dialog box displays. The **Save as type** is **Unreal Engine** (*.udatasmith).
3. Type a name or accept the default name, then click the **Save** button. The exported model can now be imported in Twinmotion.

Importing your model in Twinmotion

1. Launch Twinmotion.
2. Do one of the following:
   - Click the **Import Files** button.
   - Press **Ctrl + I**
3. Make sure **Geometry** is selected, then click the **Open** button. (1.1336 on the next page)
4. On the Import dialog, select a **Unreal Engine** (*.udatasmith) model file. (1.1337 on the following page)
5. Click **Options**, and set the **Collapse** option to **Keep Hierarchy**. This structures the model the same way as the layers used in BricsCAD.
6. Click the **OK** button to import the model.

Figure 1.1336

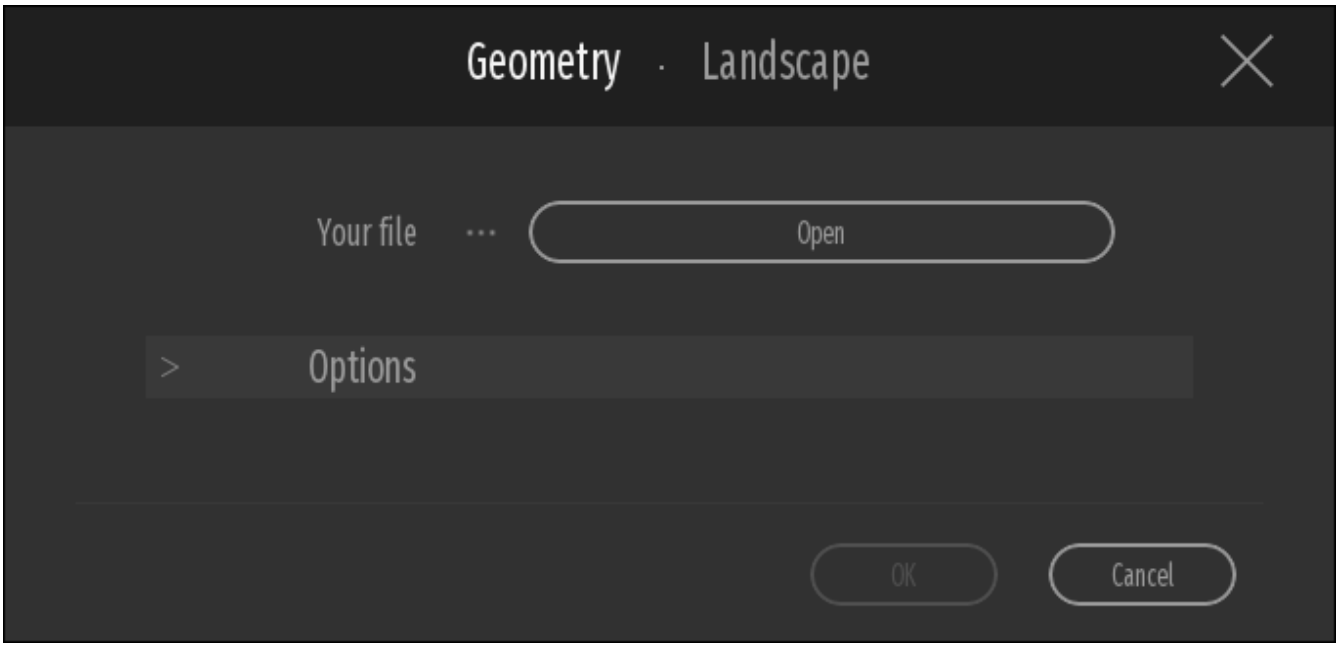

Figure 1.1337

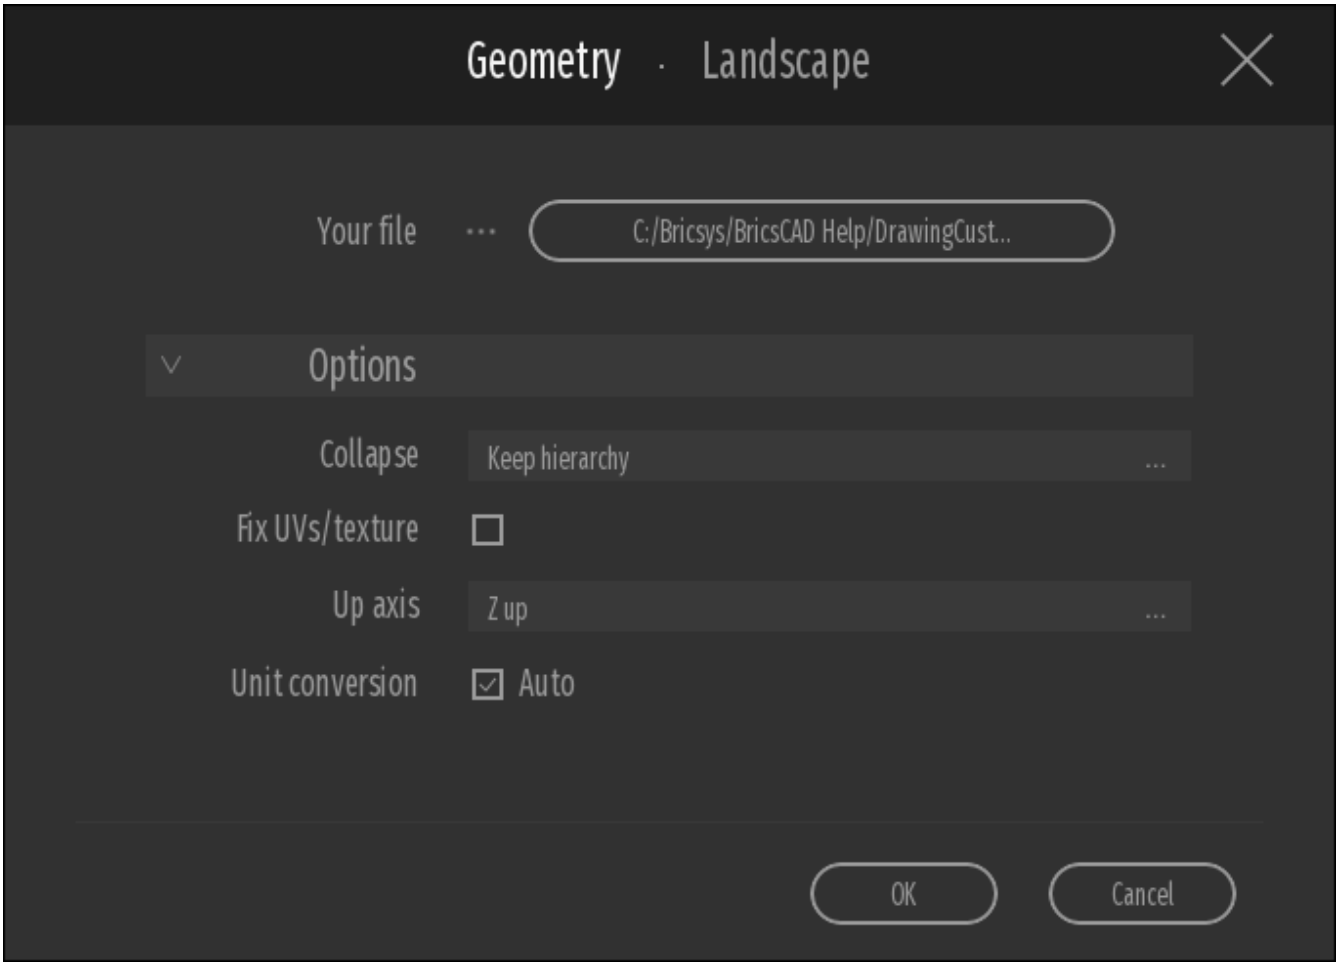


1.34.2 Rendering Overview

Commands: -RENDER (6.26.35), RENDER (6.26.21), SHADEMODE (6.27.31), RENDERPRESETS (6.26.27), ANIPATH (6.4.13) Rendering is the process of generating an image from a 3D model. The model contains the geometry, viewpoint, texture, lighting and shading information. The result is a digital image which can be saved as a raster image file: bmp, jpeg or png. Rendering in BricsCAD is based on the Redway3d rendering engine. By default the rendering engine will try to leverage the hardware on the graphics card. If experiencing problems, please switch off the RenderUsingHardware user preference. It is recommended to install the most recent drivers for your graphics card. The IsRedSdkHardwareRenderingSupported user preference reports if Red SDK hardware rendering is fully supported and the initial value of RenderUsingHardwareuser preference is set accordingly. The RenderPresets command allows to create and edit render presets, and to set the current render preset through a dialog box.

1.34.3 Rendering

Commands: RENDER (6.26.21), SHADEMODE (6.27.31), RENDERPRESETS (6.26.27), ANIPATH (6.4.13) Rendering is the process of generating an image from a 3D model. The model contains the geometry, viewpoint, texture, lighting and shading information. The result is a digital image which can be saved as a raster image file: bmp, jpeg or png. Rendering in BricsCAD is based on the Redway3d rendering engine. By default the rendering engine will try to leverage the hardware on the graphics card. If experiencing problems, please switch off the **RenderUsingHardware** user preference. It is recommended to install the most recent drivers for your graphics card. The **IsRedSdkHardwareRenderingSupported** user preference reports if Red SDK hardware rendering is fully supported and the initial value of **RenderUsingHardware** user preference is set accordingly. The **RenderPresets** command allows to create and edit render presets, and to set the current render preset through a dialog box.

Setting the render preferences

1. Open the Settings dialog.

2. Under **Program Options** expand the **Rendering** settings category. (1.1338) Current material : Specifies the material for new entities. By default the **Global** material is used. Lighting units :

   - 0: No lighting units are used. Enables generic lighting.
   - 1: Enables American lighting units: Foot-Candles
   - 2: Enables International lighting units: Lux.

   Web lights can be created only if the LIGHTINGUNITS system variable is set to 1 or 2. Default lighting : A distant light that follows the view direction. This setting can be different per viewport.

   - 0: Default lighting is used if no lights are switched ON.
   - 1: Default lighting is used instead of the light sources defined in the drawing.

Figure 1.1338

Rendering	
Current material	
Lighting units	[2] Enable photometric lighting using International units (lux)
Default lighting	[0] Default lighting is used only in case no other lights are switched on
Linear contrast	0
Linear brightness	0
Render using hardware	[1] Prefer hardware (faster)
Real world scale	☑ Render real-world scale materials
Sky status	[0] No sky
Texture map path	C:\ProgramData\Bricsys\RenderMaterials\textures;
Render material directory path	C:\ProgramData\Bricsys\RenderMaterials\materials\
Render material static directory path	C:\Program Files\Bricsys\BricsCAD V17 en_US\RenderMaterialStatic\
Tile mode light synch	☑ Synchronize lighting

Linear contrast : Specifies the ambient light intensity. Values between -10 and 10 are accepted. A value of -10 results in maximum ambient light. A value of 10 results in no ambient light. Linear brightness : Specifies a scaling factor for the light intensity. Values between -10 and 10 are accepted. The default value is 0 (no scaling). Negative values decrease the light intensity, positive values increase the light intensity. This setting can be different per viewport. Render using hardware : Choose **User software only (slower)** if hardware rendering fails. It might be necessary to restart BricsCAD after changing the setting. Real world scale : Controls the rendering of materials with units set to real-world scale Sky status :Specifies whether sky illuminiation is computed at render time. (Not implemented yet) Texture map path : Defines the search path for texture map images. In the BricsCAD program folder exist three subfolders under **Textures** , each containing a number of texture files of the same name. Images in folder 1 have a size of 256 x 256 pixels, folder 2 contains images of 512 x 512 pixels, images in folder 3 have a size of 1024 x 1024 pixels. If the **Diffuse map** setting of a material uses the image name only (not path), you can control the quality of a rendered image by setting the TextureMapPath user preference to folder 1, 2 or 3. Render material directory path : Specifies the path of the folder where the render materials for the Material Browser are installed. Render material static directory path : Specifies the path of the folder which contains read-only resources for predefined materials, such as their previews. Tile mode light synch : Controls the synchronization of lighting in all model space viewports. (Internal use only)

Rendering tools

Icon	Tool Name	Keyboard	Description
	Render	render	Photorealistic rendering using materials and lights
	Hide	hide	Hidden line view (*). If the previous shademode option was **2Dwireframe** , wireframe representation is restored if you zoom or pan. If the previous shademode option was other than**2Dwireframe,** the hidden line representation is kept until a different shade mode is chosen.
	Shade	shade	Shade s the entities between the polygon faces. Curved surfaces are segmented.
	2D Wireframe	shademode + 2	Wireframe representation
	3D Wireframe	shademode + 3	Wireframe representation
	Hidden	shademode + H	Hidden line view (*)
	Flat	shademode + F	Shade s the entities between the polygon faces. Curved surfaces are segmented
	Gouraud	shademode + G	Shade s the entities between the polygon faces. Curved surfaces are smoother and more realistic
	Flat + Edges	shademode + L	Combines flat shading and wireframe lines and curves

	Gouraud + Edges	shademode + O	Combines gouraud shading and wireframe lines and curves
	Materials	materials	Opens the Drawing Explorer - Materials
	Material Map	materialmap	Allows to adjust how a texture image is mapped to faces of a 3D solid and filled entities such as 3D faces, wide polylines and polygon meshes.
	Light List	lightlist	Opens the Drawing Explorer - Lights
	Sun Properties	sunproperties	Opens the sun properties editor
	Geographic Location	geographiclocation	Opens the Geographic Location dialog.
	Animation Path	anipath	Records the animation of a camera moving along a path or panning in a 3D model and saves it to a movie file.

(*) Set the **DISPSILH** system variable On to display silhouette lines instead of a polygon mesh for curved surfaces.

(1.1342 on page 1497)
Hidden line of a cone, a cylinder and a sphere with DISPSILH Off (left) and On (right).

(1.1343 on page 1498)

Creating a rendered image of a model

The rendered image displays in the current viewport, in a separate window or can be exported to a file. The background of a rendered view can be controlled by the Background property of the current named view. The ANTIALIASRENDER system variable controls the amount of anti-aliasing (edge smoothing) applied during the rendering generation. The default value is 1, maximum value is 5.

NOTES

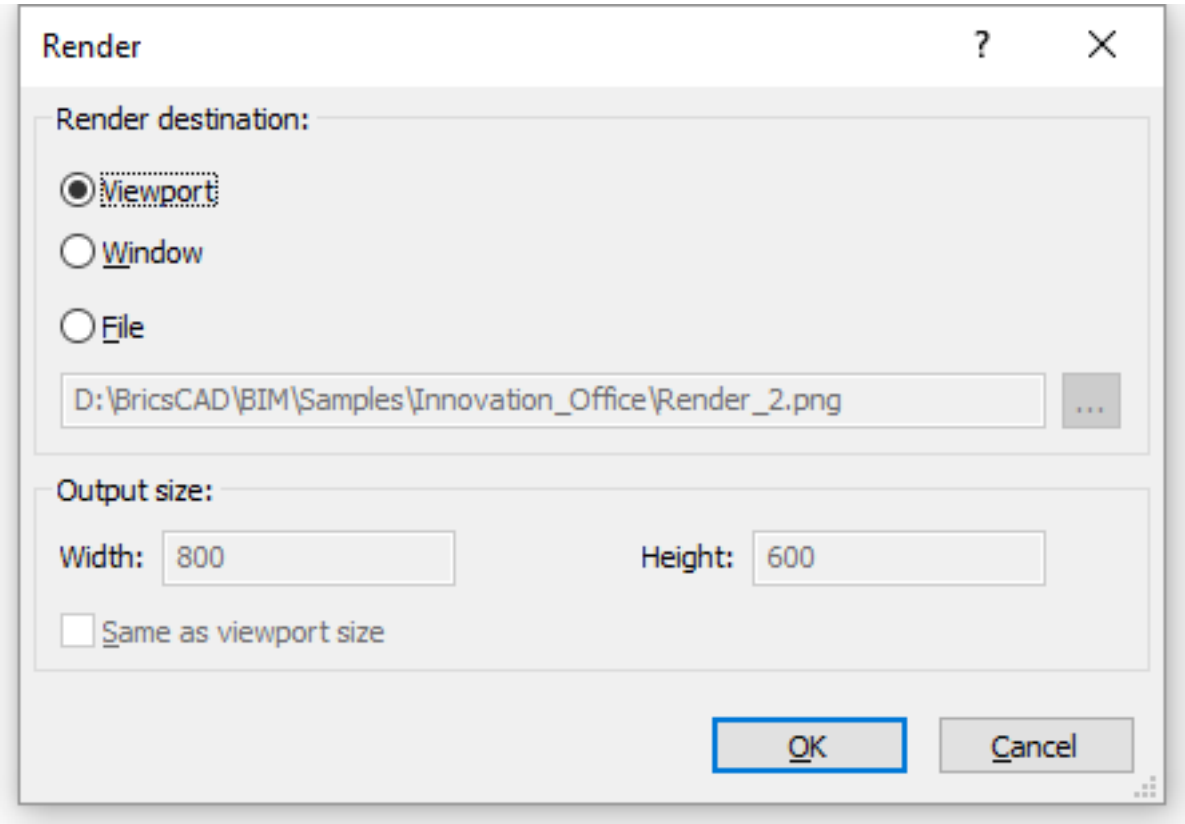
- High anti-alias values incur a high calculation cost.
- The values of the lighting system variables influence the rendering result.

To render a viewport

1. Do one of the following
   - Click the **Render** tool button ( ) on the **Rendering** toolbar.
   - Type **render** in the command bar, then press Enter.

   The **Render** dialog displays: (1.1339 on the facing page)
2. Click the **Viewport** option.
3. Click the **OK** button. The view is rendered.

Figure 1.1339



To render in a window

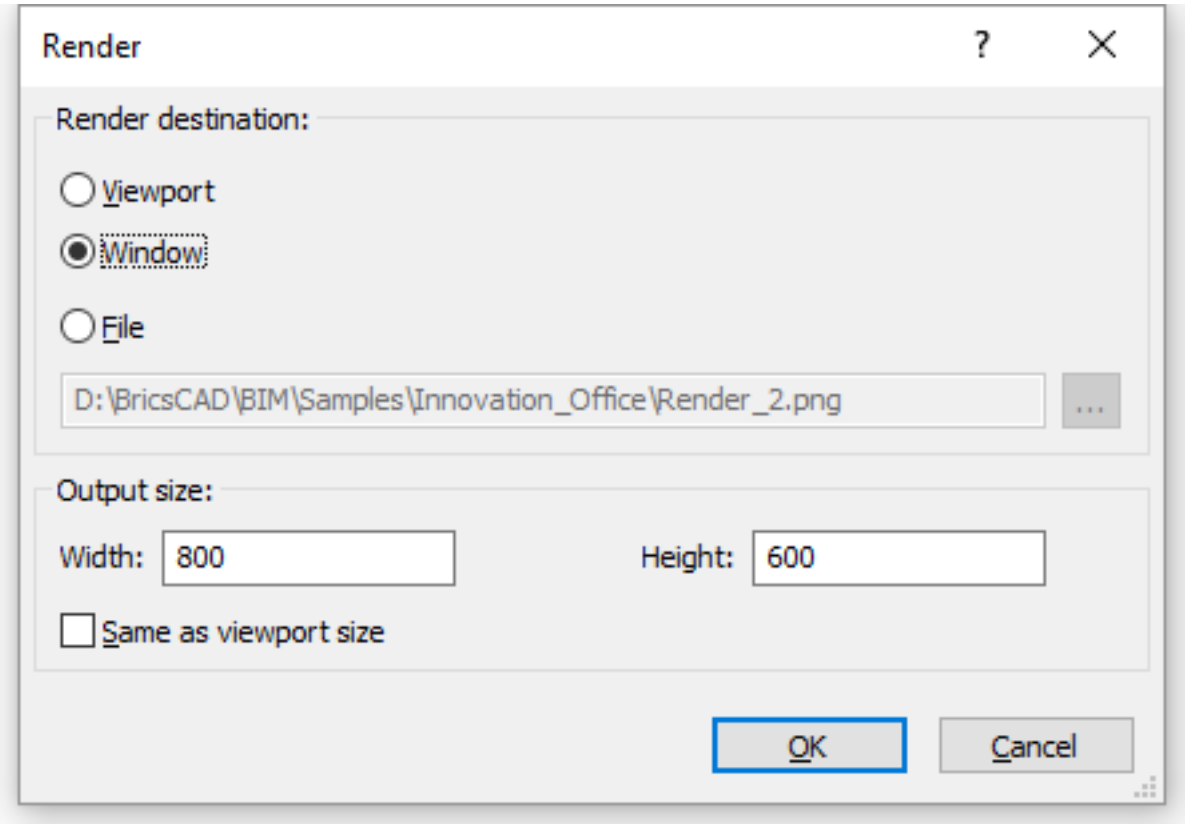
1. Do one of the following

   - Click the **Render** tool button ( ) on the **Rendering** toolbar.
   - Type **render** in the command bar, then press Enter.

   The **Render** dialog displays: (1.1340 on the next page)

2. Click the **Window** option.
3. Click the **OK** button. The view is rendered in a popup window.

Figure 1.1340



To save a rendering to a file

1. Do one of the following

   - Click the **Render** tool button ( ) on the **Rendering** toolbar.
   - Type **render** in the command bar, then press Enter.

   The **Render** dialog displays. (1.1341 on the facing page)

2. Click the **File** option.
3. Click the **Browse** button ( ), at the right hand side of the **File** field. The **Render output file** dialog displays.
4. Select a folder and type a name for the output file in the **File name** field.
5. Click the **Save as type** button to select the file type. The options are: **bmp**, **jpg** and **png**.
6. Click the **OK** button The **Render Output File** dialog closes.
7. Do one of the following:

   - Type the desired resolution for the output size in the **Width** and **Height** fields.
   - Check the **Same as viewport** size option to set the outsize to the size of the current viewport.
   - Click the **OK** button to create the file.

Figure 1.1341

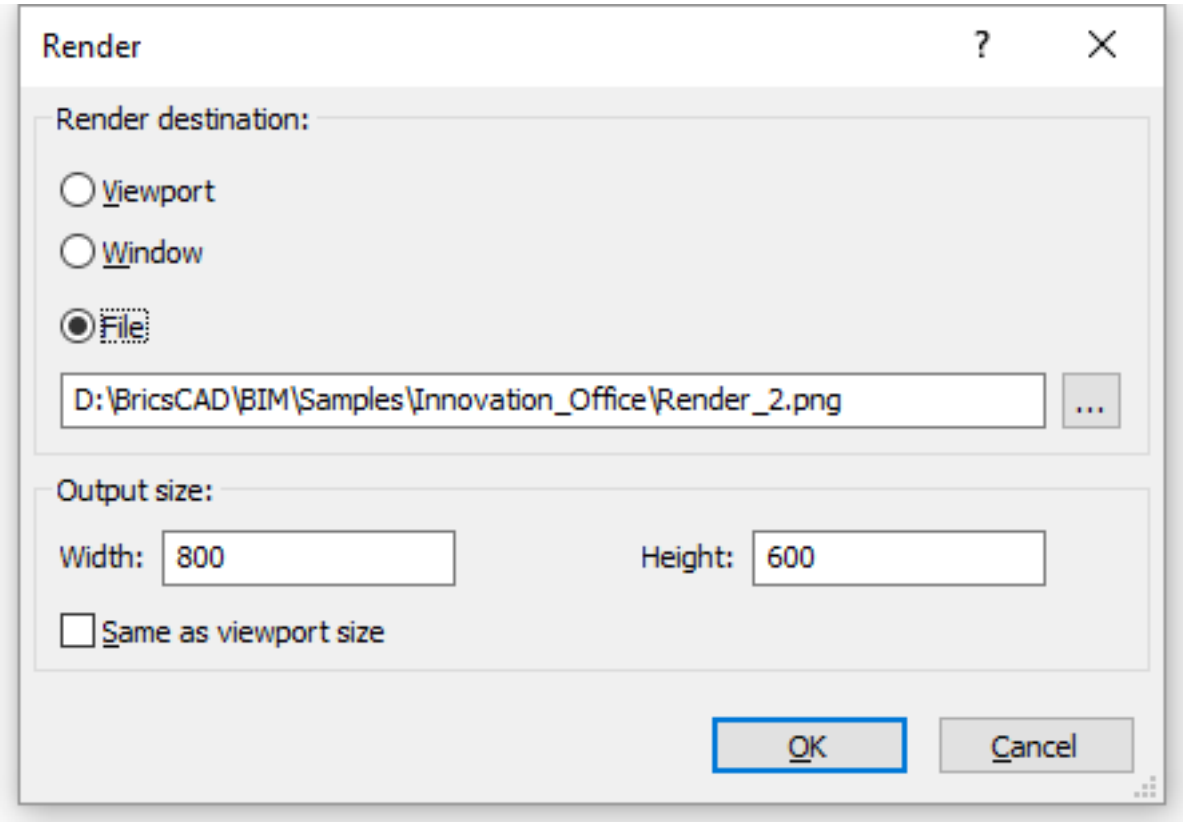


Figure 1.1342

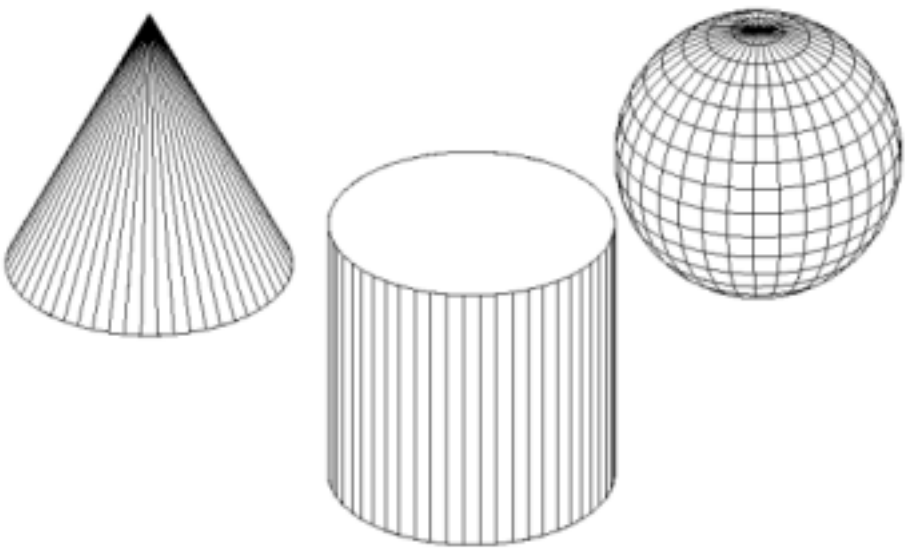

Figure 1.1343

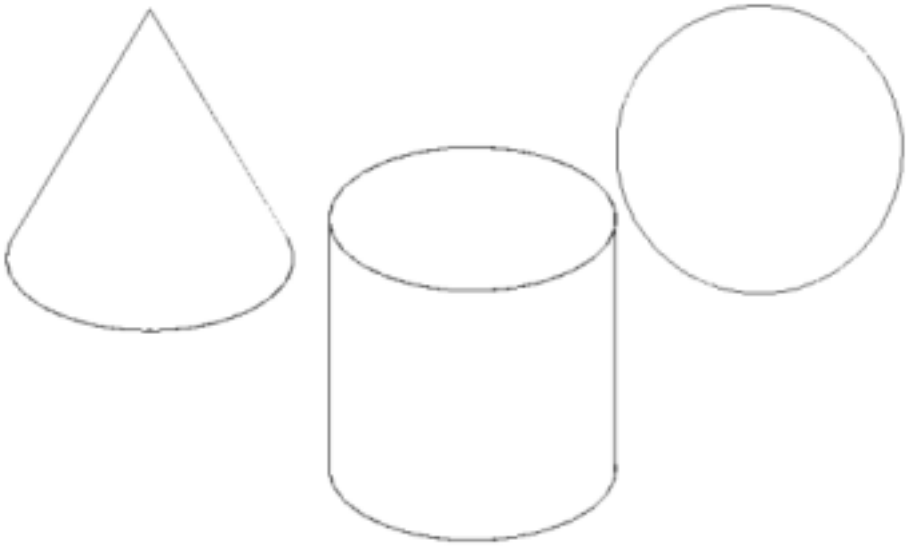

1.34.4 Rendering Materials

Command: Materials (6.21.10), MatBrowserOpen (6.21.6), MatBrowserClose (6.21.4), MaterialMap (6.21.9) The **Materials** command creates materials and edits their properties through the Drawing Explorer. The **MatBrowserOpen** command opens the materials browser, which shows an overview of available high-resolution render materials. The **MatBrowserClose** command closes the materials browser. The **MaterialMap** command allows adjusting how a texture image is mapped to faces of a 3D solid and filled entities such as 3D faces, wide polylines and polygon meshes. Material definitions are saved in the drawing. Each drawing contains the **Global** material. It is not possible to delete or rename the **Global** material. You can edit the properties of the **Global** material though.

Materials glossary

- **Diffuse color**: the color that the object reveals under pure direct, white light. It is perceived as the color of the object itself.
- **Ambient color**: the color of the object in the shadow, under ambient light rather than direct light. (1.1344 on the next page)
- **Highlights**: highly reflective highlights in the color of the material. (1.1345 on the following page) (1.1346 on page 1501) **Metallic Highlights (left) and Non-metallic Highlights (right)**
- **Shading**: how the color and brightness of a surface varies with lighting.
- **Texture-Mapping**: adds detail to a surface that is not included in the 3D model itself.
- **Diffuse map**: adds a structure or pattern to a surface to simulate a material.
- **Transparency map**: sets the transparency of a texture from 0% (black) to 100% (white) and anything between (greyscales). (Black=Transparency map) (1.1347 on page 1501)  (1.1348 on page 1501)
- **Bump map**: simulates a certain roughness or bumpiness on surfaces. (left = with bump map) (1.1349 on page 1502) (1.1350 on page 1502)
- **Reflectivity**: the property of a surface to reflect light.
- **Transparency**: sharp transmission of light through solid objects.
- **Translucency**: scattered transmission of light through solid objects.
- **Refraction**: bending of light when passing through transparent objects.
- **Self-illumination**: it appears as if a surface is emitting its own light. No light is cast on other objects.

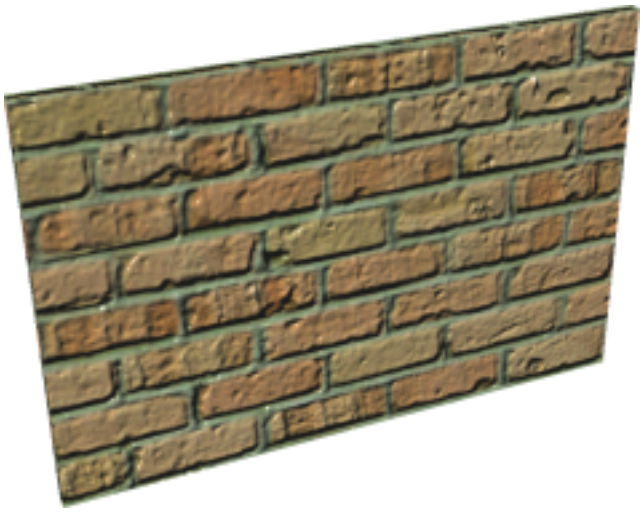

Figure 1.1350

Defining materials

See the Materials (6.21.10) command.

Assigning materials

Materials can be assigned to a layer and to entities. If the **Material** property of an entity is **BYLAYER**, the material assigned to the layer of the entity will be used. By default, new entities get the **BYLAYER** material setting.

Procedure: To assign a material to the drawing

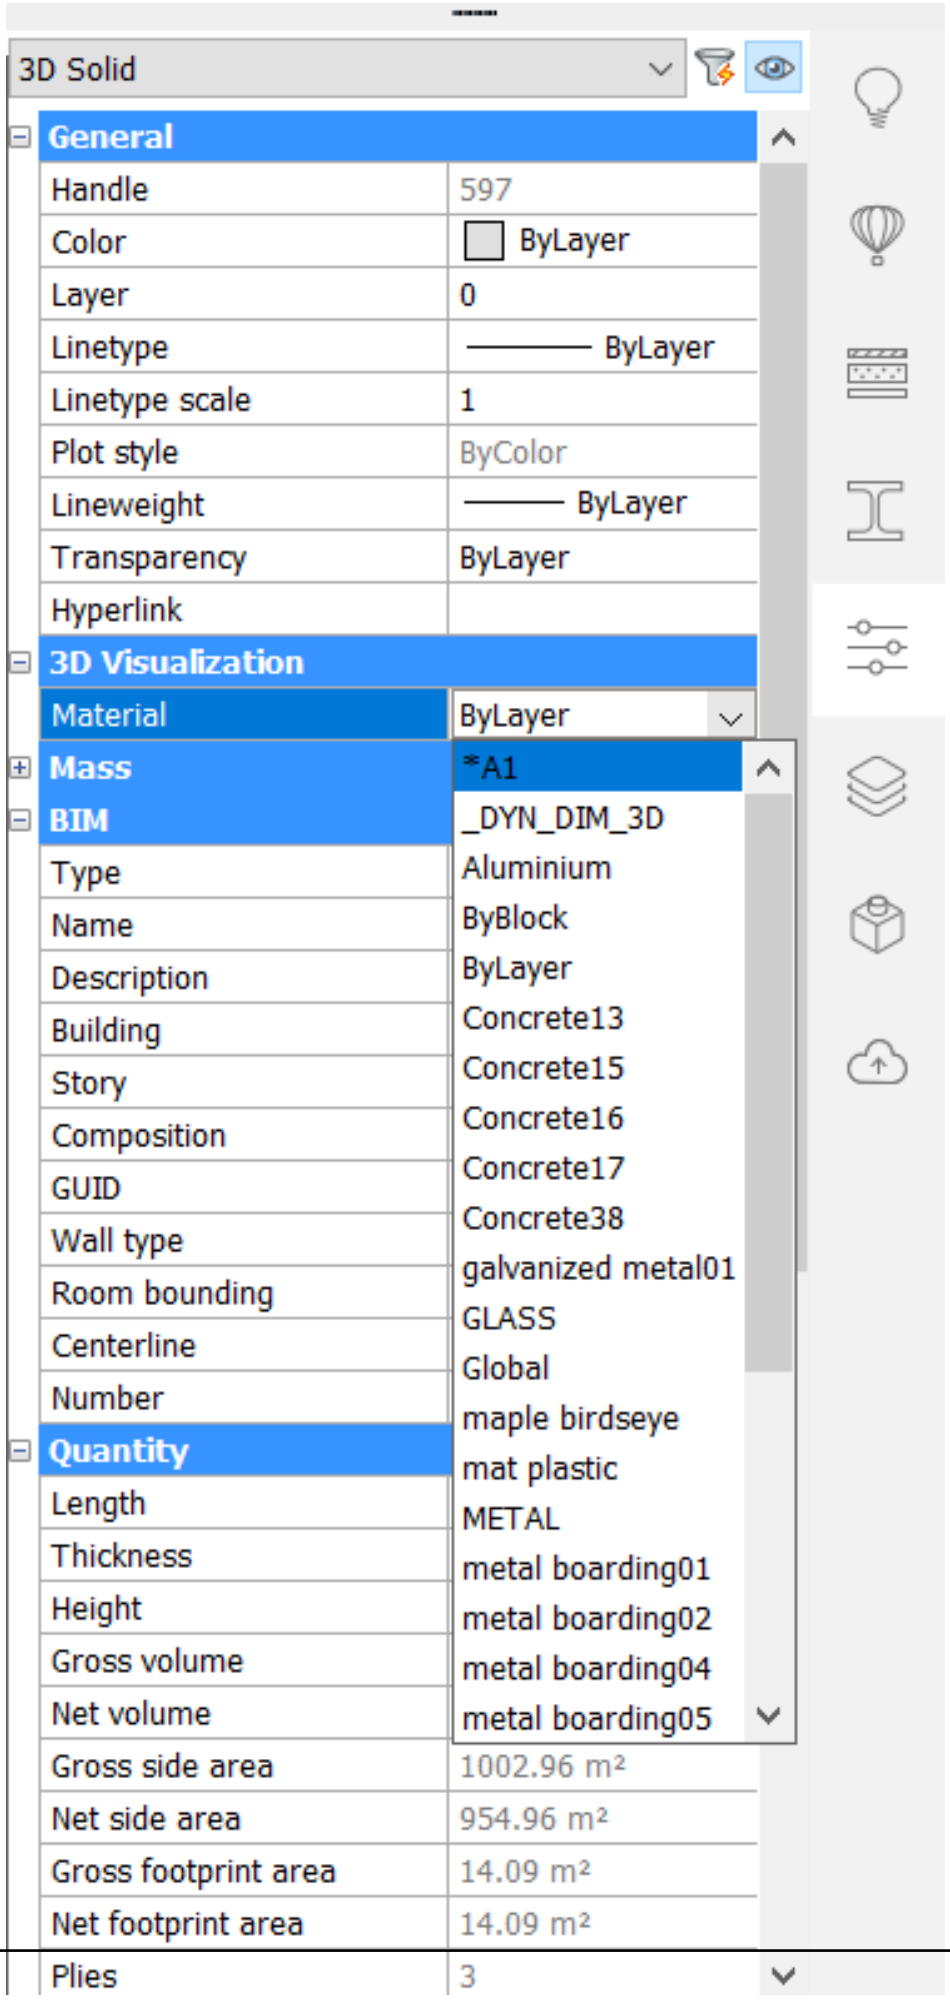
1. Search the material in the Render Materials (6.21.6) panel.
2. Right-click the material and choose the 'Add to drawing' option.

Procedure: To assign a material to entities

Method 1: Using the Properties Bar.

1. Select the entities or sub-entities (e.g. faces or 3D solids).
2. In the Properties (1.15.4) bar, under **3D Visualization > Material**, click the down arrow and select the material in the **Material** list. (1.1351 on the following page)

Figure 1.1351



Method 2: The Render Materials panel

Tutorial: Using Render Materials in BricsCAD Click here (1.18.34) to watch

To assign a material to a single entity:

1. Select the material in the Render Materials (6.21.6) panel.
2. Click on the entity **or** press and hold the left mouse button, then drag the material onto the entity

To assign a material to multiple entities:

1. Select the entities.
2. Search the material in the Render Materials (6.21.6) panel.
3. Click on the material.

Procedure: To assign a material to a layer

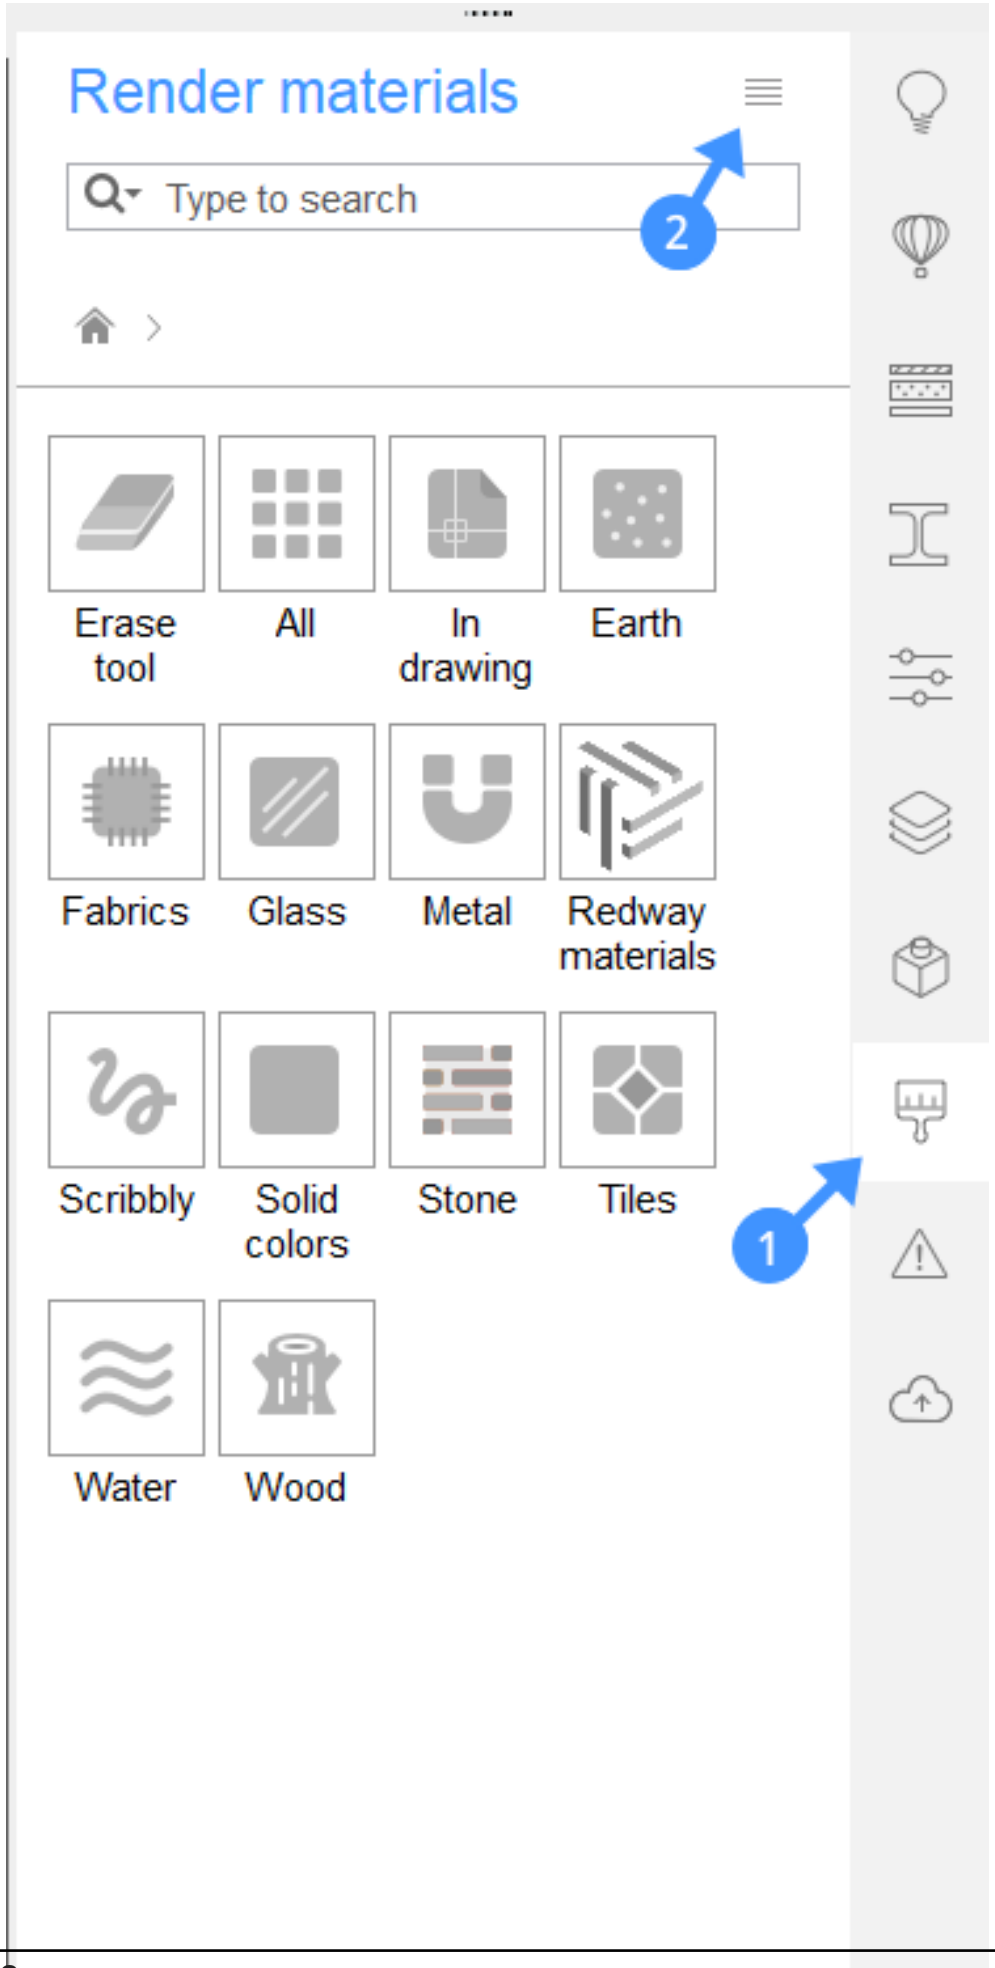
1. Do one of the following
   - Open the **Layers** panel by:
     - Typing **Layer** in the command bar, then press Enter.
     - Opening the dockable panel (1.34.4) to the right-hand side.
   - Open the **Drawing Explorer - Layers** dialog by:
     - Clicking the **Explore Layers** tool button () in the **Entity Properties** toolbar.
     - Typing **Explorer** in the command bar and going to the **Layers** section.
2. (Optional) In the **Drawing Explorer - Layers** dialog click the **Detail view** tool button ().
3. Click the **Material** column of the layer you want to assign a material to.
4. Click the down arrow and select the material in the **Material** list. You can only choose from the materials that you already assigned to the drawing, as described in 'Procedure: To assign a material to the drawing'.

Procedure: To add the Redway material library

Materials in the folder linked under **RENDERSMATERIALSPATH** will be displayed in the Render materials panel. To add the **Redway Material Library** follow this procedure:

1. Download the complete **Redway Material Library** here.
2. Unzip the downloaded file and copy the path of the folder. The path should end with ...\all_redway_materials.
3. Go to BricsCAD and open the **Render Materials panel** (1).
4. Click the hamburger icon (), a context menu appears (2). (1.1352 on the next page)
5. Select **Manage libraries** (3). (1.1353 on page 1507)

Figure 1.1352



6. The path can be copied or edited (...). Paste the path you have copied underneath the existing path. The downloaded materials are now displayed in the panel. (1.1354 on the next page)

Figure 1.1353

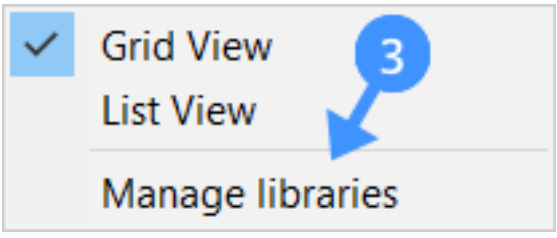


Figure 1.1354

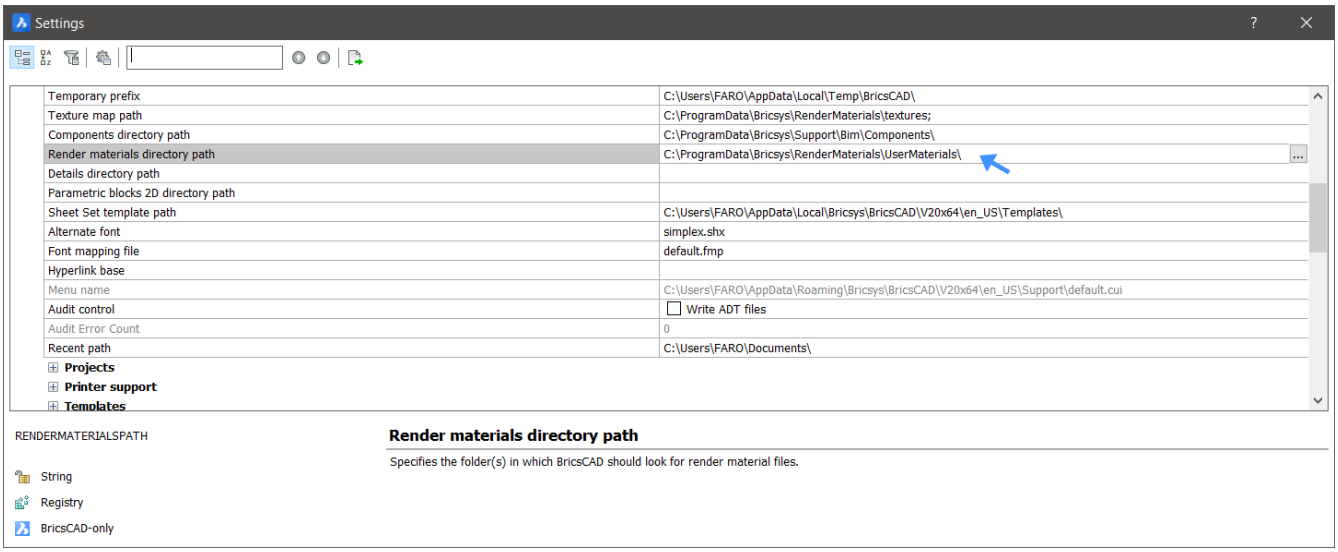

Procedure: Adding your own materials

1. Download the textures you want to use. **Note:** you can download a photo of your texture, but in order to get the most realistic view it is best to download a zip file that gives you different representations of the texture: (1.1355)
2. Type **Materials** in the command bar, then press Enter. The drawing explorer opens.
3. Add a new material. (1.1356 on the next page)
4. Give your new material a name. (1.1357 on the facing page)
5. Check on the Diffuse Map and the Bump Map. (1.1358 on page 1510)
6. Edit the path of the diffuse map (…) to the colored image of your texture. (1.1359 on page 1510)
7. Edit the path of the bump map (…) to the normal image of your texture. This will give your render material a more 3D and realistic look. (1.1360 on page 1511)
8. Edit the scale of your image until you get a realistic image in the preview. The scale of the texture represents the number of drawing units covered by the full width of your image. (1.1361 on page 1511)
9. Close the drawing explorer.
10. Select the elements you want to attach your new material to.
11. Open the properties panel and select your new material in the drop-down menu. Your material will be attached to the selected solids. (1.1362 on page 1512)
12. Type **Materials** in the command bar again and press Enter. The drawing explorer opens.
13. You can still edit the settings of the material, to see the changes in the drawing, press **Regen** ().
14. Right-click on your new material and add it to the library. (1.1363 on page 1513)

Figure 1.1355

Figure 1.1356

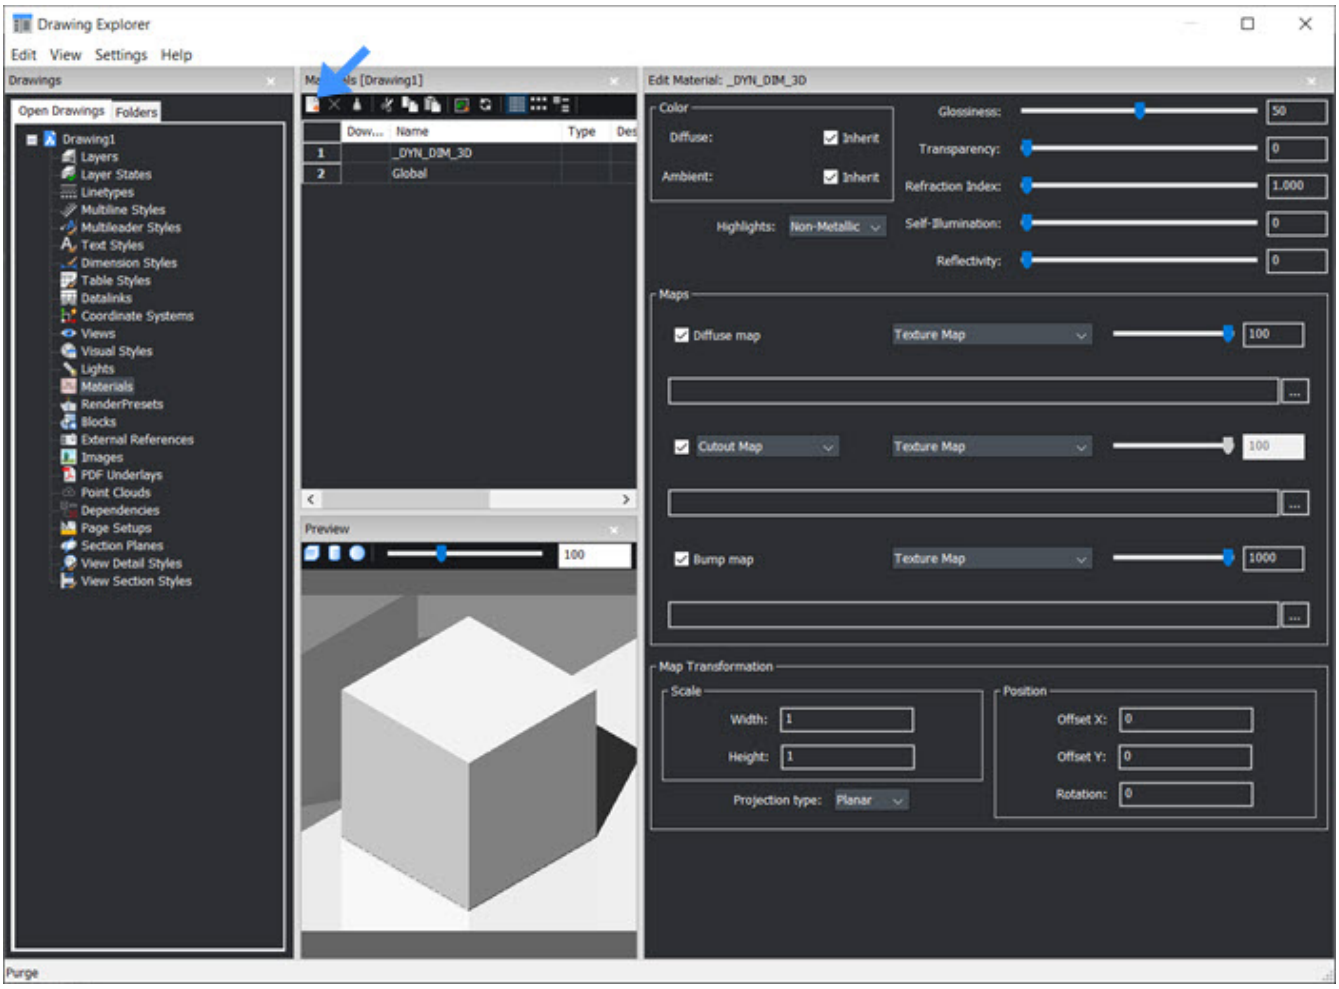

Figure 1.1357

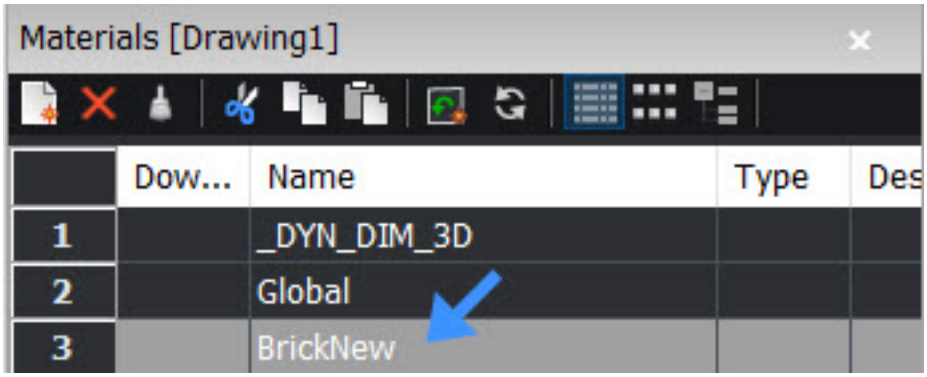

Figure 1.1358

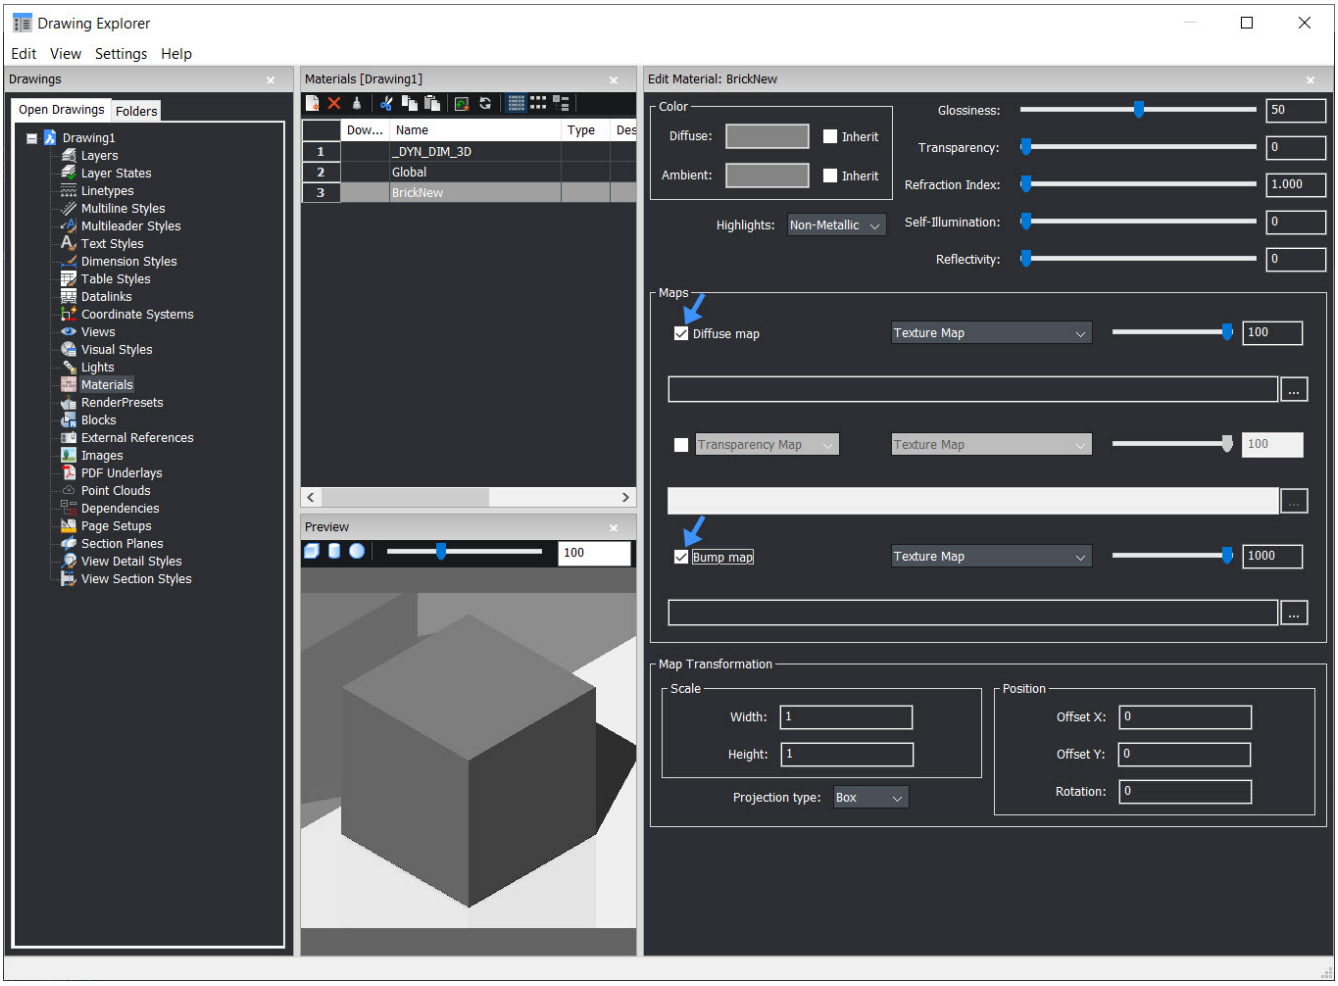

Figure 1.1359

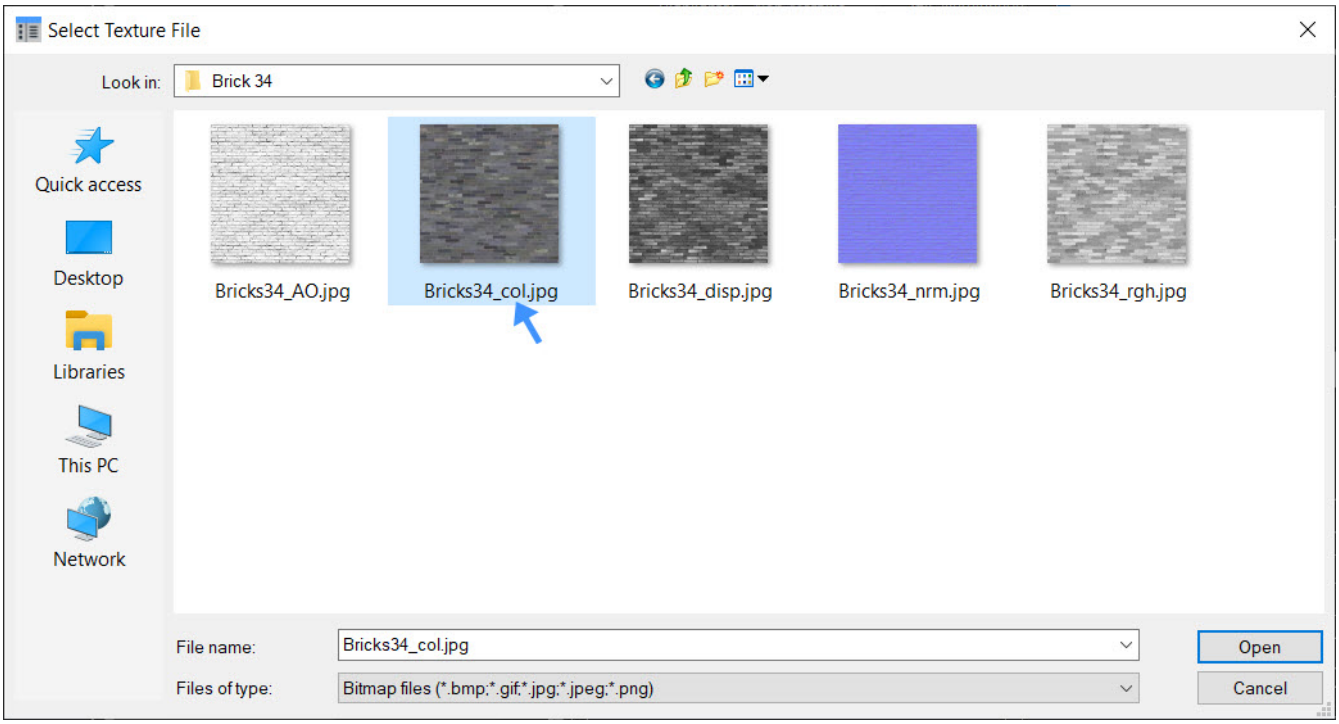

Figure 1.1360

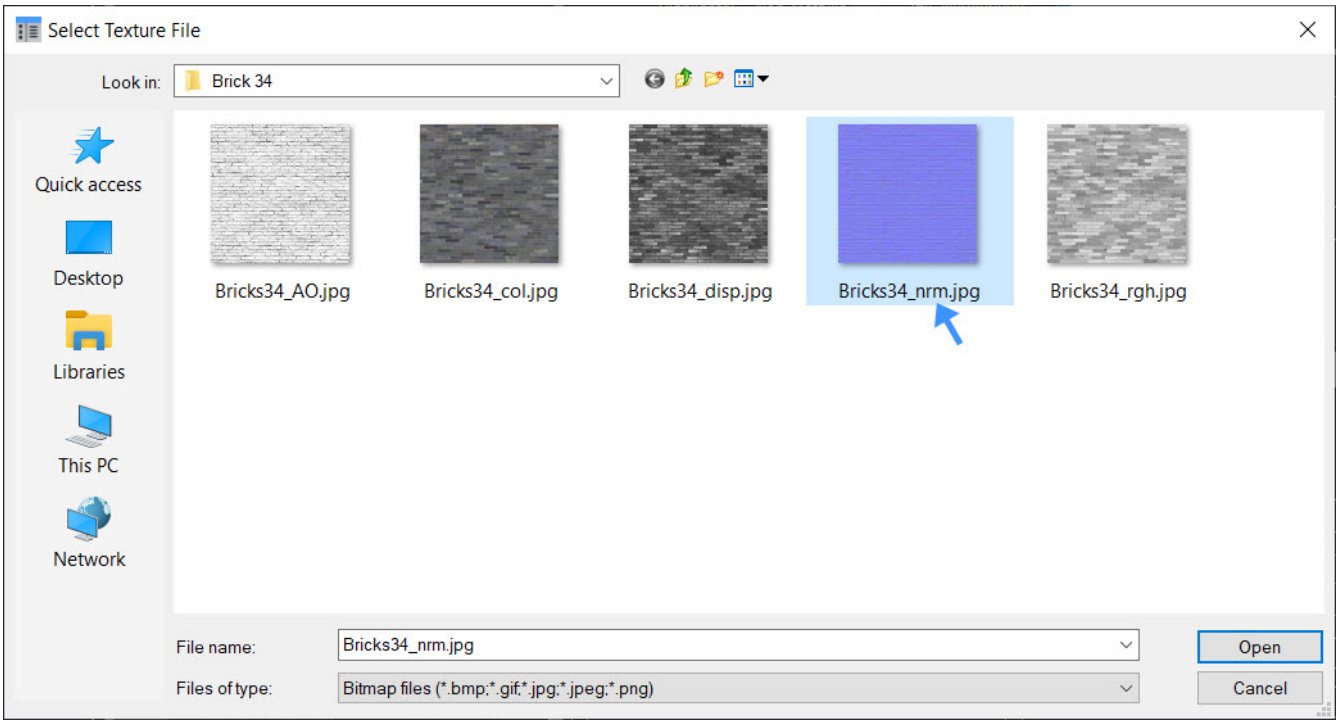

Figure 1.1361

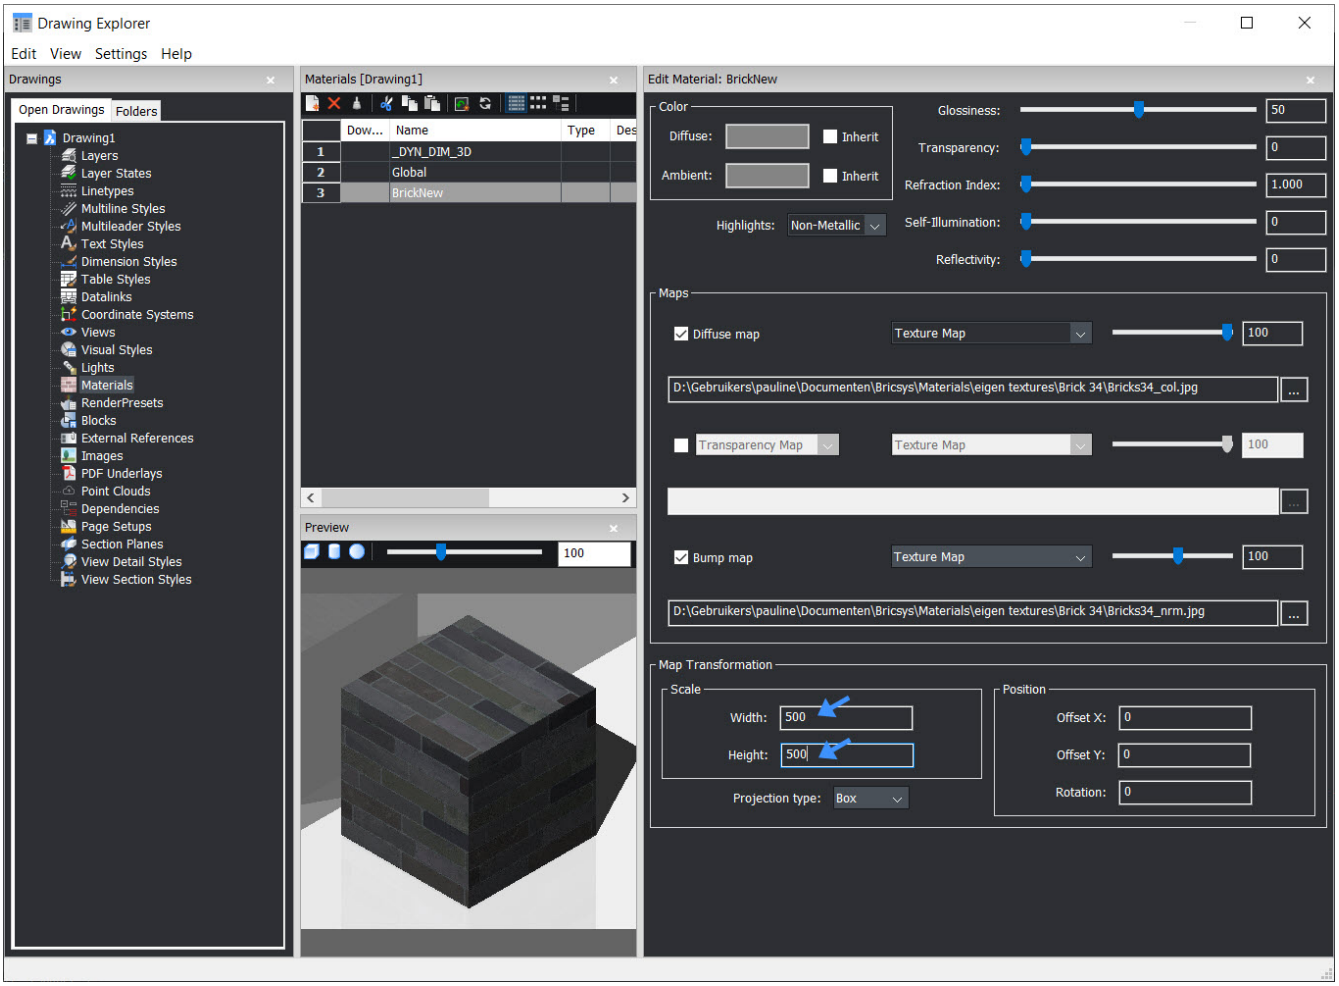

Figure 1.1362

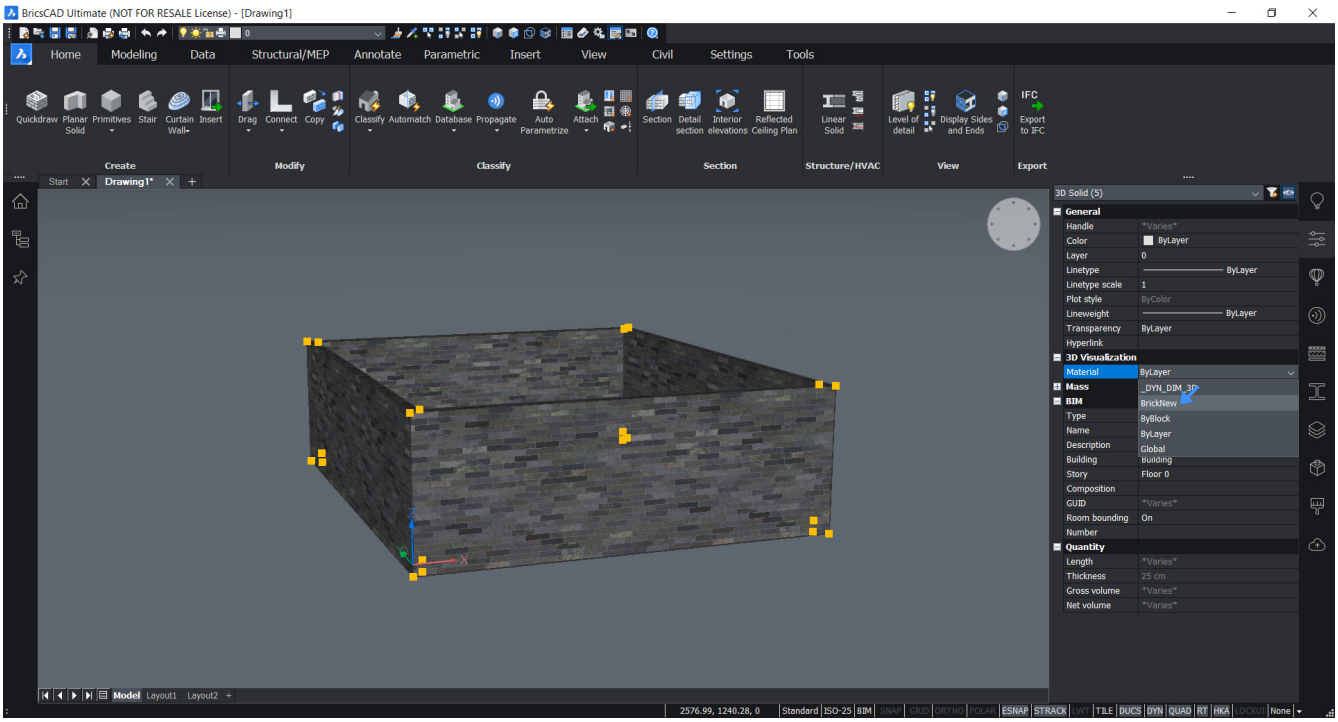

15. Close the drawing explorer
16. Open the Render Materials panel and click on the folder **User Defined**. This folder of new materials is automatically generated in the following path: **C:\ProgramData\Bricsys\RenderMaterials\UserMaterials\User defined.** (1.1364 on the next page)
17. You find your new material in this folder of the library, drag and drop to assign the new material to the entities in your drawing.

Render material static directory path	C:\Program Files\Bricsys\BricsCAD V17 en_US\RenderMaterialStatic\
Tile mode light synch	☑ Synchronize lighting

1.34.5 Setting the Render Preferences

Setting the render preferences

1. Open the **Settings (1.17.10)** dialog.
2. Under **Program Options** expand **the Rendering**settings category. (1.1365) **Current material**: Specifies the material for new entities. By default the Global material is used. **Lighting units**:

   - 0: No lighting units are used. Enables generic lighting.
   - 1: Enables American lighting units: Foot-Candles.
   - 2: Enables International lighting units: Lux.

   Web lights can be created only if the LIGHTINGUNITS (1.17.10) system variable is set to 1 or 2. Default lighting: A distant light that follows the view direction. This setting can be different per viewport.

   - 0: Default lighting is used if no lights are switched ON.
   - 1: Default lighting is used instead of the light sources defined in the drawing.

   Linear contrast: Specifies the ambient light intensity. Values between -10 and 10 are accepted. A value of -10 results in maximum ambient light. A value of 10 results in no ambient light. **Linear brightness**: Specifies a scaling factor for the light intensity. Values between -10 and 10 are accepted. The default value is 0 (no scaling). Negative values decrease the light intensity, positive values increase the light intensity. This setting can be different per viewport. **Render using hardware**: Choose User software only (slower) if hardware rendering fails. It might be necessary to restart BricsCAD after changing the setting. **Real world scale**: Controls the rendering of materials with units set to real-world scale **Sky status**: Specifies whether sky illuminiation is computed at render time. (Not implemented yet) **Texture map path:** Defines the search path for texture map images. In the BricsCAD program folder exist three subfolders under Textures, each containing a number of texture files of the same name. Images in folder 1 have a size of 256 x 256 pixels, folder 2 contains images of 512 x 512 pixels, images in folder 3 have a size of 1024 x 1024 pixels. If the Diffuse map setting of a material uses the image name only (not path), you can control the quality of a rendered image by setting the TextureMapPath user preference to folder 1, 2 or 3. **Render material directory path**: Specifies the path of the folder where the render materials for the Material Browser (6.21.6) are installed. **Render material static directory path**: Specifies the path of the folder which contains read-only resources for predefined materials, such as their previews. **Tile mode light synch**: Controls the synchronization of lighting in all model space viewports. (Internal use only)

1.34.6 Lights

Commands: DISTANTLIGHT (6.10.34), GEOGRAPHICLOCATION (6.15.15), LIGHT (6.20.30), LIGHTLIST (6.20.36), POINTLIGHT (6.24.47), SPOTLIGHT (6.27.47), SUNPROPERTIES (6.27.70), WEBLIGHT (6.33.4) Lighting is the key to make the viewer believe to look at a realistic scene.

Lighting glossary

- Ambient light: light from an unspecified source.
- Back light: light that adds depth and dimension by creating highlights.
- Distant light: light that is cast evenly throughout a scene with shadows all in the same direction.
- Fall-off: the attenuation or decrease in brightness the further from the light source.
- Fill light: the light that brightens dark areas and softens shadows from the main light.
- Point light: light that shines in all directions from a central spot.
- Spot light: focusable light that is aimed in one area.
- Photometric web: a 3D representation of the light intensity distribution of a light source.
- Web light: approximates real-world light distribution using a 3D representation of the light intensity. Web lights can be created only if the LIGHTINGUNITS (1.17.10) system variable is set to 1 (American lighting units) or 2 (International lighting units).
- Attenuation: the fall-off in brightness the further from the light source.

System variables

LIGHTINGUNITS (Lighting units):

- 0: No lighting units are used. Enables generic lighting.
- 1: Enables American lighting units: Foot-Candles
- 2: Enables International lighting units: Lux.

DEFAULTLIGHTING (Default lighting): A distant light that follows the view direction. This setting can be different per viewport.

- 0: Default lighting is used if no lights are switched ON.
- 1: Default lighting is used instead of the light sources defined in the drawing.

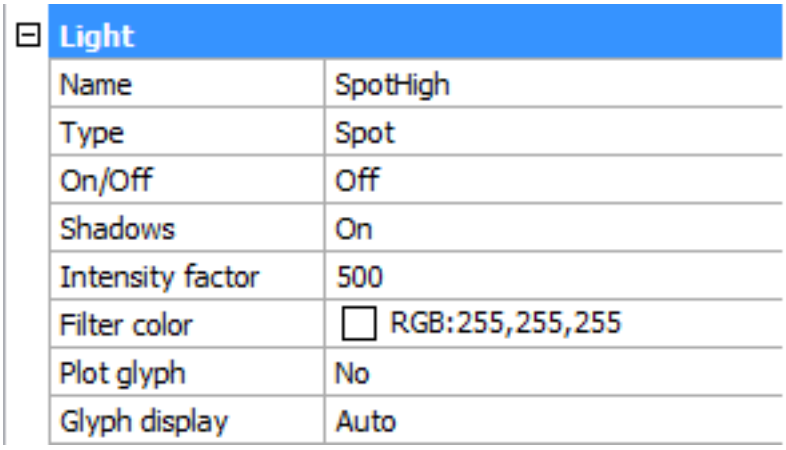
LINEARCONTRAST (Linear contrast): Specifies the ambient light intensity. Values between -10 and 10 are accepted. A value of -10 results in maximum ambient light. A value of 10 results in no ambient light. LINEARBRIGHTNESS (Linear brightness): Specifies a scaling factor for the light intensity. Values between -10 and 10 are accepted. The default value is 0 (no scaling). Negative values decrease the light intensity, positive values increase the light intensity. This setting can be different per viewport.

General properties

The general properties are common to all lights: (1.1366 on the next page)

- Name: a user defined name for the light.
- Type: defines the type of light: spot, point, web or distant.
- On/Off: specifies whether the light is turned on or off.
- Shadows: specifies whether the light casts shadows or not. Turning shadows off to increases performance.
- Intensity factor: multiplies the **Lamp Intensity** property, the result is the **Resulting Intensity**.
- Filter color: defines the color of the light.
- Plot glyph: if on, the light glyph is plotted.
- Glyph display: controls the display of the light glyph.

Figure 1.1366



Photometric light properties

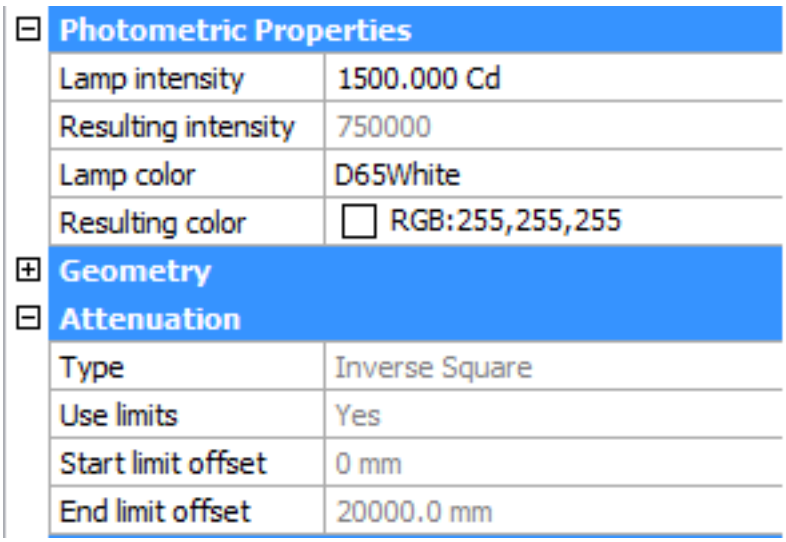
LIGHTINGUNITS = 1 (American units) or 2 (International units). (1.1367)

- Lamp intensity: Defines the brightness of the light. The lamp intensity is expressed in candela (cd) which is the SI base unit of luminous intensity: the power emitted by a light source in a particular direction, weighted by the luminosity function (a standardized model of the sensitivity of the human eye to different wavelengths, also known as the luminous efficiency function)
- Resulting intensity: the product of the lamp intensity and and intensity factor.
- Lamp color: defines the inherent color of the light or color temperature in Kelvin or standards.

(1.1378 on page 1528) color temperatures	(1.1379 on page 1528) lamp color list

- Resulting color: this is the final color of the light: a combination of the lamp color and the filter color.
- Photometric web: If the light type is **Web**, **Photometric Web** and **Web offsets** are available (not implemented yet).

Figure 1.1367

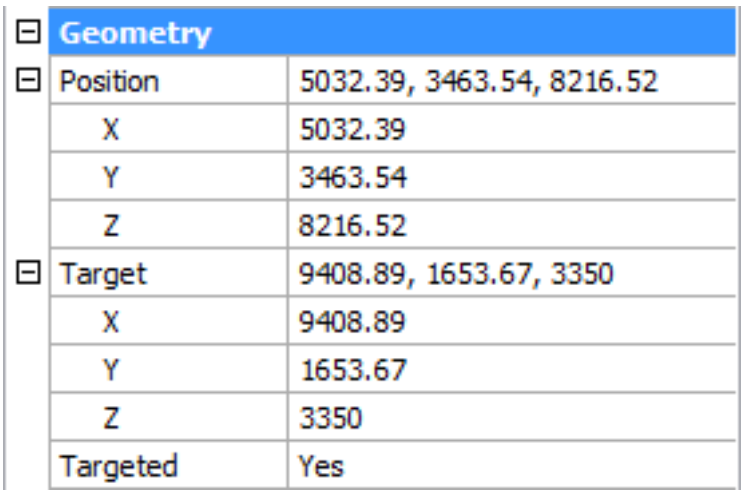


Geometry properties

(1.1368)

- Position: controls the location of the light.
- Target: defines the target point for point lights, spotlights and weblights.
- Targeted: switches the **target** property on/off.

Figure 1.1368



Attenuation properties

(1.1369) In the real world, an object appears darker if it is farther away from the light source. The attenuation properties define how the light diminishes over distance. Attenuation does not apply to photometric lights. An alternative method to control the distance a light shines is the use of limits, which define the points from where a light starts to shine and where it stops. Using limits decreases the time needed to calculate the illumination of a scene. Attenuation properties apply to spot lights and point lights.

- Type: the options are **none**, **inverse linear** and **inverse square**
- None: no attenuation. The distance to the light source has no influence.
- Inverse Linear : the attenuation is the inverse of the linear distance from the light: at a distance of 2 units from the light source, light is half as strong; at a distance of 4 units, light is one quarter as strong.
- Inverse Square: the attenuation is the inverse of the square of the distance from the light: at a distance of 2 units, light is one quarter as strong; at a distance of 4 units, light is one sixteenth as strong.
- Use Limits: if this property is set to Yes, the **Start limit offset** and **End limit offset** fields become active.
- Start limit offset: defines the point where the light starts to shine, measured from the center of the light.
- End limit offset: defines the point where the light stops to shine, measured from the center of the light.

(1.1380 on page 1529) No attenuation	(1.1381 on page 1529) Inverse linear attenuation	(1.1382 on page 1529) Inverse square attenuation

The **Attenuation** properties apply to generic lights only (LIGHTINGUNITS = 0). Inverse square attenuation is applied automatically for photometric lights (LIGHTINGUNITS = 1 or 2).

Figure 1.1369

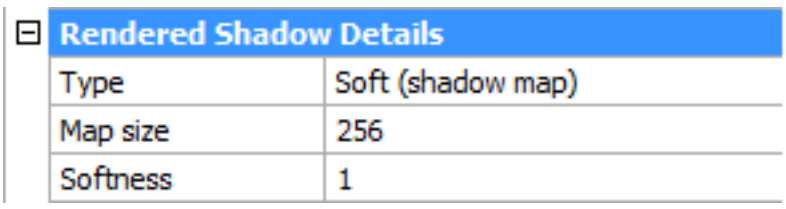
Attenuation	
Type	Inverse Linear
Use limits	Yes
Start limit offset	0 mm
End limit offset	20000.0 mm

Rendered shadow details

(1.1370)

- Type: Sets the shadow type.
- Sharp (raytraced): generates sharp edged shadows.
- Soft (shadow map): generates realistic shadows with soft edges.
- Soft (sampled): Not supported yet
- Map size : specifies the amount of memory for shadow calculation. Click the field, then select a value in the drop-down list (64/128/256/512/1024/2048/4096).
- Softness : sets the softness of the shadow map. Enter a value between 1 and 10.

Figure 1.1370



Spotlight hotspot and falloff properties

(1.1371) When a surface is illuminated by a spotlight, there is an area of maximum illumination (hotspot = 1) that is surrounded by an area of lesser intensity (falloff = 2). (1.1372 on the facing page)

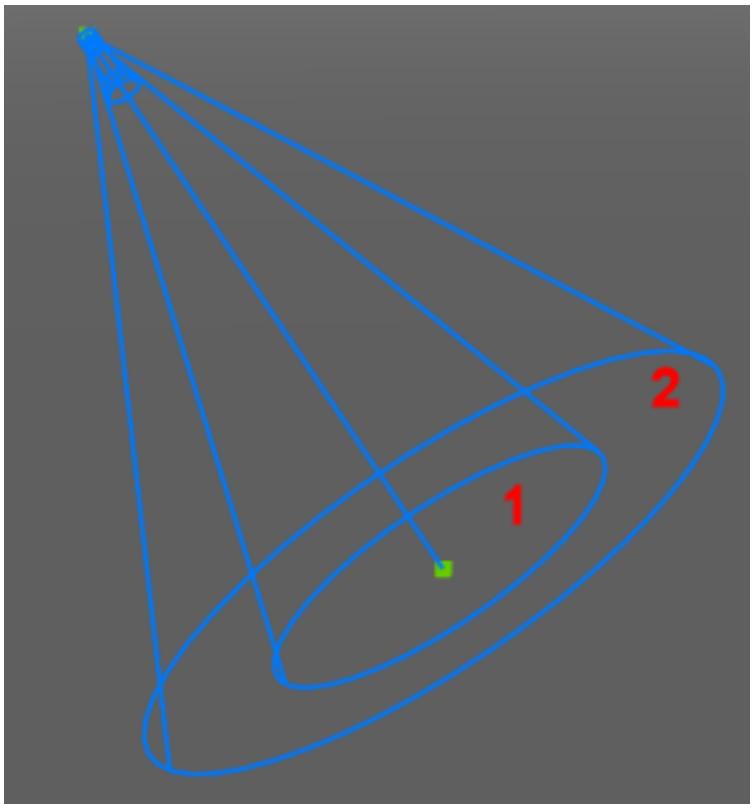
- Hotspot angle: angle of the central light cone (defines the hotspot)
- Falloff angle: angle of the full light cone

(1.1383 on page 1530) Hotspot angle = 55, Falloff angle = 60	(1.1384 on page 1530) Hotspot angle = 30, Falloff angle = 60

The difference between the hotspot angle and the falloff angle defines the area of lesser light intensity. If the falloff angle and the hotspot angle are almost equal the edge of light cone is rather sharp (left). The greater the difference between both angles, the softer the edge of the light cone (right).

Figure 1.1371

Figure 1.1372



To open the light list in the Drawing Explorer

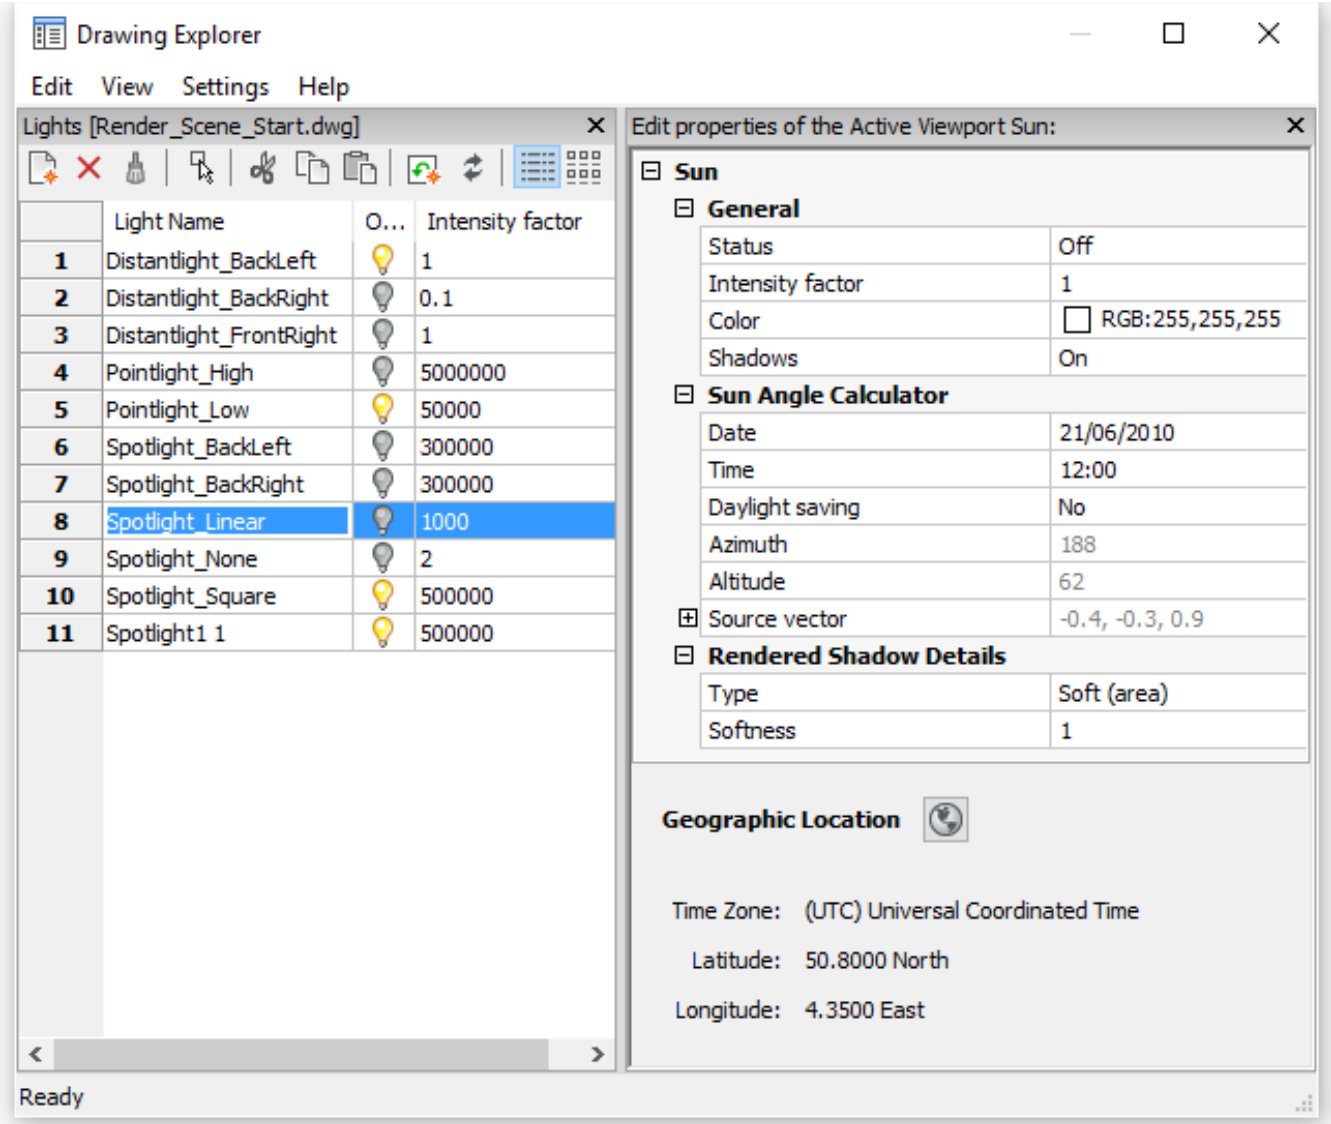
Do one of the following:

- Click the **Light List...** button ( ) on the **Lights** toolbar.
- Choose **Drawing Explorer > Lights** in the **Tools** menu.
- Choose **Light List..** in the **View | Rendering | Lights** menu.
- Type **lightlist** or **LL** in the command bar, then press Enter.

(1.1373 on the next page)

Icon	Tool name	Description
	New light	Closes the **Drawing Explorer - Lights** dialog, then guides you to the creation of a new light in the drawing.
	Delete light	Deletes the selected light.
	Select in drawing	Closes the **Drawing Explorer - Lights** dialog and selects the light's glyph in the drawing. The properties of the light display in the **Properties Bar**.
	Light ON	Click to switch light off.
	Light OFF	Click to switch light on.

Figure 1.1373



To define a light

1. Do one of the following:
   - Type **light** in the command bar, then press Enter. **You are prompted:** Enter light type [Point/Spot/Web/Distant] <Point>: A prompt menu displays: (1.1374) Choose a light type in the prompt menu.
   - Click the tool button of the light type you want to create on the **Lights** toolbar:
     - New spot light
     - New point light
     - New distant light
     - New web light
2. Do one of the following:
   - Specify the source position in the drawing.
   - Type the coordinates of the source position in the command bar and press Enter.
   - Press Enter to accept the default coordinates.

   You are prompted: Specify target position <0,0,-10>:
3. Do one of the following:
   - Specify the target position in the drawing.
   - Type the coordinates of the target position in the command bar and press Enter.
   - Press Enter to accept the default coordinates.

   You are prompted: Enter an option to change: Name/Intensity factor/Status/Photometry/Hotspot/Falloff/Shadow/Atte
   A prompt menu displays: (1.1375 on page 1525)

Figure 1.1374

4. Do one of the following:

   - Select **Name** in the prompt box.
   - Type **N** in the command bar and press Enter.

   You are prompted: Enter light name <Spotlight1>:

5. Do one of the following:

   - Type a name in the command bar and press Enter.
   - Press Enter to accept the default name.

   You are prompted: Enter an option to change: Name/Intensity factor/Status/Photometry/Hotspot/Falloff/Shadow/Atte

6. Do one of the following:

   - Click a light property in the prompt menu.
   - Type the capitalized letter of a light property in the command bar and press Enter.

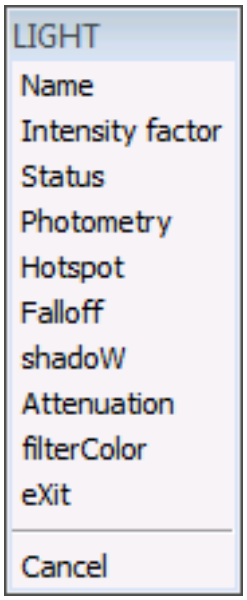
   You are prompted to define the selected property in the command bar.

7. Do one of the following to conclude the creation of the light:

   - Choose Exit in the prompt menu.
   - Press Enter.

NOTE	It is not possible to define a web light if the **LIGHTINGUNITS** system variable is zero (No lighting units).

Figure 1.1375



To edit a light

1. Select the light in the drawing. If the Properties bar is not open yet, double click the light. The properties of the selected light display in the Properties Bar:

(1.1385 on page 1531)	(1.1386 on page 1532)
Generic light properties	Photometric light properties

2. To edit a property:
   - Expand the settings group if needed.
   - Select the property
   - Edit the selected property.

To define the sun properties

1. Do one of the following:
   - Click the **Sun Properties...** tool button ( ) on the **Render** toolbar.
   - Type **sunproperties** or **sun** in the command bar, then press Enter.

   The **Drawing Explorer - Lights** dialog displays, showing the sun properties in the **Editor** pane.
2. To edit a property:
   - Expand the settings group if needed.
   - Select the property
   - Edit the selected property.

NOTE	When **LIGHTINGUNITS** = 1 or 2, the **Color** property of the sun cannot be edited.

To define the geographic location

1. Do one of the following:
   - Click the **Geographic location...** tool button ( ) on the **Render** toolbar.
   - Click the **Geographic location...** tool button ( ) on **Editor** pane of the **Drawing Explorer - Lights** dialog.
   - Type **geographiclocation** or **geo** in the command bar, then press Enter.

   The **Geographic Location** dialog displays: (1.1376 on the following page)
2. (option) Check the **Store geographic location information in drawing** option.
3. (option) Check the **Use Map Grid coordinate system** option.

1.34.7 The Rendering Tools

Icon	Tool Name	Keyboard	Description
	Render (6.26.21)	render	Photorealistic rendering using materials and lights
	Hide (6.16.9)	hide	Hidden line view (*). If the previous shademode option was 2Dwireframe, wireframe representation is restored if you zoom or pan. If the previous shademode option was other than2Dwireframe, the hidden line representation is kept until a different shade mode is chosen.
	Shade (6.27.30)	shade	Shades the entities between the polygon faces. Curved surfaces are segmented.
	2D Wireframe (6.27.31)	shademode + 2	Wireframe representation
	3D Wireframe (6.27.31)	shademode + 3	Wireframe representation
	Hidden (6.27.31)	shademode + H	Hidden line view (*)
	Flat (6.27.31)	shademode + F	Shades the entities between the polygon faces. Curved surfaces are segmented
	Gouraud (6.27.31)	shademode + G	Shades the entities between the polygon faces. Curved surfaces are smoother and more realistic
	Flat + Edges (6.27.31)	shademode + L	Combines flat shading and wireframe lines and curves
===ERROR WITH DOWNLOADED IMAGE===	Gouraud + Edges (6.27.31)	shademode + O	Combines gouraud shading and wireframe lines and curves
	Materials (6.21.10)	materials	Opens the Drawing Explorer - Materials
	Material Map (6.21.9)	materialmap	Allows to adjust how a texture image is mapped to faces of a 3D solid and filled entities such as 3D faces, wide polylines and polygon meshes.
	Light List (6.20.36)	lightlist	Opens the Drawing Explorer - Lights
	Sun Properties (6.27.70)	sunproperties	Opens the sun properties editor
	Geographic Location (6.15.15)	geographiclocation	Opens the Geographic Location dialog.
	Animation Path (6.4.13)	anipath	Records the animation of a camera moving along a path or panning in a 3D model and saves it to a movie file.

Figure 1.1387

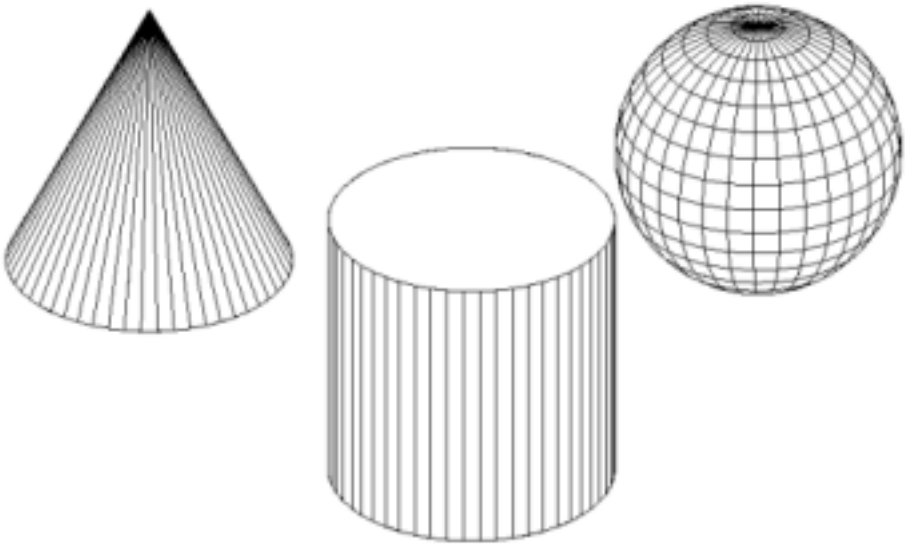

Figure 1.1388

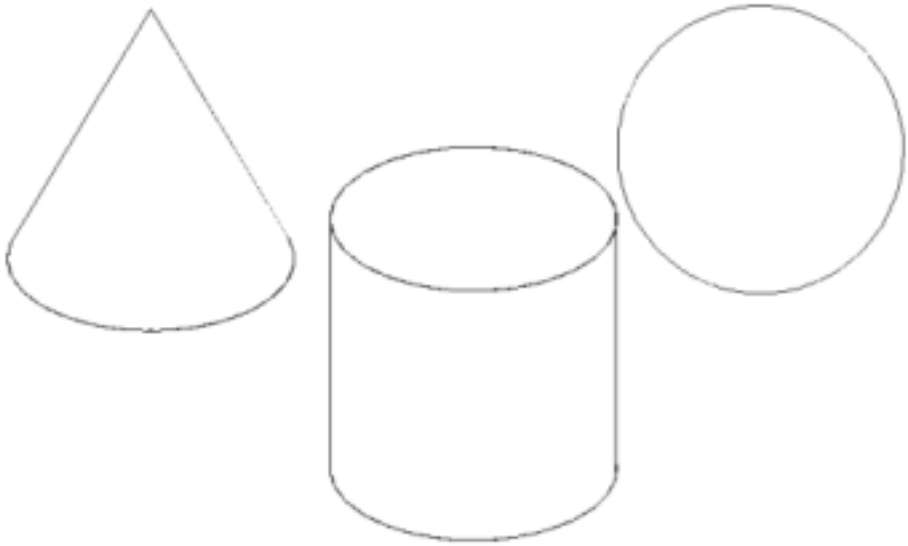


(*) Set the DISPSILH (1.17.10) system variable On to display silhouette lines instead of a polygon mesh for curved surfaces.

(1.1387) (1.1388)
Hidden line of a cone, a cylinder and a sphere with DISPSILH Off (left) and On (right).

1.34.8 Creating a Rendered Image of a Model

The rendered image displays in the current viewport, in a separate window or can be exported to a file. The background of a rendered view can be controlled by the Background (6.6.3) property of the current named view (1.23.10). The ANTIALIASRENDER (1.17.10) system variable controls the amount of anti-aliasing (edge smoothing) applied during the rendering generation. The default value is 1, maximum value is 5.

NOTES

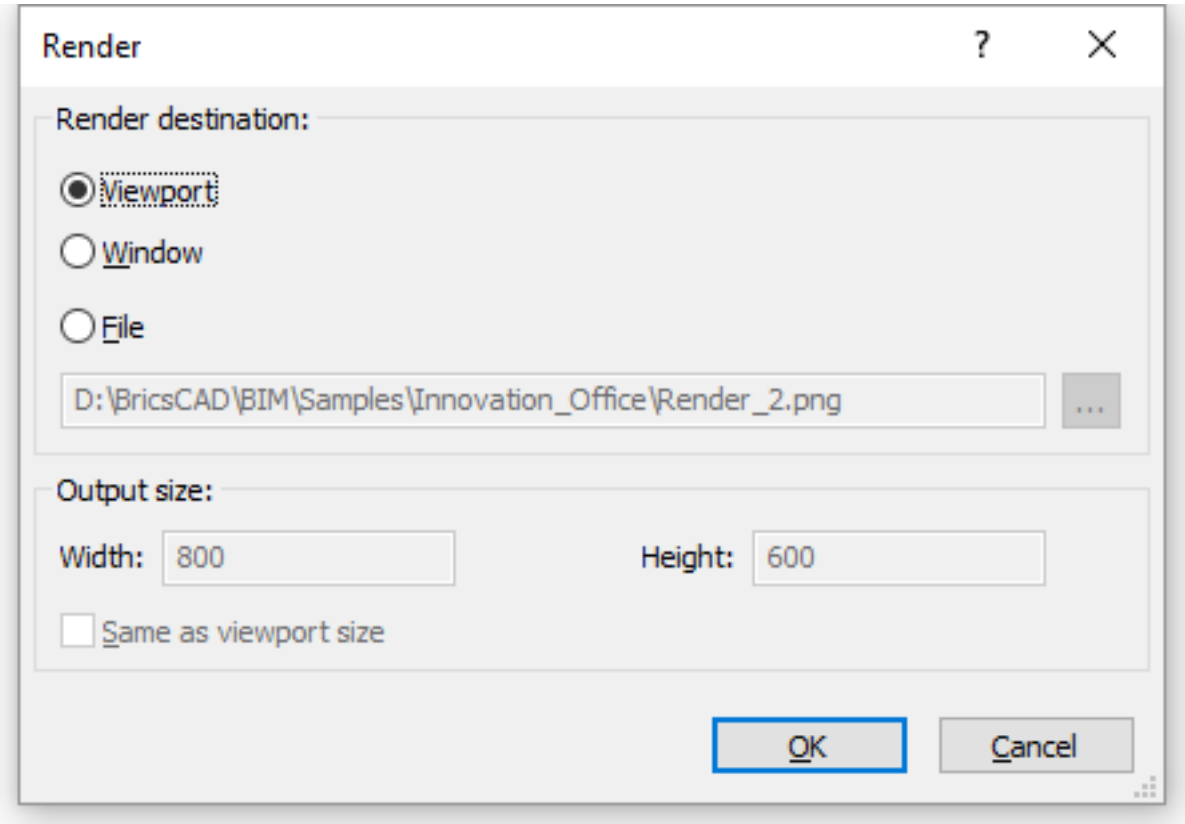
- The values of the lighting system variables (1.17.10) influence the rendering result.
- High anti-alias values incur a high calculation cost.

To render a viewport

1. Do one of the following
   - Click the **Render tool button** () on the Rendering toolbar.
   - Type **Render** in the command bar, then press Enter.

   The Render dialog displays: (1.1389 on the following page)
2. Click the **Viewport option**.
3. Click the **OK** button. The view is rendered.

Figure 1.1389



To render in a window

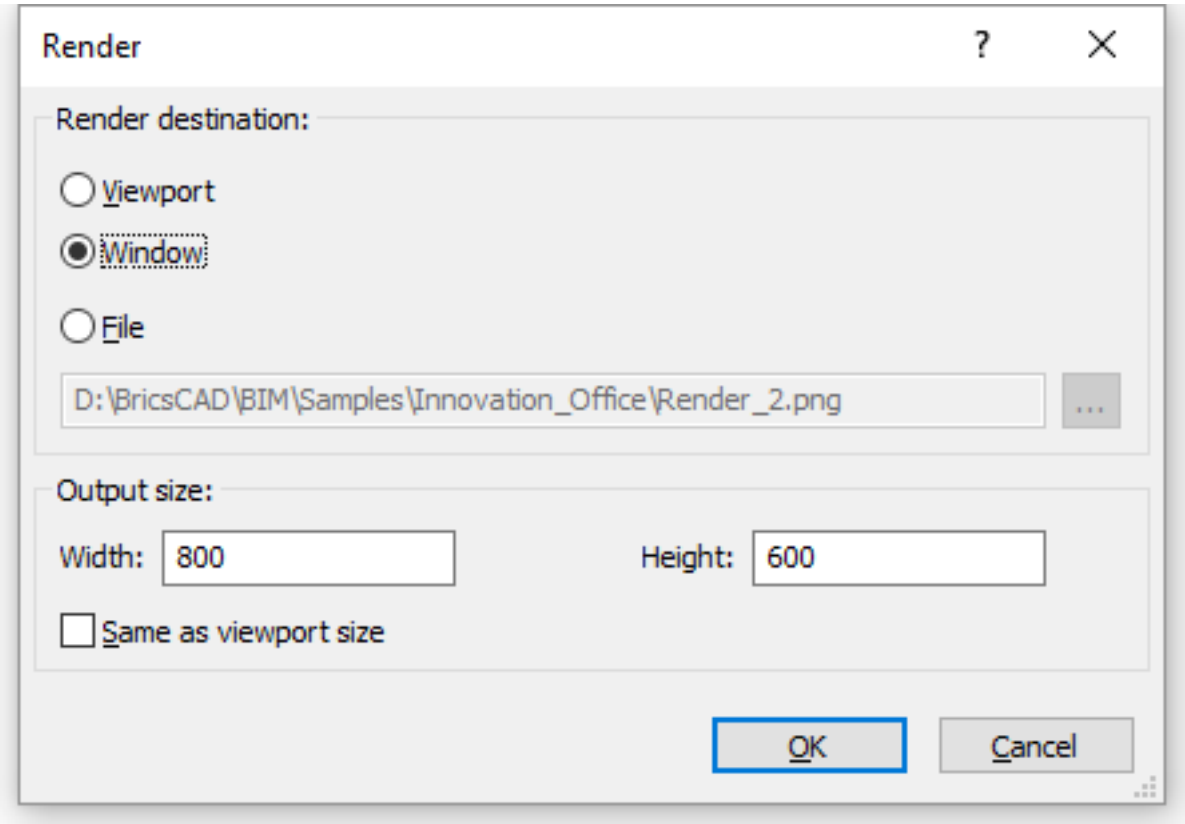
1. Do one of the following

   - Click the **Render tool button** ( ) on the Rendering toolbar.
   - Type **Render** in the command bar, then press Enter.

   The Render dialog displays: (1.1390 on the next page)

2. Click the **Window option**.
3. Click the **OK** button. The view is rendered in a popup window.

Figure 1.1390



To save a rendering to a file

1. Do one of the following

   - Click the **Render tool button** ( ) on the Rendering toolbar.
   - Type **Render** in the command bar, then press Enter.

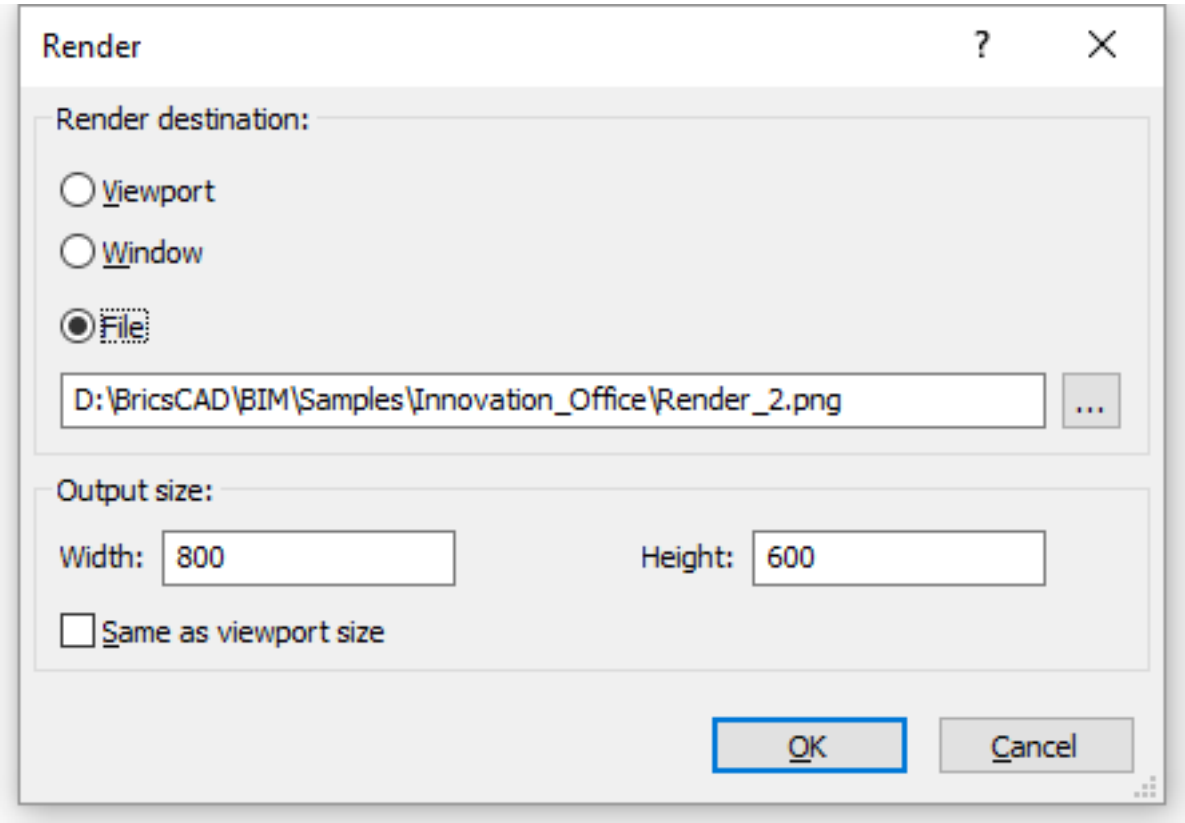
   The Render dialog displays. (1.1391 on the following page)

2. Click the **File option**.
3. Click the **Browse button** ( ), at the right hand side of the File field. The Render output file dialog displays.
4. Select a folder and type a name for the output file in the File Name field.
5. Click the Save as type button to select the file type. The options are: bmp, jpg and png.
6. Do one of the following:

   - Type the desired resolution for the output size in the Width and Height fields.
   - Check theSame as viewport size option to set the outsize to the size of the current viewport.

7. Click the **OK** button to create the file.

Figure 1.1391



1.35 User feedback

1.35.1 Diagnostics and Usage Data Collection

The Diagnostics and Usage Data Collection process allows users to help improve BricsCAD by sending pseudonymized diagnostics and usage data to Bricsys. You can decide at any time to withdraw your consent and have your data removed from our databases. When transferring data:

- A unique, anonymous ID is used.
- The following data and information are removed:
  - All personal project information .
  - All texts and leaders.
  - All information that is stored in the Settings dialog.

When you launch BricsCAD the second time, a dialog box displays asking you to participate. (1.1392 on the next page) When you agree, you are prompted to login with your Bricsys account. (1.1393 on page 1541) If you check the **Remember me option**, you will be signed in automatically each time you launch BricsCAD. The status of your agreement is saved through the **DataCollection** user preference as indicated in the table below.

Value	Status	Result
-2	Not Asked	When you close BricsCAD the value is set to [-1] Not Set.
-1	Not Set	When you restart BricsCAD the **Diagnostics & Usage** dialog displays, asking you to participate.
0	Off	The Diagnostics and Usage Data Collection process is switched Off.
1	On	The Diagnostics and Usage Data Collection process is switched On. Data will be transferred when you are logged in only. To temporarily stop transferring data, choose **Logout...** in the **File** menu or launch the **-LOGOUT** command. To restart transferring data, choose **Login...** in the **File** menu or launch the **-LOGIN** command.

Figure 1.1392

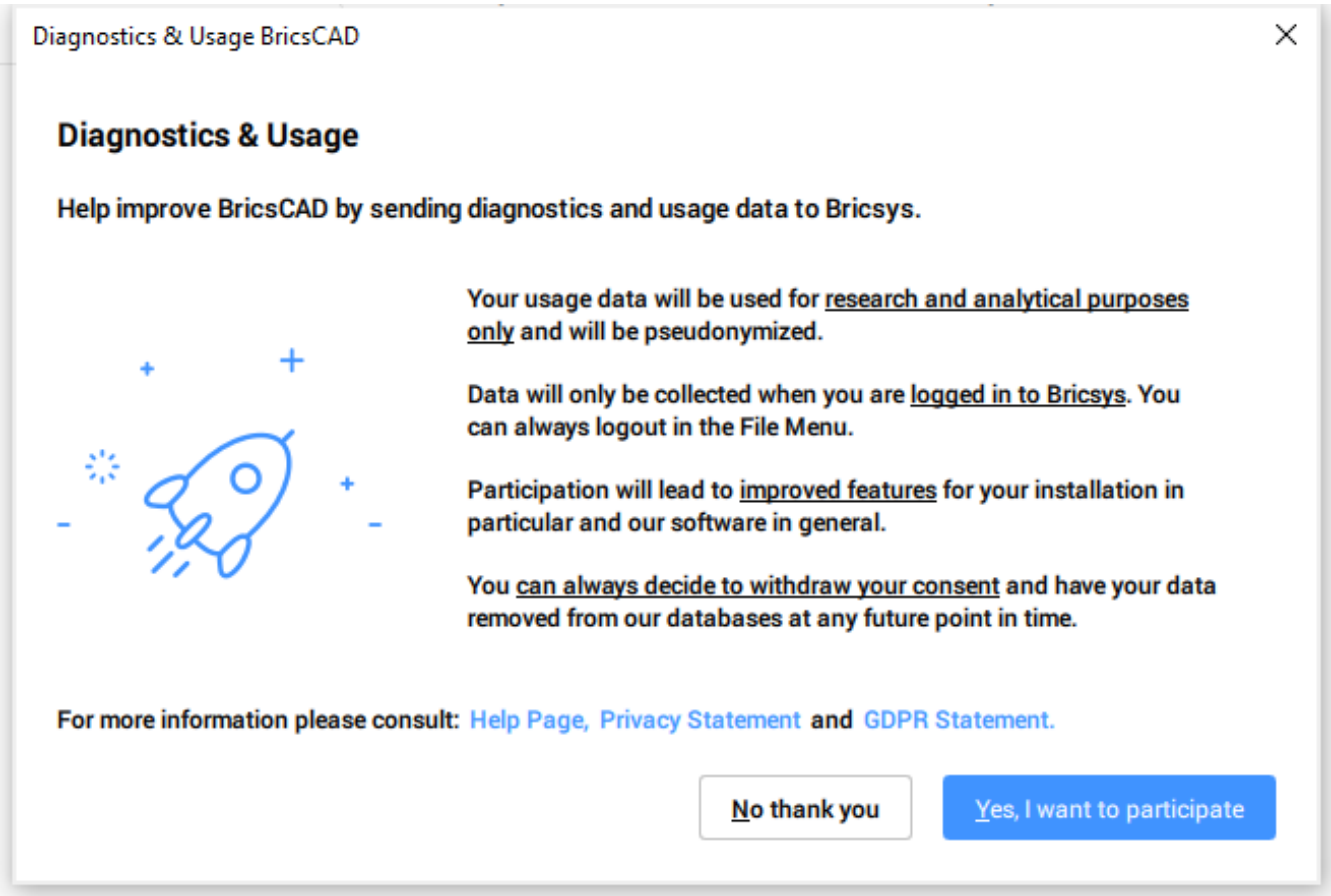


Figure 1.1393

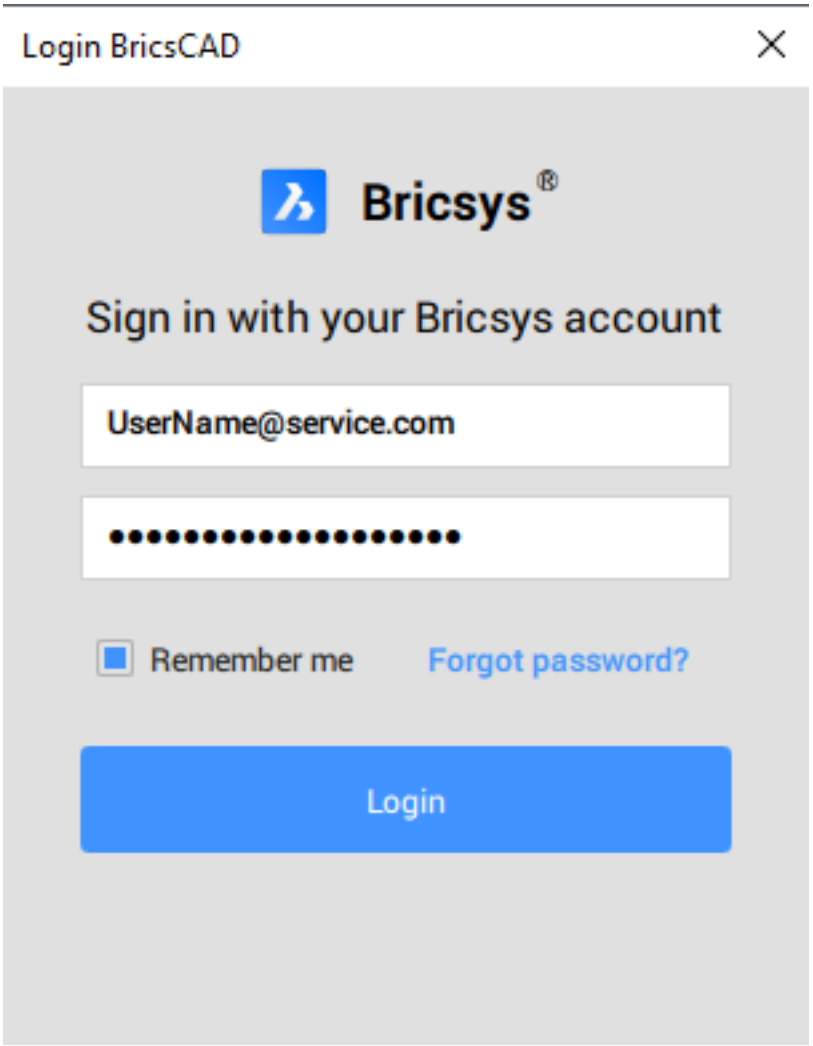


To stop the process

1. In the Settings dialog, under User Preferences, set **DataCollection** to **[0] Off**.
2. Close and restart BricsCAD.

To restart the process

1. In the Settings dialog, under User Preferences, set **DataCollection** to **[-1] Not Set**.
2. Close and restart BricsCAD.
3. Choose **Yes, I want to participate**, then login with your Bricsys account.

Removing your data from the database

To withdraw your consent and have your data removed from our databases send in a support request. Select the **Data Collection** category under **BricsCAD**.

1.36 Programming

1.36.1 Developing in BricsCAD

With BricsCAD, you can run many programs originally created for use with AutoCAD without modification on BricsCAD. BricsCAD supports the AutoCAD dialog control language (DCL). You can use all DCL files unmodified within BricsCAD. To write applications in C or C++, BricsCAD offers BRX, a C/C++ language interface, code-compatible with the AutoCAD Runtime eXtension (ARX) interface in AutoCAD. Available topics:

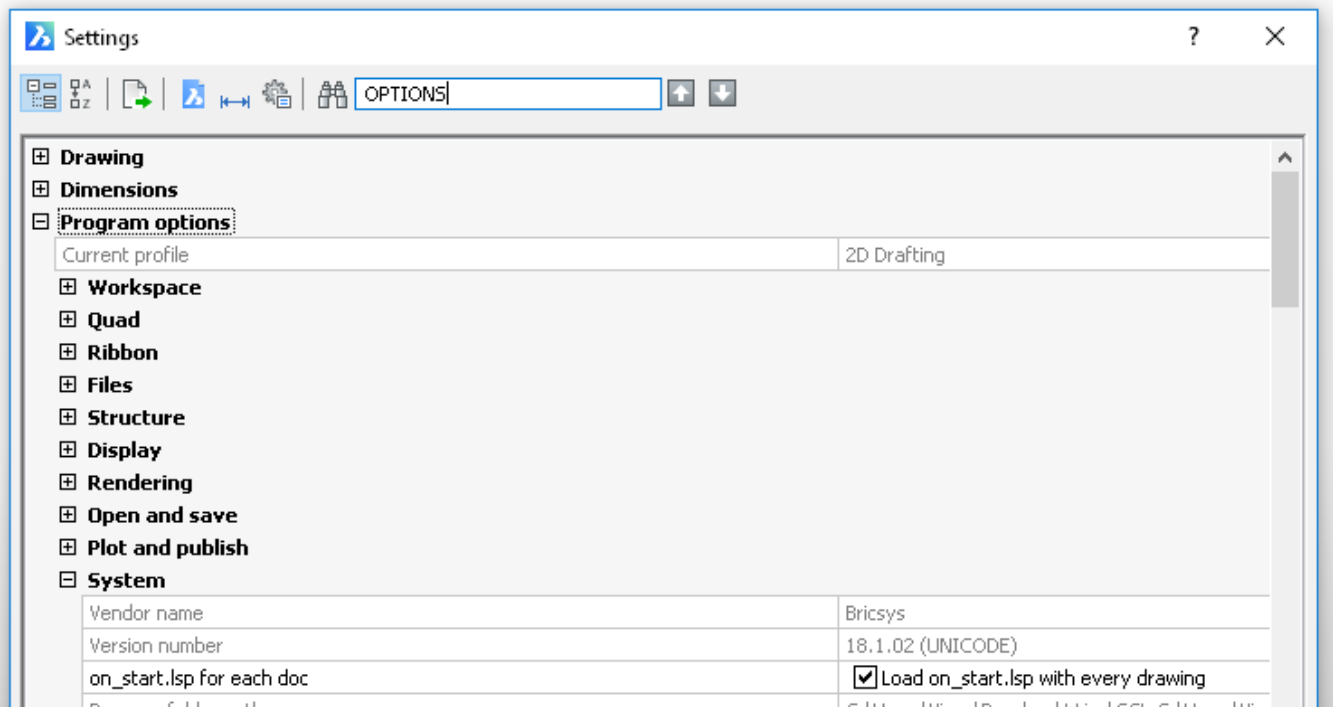
- BricsCAD Solution Build (9.1.1)
- Developer Reference Guide (9.2.1)
  - LISP (LISt Processing)
  - DCL (Dialog Control Language)
  - DIESEL (Direct Interactively Evaluated String Expression Language)
  - COM (Component Object Model)
  - VBA (Visual Basic for Applications)
  - BRX (BricsCAD Runtime eXtension)
  - TX (Teigha eXtension)
  - .NET
- Application Porting Process
  - What are Bricsys LGS components (9.3.1)
  - How to port and add my application? (9.3.2)
  - Supported APIs (9.3.3)
- How to add your application to our catalog (9.4.1)

1.36.2 BricsCAD Lisp – Migrating from AutoCAD

Almost no differences

When you're ready to start migrating, you'll find that there are virtually no differences in BricsCAD LISP versus OtherLISP. Your code loads and runs, and the functionality is identical. The primary differences when "porting" your apps will be a few minor setup steps, command line structure, and possibly file locations. To start, let review the setup and launch of your existing programs in BricsCAD. If you are auto-launching your programs using **Acad.lsp** or **Acaddoc.lsp**, you will simply need to rename and or combine those files into a single file named "**on_start.lsp**". To enable this feature, simply toggle the option in Settings / Program options / System: (1.1394 on the next page)

Figure 1.1394



Enjoy the BricsCAD Settings Panel

I would also recommend that you prepare to spend a little time familiarizing yourself with the Options/Setting menu in BricsCAD. As you dive in, you will find a ton of settings and options you probably wish you had in your "other" CAD environment. Welcome to BricsCAD! The next step in the settings dialog would be to add your support folders to the Files search path, which is found within Settings / Program Options / Files: (1.1395 on the following page) As a rule, I never hard code any paths unless absolutely necessary. The support paths I use will typically be added as in the manner above and/or located one level below the current project folder. Typically, I will use a "findfile" function to validate the file exists before proceeding with my commands, as in the method below:

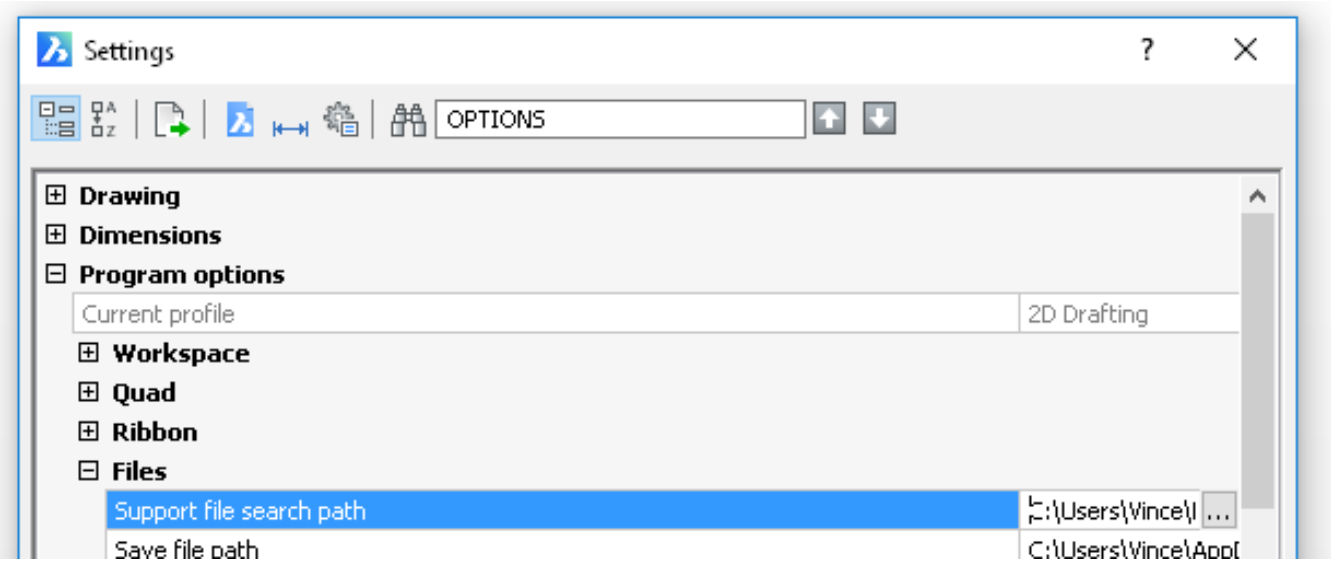
```
(if (findfile "custom-code.lsp") (load "custom-code"))
```

In fact, this is one of the methods I've used to demand-load my functions within the **on_start.lsp** file:

```
(defun c:my-function ()                          ; this defines the command(if (findfile "custom-code.lsp"
```

The command defun (DEfine FUNction) is the same name as the function inside of your **on_start.lsp** file and that function redefines the calling function when it's launched. This is another cool reason for using this method, as it demonstrates how dynamic LISP can be!

Figure 1.1395



Take advantage of your move to BricsCAD

When your engineering workflow is running, you usually build a long list of maintenance items that you keep putting off. Migrating to a new CAD environment offers an opportunity to make some of those updates and update your documentation standards. Almost every client that I've helped to migrate need to address old-style hard-coded paths, 8.3 syntax filenames, old layer naming conventions and other no-nos within their standards. As we move forward in this series, I will share some of the methods I use to store user settings and defaults external to your LISP code, so that they can be updated more easily. Until next time, happy coding!

1.36.3 Drawing Setup Lisp Routines for BricsCAD

This simple drawing setup routine might work for you, with just minimal changes. Here's the code with comments and detailed notes in the comments below:

```
(defun c:mysetup ()                    ;define the command line function "mysetup" (command "audit" "y")
```

How does this drawing setup routine work?

First, you'll see that each individual line in this drawing setup routine could have been typed in at the command line in BricsCAD – and you probably do that today. By wrapping them into a Lisp routine, the **defun** (**define function**) makes the drawing setup routine "callable" from a menu or by typing its name on the BricsCAD command line.

- If we don't include the **defun**, the program will run once, when you load it by its file name. Using the **defun**, and loading this routine within your **lsp** will make the function available at any time by typing its function name: **mysetup**.

Next, look at the **command** strings themselves. The commands with the preceding dashes (e.g. **-layer** and **-purge**) are used to prevent the command's dialog boxes from launching. As a first step when opening files from others, I usually execute an **audit**followed by a **purge** to remove any unused items. In the case of the **purge** command, I often run it multiple times to remove nested items. Here's a bit of added Lisp logic that can make that three-peat happen:

```
(repeat 3 (command "-purge" "all" "*" "n"))
```

Notice that **purge** is done before adding the new, empty layers… as they would be removed if we did it after! The **command** calls for setting layers could be combined into a single command statement, but I think that it's easier to read when each line stands alone. **Filedia** is a global setting (a.k.a. "system variable"), so it is not drawing dependent. I add these types of settings to routines like this to ensure that I get the behavior I expect from the new drawing.

Max what? I included the **maxsort** setting for two reasons. First, to show that some settings require a numeric value instead of a text string (notice the missing quotes in **maxsort**'s command line). **Maxsort** controls the maximum number of dialog box entries that will be sorted. The second reason is that the "factory default" for **maxsort** is 1,000. With today's computers and often found larger project files, that number can be too low. If you open drawings where the layer names won't sort into alphabetical order, the default **maxsort** value could be the reason! Additional **setvar** "calls" include style settings for dimensions and text, unit settings, etc…

A more versatile Layer Maker for your drawing setup routine I'll leave you for now with the following example, which could be added to your version of mysetup.lsp. By creating a simple text file with an editor like Notepad, we can add a list of layer names to be created when the routine is run. This is an alternative to the hard-coded process shown above. By using the **findfile** function, BricsCAD will first search the current directory, then sequentially through your defined support folders to find the layers.txt file. This being known, you can place your default layer setup text file in the support path and place alternative versions of the in individual project folders. This way, you can support multiple layer layouts easily.

```
  (if (not (findfile "Layers.txt"))    ;"not" = looking for no result from findfile (alert "Can't find La
```

1.37 Moving from AutoCAD

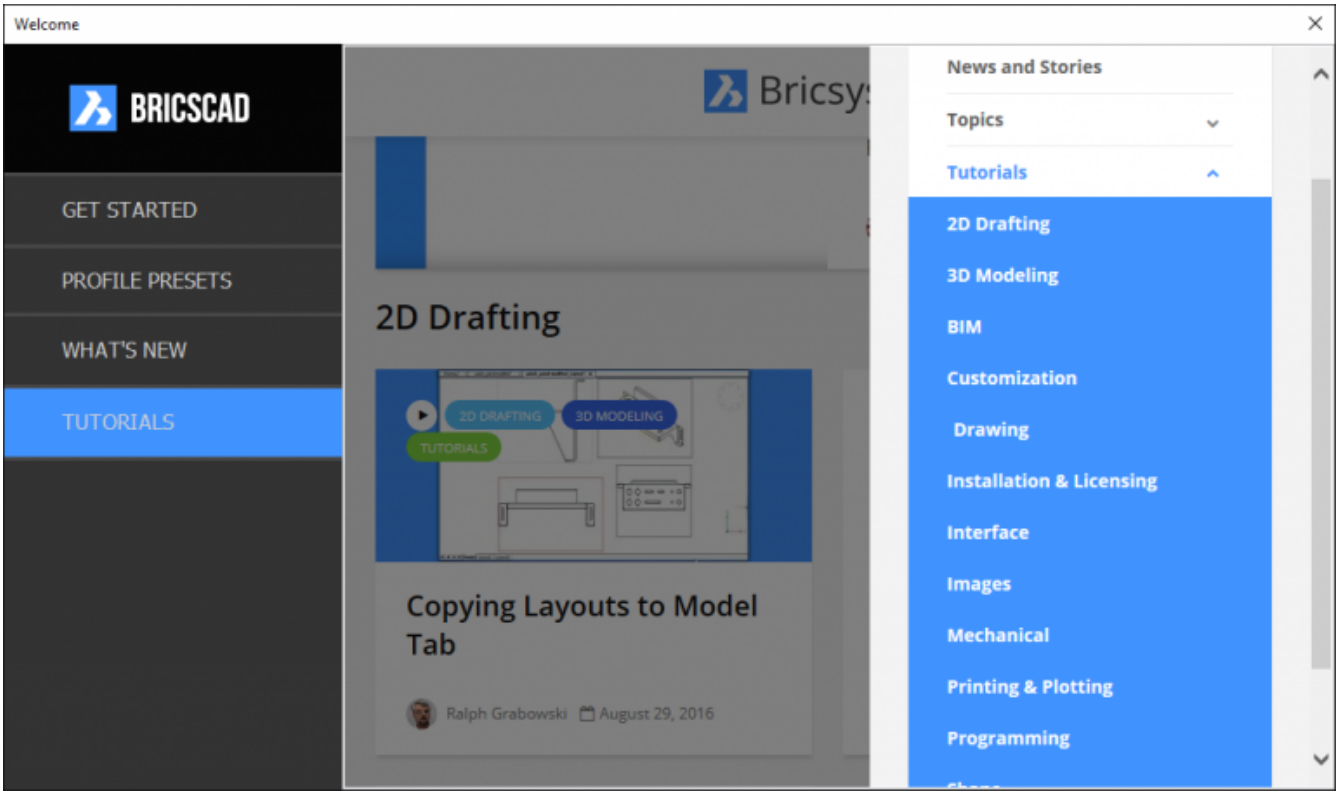
1.37.1 BricsCAD Welcome Window

The first thing you'll notice when you launch BricsCAD, after installing, is the Welcome window. Initially the Welcome window has only 3 tabs: Profile Presets, What's New, and Tutorials. A fourth tab, Get Started, is added based on your profile selections. I'll introduce you to these tabs from the bottom up.

Welcome – Tutorials

The Tutorials tab is what you would expect from the title and more! It's a great resource whether you're completely new to BricsCAD or a veteran user trying to advance your skills. Scrolling through the Tutorials list you can select from a variety of categories including 2D drafting and Programming as well as industry-specific topics for BIM, mechanical and sheet metal design. Link to instructional blog posts in addition to more than 100 videos. The Tutorials tab also provides easy access to the Bricsys website and other relevant topics and news. (1.1396 on the next page)

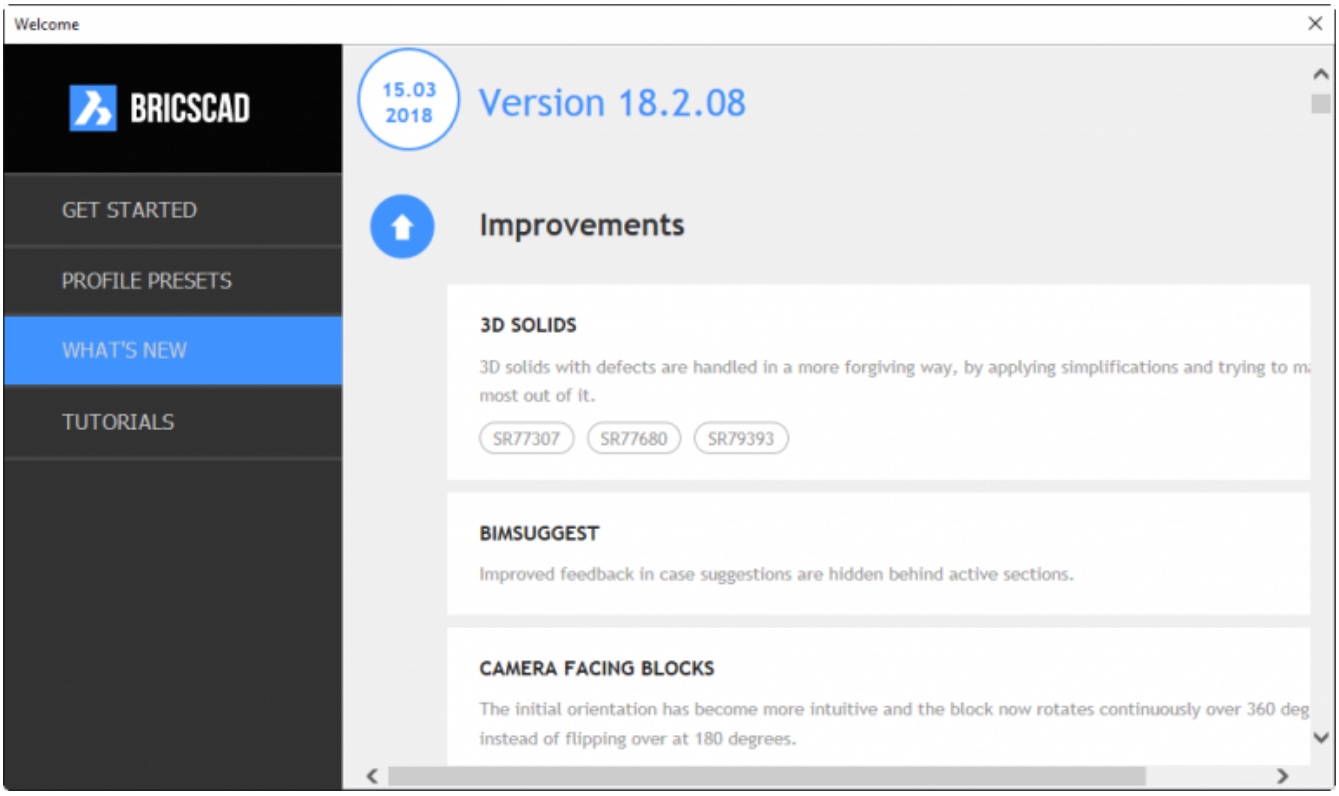
Figure 1.1396



Welcome – What's New

The What's New tab offers important information about software fixes and improvements. (1.1397 on the following page)

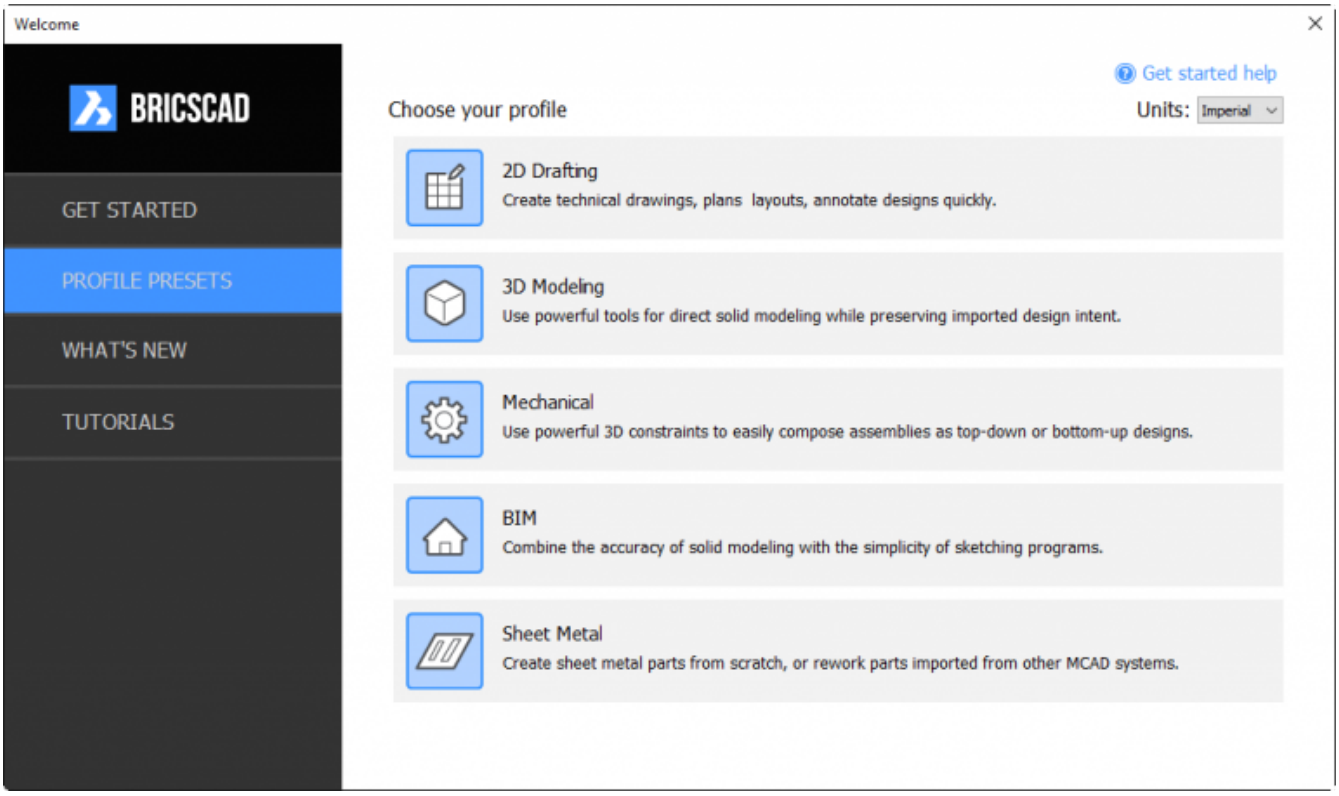
Figure 1.1397



Welcome – Profile Presets

If you're like me, you greatly value Tutorials and Important stuff. But, when launching a new CAD application for the first time, you want to jump in and give it a try! This is where the Profile Presets tab comes in. The BricsCAD trial includes 5 preset profiles. First select the profile (2D drafting, 3D Modeling, Mechanical, BIM, or Sheet Metal) and the units (Imperial or Metric) you want to use. Then enter a name for the profile or accept the default profile name. Each time you select a Profile Preset, it's added to the Get Started tab. (1.1398 on the next page)

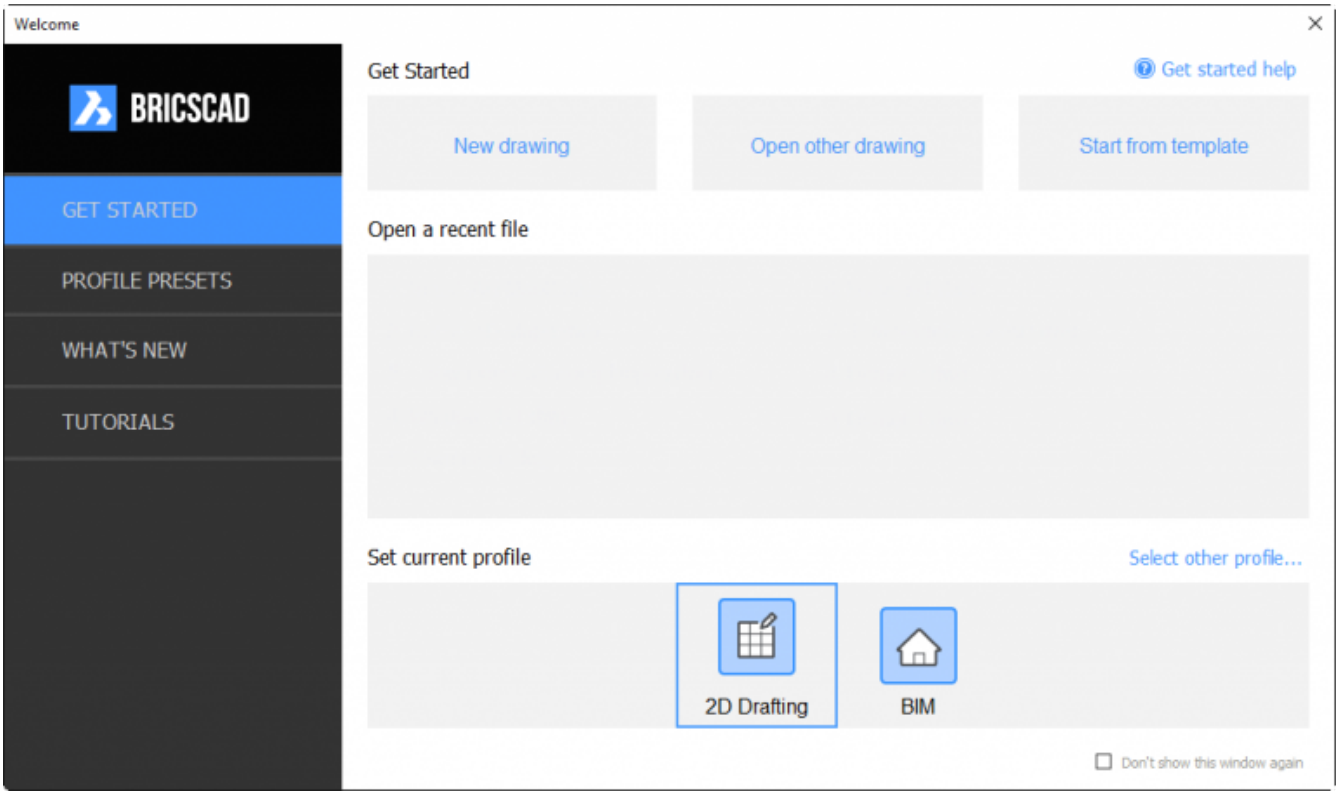
Figure 1.1398



Welcome – Get Started

The Get Started tab is just that! It's where you launch into BricsCAD to start your design. First, at the bottom of the tab, set your current profile. Then, at the top of the tab, select one of the options to create or open a drawing. You can always change the profile, later, within BricsCAD. The Get Started tab is simply specifying which profile is used when it launches. (1.1399 on the following page)

Figure 1.1399



Coming from AutoCAD®

If you're moving to BricsCAD as a former AutoCAD user, you may prefer to skip the Welcome window in the future and simply launch BricsCAD like AutoCAD does by default. No Problem. Here's how!

1. From the Profile Presets tab, choose 2D Drafting and choose **OK**.
2. From the Get Started tab, set 2D Drafting as the current profile.
3. Select the option in the lower right corner to turn off the Welcome window.
4. Select **New drawing**.

When you launch BricsCAD in the future, you go straight into the application using the default drawing template and with the 2D Drafting workspace active. Later, if you change your mind and want to restore the Welcome window, simply set the GETSTARTED system variable to On and relaunch BricsCAD. (1.1400 on the next page)

Font Awesome icons

Font Awesome is a variety of scalable vector icons that can instantly be customized — size, color, shadow, and other changes that can be done with the power of CSS. You can use any of 650+ icons free of charge anywhere in your Help Center (layout, articles, etc.). They are already included in all our themes. Find all Font Awesome icons and their codes on this page.

Font Awesome inside the text It is rather easy to insert a Font Awesome icon to any text of your Help Center . Font Awesome is completely free for commercial use . The icons are vector, which means they're gorgeous on high-resolution displays . It is very easy to make your own design by changing icons' color, size, shadow, and anything that's possible with CSS .

Font Awesome titles Additionally, you can use any icons from Font Awesome library to make your titles more eye-catching.

Title with a motorcycle

Title with a calculator

Title with binoculars

Title with a heartbeat

And not only your titles: Tomorrow we will run faster, stretch out our arms further... And then one fine morning So we beat on, boats against the current, borne back ceaselessly into the past.

Animate them!

And mix them: fa-twitter and fa-square-o fa-flag and fa-circle fa-terminal and fa-square

Chapter 2

BricsCAD BIM

2.1 What's new in BricsCAD V21 BIM

2.1.1 Overview

BricsCAD V21 offers a plethora of new and improved tools to help maximize your productivity. This section gives an overview of all the new features and improvements in **BricsCAD V21 BIM** : Modeling Techniques (2.1.2) Building Data (2.1.3) Project Collaboration (2.1.4) Design Documentation (2.1.5) Point clouds (2.1.6) For information about the new features and improvements in **BricsCAD V21 Core and Civil tools**, go to the What's new in BricsCAD V21 section. It contains the following articles: Overview (1.1.1) User interface (1.1.2) Productivity (1.1.3) Drafting (1.1.4) Modeling (1.1.5) Civil Tools (1.1.6) Performance and compatibility (1.1.7) For information about the new features and improvements in **BricsCAD V21 Mechanical tools**, go to the What's new in BricsCAD V21 Mechanical section. It contains the following articles: Overview (3.1.1) BOM Manager (3.1.2) Parts Libraries (3.1.3) Parameters and Constraints (3.1.5) Standard parts (3.1.4) Sheet Metal (3.1.6)

Release notes

Click here for an overview of the release notes.

Diagnostics and Usage Data Collection

Many of the improvements were inspired by requests and suggestions from you, BricsCAD users. At Bricsys, we continue to expand our methods of gathering user feedback with new data collection tools. When you launch BricsCAD for the second time, a dialog box displays, inviting you to participate in the Diagnostics and Usage Data Collection program (1.35.1). The data collection process enables you to share anonymous diagnostic and usage data with Bricsys to help improve BricsCAD. You can withdraw your consent and have your data removed from our databases at any time.

2.1.2 Modeling Techniques

BIM Profiles

BIMAPPLYPROFILE / BIMLINEARSOLID The composition material of a profile is now attached to the created solid in the **BIMAPPLYPROFILE** and **BIMLINEARSOLID** commands. (2.1 on the facing page) **BIMPROFILES** When changing the Offset property of a **CustomShape** profile via the Profiles dialog, you can choose whether to keep the position of the solid or its axis, for linear solids using said profile. (2.2 on the next page) **BIMPROFILESTANDARDS** The **BIMPROFILESTANDARDS** setting is no longer case sensitive. In case there are no profiles matching the value of the **BIMPROFILESTANDARDS** setting, a warning message displays.

Figure 2.1

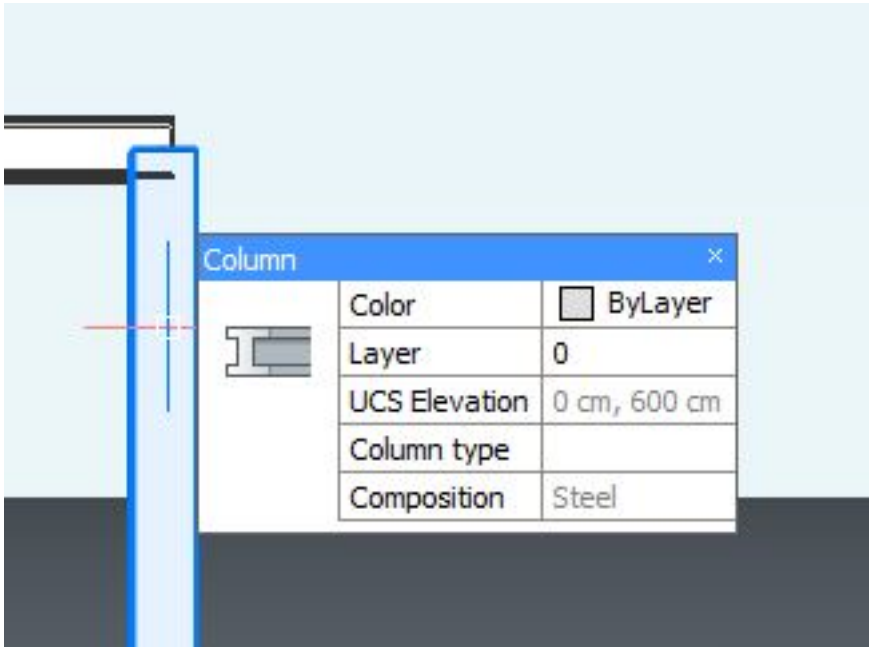

Figure 2.2

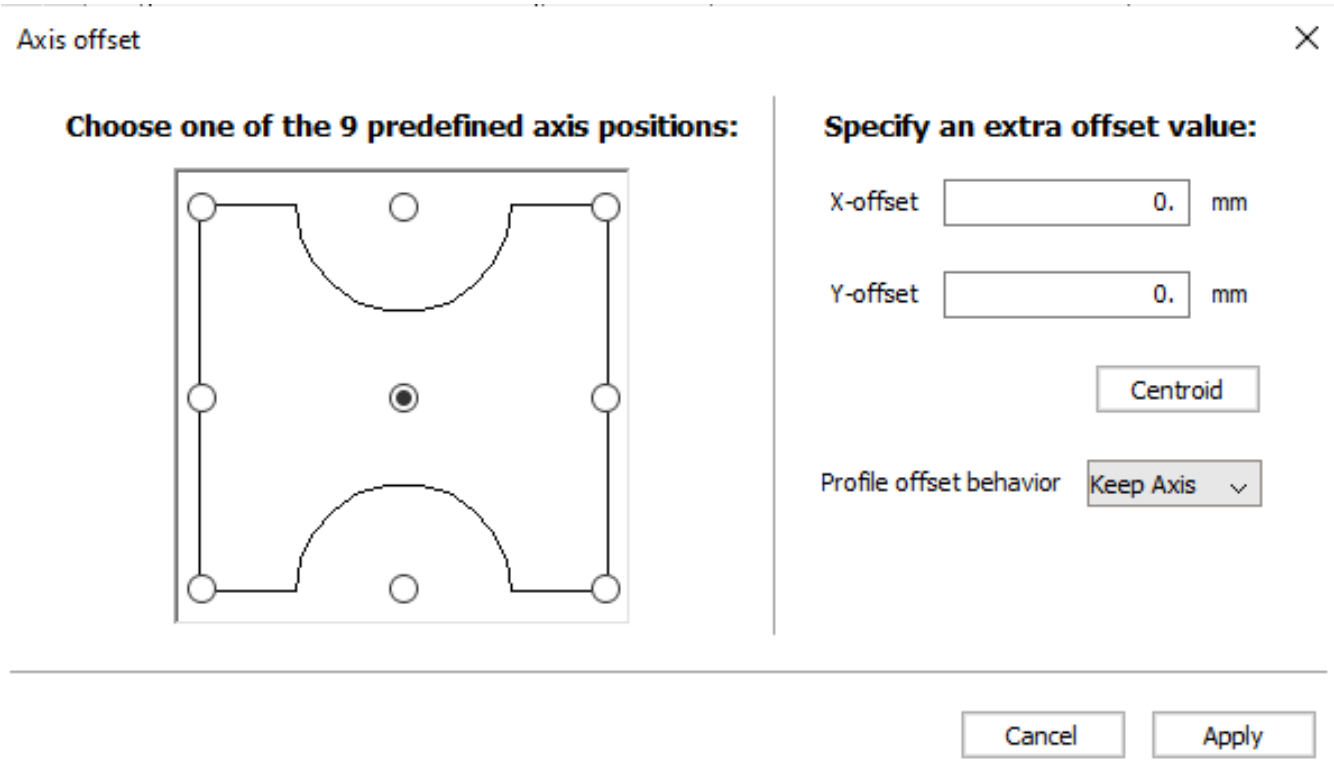


Mass Modeling tools

The first prototype of the new **BIMQUICKBUILDING** command has been implemented. The QuickBuilding tool allows you to generate a BIM building just from one massing solid. It automatically generates different levels, walls, spatial locations, etc. It can be very useful in early design stages, volume studies and conceptual design. The tool will assign BIM properties to each part of the new building. Spatial Locations can now be used as input for **BIMQUICKBUILDING**. This workflow allows you to process different buildings simultaneously. The command also works on solids without edges, for example, a sphere or a torus.

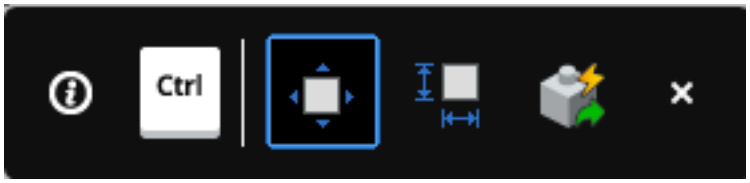
(2.5 on page 1574) Solids
(2.6 on page 1575) Building
(2.7 on page 1575)

Insert BIM Component

The **BMINSERT** command now includes a SMART insert option, which automatically adjusts parts to match current and relevant parts in the model file when inserted. You can select SMART insert by clicking the option in the command line, or toggle CTRL to the rightmost icon when prompted in the HotKey Assistant. (2.3) By detecting and creating 3D constraints between the relevant connection points, SMART insert resizes and attaches your desired component onto the current component/s with assembly constraints and common parameters to form a bigger part of a parametric assembly. This is particularly useful in modelling parametric MEP piping systems.

(2.8 on page 1576)
(2.9 on page 1576)
(2.10 on page 1577)
(2.11 on page 1577)

Figure 2.3



Disconnect

The **LCONNECT** and **BIMSTRUCTURALCONNECT** commands now include a fourth option: **DISCONNECTED**. You can cycle through the options with the CTRL button in the HotKey Assistant.

(2.12 on page 1578) (2.13 on page 1578)
(2.14 on page 1579) (2.15 on page 1580)

Quickdraw

The Quickdraw cursor now supports snapping to (double) lines inside XREFs. Walls now inherit the spatial location of the slab on which they are created.

Standards Parts

Piping parts were added to the standard parts category of the Library panel. (2.4 on the following page)

Figure 2.4

2.1.3 Building Data

Analytical Model

This command allows you to generate an analytical model from a full 3D model of a structure. The command starts with an automatically generated proposal, but allows you to further adapt the model to your desire. (2.16 on the next page) The automatic proposal will try to minimize rigid links (eccentricities) as much as possible by shifting, extending and even rotating some axis lines. You can control the amount of such changes by the deviation settings. (2.17 on the following page) After editing the model, you can export it to an IFC.

Figure 2.16

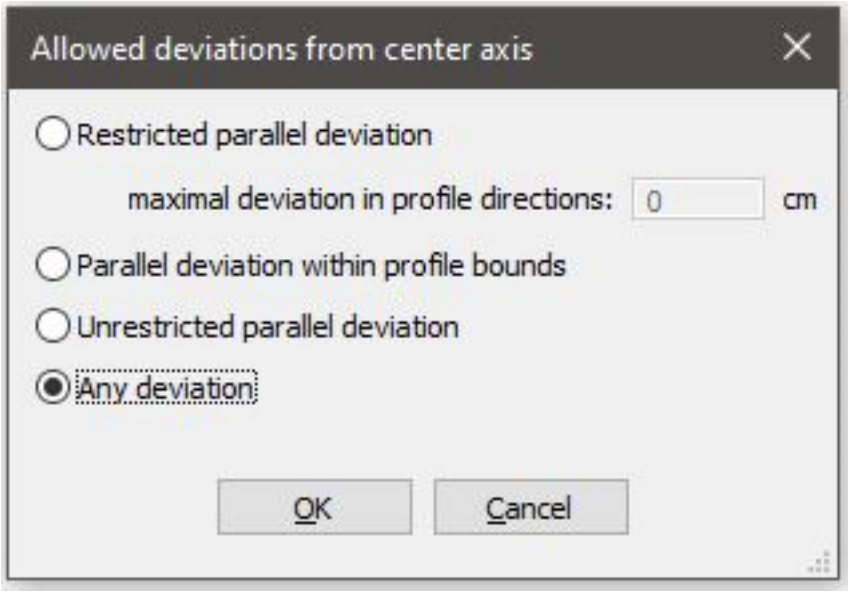

Figure 2.17

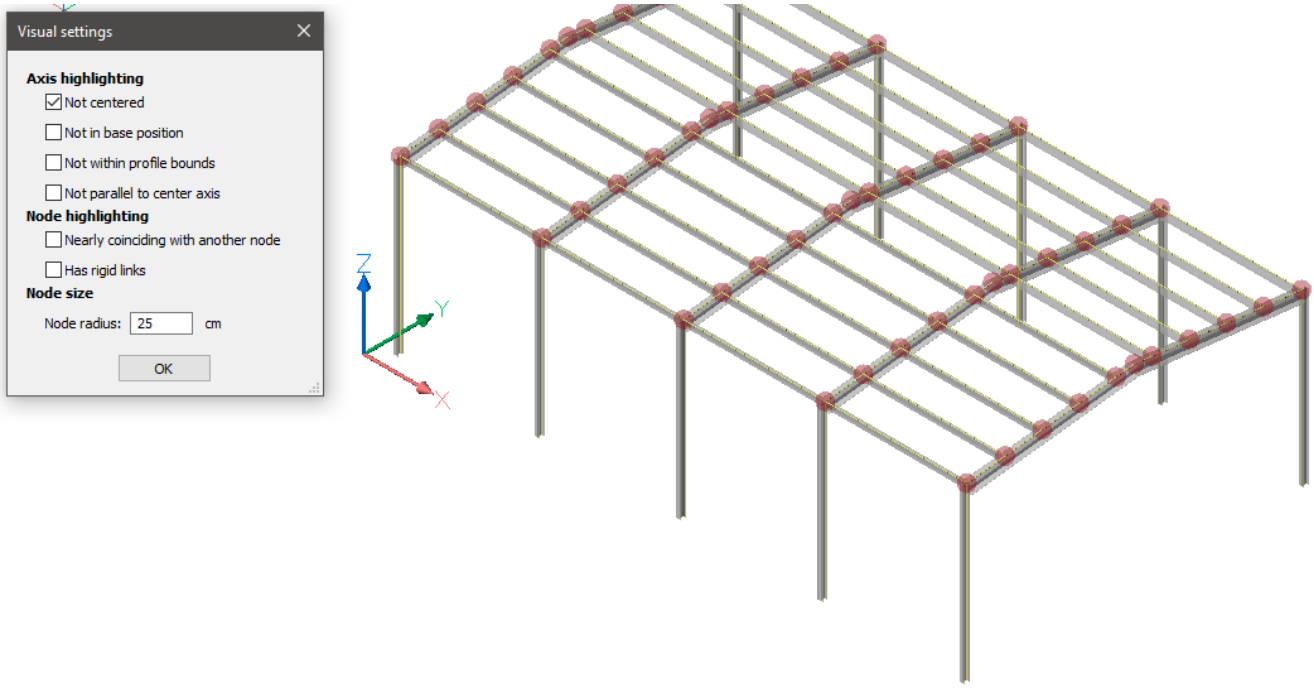

BIM API

Configurable quantities are now available in the BIM API, as well as the BIM API for Spaces.

BIM Compositions

In V21, the render material display and LOD setting have been separated. A new button has been added in the Home/View ribbon panel, next to the LOD button to toggle the rendering composition materials.  LOD settings control whether ply solids are shown or not. If ply solids are not visible and render composition materials is on, only major faces of the multi ply solids will get render materials.

Custom BIM Properties

The **Per Instance** option of a custom property set allows you to enable/disable user-defined properties, on a per-entity basis. The **Enum** option allows you to define a fixed number of possible values for custom BIM properties. (2.18 on the next page)

Spatial Elements

BimRoom The **BIMROOM** command has been replaced by the **BIMSPACE** command. You can still open BIMROOMs created in V20, but it is not possible to create new BIMROOMs or update the geometry of existing BIMROOMs in BricsCAD BIM V21. Use the Space option of the BIMCLASSIFY command to convert a BIM room to a BIM space. Room properties and interior elevations, if any, are transferred to the corresponding Space. **BimSpace** You can create BIM Spaces entities from enclosed boundaries. When the wall elements enclose a space in your model, you can use the **BIMSPACE** tool to define a BIM Space. The space footprint preview now displays when executing the **BIMSPACE** command. These spaces are represented as regular solids so they can be easily manipulated. The **Edit** option of the **BIMSPACE** command allows you to add or remove the bounding elements of a space. (2.19 on the following page) **BimUpdateSpace** Recalculates a BIM space which is out-of-date, for example after adding or removing bounding entities. In the Properties Panel, the Update Method property is added with the options **Automatic** and **Manual**. The new Representation property allows toggling between **Solid** or **Footprint** representation of a space. The Space tag has been added. The Space tag is a block that contains a hatch and attributes. The default attributes of the Space tag include a space name and a space number. You can change the values of each attribute using the Properties Panel. The new Status property indicates whether a space is up-to-date or out-of-date. (2.20 on the next page) **Space icons** BIM Space tool icons for **Edit Space**, **Update Space** and **Define Interior Elevations** are available in the Quad, the Ribbon and the BIM Spaces toolbar. (2.21 on page 1587) **Spatial Structure Elements** When using the command **BIMCLASSIFY**, a new category of classification has been added to the dialog box. The name of the new category is **Spatial Structure Elements**. Under this category you will find **Space, Building** and **Story.** (2.22 on page 1587) **DefaultSpaceHeight** The **ROOMHEIGHT** system variable is replaced by the **DefaultSpaceHeight** user preference, the setting applies to Spaces.

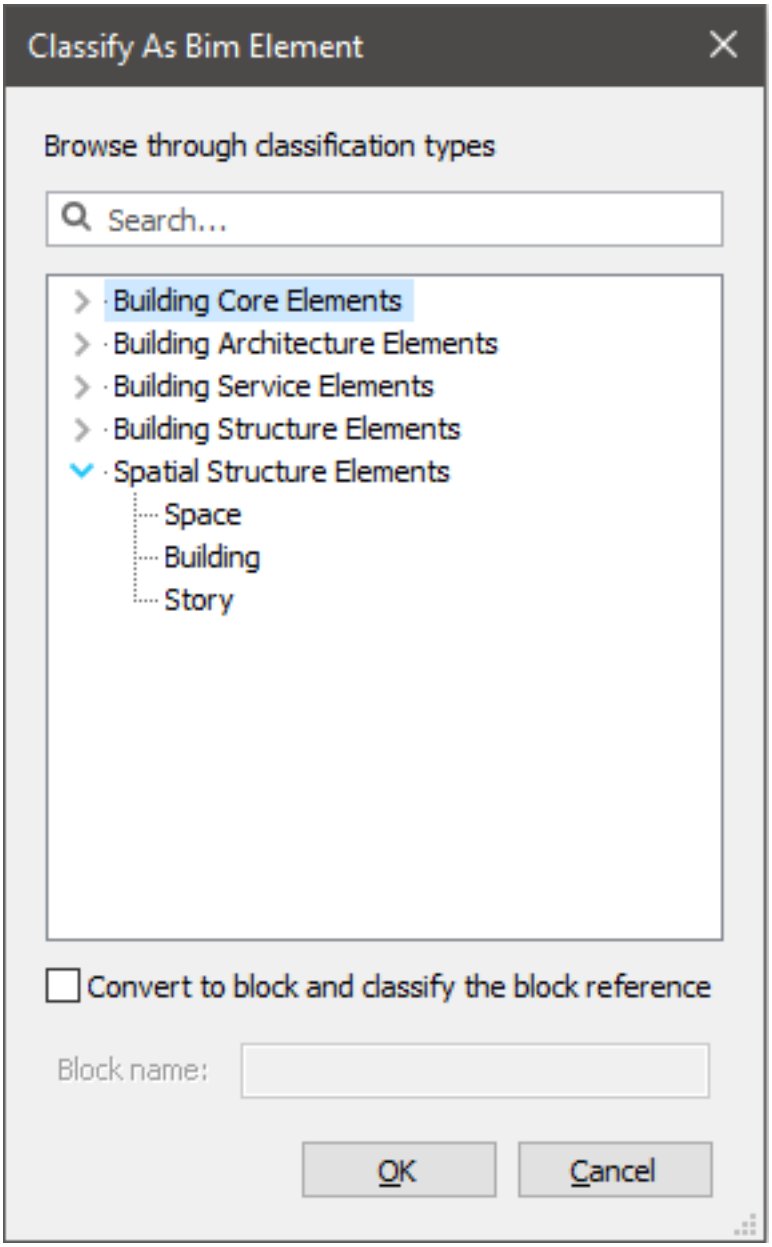
Figure 2.21

Figure 2.22



BIMSETLOADBEARINGDIRECTION

With the new tool button that launches the command **BIMSETLOADBEARINGDIRECTION,** in V21 it is easy to set your loadbearing direction of your slab through the Quad. (2.23 on the facing page) As a result, you will get a black dot on your slab. Once you click on it, you can change the load-bearing direction of the slab in one of the two main directions of the slab or in both. (2.24 on the next page) (2.25 on page 1590)

Figure 2.23

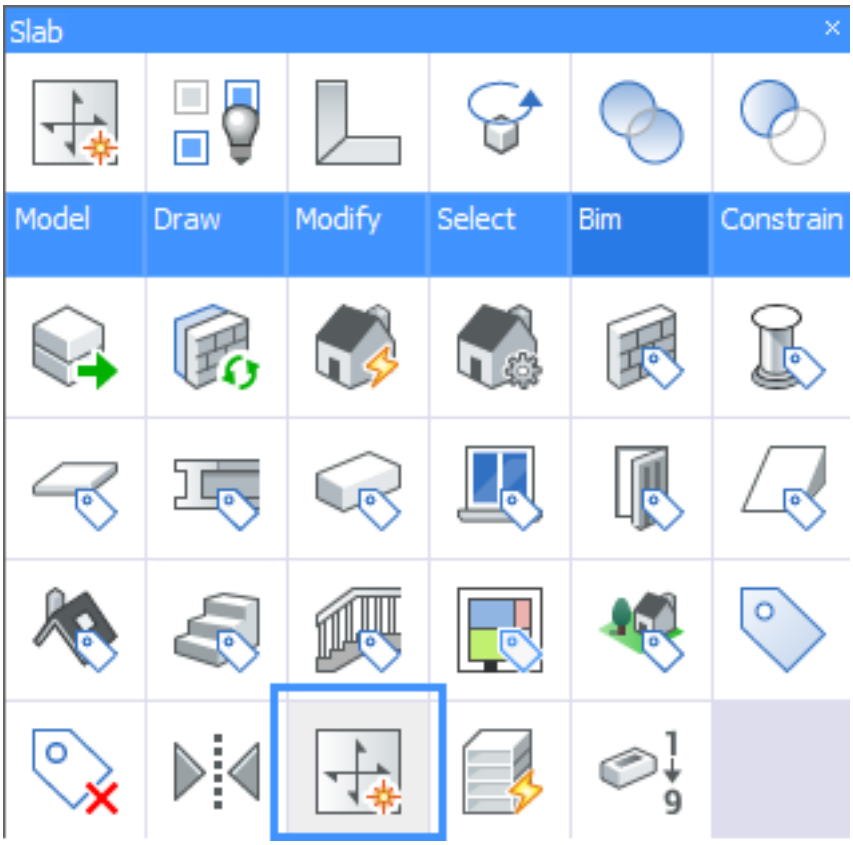


Figure 2.24

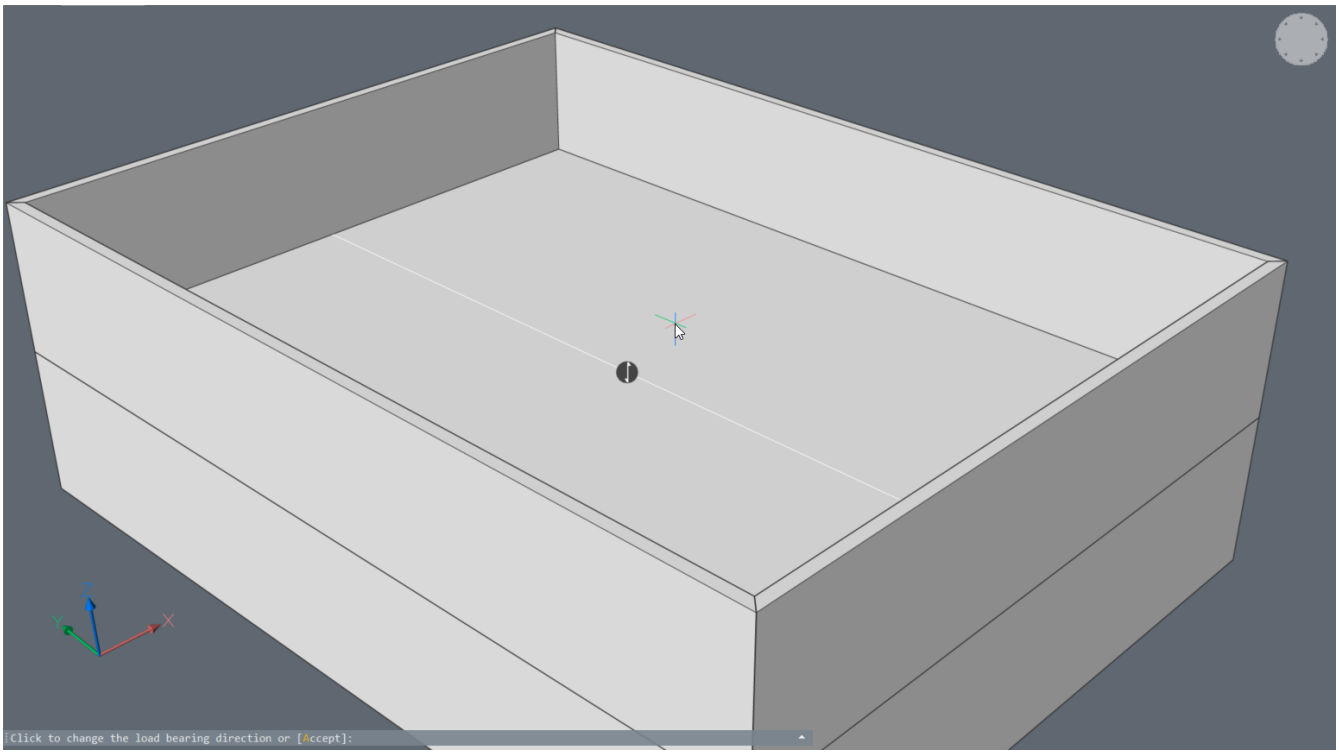

Figure 2.25

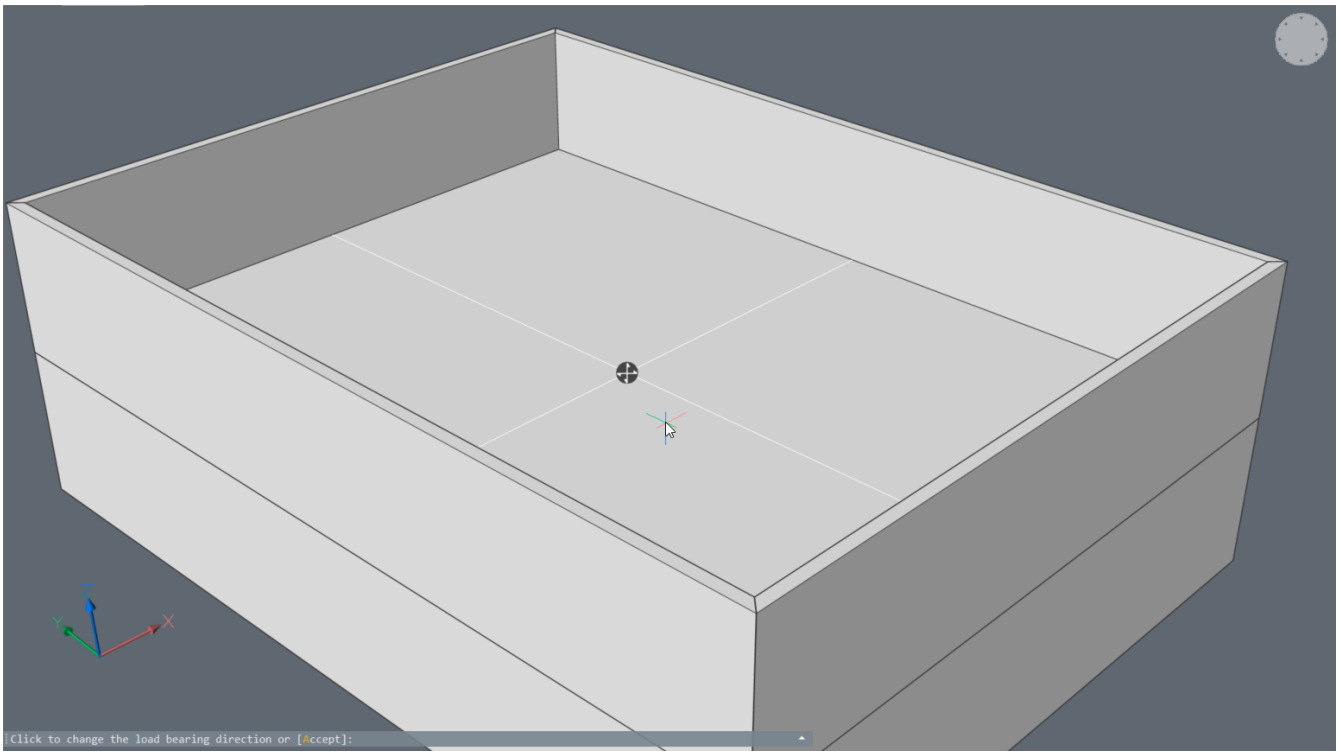

Python scripts in BricsCAD BIM

Note: This is a V21 Beta feature. The new **BIMPYTHON** command enables you to query and manage data from a model within BricsCAD BIM, with a .py python script. The python scripts can be as simple as obtaining quantities and associated properties of objects and BIM entities, or as elaborate as implementing a series of calculations based on the model parameters available. Executing BIMPYTHON opens a Windows dialog box where you can navigate and run your python script in .py format. The new BIMACTIVATEPYTHON command allows you to activate and deactivate the virtual python environment in BricsCAD BIM, by toggling the values 0 and 1 for **OFF** and **ON** respectively. You need to ensure it is turned **ON** before using BIMPYTHON. The Python Programming Language, together with its standard libraries, is embedded in BricsCAD BIM so there is no need for you to install them separately, unless you have custom packages and libraries which you wish to use in your scripts.

Project Browser

BIM project data are now stored in an external project **.bsyslib**, instead of the previously used **.projectroot**. When opening a pre-V21 BIM project, you can convert the **.projectroot** to a V21 project **.bsyslib**. To simplify the opening of a BIM project at a new location, paths to **.bsyslib** files are now stored with a relative path. **Sheets** It is now possible to create a layout from scratch in the Sheetset setup dialog box. (2.26) The Project Browser displays the Sheet Number (if it exists). The Sheet Number is assigned by the **Create Sheets** procedure. Sheet View Numbers are assigned starting from 1 for all section results created by the BIMSECTIONUPDATE command. (2.27 on the following page)
Models Master drawings and external references are listed in a tree-structured manner in the Models tab of the Project Browser: (2.28 on the next page) A balloon is available to fix a project libraries' connection to a drawing sheet. **Schedules** The **Add Schedule** wizard, available in a context menu, allows you to quickly add a BIM schedule without the creation of a new .dxd file. The use of relative paths is now supported for Schedules. (2.29 on the following page) The **Create/Update Table** and **Create/Update CSV** options are available in a context menu for creating or updating a schedule or a CSV output file. (2.30 on page 1593)

2.1.4 Project Collaboration

IFC IMPORT/EXPORT

A mechanism has been implemented to map **IFC/BIM** entities to **BIM/IFC** entities, to control which entities are imported/exported. BricsCAD BIM also added IFC Export of Annotation entities. You can do this mapping by using mapping files. The **IfcImportMappingMath** and **IfcExportMappingPath** user preferences set the paths to the necessary mapping files. These files are simple text files containing some rules. This mapping can be used to export BIM entities as IFC entities of another type, or to skip certain types altogether. An example of such an export file can be: BimDbColumn IfcMember BimDbBeam IfcMember BimDbFurnishingElement skip In this example, columns and beams in the BricsCAD BIM model will be exported as Members in the IFC file, and furnishing elements will be skipped in the export process. A similar process can be used when importing IFC files. An example of such an import file can be: IfcWall BimDbSlab IfcSlab BimDbWall * skip In this case, walls will be imported as slabs and slabs will be imported as walls. No other entities will be imported, as the asterisk means that only listed entity types will be taken into account, all unlisted entity types will be skipped. The **IfcCreateUniqueGuid** user preference has been added to enable/disable the creation of unique GUIDs for nested elements inside classified blocks and Xrefs. The flow connection point is exported to IFC as **IfcBuildingElementProxy.** Only 2D geometry or a block reference with 2D geometry can be classified as a flow connection point.

Importing RVT files

When importing Revit Objects using **IMPORT,** you can choose for Import all the solids or only import as an Overlay. You can filter the import based on Revit Views, Categories, Levels or WorkSets. (2.31 on the facing page) This is an example for the option **Categories** where you can map specific categories for your RVT import. Colors and transparencies are now imported when importing a RVT file. (2.32 on page 1596)

2.1.5 Design Documentation

Sections

Activate SectionView This new command allows you to look at the model from a section plane's perspective, without generating the section. This view allows you to manipulate the 3D model from a 2D point of view. To exit the active view, just orbit around the model. **Open BimSections** When switching to the model from a sheet view using the **BIMSECTIONOPEN** command, the model is rotated and zoomed in to the same zoom level as the sheet view. Available properties and property values display in the filter parameters form. The **BIMSECTIONOPEN** command now allows you to transition between the sheet viewport and drawing model seamlessly at the same zoom level, without the need to reorientate yourself and the model to where you have been working earlier on the sheet. When you switch between a sheet viewport to the drawing model using the updated **BIMSECTIONOPEN** command, the drawing model displays and orientates itself to the same zoom level as in the sheet viewport, regardless of the scale of the Standard Scale or Annotation Scale of the drawing or viewport. **Update BimSections** The associative data for 3D solids, needed for section generation and tagging of the section results by the **BIMTAG** command, are generated automatically in BricsCAD BIM V21 as you model, unless the new **GENERATEASSOCATTRS** (Generate Associative Attributes) system variable is set to **Off**. **Interior Elevations** Since Rooms in V20 and older are now deprecated and replaced by Spaces, the Interior option of the **BIMSECTION** command now supports Spaces.

Tags

The BIM Tags tool now includes options of tagging load-bearing directions and spot elevations on viewports on Paper Space. Both tag types work on plan and section drawings. Spot elevation tags also work on elevation drawings. (2.33) Automatically generated tags can have an offset, which is defined through the Offset attribute in TagTypeToStyle.xml found in SUPPORTFOLDER – Bim – Sections folder. If the offset is not specified, the center of the tag block will be used. Similarly, automatic and manually placed tags can be rotated if the autoRotation attribute is set **true** in TagTypeToStyle.xml. **Tag Load-bearing** Load-bearing tags is only applicable if the load-bearing direction of the slab has already been set. Refer to BIMSETLOADBEARINGDIRECTION (6.7.50) for more information. **Tag Spot-elevation** The spot elevation level tag displays the actual elevation of a selected point of a BIM object in a section view. The height is measured relative to level 0. **Tags in general** On Paper Space, click **Tag Load-bearing** from the ribbon and pick point on a sectioned BIM element as prompted. You will be prompted to pick a point on your desired sectioned BIM element or to change the current mleader style settings, like how you set BIMTAG in V20. For example, you can have a two-way load-bearing span graphic tag on structural drawing plans. (2.34 on the next page) Or you can have spot elevations displaying elevation levels relative to the WCS. (2.35 on the following page) Like all other BIM Tags, they are customizable multileader blocks. Therefore, for example, Spot Elevation tags can be further adjusted to suit your graphic and information preferences.

Figure 2.33

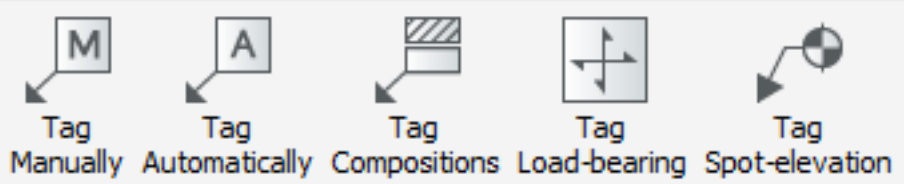

Figure 2.34

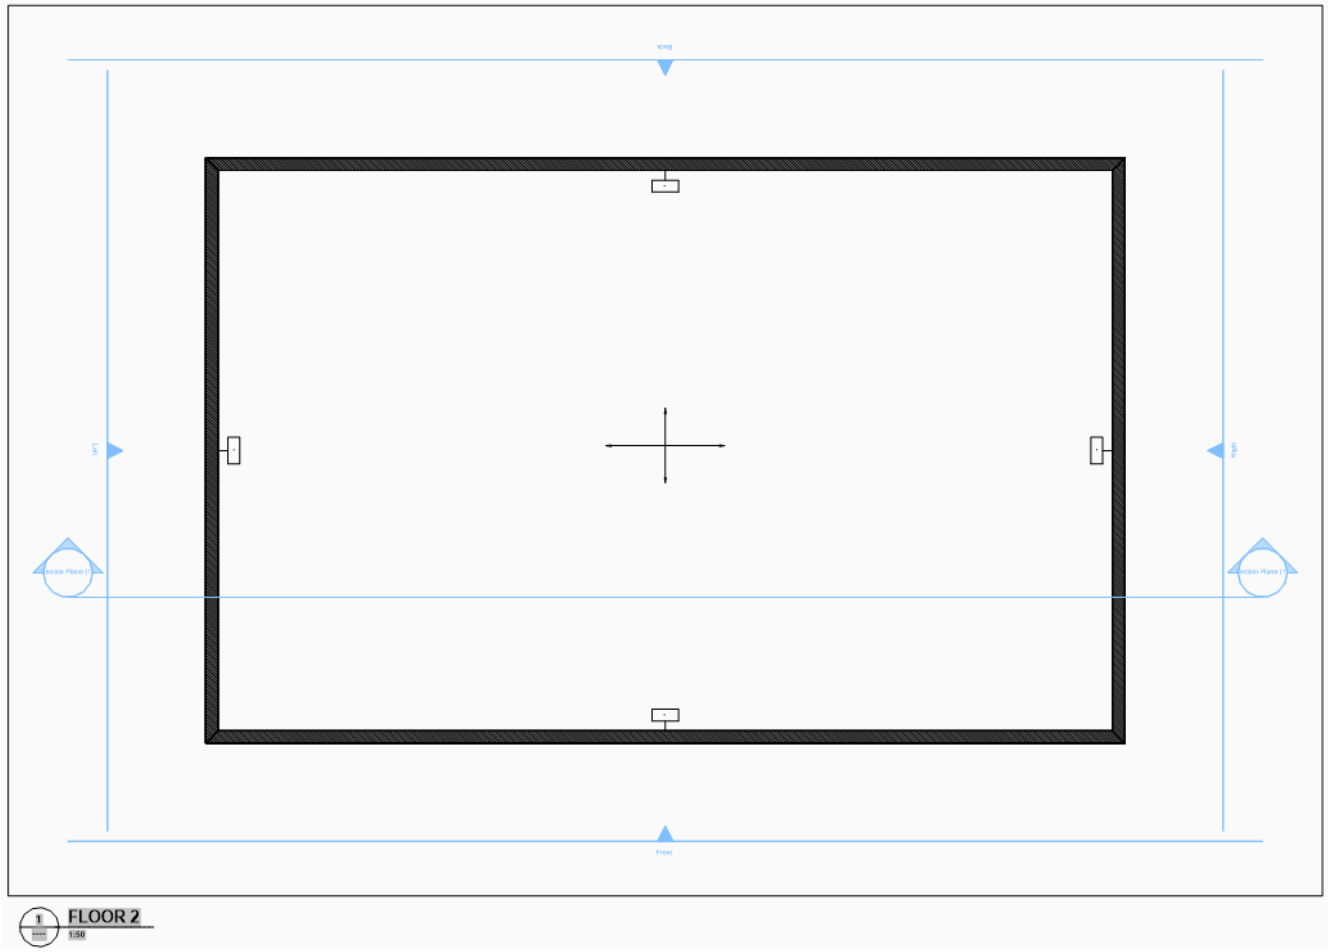

Figure 2.35

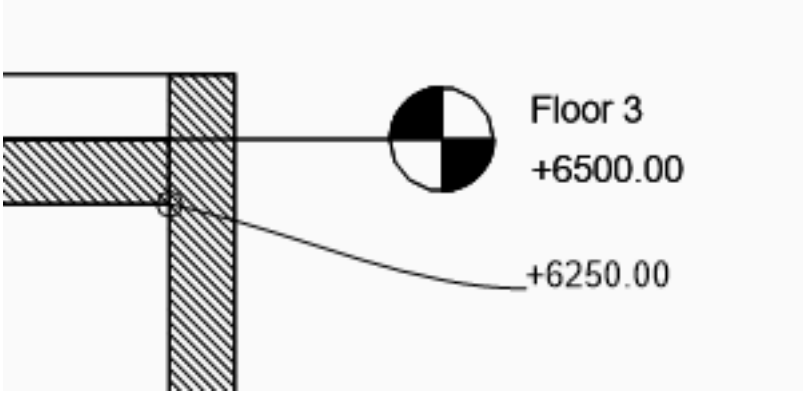

Data Extraction

The **DATAEXTRACTION** command now allows you to include all blocks and also extract from layouts in the new filter rule settings. You can now extract composition and physical material data. (2.36 on the next page) You can now extract and schedule quantity data based on IFC2x3 Element Types. (2.37 on page 1601)

Drawing Customizations

Drawing Customization is a new tool that is available and only accessible from the panel. All the controls of Drawing Customizations are represented as graphic icons within the User Interface panel, such as the **+** symbol in a blue circle to create a new template. You can duplicate, rename or delete your customization templates. It allows you to create view templates to control and customize the visibility settings of your drawings on layouts. The Drawing Customizations tool in BricsCAD is operated by 3 principles – Entity Customizations, Styles and Filter Rules. (2.38 on the next page) Drawing Customization templates are stored within the Customization folder located in the SUPPORTFOLDER, under Bim folder > Sections subfolder. Each customization template is saved as an individual folder which contains in its basic form Settings.dwg, a Filter.json and a New customization.json files. The folder will also contain any external symbol sources which you have created new using the Create New buttons. Settings.dwg contains the values created in the Style tab in the form of layers and if you have created any custom properties that you wish to use as a Filter parameter, you have to ensure they are also reflected in the Settings.dwg. (2.39 on the facing page) **Entity Customizations** Entity Customizations refer to the visibility settings of how you would like to have your elements in your model drawing to look like. One level deeper within one of those entity customization tabs brings you to its settings tab, where you can choose how the element should look like as a section result, or how a center line type representation should overlap, or how an external symbol representation should replace the original asset. You can further modify and customize a specific ply layer of your desired entity composition, but only if appropriate. (2.40 on page 1604) The section result customization displays a series of controls with drop-down values from the Styles tab for more specific control of the section result graphics. You can override the entities' hatches via the Appearance Override with preset or custom Physical Materials available in your project. For the Symbol Customization settings, you can find an input dialog to specify your desired external symbol drawing in .dwg format. There are additional buttons to allow you to edit the selected symbol drawing or to create a new .dwg symbol. You can further apply your saved Styles to specific layers within your external symbol source, thereby allowing you to retain a general symbol drawing across several customization templates with different output results. **Styles** This is where your desired style options like Lineweight, line colors, etc, are stored and will appear as drop-down options in the Entity Customizations and Center Customizations settings as shown in the previous section above. The operation of the Styles tabs is like how Entity Customization tabs can be controlled. To edit any of the styles available, click the relevant tab to enter the styles settings, where you can specify your desired values for the style's colour, linetype, lineweight and linetype scale. (2.41 on page 1605) **Filter Rules** To be able to apply the right customization styles to specific entities, you have to set the appropriate filter rules to target those entities correctly in the Filter Rules tab. (2.42 on page 1607)

Filter rules can be further classed into sub-rules, which falls as a sub-set of the parent rule, ie. Fire Equipment as a Filter Rule, whereas Fire Extinguisher is classed as a sub-rule. The blue **+** symbol also appears respectively and accordingly at each rule level, where at the end of each rule, regardless of it being a subset or otherwise, has to end with an Entity Customization. (2.43 on page 1608) Adding and editing a filter parameter will lead you to a prompt, where the options of filter property is determined by the BIMPROPERTIES imported in the namespace settings. To end and legitimize a filter rule, the entity customization value must be added and filled in. The options available in the drop-down selection reflects the existing customizations tab available in the Entity Customization page.

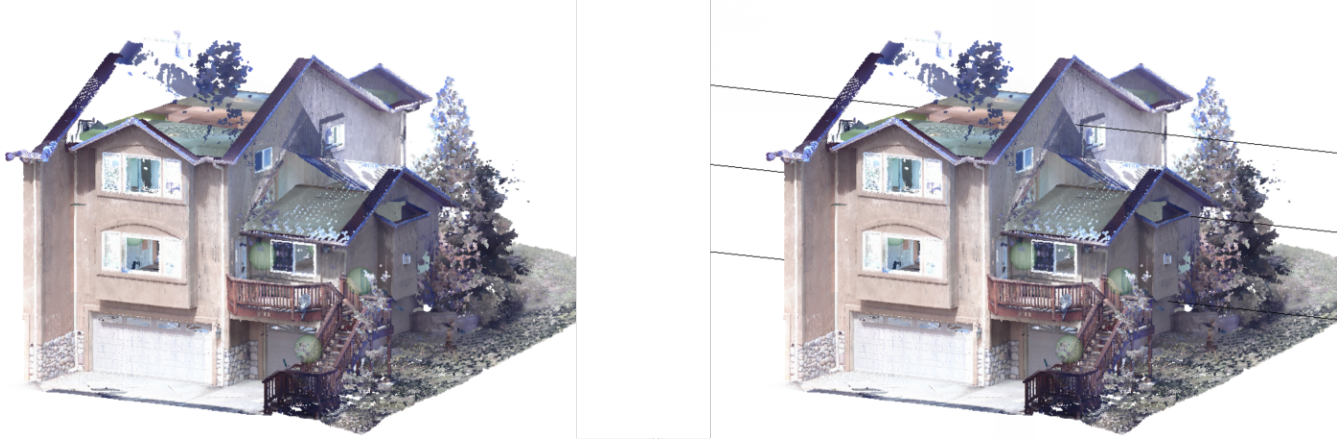
2.1.6 Point clouds

Point cloud functionality is even more powerful with a BIM license.

Floor Detection

Sectionplanes work on point clouds as well, they can be used to show parts of point clouds. The difference between point cloud crops and sectionplanes is that point cloud crop only clips the point cloud while section planes will clip all geometry in your drawing. The new **POINTCLOUDDETECTFLOORS** command generates volume sections for each floor found in a point cloud representing a building. The detection is based on regions of points with similar Z-coordinates. The generated volume sections can help in navigating point clouds of buildings. (2.927 on page 2523)

Figure 2.44



Planar Fit

The new **POINTCLOUDFITPLANAR** command enables you to create 3d geometry based on the point cloud. It will create a planar surface or solid after a selection of one point in a point cloud. The points that seem to be in a plane are never exactly in one plane, therefore a threshold value is set as a property of the point cloud entity. This also works in bubble view. **In bubble view** If the bubble viewer is open before launching the command, BricsCAD expects you to select in the bubble viewer. The cursor will give you a preview of the direction of the plane. When you click you get a preview in both bubble view and model view. You can toggle between 2 shape representations using the CTRL-key. (2.929 on page 2525) (2.931 on page 2526) **In model space** You can also use this command in the model space when the bubble viewer is not open. BricsCAD will ask you to select a point of the point cloud in model space. Depending on the size of the cropped point cloud, it takes more time but it has 2 advantages by searching multiple scan positions:

- It can create larger surfaces where only parts are visible in each scan position
- It can detect wall and slab thickness since it can take the opposite surface into account.

(2.47 on page 1612) (2.48 on page 1612)

Figure 2.45

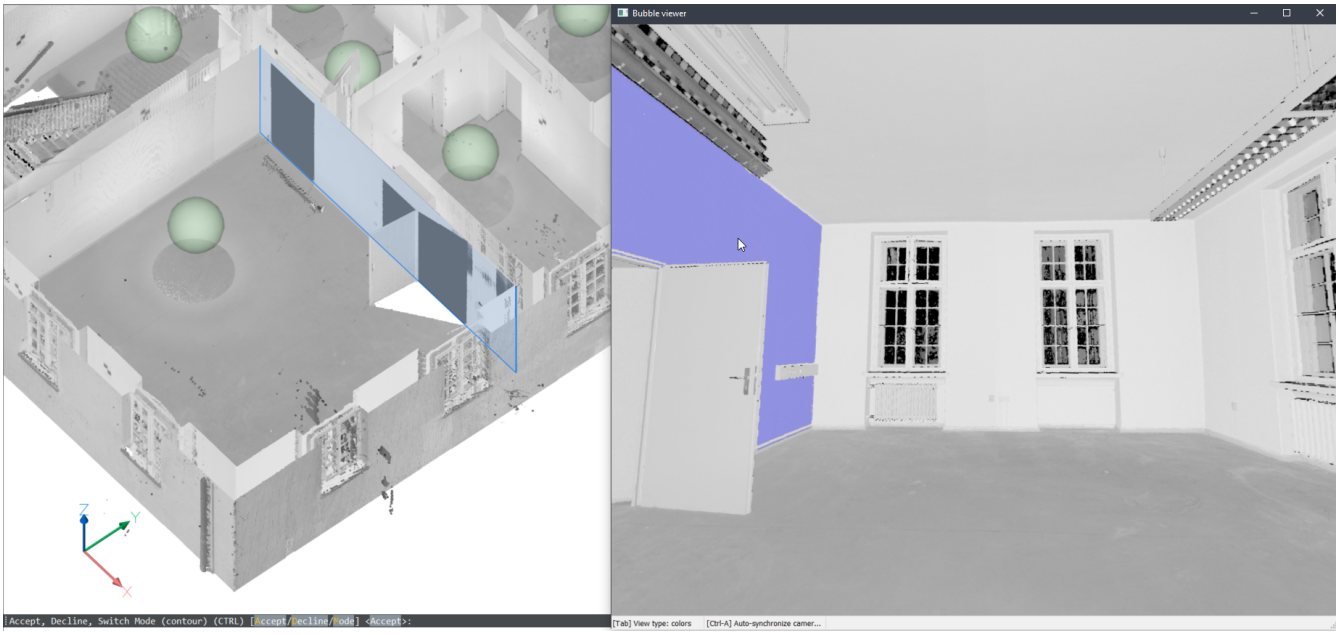


Figure 2.46

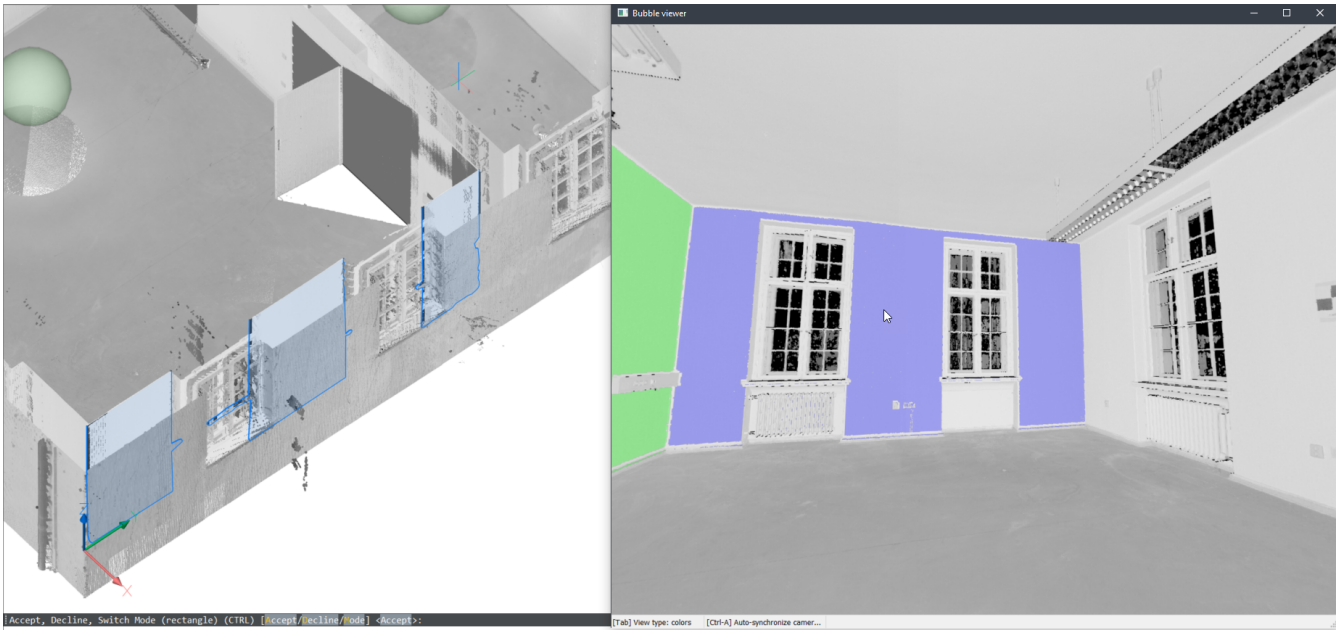

Figure 2.47

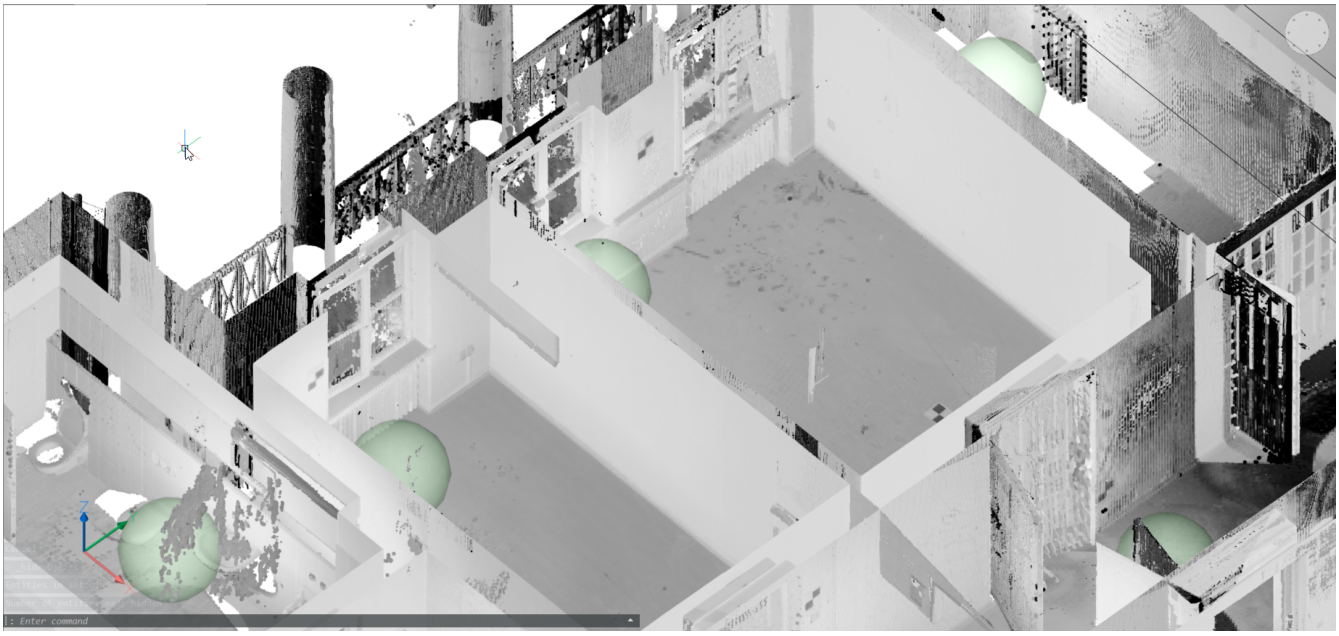

Figure 2.48

Point cloud projection

The new **POINTCLOUDPROJECTSECTION** command enables you to detect walls from the volume section of a point cloud based on a variety of wall detection options. You can create volume sections automatically for each floor in a building. You can use these sections to generate 2d lines to create a 2d floorplan or a vertical section. This is a background process and multiple sections can be processed in a queue. This way it is possible to run this command in full resolution on all sections. (2.940 on page 2535) At the same time, a raster image will be generated. In some cases it is not necessary to recreate the existing building. Background images can give so much more context to the design documents. These can be used to verify the created 2d geometry but in high quality scans these images can also be used as graphical material. For example, as a background image for a BIM model in renovation projects where modern intervention are made in historical buildings. (2.942 on page 2537)

https://www.youtube-nocookie.com/embed/WJLSzSCKO-E

This tutorial explains how to navigate in a 3D model space, using the keyboard and mouse shortcuts as well as the LookFrom widget. Back to Tutorial Overview

2.2.3 How to use Quad Cursor & Rollover Tips

https://www.youtube-nocookie.com/embed/-UZvYKVOX0Q

This tutorial explains what the Rollover Tips are and how to use them. It also explains how to use the Quad Cursor in different scenarios. Back to Tutorial Overview

2.3 Getting Started

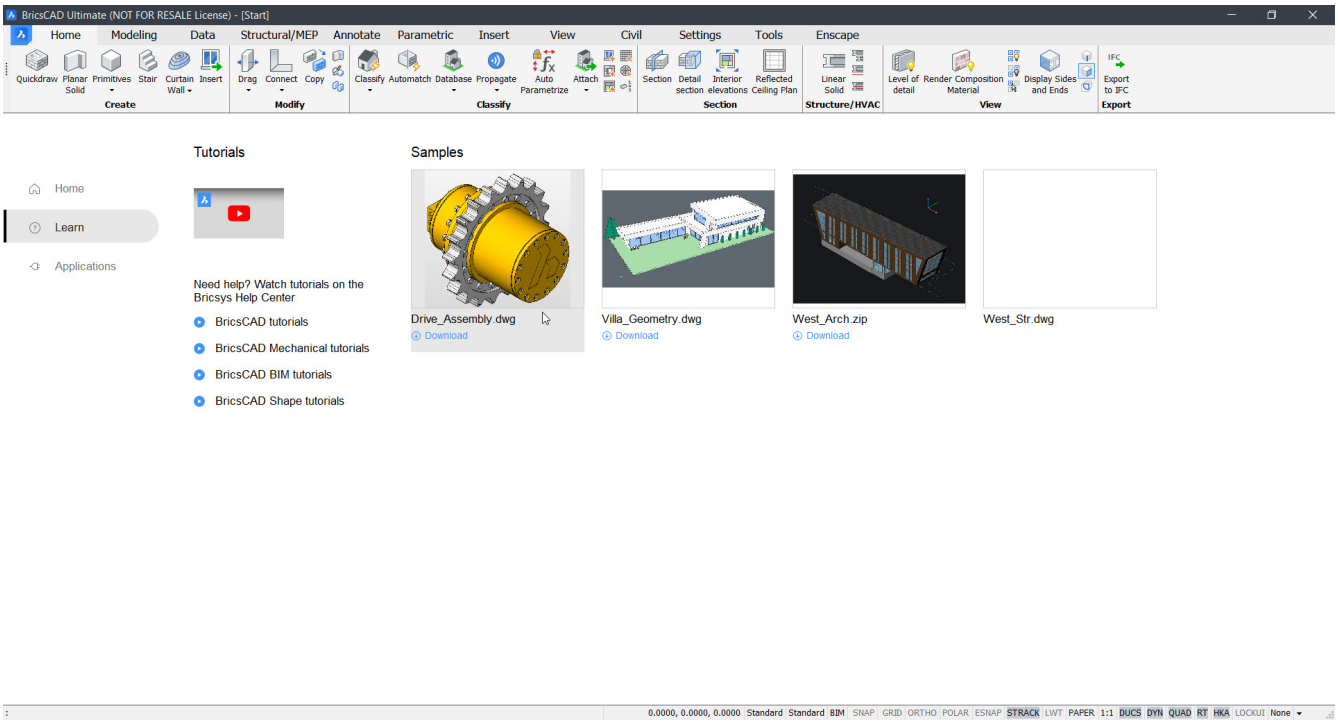
2.3.1 Creating a BIM Model

Do the following:

1. Start BricsCAD and choose the BIM workspace on the BricsCAD Launcher (1.2.1). In this workspace, all BIM tools and resources are available in the Ribbon, the Quad and various dockable panels (1.15.7).
2. On the Start tab (1.6.1), select a BIM template.
3. Click the **New Drawing** button to create the model.

Learn (2.51 on the facing page) Here you will find links to tutorials for Shape, Core, BIM and Mechanical. You can also find some sample files that you can download and try out yourself.

Figure 2.51



Applications Here you can find some of the third party applications that are available for BricsCAD. You can find more applications on our Applications Store website. (2.52 on the next page)

2.3.2 Exploring the Interface

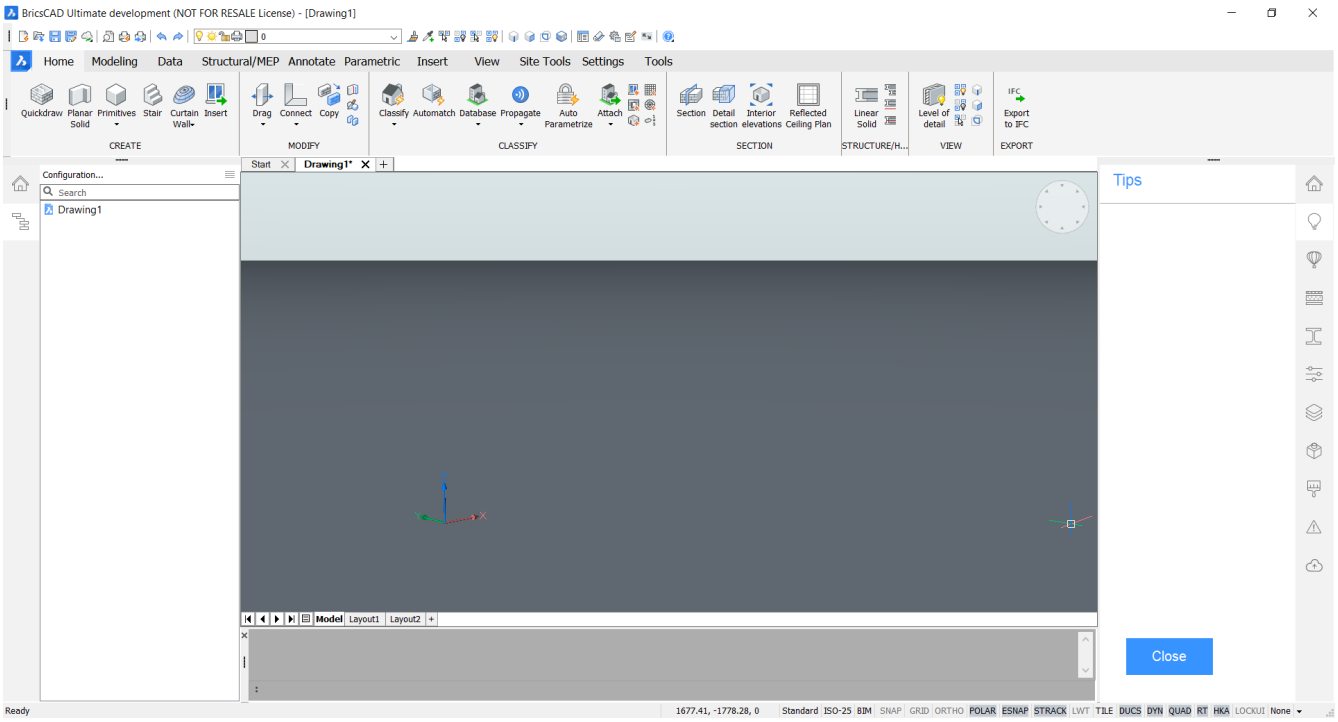
Overview: In this lesson, you explore the BricsCAD BIM user interface. Knowing and understanding the user interface will make you more efficient in your daily workflow. **Lesson Objectives** After completing this lesson, you will be able to:

- Identify the important elements of the BricsCAD BIM user interface.
- Use the different methods in the BricsCAD BIM user interface to access different tools.

User Interface

The BricsCAD BIM interface includes all tools, commands, and settings required to create and edit building elements. Start by creating building elements, opening an existing drawing or importing a building model. (2.53 on the following page)

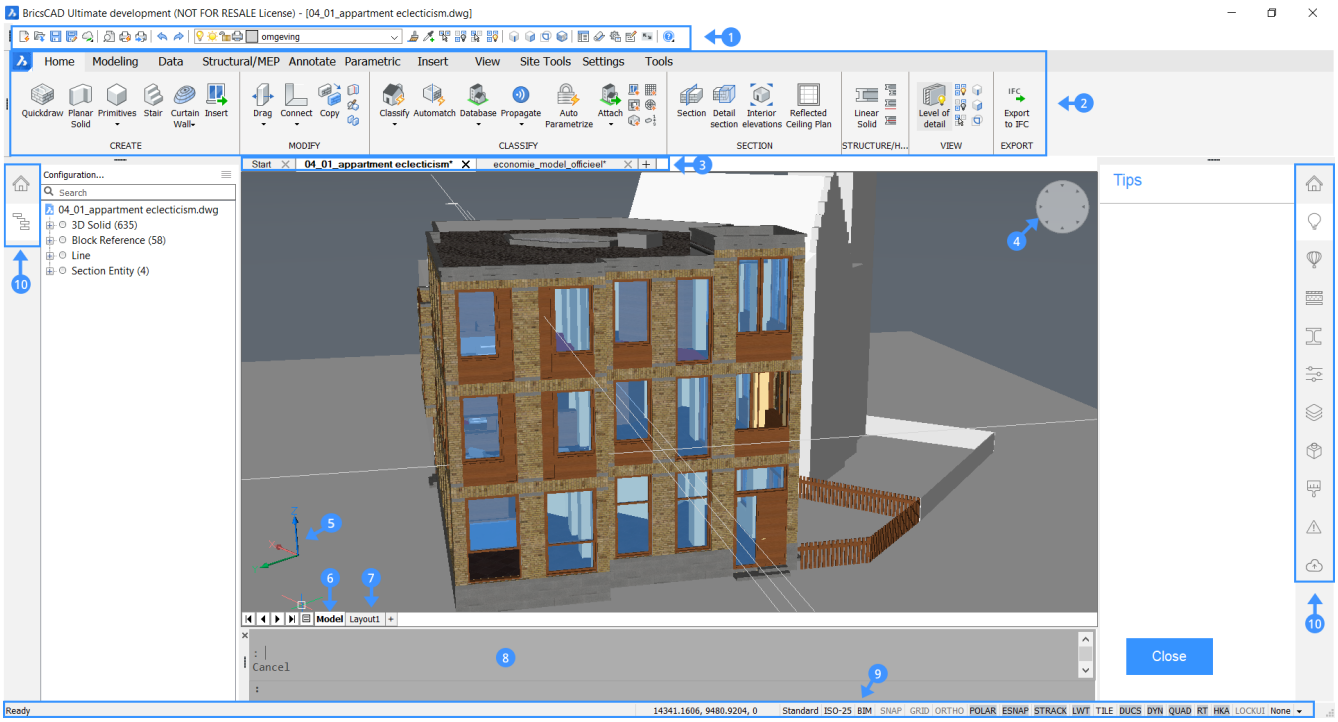
Figure 2.53



Interface Elements

(2.54 on the next page)

Figure 2.54



1. Toolbar In BricsCAD, toolbars are arranged in collections of similar functions within a bar of tools. Each function is displayed with an icon and is categorized by topic. Toolbars are available for all command categories. For example, a BIM toolbar is one of the tool categories available in BricsCAD BIM. This toolbar includes the most used BIM tools for modeling. It is possible to customize existing toolbars or create your own custom toolbars. By default, the Access 3D Toolbar is shown on top of the screen. (2.55) **Note:** To open more toolbars you can right-click, choose toolbars and check the topics you want. (2.56 on the next page)

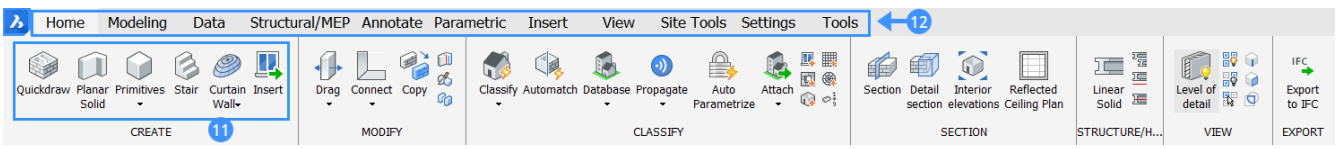
2. BIM Ribbon A ribbon organizes tools in a series of **panels (11)** which are grouped in different **tabs (12)**. Each tab is separated by a series of panels, and each panel contains a group of buttons and flyouts. (2.57) **Note:** The content of the ribbon depends on the current workspace. (see Editing In Workspace (1.17.11)) **Note:** Use the RIBBON (6.26.32) and RIBBONCLOSE (6.26.49) commands to open or close the ribbon.

Creating a ribbon tab	Open the C (6.9.47)ustomize (6.9.47) Dialog and click on the Ribbon tab. Right-click the Ribbon tabs group and choose Append ribbon tab in the context menu. (2.63 on page 1634) Fill out the fields in the Add Ribbon Tab dialog box: (2.64 on page 1634) Label: Caption on the ribbon tab. Title: Used in the Select Ribbon Tab dialog when selecting ribbon tabs for a workspace. ID: A unique name to identify the ribbon tab.
Editing a ribbon tab	Open the Customize (6.9.47) Dialog and click on the Ribbon Tag. Expand the Ribbon Tabs group and you can edit each tab.
Creating a ribbon panel	Open the C (6.9.47)ustomize (6.9.47) Dialog and click on the Ribbon Tag. Right-click the Ribbon panel group and choose Append ribbon panel in the context menu. (2.65 on page 1635) Fill out the fields in the Add Ribbon Panel dialog box: (2.66 on page 1635) Label: Caption of the panel in the ribbon. Title: Used in the **Select Ribbon Panel** dialog when selecting the panels for a ribbon tab ID: A unique name to identify the ribbon panel
Editing a ribbon panel	Open the C (6.9.47)ustomize (6.9.47) Dialog and click on the Ribbon Tag. Expand the Ribbon panel group and you can edit each panel.

Figure 2.57



3. Working with Document Tabs Document tabs allow you to:

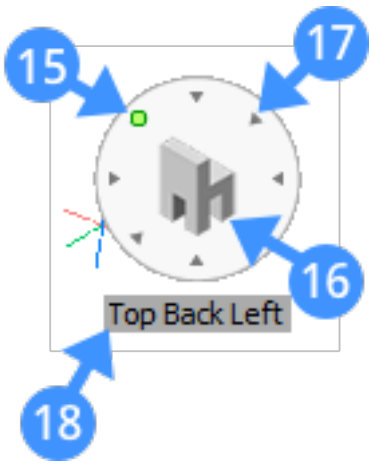
- Easily switch between all open drawings.
- Drag and drop the tabs to change their order.
- Click the **X icon (13)** at the right-hand side of the tab to close it.
- Right-click on a document tab to display a context menu.
- Click the **+ icon (14)** at the end of the document tab to open a new drawing.

(2.58)

Figure 2.58

4. Look from Widget The Look From Widget appears in the upper right corner of the drawing area. When you hover the cursor over the widget, a small green rectangle appears **(15)**, as does the preview of a chair **(16)**. Clicking the cursor over one of the triangle shapes **(17)** shows what the 3D view will look like **(18)**. The default location of the widget is the top right corner of the drawing area. (2.59)

Figure 2.59



5. UCS Icon UCS stands for a User-defined Coordinate System. The UCS icon shows the nature of the current coordinate system. 

The display of the icon is controlled through the UCS icon (6.30.2) system variable and the position of the UCS icon is defined by the UCS icon position system variable.

6. Model Tab When you start a drawing session, your initial working area is called Model Space. Model Space is an area in which you create two-dimensional and three-dimensional entities based on either the World Coordinate System (WCS) or User Coordinate System (UCS). You view and work in model space while using the Model tab.

7. Layout Tab Each drawing has at least one layout and each layout is composed of one or more viewports. Each viewport can show a different part of the drawing at a different scale. Paper space is a work environment that provides the model space view at a given scale, depending on the size of the paper. In each layout, you can add the entities needed to complete a printed copy of the drawing; title blocks, legends, frames, etc. These entities are only visible in the layout when you add. They are not visible in the other layouts or in the model space.

UCS in Layout Mode In paper space of layout modes, a W **(19)** letter appears in the UCS icon, which means the WCS is active. 
Note: WCS stands for World Coordinate System.

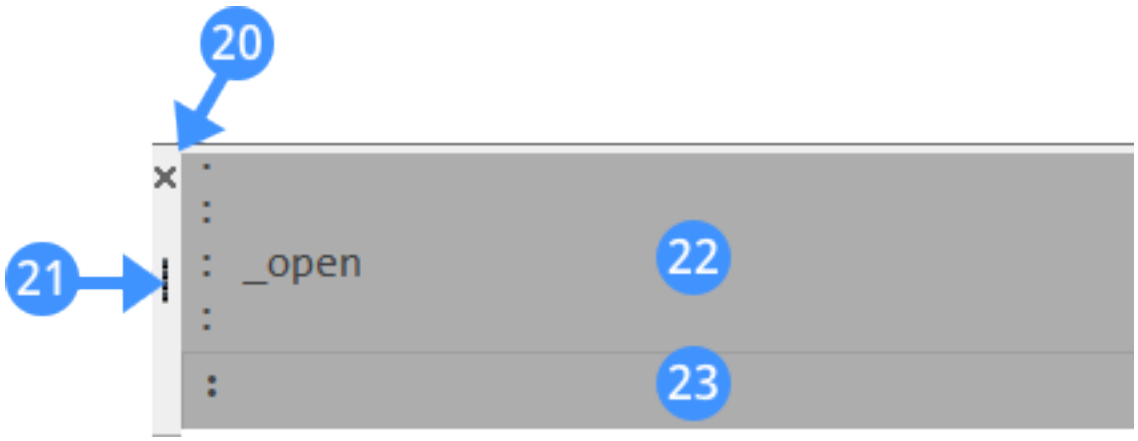
8. Command Bar The command bar consists of two fields.

- In the lower field, you can type the commands and BricsCAD shows prompt, options and other information regarding the execution of commands here. If the command bar is closed, this information shows in the Status Bar.
- The command history displays in the upper field of the command bar.

(2.60)

Close (20)	Click to close the command bar
Grip (21)	Press and hold the left mouse button to drag the command bar
Command history (22)	Shows the previously typed commands
Command edit (23)	Type the commands and command options here

Figure 2.60



9. Status bar The Status Bar sits along the bottom edge of the BricsCAD application window. It contains a lot of information about the settings in the current drawing. The status bar consists of 16 fields. All of these fields are optional, except for the **Status field (24)**. If you click the small black down arrow button at the right end of the status bar **(25)** a list of all field displays. Click a field to toggle its display. Right-click a field to display an options menu for this field. (2.61)

Status field (24)	Displays the status of the software
List button (25)	Click the arrow to display a list of available Status Bar fields
Fields (26)	Click a field to toggle it ON/OFF. Right-click to display a context menu.

Figure 2.61

10. Tool Panel In BricsCAD BIM, the Tool Panel is displayed on both sides of the workspace. The Tool panel consists of BIM panels. The BIM panels are dockable and thus they are movable. The panels can be moved to another docked panel using the drag and drop method. By default the Tool Panel looks like the image below: on the left-hand side it displays the Structure Browser and the Project Browser and on the right-hand side it displays Tips, Components, BIM Compositions, BIM Profiles, Properties, Layers, Mechanical Browser, Materials, Report and Bricsys 24/7. (2.62 on page 1633)

Note: You can always add panels in the Tool Panel by right-clicking and checking those you want. We will now have a look at the functions of the different dockable Panels from the Tool Panel:

Project Browser

The BIM Project Browser allows you to easily navigate through the entire content of a project: models, sections, drawings, and schedules. See The BIM Project Browser (2.7.15) article on how to use this panel.

Structure Browser

The structure browser is an interactive tree that displays the entities in the current model. Using the configurable structure tree on the Structure Browser the BIM model can be organized in a way that you want to view the elements. Once you configured the tree, you can easily save this structured tree as a .cst file. By default, the .cst files are stored in the **Support Folder**. See The Structure Browser (2.7.18) article on how to use this panel.

Tips

Tips Panel gives general information about the tools and commands. The tips can change depending on the active command. The tips can only be seen when the panel is open. The following illustration shows the Tips Panel when the DRAG command is active: (2.67 on page 1636)

Components

The components panel gives a list of components that you have by default. You can simply click and drag these components into your drawing. (2.68 on page 1637) At the bottom of the panel, you have the button 'Create component'. When you have made for example a drawing of a window, you can click on this button and add your own drawing to the component library. This way your window can be used as a component in all of your other drawings.

BIM Compositions

In the BIM Compositions Panel, you find a library of predefined composition that you can assign to various solids of the BIM model by dragging them on. Assigning compositions to the elements in your model is a core step to increase the BIM model accuracy. Compositions can contain either multiple materials or a single ply. See The BIM Compositions (6.7.8) article on how to use this panel in more detail.

BIM Profiles

The BIM Profiles Panel shows a library of predefined profiles that you can assign to linear solids by dragging them on. (2.69 on page 1638) See The BIMProfiles (6.7.26) article to see how to work with this panel in more detail.

Properties

The Properties Panel shows all the properties of a selected element. You always have some general info first, the other different tabs within this panel depend on the type of element that is selected. (2.70 on page 1639) for example, here we can see that the selected item is a window and is colored by layer. You can adjust the properties as you like. See the Properties (6.24.54) article to see how to work with this panel in more detail.

Layers

The Layer Panel shows all the layers of your drawing. It shows you the current layer **(27)**, you can change it by clicking left of another layer. It also shows if a layer is ON or OFF by the state its lightbulb icon **(28)**. Other layer properties such as color, line type,... can be found and adjusted by scrolling to the right. (2.71 on page 1640) In this example the current layer is 'DOOR_FRAME' and it is turned ON.

Mechanical Browser

The Mechanical Browser panel displays the hierarchy of components, features, arrays, parameters, and constraints for the current drawing. They are displayed in a tree-like form: you can expand and collapse every node to see its child nodes (for example, nested components). (2.72 on page 1641) The Mechanical Browser allows you to edit properties of a particular node, displayed at the bottom of the panel and calls different tools depending on what type is available in the context menu by right click on a particular node. For example in the image above you could add a description for the selected window.

Materials

The Materials Panel a library of predefined materials that you can assign to solids by dragging them on. You can also see a list of all the materials that you are currently using in your drawing. See the Materials (6.21.10) article to see how to edit and create materials.

Report

Some commands use the **Report** panel to report the command output; e.g. all SheetMetal (Sm*) commands, DmAudit (6.12.2) and DmStitch (6.12.29).

Bricsys 24/7

Login to your Bricsys 24/7 account here to collaborate on your project in the cloud. Bricscad 24/7 makes project management, a collaboration between project teams, cloud computing security, and task automation possible. When logged on, you can see an overview of your in the cloud Projects, Folders and Documents as shown in the image below: (2.73 on page 1642) See the Bricscad 24/7 Panel article (2.11.2) to see in detail how this panel works.

 **BIM BCF**	Here you can import BCF (Bim Collaboration Format) files and connect to a BCF server. The BCF topics are listed in this panel. (2.74 on page 1643) The top part of the new BCF panel shows all the topics and can look similar to the Components panel. The lower part of the new BCF panel shows the currently active topic, with a bigger snapshot and the most common metadata: comment, author, status, etc. Double-clicking on an issue activates the topic.
 **Details**	In the **Details** panel you can: • View saved details • Organize saved details • Propagate details • Open details and adjust them in the model space.

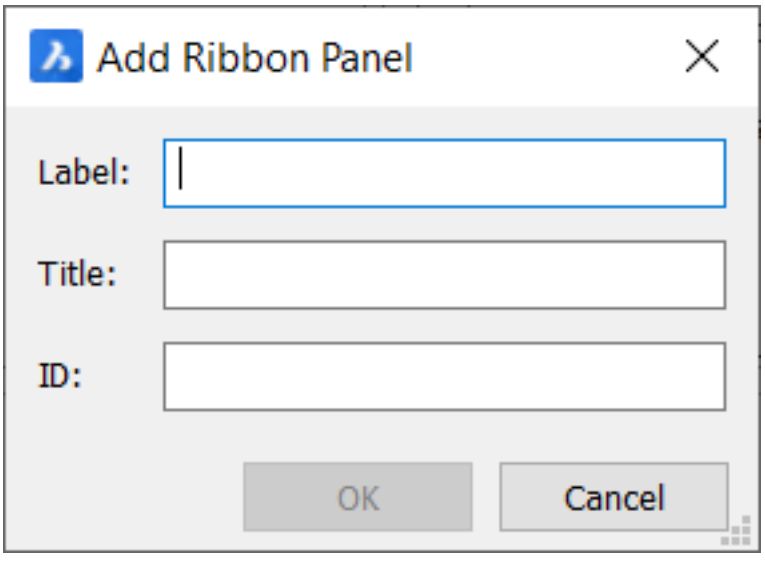

Figure 2.67

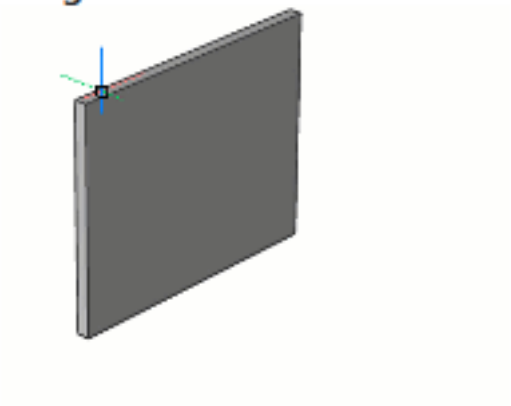
Tips

Drag



Select a major solid face, and Drag can:

Drag the selected solid and keep minor faces connected.

Change the thickness of the selected solid.

Create a copy of the selected solid.

Select a minor solid face and Drag can:

Change the height or length of a solid.

Connect the selected face to another solid.

2.3.3 Quad Cursor

Overview: In this lesson, you learn how to display the entities properties and how to quickly and easily modify 3D solids using the Quad cursor. **Lesson Objectives** After completing this lesson, you will be able to:

- Manage the context-sensitive Quad cursor.

Tutorial: How to use Quad Cursor & Rollover Tips Click here (2.2.3) to watch

About

The Quad cursor menu, or Quad for short, is an alternative to the command line or toolbars, offering a rich set of tools while requiring fewer clicks, without cluttering the screen with loads of grip-glyphs. The rollover tips are a limited set of properties displayed when selecting or hovering over an entity.  To toggle the **Quad** on/off, do one of the following:

- Click the Quad field in the Status bar.
- Press the F12 function key.
- Edit the QUADDISPLAY system variable in the Settings dialog.
- Type QUADDISPLAY in the command bar, then choose an option.

To toggle the **Rollover Tips** on/off, do one of the following:

- Click the RT field in the Status bar.
- Type rollovertips in the command bar then set a value.

Quad Layout

The Quad has a floating feature set that adjusts its content, depending on what you are or are not highlighting, and what you may have selected in the current workspace

- Based on the highlighted entity type, the Quad displays the most recently used tool (1) with the entity name(2). **Note:** When multiple entities are under the cursor, hit the TAB key to cycle through the different entities. (2.75)

- When the Rollover Tips setting is on, a limited set of properties (3) of the entity under the cursor display in the Quad. (2.76 on the next page) The property values in the Rollover tips can be edited. The following figure shows the color of an arc being changed using the Rollover Tips. (2.77 on the facing page) **Note:** To display the Rollover tips, simply click the title bar of the Quad after expanding it.

- When the cursor is moved on the Quad, a number of tool tabs display at the bottom (4). **Note:** The number of tool tabs is controlled by the **Quadwidth** user preference (default = 6). (2.78 on the next page)

- When you move the cursor over the tool tabs title bar (5), the tool groups expand (6) under the cursor, which provides you with more tool options. **Note:** The number of available tool groups and the number of tools within a tool group depend on the entity type under the cursor. (2.79 on the facing page)

Figure 2.75

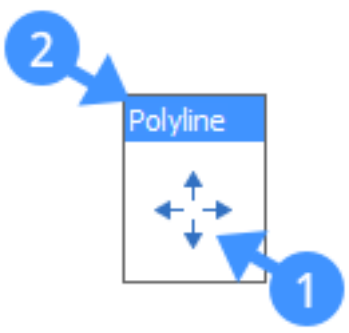

Figure 2.76

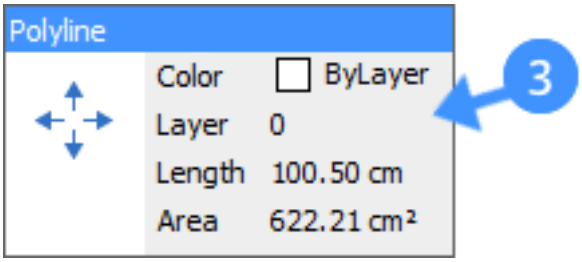

Figure 2.77

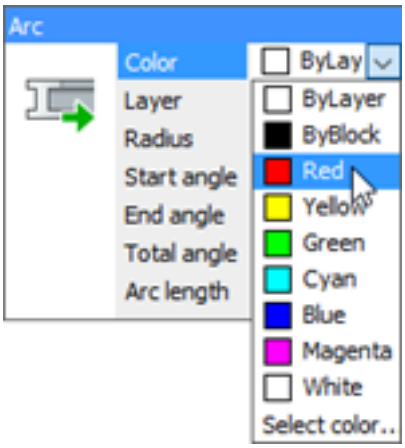

Figure 2.78

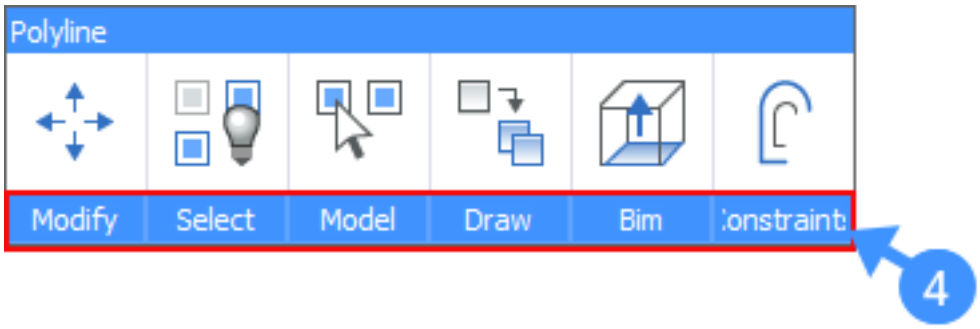

Figure 2.79

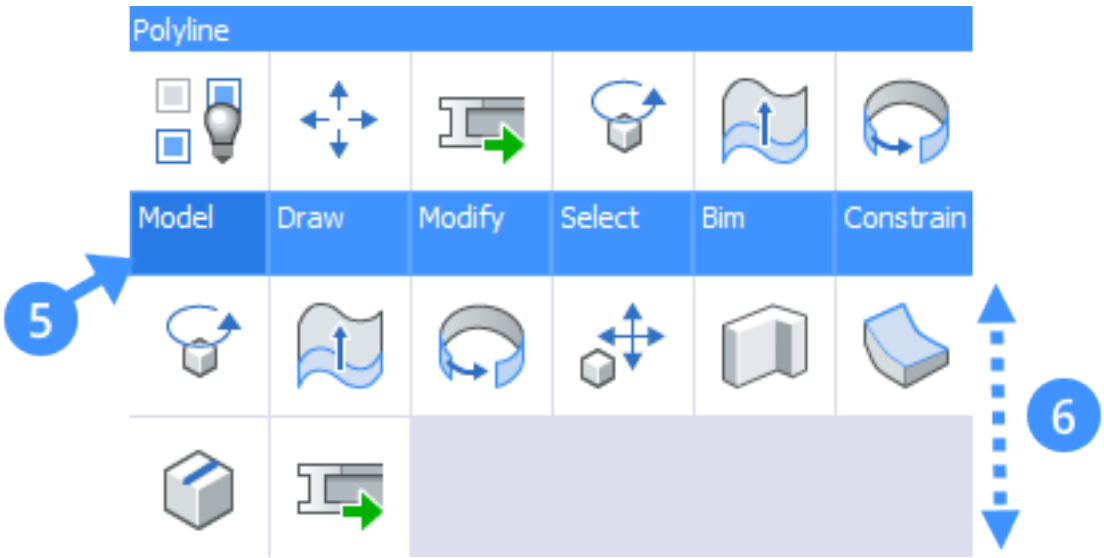

Figure 2.80

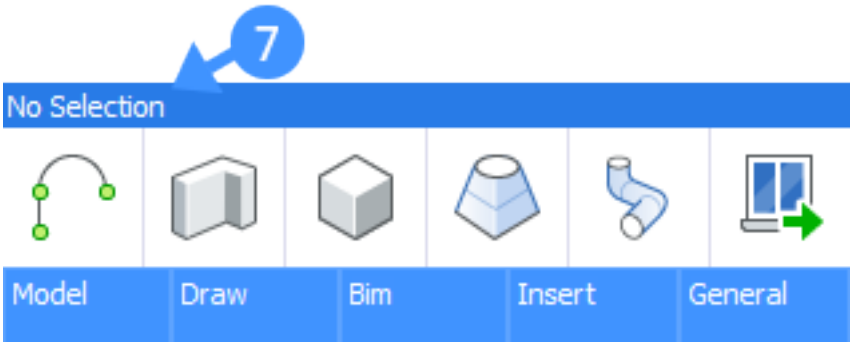

Figure 2.81

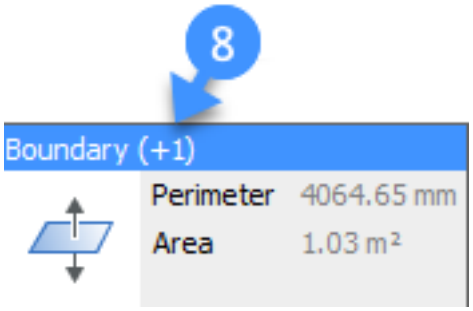

- The Quad can also be accessed in the no selection If the cursor is on an entity, hold down the right mouse button longer to display the No Selection Quad (7). Or when there is no selected/highlighted entity in the drawing, right-click to display the No Selection Quad. (2.80)
- When an entity is selected and another one is highlighted, next to the entity type (title bar on the top) a plus one (8) appears in the parentheses. The count, regardless of the type, increases each time you select an entity. To reveal the selected the entity types which are hidden in the parentheses, expand the quad by moving your cursor on it. (2.81) **Note:** The Quad also adapts to the type of entities that have been selected. If you select two surfaces, you will be provided with different tool options in the Quad, then if you selected a solid and a surface.

About: Selecting entities

The Quad adapts to the type of entities that you have selected. If you select a surface, you will be provided with different tool options in the Quad, then selecting a solid or edge.

- Selecting an **edge**, the QUAD appears showing the edge length, slope, and elevation (9). (2.82 on the next page)
- Selecting a **solid face**, the surface area is shown in the Quad (10). (2.83 on the facing page)
- Highlighting a **boundary**, the Quad displays the perimeter and area of this boundary (11). (2.84 on page 1649)

Figure 2.82

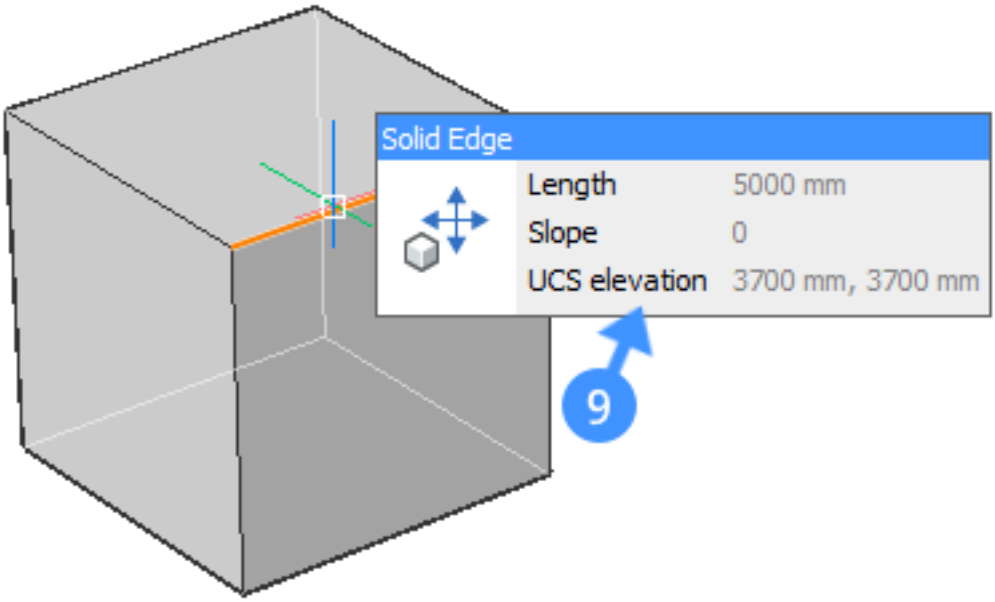

Figure 2.83

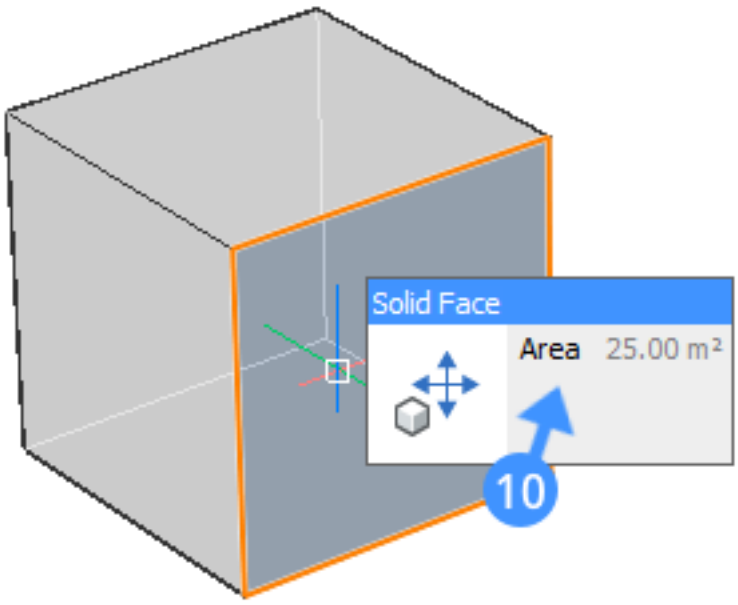

- Highlighting a **solid**, the Quad displays the color, layer, and elevation of the solid (12)(2.85 on the facing page)

Tutorial: How to use Quad Cursor & Rollover Tips Click here (2.2.3) to watch

Figure 2.84

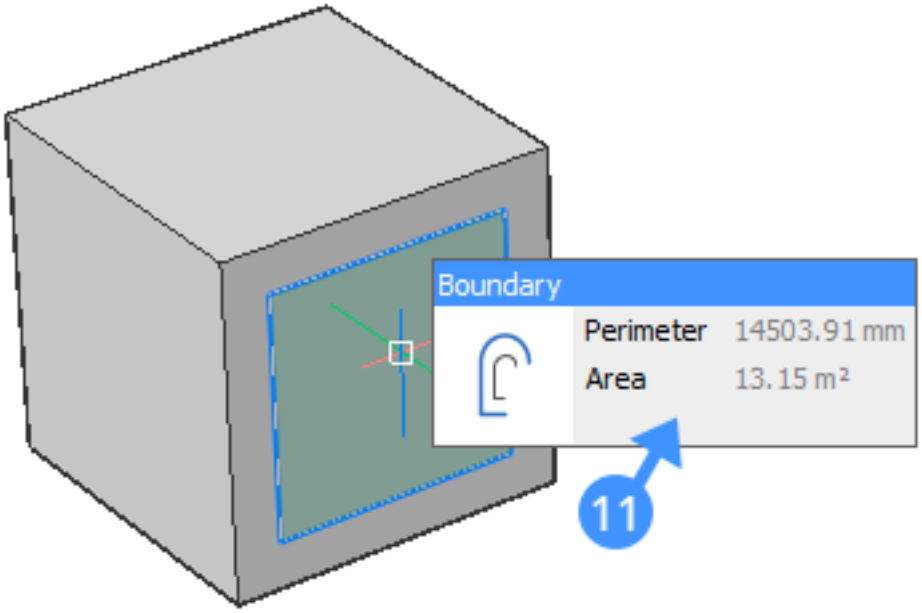

Figure 2.85

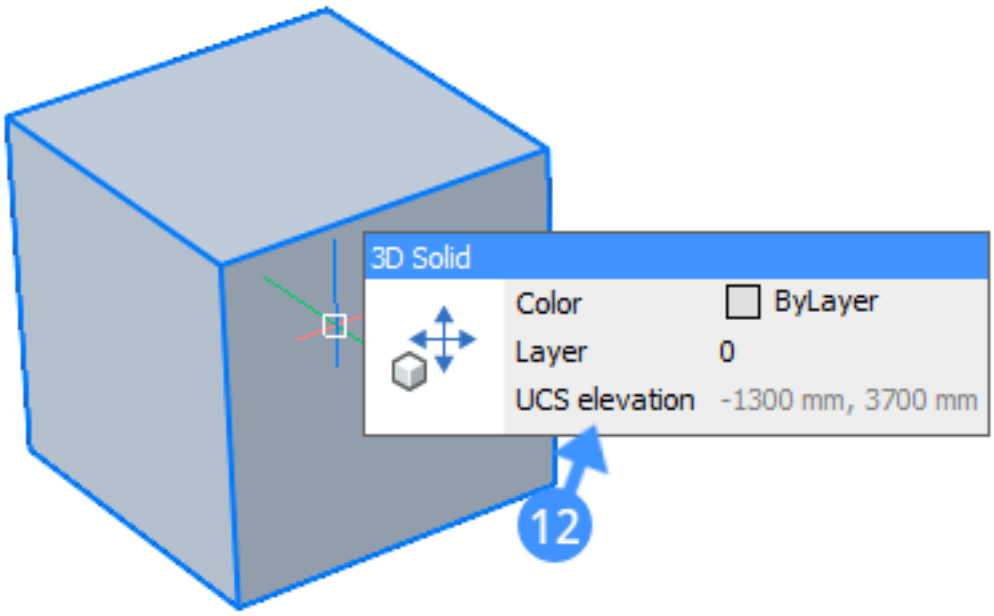

Procedure: Using the Quad

The following are general steps to use the Quad cursor. **Note:** The Quad and Rollover tips are both enabled.

1. Hover the cursor over the entity you want to manipulate. The entity under the cursor highlights. The Quad displays a single icon (13), which is the most recently used tool with this entity type, and a limited set of properties (14) of the highlighted entity. (2.86 on the next page)

2. Right-click to launch the recently used tool. Or move the cursor to the single icon to expand the Quad (15), then select one of the available tools to manipulate the entity. (2.87 on the facing page)

3. Move the cursor over the blue field to further expand the Quad. All Quad tool groups for the current workspace display. When the first tool group is expanded, click an icon to use a tool or move the cursor to a different tool group.

Figure 2.86

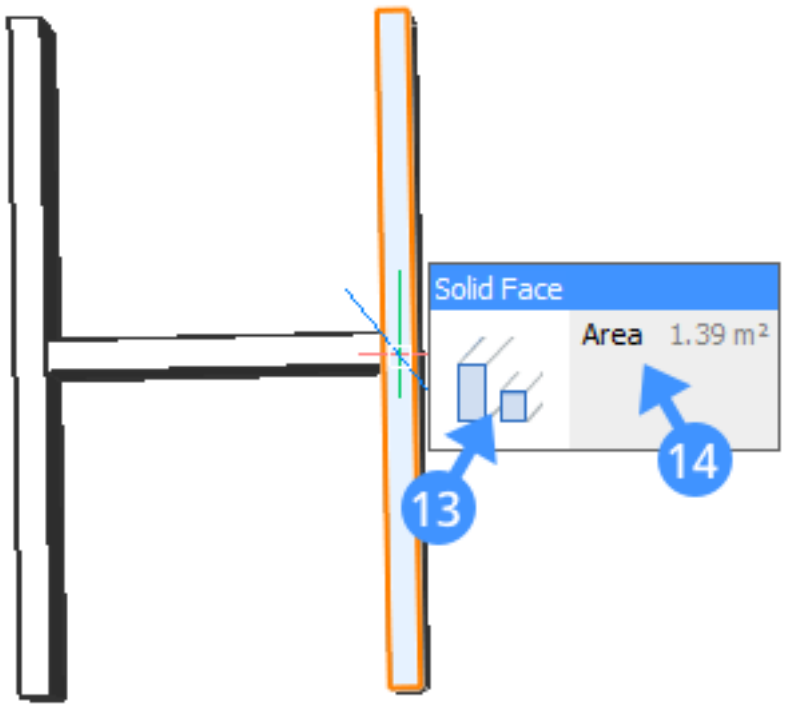

Figure 2.87

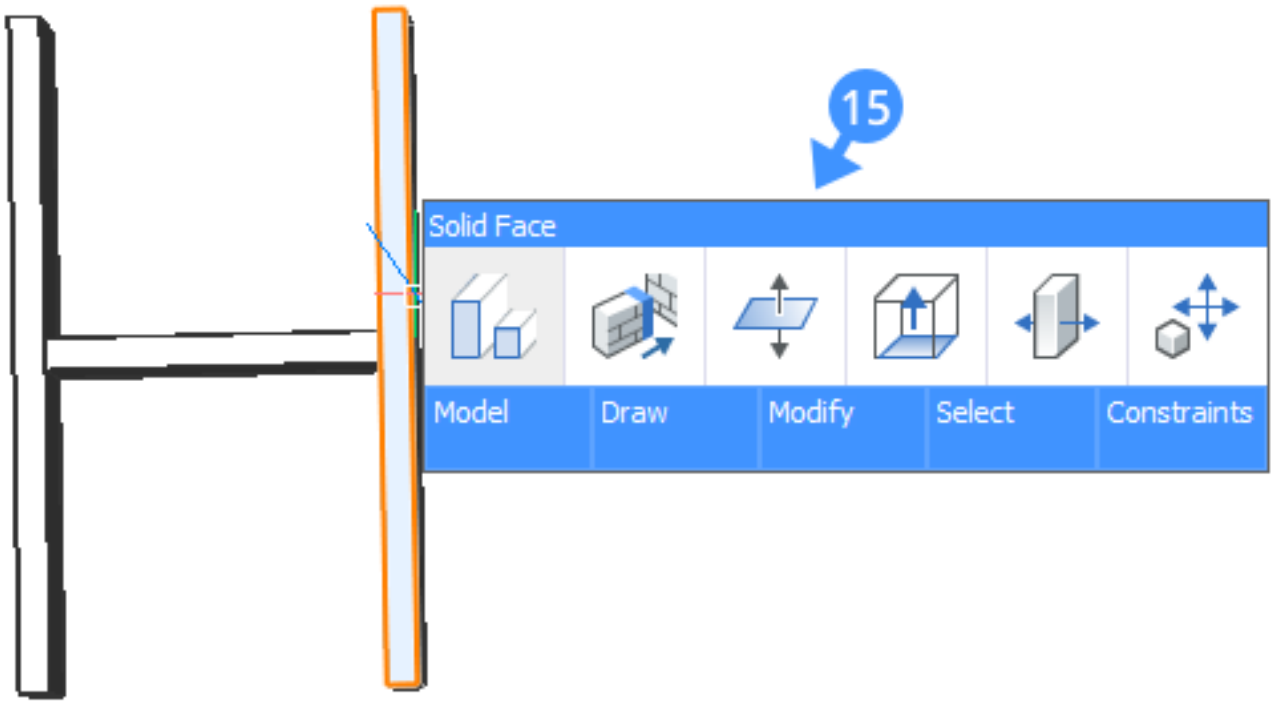


2.3.4 Viewing Entities

Command: HideObjects (6.16.10), IsolateObjects (6.17.22), UnisolateObjects (6.30.7) **Overview:** In this lesson, you will learn to use different tools to view and manage your entities in a drawing. **Lesson Objectives** After completing this lesson, you will be able to:

- Hide selected entities.
- Isolate selected entities to keep only those visible.
- Reveal all hidden entities.

Tutorial: How to hide and isolate objects Click here (2.4.8) to watch

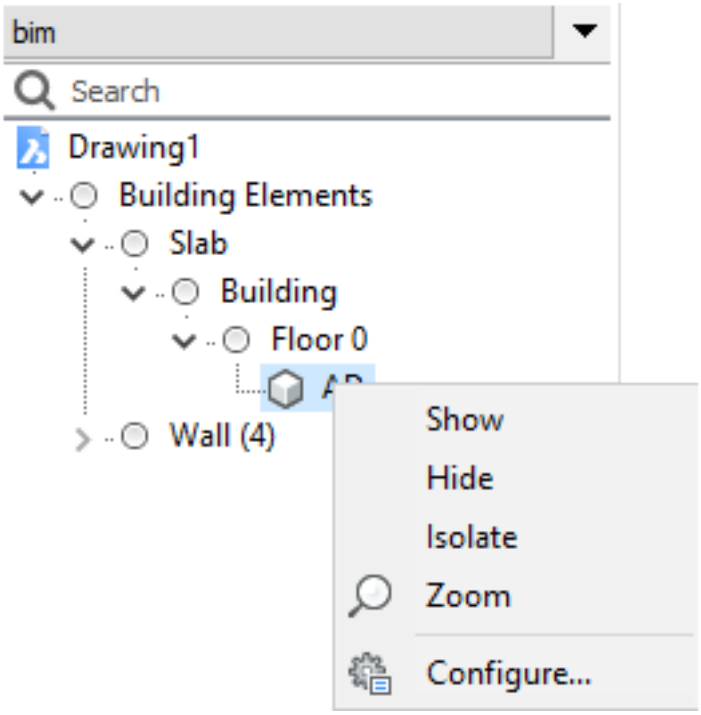
About

If you work with many entities in a drawing, everything that you have in the drawing is visible in the view. When you want to temporarily make only a few entities or a particular entity visible and manage them in a view, you can use the Hide or Isolate tools.

Hiding Entities

The Hide tool temporarily hides the selected entities in the view.  For more information about this command, visit the Command Reference article HideObjects (6.16.10). **Optional** Structure Browser can also be used to hide and isolate selected entities as well as revealing all hidden entities in the model space. This is an easy way to quickly hide or isolate a certain category of objects or entities with a certain property value etc. To do so, right-click on the entity in the Structure Browser and choose one of the options in the context menu (see below image). (2.88 on the next page)

Figure 2.88



Procedure: Hiding Entities

1. Select one or more entities in the drawing area.
2. Select **Hide Entities** from the Quad. All entities that have been selected are hidden in the view. The following illustration shows an entire model on the left. In the second image, the roof was temporarily hidden. (2.94 on page 1658) (2.90 on the next page)

Figure 2.89

Figure 2.90

Isolating Entities

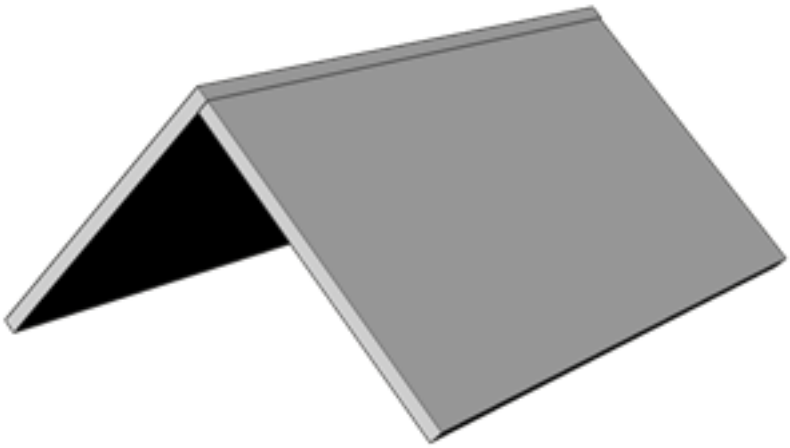
The Isolate tool temporarily hides all entities except those that have been selected.  For more information about this command, visit the Command Reference article IsolateObjects (6.17.22).

Procedure: Isolating Entities

1. Select one or more entities in the drawing area.
2. Select **Isolate Entities** from the Quad. All entities that have been selected before are isolated in the view. The following illustration shows the same building model from the below. In the second image, the roof was temporarily isolated. (2.94 on page 1658) (2.93 on page 1657)

Figure 2.91

Figure 2.92



Showing Entities

The Show Entities tool brings back all hidden entities in the view. For more information about this command, visit the Command Reference article UnisolateObjects (6.30.7). If you have any hidden entities in your drawing, you can reveal them in the view using the show entities tool. The following illustration shows the isolated roof elements from the above example. The second image shows the result after using the Show Entities tool. (2.93) (2.94 on the next page)

Figure 2.93

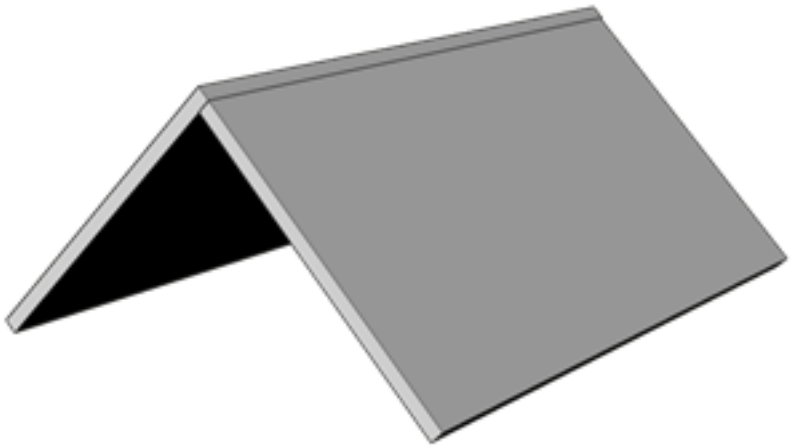


Figure 2.94

2.3.5 Selecting Entities

Overview: In this lesson, you learn how to highlight and select 3D model entities in BricsCAD BIM. **Lesson Objectives** After completing this lesson, you will be able to:

- Identify the difference between highlighting and selecting.
- Use the different selection modes.
- Highlight and select entities and sub-entities.
- Select entities and sub-entities using the selection boxes.

Tutorial: How to select elements Click here (2.4.10) to watch

About

In BricsCAD, when you hover over an object, it will be highlighted. After highlighting an entity, you left click to select the highlighted entity, then it will be selected. **Highlighting:** you only can highlight one entity at a time. **Selecting:** you can select as many entities as you want. Most of the modeling process can be done by highlighting the entity and using the Quad. For example, when you highlight a surface, the Quad will open, pick the command you want, without having to select the surface first.

Tutorial: How to detect boundaries in BricsCAD BIM Click here (2.4.4) to watch

Selection Modes

The selection modes allow you to control which sub-entities (faces, edges, and boundaries) should highlight in selection preview, and can be selected. **Ribbon:** Home tab > View panel > Selection modes (2.95) **Note:** To display the Ribbon, right-click on a toolbar, then choose Ribbon in the context menu. **Settings:** Program options > Selection > Selection Preview > Selection Modes (2.96 on the next page) **Keyboard:** SELECTIONMODES In the following steps, each selection mode option is given with its figure and explanation.

- **Enable detection of 3D solid edges** ( ): controls whether 3D solid edges are highlighted by selection preview, and can be selected. If you enable this option, you can select the edges of 3D solids by clicking it once.
- **Enable detection of 3D solid faces** ( ): controls whether 3D solid faces are highlighted by selection preview, and can be selected. If you enable this option, you can select the faces of the 3D solids by clicking it once.
- **Enable boundary detection** ( ): controls whether closed boundaries in XY-plane of the current coordinate system or on the face of 3D solids are detected. If you enable this option, you can select closed boundaries from the faces of 3D solids by clicking it once.
- **Enable selection of Sides and Ends** ( ): controls the bimSides and BimEnds visibility of all linear elements.

Note: BIM Sides/Ends are only available on classified linear elements with the attached library profile.

Figure 2.95

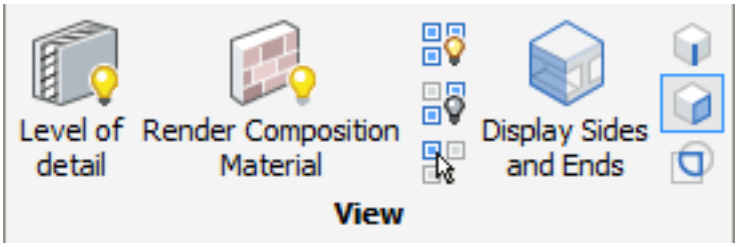

Figure 2.96

Selection modes	0x0007 (7)
1	Select edges
2	Select faces
4	Select detected boundaries

Changing selection modes setting

A sub-entity is a face, edge or boundary of a 3D solid. To control which sub-entities you select in your model do one of the following: **Note:** the default value of the selection modes = 6 which means the detection of 3D solid edge is disabled, while the detection of 3D solid faces and boundaries are enabled.

- Click the buttons on the Selection Modes toolbar to edit the value of SELECTIONMODES. The following illustration shows the sum of the values (1) of the selection modes system variable when the select edges option is disabled (2) after clicking the checkbox once, the select faces and selected detected boundaries are enabled (3). (2.97)
- Click the buttons on the settings panel on the Ribbon. The selection mode options can be enabled or disabled by clicking the button once. When one of the selection mode options is enabled this will be indicated in blue. The following illustration shows when the **select edges** option is inactive (4) whereas the **select faces** and **select boundaries** are active (5).

- Type SELECTIONMODES in the command line and change the current parameter.
- Use the CTRL key on the keyboard to temporarily toggle between the different selection modes. These key functions enable you to select any type of entity. To display the BimSides/Ends for linear elements you can use "Display Sides and Ends" system variable in the settings dialog box. The following illustration shows the BIM > General system variable when the "Display Sides and Ends" is enabled (6) after clicking the checkbox once. (2.98 on the next page)

Figure 2.97

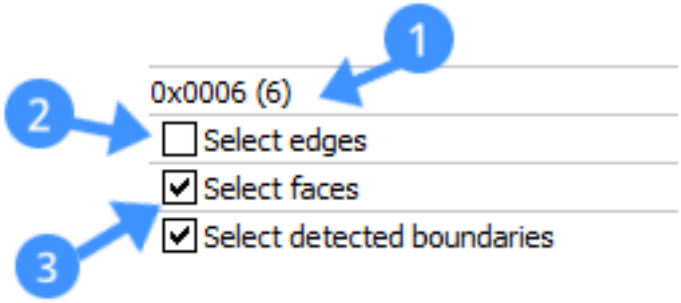

Figure 2.98

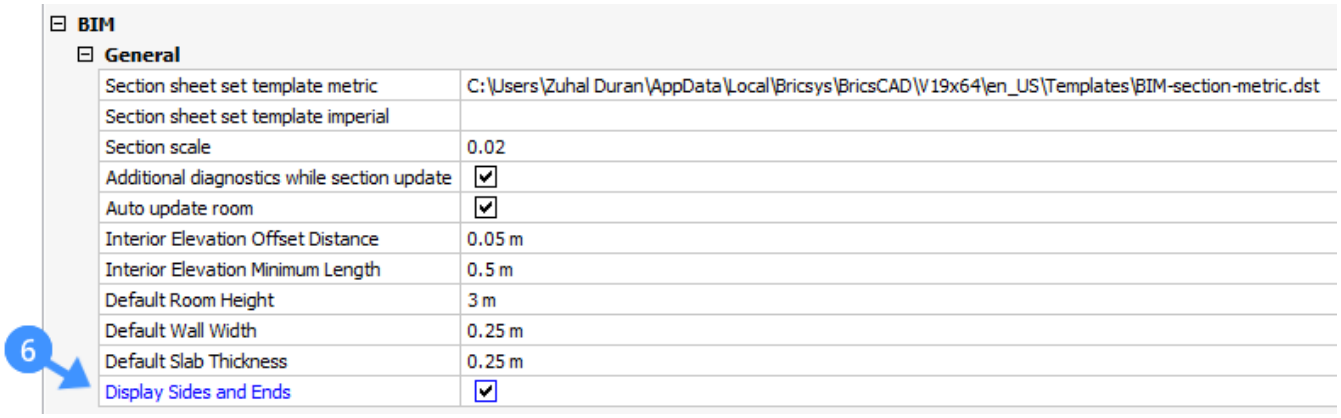

Selecting sub-entities

When select Edges is off, select Faces is on, Boundary Detection is on (default), do one of the following:

- To highlight a solid face, hover over the face with your mouse cursor. The highlighted face displays in orange (7). To select the face, left-click it when the face is highlighted. To select multiple faces of the solid, left-click them one by one. (2.99 on the following page)
- To highlight a solid, hover over one of its faces while holding down the CTRL-key. The solid displays in blue (8). To select the solid, left-click it while the solid is highlighted. To select multiple solids left-click them one by one. (2.100 on the next page)
- To highlight an edge, hover over the edge of the solid while holding down the CTRL-key. The edge displays in orange (9). To select the edge, left-click it while the edge is highlighted. To select multiple edges left-click them one by one. (2.101 on page 1663)
- To highlight a boundary, hover over the detected boundary on the face of the 3D solid. When the detected boundary is highlighted, it displays with a color. By default, inside of the boundary displays in green (10) and the outer edge of the boundary displays in blue (11). (2.102 on page 1663)

Note: This setting can be changed by typing BOUNDARYCOLOR on the command line (default value = 95).

Figure 2.99

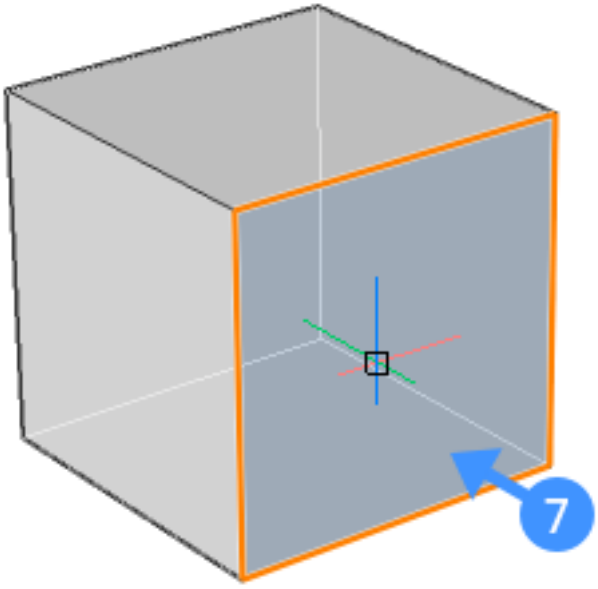

Figure 2.100

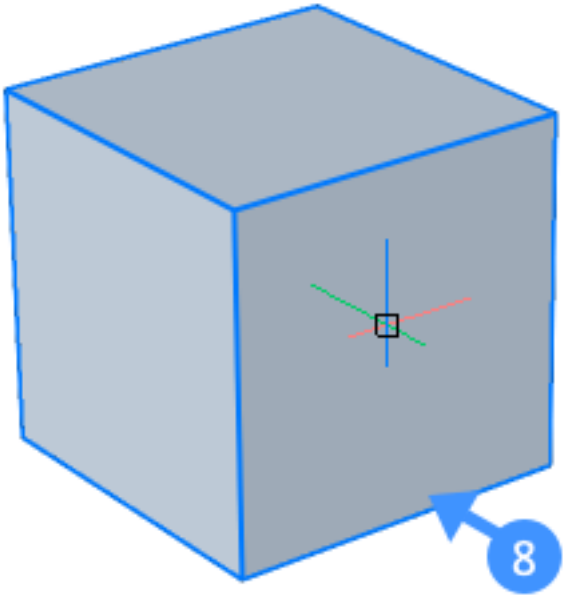

Figure 2.101

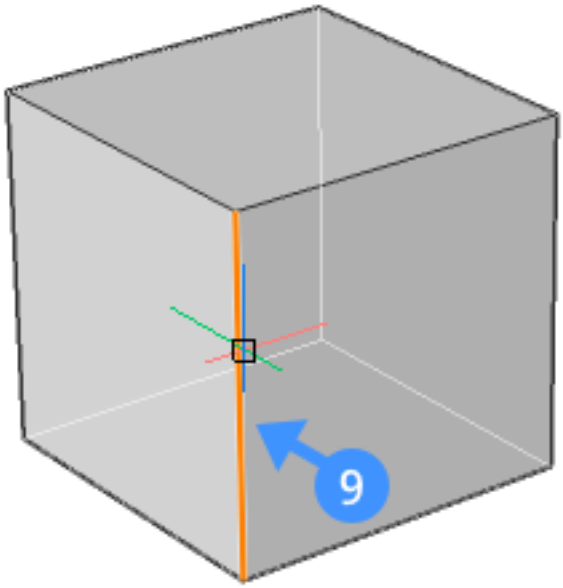

Figure 2.102

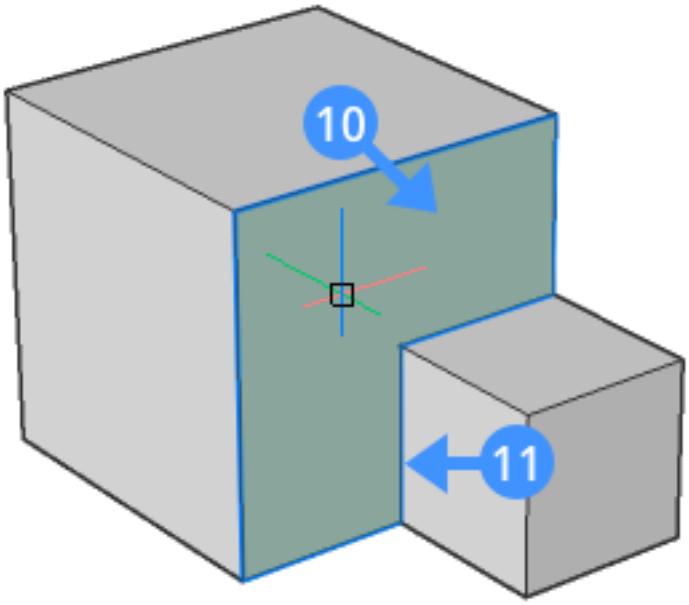
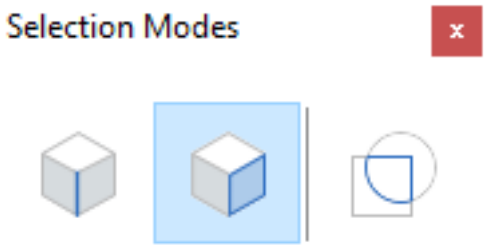


Procedure: Modify the thickness of a solid

1. Make sure the Select Faces option of the SelectionModes system variable is selected. (2.167 on page 1747)
2. Move the cursor over the face of a solid If necessary, press Tab to highlight an obscured face
3. When the face highlights, choose Push/Pull in the Model command group of the Quad.
4. The selected face of the solid is dragged The dynamic dimension field displays the relative displacement of the face (= with respect to its original position)
5. **(Optionally)** Press Tab to change the face selected as the reference face for the dynamic dimension.

Note: When a composition with locked thicknesses (non-variable thickness) is applied to a solid and if the thickness of the solid is not equal to the total amount of the composition thickness, the solid displays with red hatches. Execute the BimUpdateThickness (6.7.62) command to re-apply the composition to such solid.

Figure 2.103

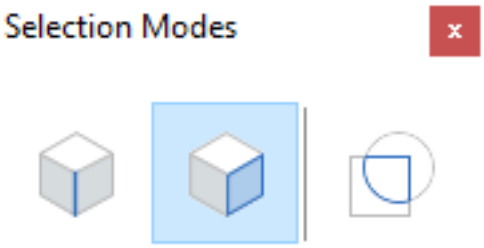


Procedure: Modify the height of a wall

Modify the dimensions of a single wall

1. Make sure the Select Faces option of the SELECTIONMODES system variable is selected. (2.167 on page 1747)
2. Move the cursor over the top face of the wall. If necessary, press Tab to highlight an obscured face.
3. When the face highlights, choose Push/Pull in the Model command group of the Quad. The selected face moves dynamically with the cursor. The dynamic dimension fields display the incremental height.
4. Type a value in the dynamic dimension field and press Enter.
5. Press Tab to use another reference face, e.g. the bottom face of the solid, then type a value in the dynamic dimension field.

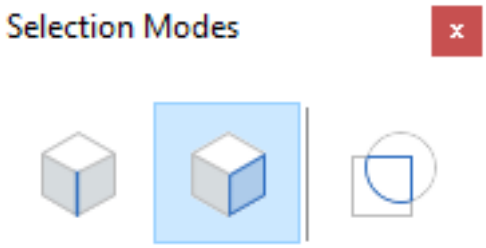
Figure 2.104



Modify the height of multiple walls Use the SelectAlignedFaces (6.27.17) command (Quad > Select:) it is easy to select the top face of all solids that lie in the same horizontal plane.

1. Make sure the Select Faces option of the SELECTIONMODES system variable is selected. (2.167 on page 1747)
2. Move the cursor over the top face of one of the walls. If necessary, press Tab to highlight an obscured face.
3. When the face highlights, choose Select Aligned Faces in the Solid/Face Selection command group in the Quad. All faces lying in the plane of the selected face are selected.
4. Now follow the same steps as for a single wall

Figure 2.105



Modify the height ply-by-ply When the Display Composition (2.7.4) property of a solid is set, and the Select Faces option of the SELECTIONMODES system variable is selected, the height or length of the composition plies can be modified separately.

1. Move the cursor over the ply you want to edit and choose Push/Pull in the Model command group of the Quad when the ply highlights. (2.106 on the next page)
2. Type value in the dynamic distance field. (2.107 on the following page)
3. Press Enter to accept the distance. (2.108 on page 1669)

Figure 2.106

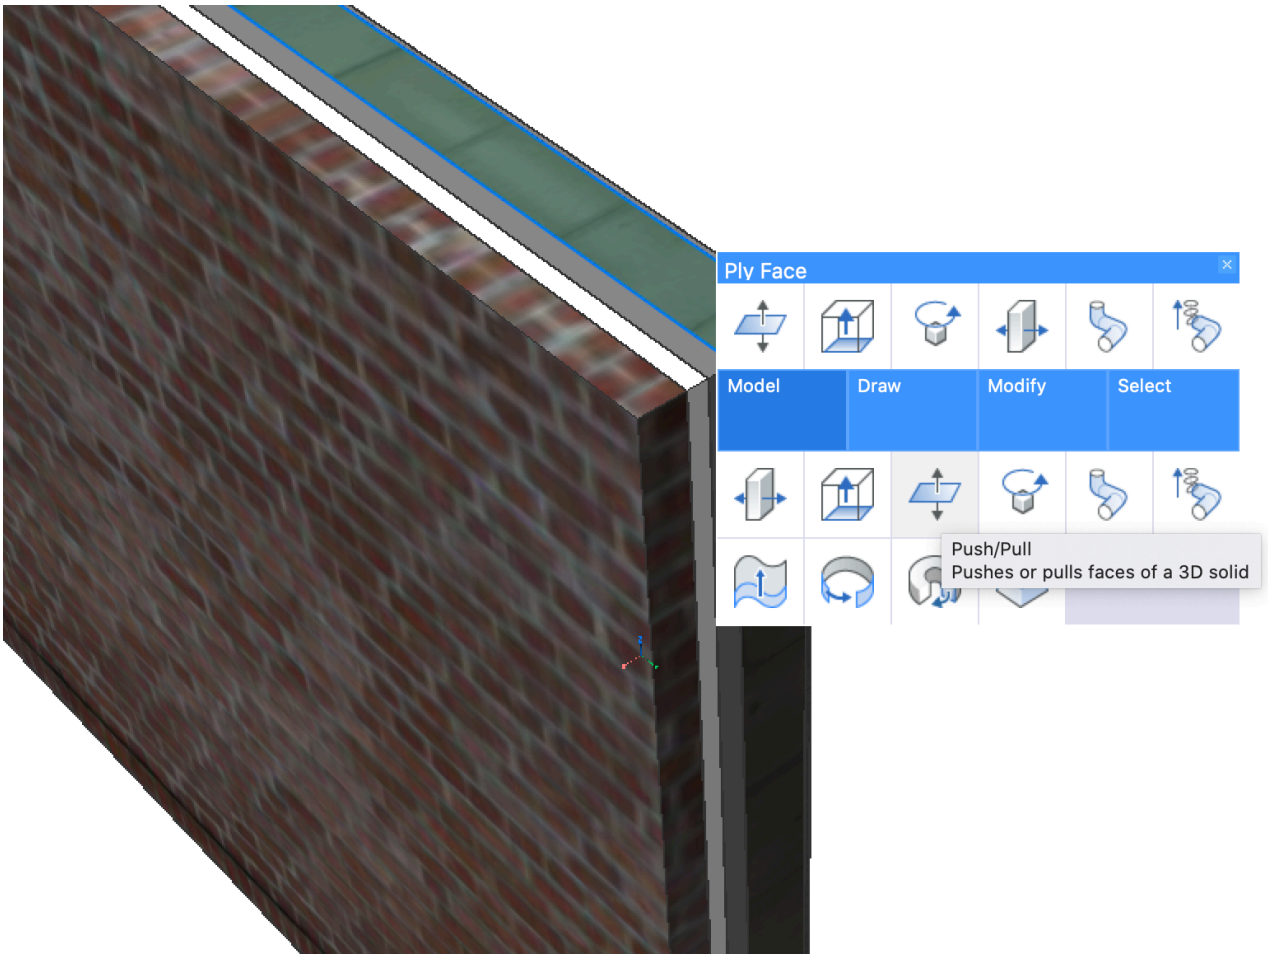


Figure 2.107

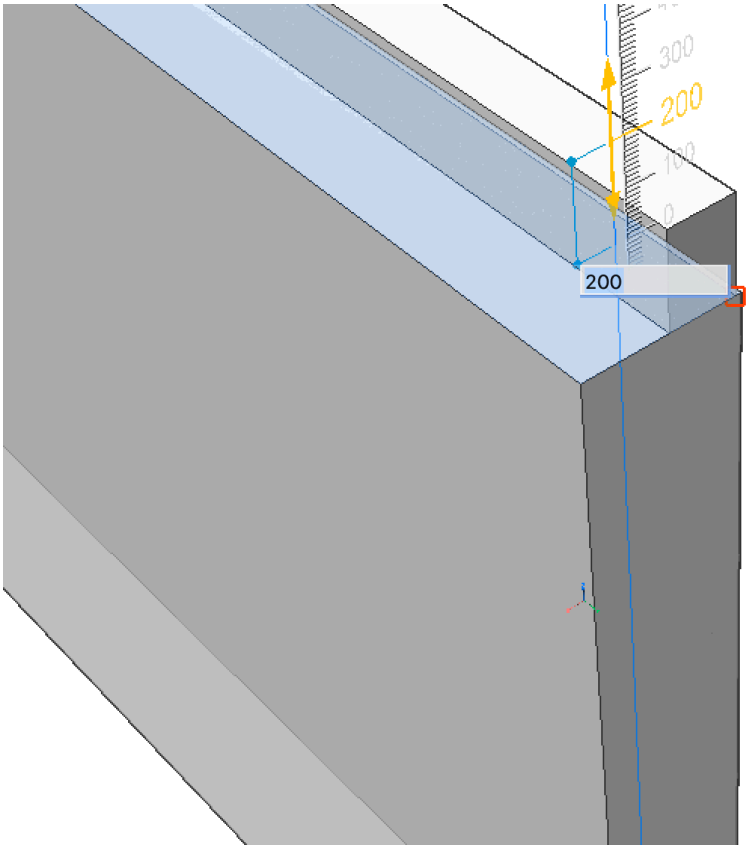

Figure 2.108

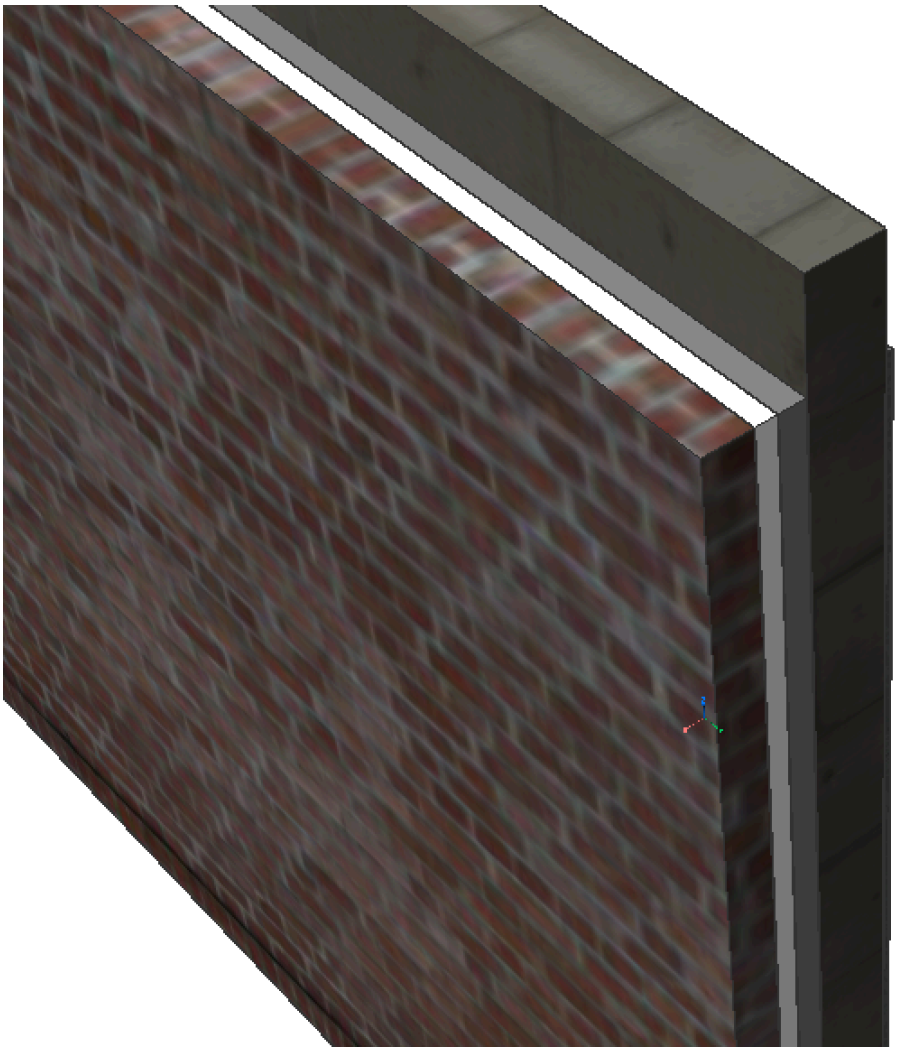


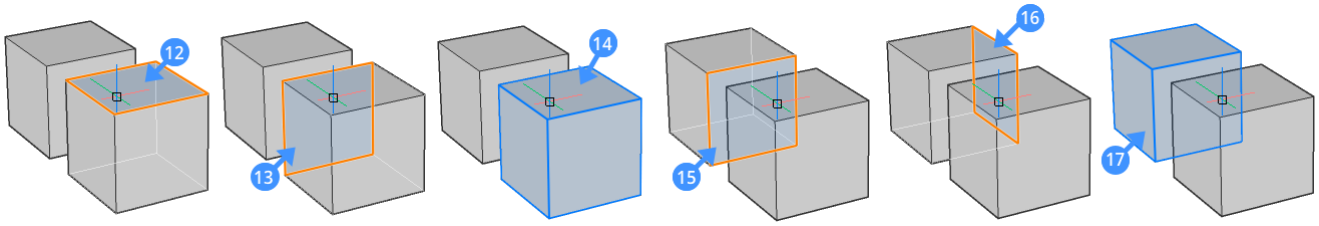
Selecting obscured sub-entities

In your drawing, some entities or sub-entities (faces, edges, and boundaries) might be hidden behind other entities. The TAB key enables you to cycle through sub-entities. The following steps show how to highlight a hidden face that lies beneath the cursor. When select Edges is off, select Faces is on, Boundary Detection is on (default).

1. Place your cursor on one of the solid faces. In the example below, the top face of the front solid is highlighted (12).
2. Press Tab-key to cycle through the hidden entity. Now, the back face of the front solid is highlighted (13).
3. Repeatedly pressing the TAB key, while keeping the cursor at the same position, allows you to highlight the entire solid in the front (14) and the front face (15) and right face (16) of the rear solid. Finally, the entire rear solid is highlighted (17).
4. When the entity or sub-entity that you want to select is highlighted, left-click it to select. (2.109)

Tutorial: How to use selection boxes Click here (2.4.23) to watch

Figure 2.109



Selecting multiple entities using the selection boxes

The selection boxes allow you to select one or more than one entity at a time. To use a selection box, left-click on an empty space in the drawing area, and move the cursor until the selection box covers the entities that you want to select. There are two types of selection boxes in BricsCAD; **Blue selection box (18)** appears when you create a box from left to right. The blue selection box will only select entities that are entirely covered by this selection box. (2.110) **Green selection box (19)** appears when you create a box from right to left. The green selection box will select all elements that are entirely covered by the selection box and all the elements that intersect with one of the edges of the box. (2.111 on the following page) The following steps show how to select multiple entities using the blue selection box: **Note:** by default, the selection box only selects entire entities (e.g. solids, lines, polylines, blocks,...) but not sub-entities (e.g. solid faces, solid edges).

1. Click and move the mouse to the right to create a blue box around the entities you want to select. When the entity is completely inside the window, it will be added to the selection set. The example below shows the blue selection box usage when the selection mode is set to Solids (default). (2.112 on the next page) (2.113 on the following page) The blue selection box covers the left cube completely and thus only this cube is selected in the model.

2. To select faces of 3D solids and surfaces, press CTRL key once during window selection. The icon (20) next to the cursor indicates the selection mode. The faces that are completely inside the window will be selected when the selection mode is set to Faces. (2.114 on page 1674)

Figure 2.110

Figure 2.111

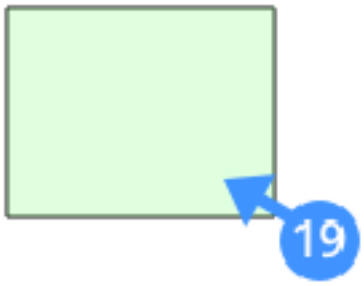


Figure 2.112

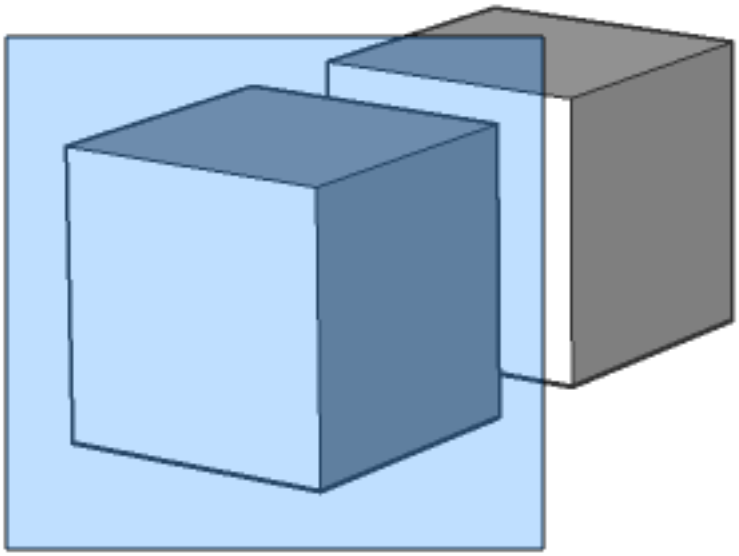

Figure 2.113

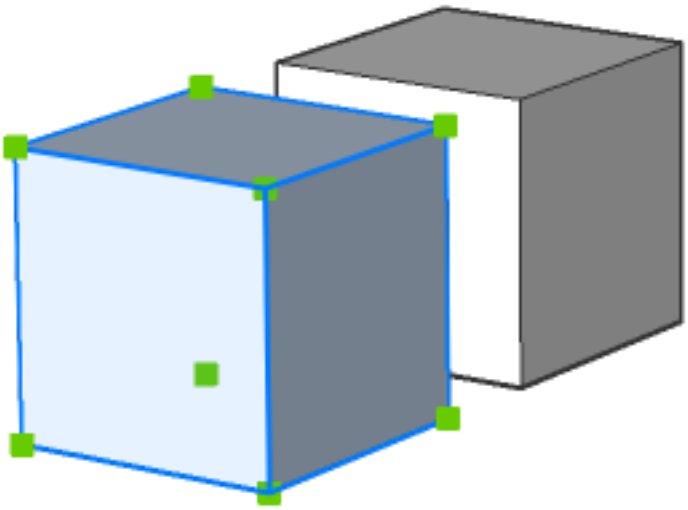

(2.115 on the following page)

3. To select edges of 3D solids and surfaces, press the CTRL-key twice during window selection. The 'Edges' icon (21) appears next to the cursor. The edges that are completely inside the window will be selected when the selection mode is set to Edges. (2.116 on page 1675) (2.117 on page 1675) The following steps show how to select multiple entities using the green selection box:

4. Click and move the mouse to the left (crossing window) to create a green box around the entities you want to select. When the entities overlap the window or are completely inside the window, they will be added to the selection set. The example below shows the green selection box usage when the selection mode is set to default. (2.118 on page 1676) (2.119 on page 1676) The green selection box selects both cubes in the model as the selection box overlaps with the two cubes.

5. To select faces of 3D solids and surfaces, making use of the green selection box, press CTRL key once during window selection. The 'Faces' icon appears next to the cursor (22). Any faces that are completely or partially inside the crossing window will be selected. (2.120 on page 1676) (2.121 on page 1677)

6. To select edges of 3D solids and surfaces, making use of the green selection box, press CTRL key twice during window selection. The 'Edges' icon appears next to the cursor (23). Any edges that are completely or partially inside the crossing window will be selected. (2.122 on page 1677) (2.123 on page 1678)

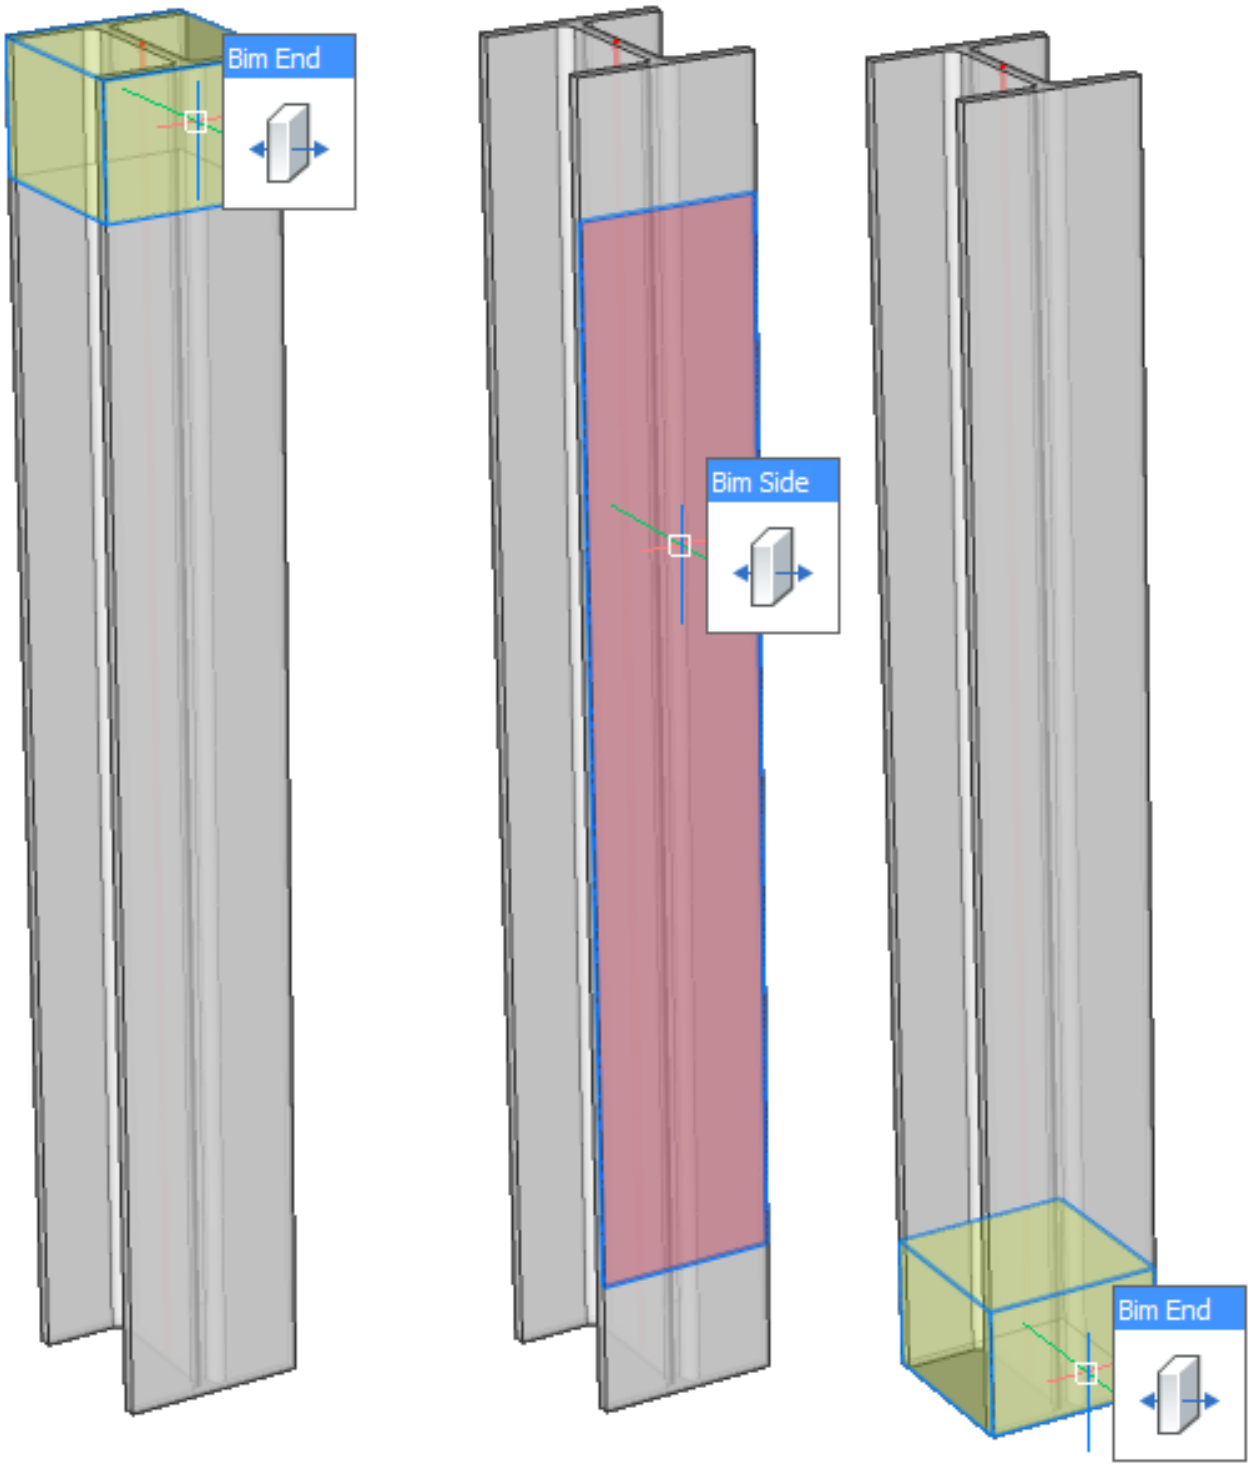
Selecting/Highlighting BIM Sides and Ends on profiles

1. Click on **Enable selection of Sides and Ends** icon in the BIM Toolbar (see below image). (2.124)
2. Hover over the linear solid in the model space when the cursor is on the top or bottom side of linear solid, Bim End face displays in yellow whereas the side face of linear solid displays in red. (2.125 on the facing page)

Figure 2.124

Figure 2.125



2.3.6 Level of Detail

The **RenderCompositionMaterial** and **LevelOfDetail** user preferences control the display of materials and multiply compositions.

Level of Detail

 Quad: **Bim** Ribbon: **Home | View** Toolbar: **BIM** Click the Icon to toggle the setting.

Option	Description
 [0] Low	Multiply compositions do not display.
 [2] High	The individual plies of the multiply compositions are visible and editable.

Render Composition Materials

 Quad: **Bim** Ribbon: **Home | View** Toolbar: **BIM** Click the Icon to toggle the setting.

Option	Description
 [0] Off	Materials are not rendered.
 [1] On	Materials are rendered. When Level Of Detail = 0 (Low), major faces of solids, that have a multiply composition attached, are rendered in the material of the underlying ply. Minor faces are rendered in the material of the exterior ply.

2.3.7 BIM Article Template

Command: (related command references should be linked with the text here) **Overview:** (a general overview of the article) **Lesson objectives:**

- (List the objectives of the article)
- (List the objectives of the article)
- (List the objectives of the article)

Tutorial: How to push or pull solids (add the related tutorial here) Click here (2.4.9) to watch

About (Command Name)

An extended general description of the command.

Procedure (Name of the procedure)

If you have multiple tutorials, the related tutorial can be added at the beginning of the procedure

1. Launch the X command...
2. Select the component... **(Blank Line: Shift+Enter)** (2.407 on page 1952) Figure 1, **a geometric model of the sample chair (title/description image) (Blank Line: Shift+Enter)**
3. Drag the component...
4. Define the location....

- Images should be referred to as a Figure
- Images should be aligned to the left
- Images should be static (upload in the Google Bucket system)
- Numbers should run between images 1,2,3 not start again at 1 (use the Bricsys callouts)

If you use alternative options for the command **Or** (make the text bold) ... The command prompt should be written as follow: **You are prompted:** (prompt:) If there are any notes in the article **Note:** (make the text bold) **(Optional)** Optional is bold and between brackets Tables:

2.4 Modeling Techniques

2.4.1 How to create and edit sections

https://www.youtube-nocookie.com/embed/N_4kG86Llqo

This video shows how Section Planes can be created and used to navigate through your model easily by clipping parts of the model. Back to Tutorial Overview

2.4.2 How to create a pitched roof

https://www.youtube-nocookie.com/embed/2po-JN5Prlc

This video shows how a pitched roof can be created starting from a polyline using the Extrude and Shell tools.
Back to Tutorial Overview

2.4.3 How to create wall layouts

https://www.youtube-nocookie.com/embed/xDuDHl36Pc0

This video explains how to use the Polysolid tool to create a series of walls, or to turn existing polylines into a wall layout. Back to Tutorial Overview

2.4.4 How to detect boundaries in BricsCAD BIM

https://www.youtube-nocookie.com/embed/m5M9QQiJces This tutorial explains how boundaries are automatically detected on flat surfaces, and how these boundaries can be used to create or edit geometry. Back to Tutorial Overview

2.4.5 How to connect walls

https://www.youtube-nocookie.com/embed/AknK6xhkh7Q

This video explains how to use the different connection tools to easily connect existing walls to each other. Back to Tutorial Overview

2.4.6 How to extrude

https://www.youtube-nocookie.com/embed/xHyOhJRx9rM

This tutorial explains what the Extrude tool can be used for. Back to Tutorial Overview

2.4.7 How to create walls

https://www.youtube-nocookie.com/embed/ihQyUxL75ps

This video explains how to use the Polysolid tool to create a wall. Back to Tutorial Overview

2.4.8 How to hide and isolate objects

https://www.youtube-nocookie.com/embed/JDqhITMz5HI

This video shows how you can temporarily hide or isolate single objects or selection sets. Back to Tutorial Overview

2.4.9 How to push or pull solids

https://www.youtube-nocookie.com/embed/-IJ3VHIGpOs

This video shows how to use Push/Pull to edit the face of a solid. Back to Tutorial Overview

2.4.10 How to select elements

https://www.youtube-nocookie.com/embed/SDYWIz0yYs4 This tutorial explains how to select entities and subentities. It explains the different selection modes and how to toggle between them, and how to use the CTRL and TAB keys to have full control over what you select. Back to Tutorial Overview

2.4.11 How to use Grids

https://www.youtube-nocookie.com/embed/Aas0bb0StV8 This tutorial explains how to create and edit a rectangular or radial grid. Back to Tutorial Overview

2.4.12 How to use linear solids

https://www.youtube-nocookie.com/embed/Nt6fyZ_xXMk

This tutorial explains how to create and use linear solids for structural modeling. Back to Tutorial Overview

2.4.13 How to add eccentricities to linear solids

https://www.youtube-nocookie.com/embed/rOYgRPJrlH0

This video shows how to give linear solids and eccentricity with respect to their axis. Back to Tutorial Overview

2.4.14 How to offset

https://www.youtube-nocookie.com/embed/SVAGhfuaxHA

This video gives an example of how the Offset tool can be used in combination with other direct modeling tools to model quickly and efficiently. Back to Tutorial Overview

2.4.15 How to create Curtain Walls

https://www.youtube-nocookie.com/embed/uP0H3zDrLiQ

This video shows how to create a curtain wall starting from a planar or non-planar face. Back to Tutorial Overview

2.4.16 How to use the BIM Insert tool

https://www.youtube-nocookie.com/embed/1qyoe16tNko

This video shows how to use the BIM Insert tool to insert windows and doors into your model. It explains how to use the dynamic dimensions for accurate placement of the components. Back to Tutorial Overview

2.4.17 How to automatically Parametrize objects

https://www.youtube-nocookie.com/embed/e5GjX33G-k8

This video shows how to parametrize an object automatically, and how to edit these constraints and parameter expressions. Back to Tutorial Overview

2.4.18 How to connect linear solids

https://www.youtube-nocookie.com/embed/-gW8L7NDjsE

This video shows how to use the Structural Connect tool to solve nodes of structural steel elements. Back to Tutorial Overview

2.4.19 How to create a Grading

https://www.youtube-nocookie.com/embed/x9ILmYT1NPU This video shows how to create a grading starting from a polyline and an existing TIN surface. Back to Tutorial Overview

2.4.20 How to use BIM Drag

https://www.youtube-nocookie.com/embed/cFQP46P4IQQ

This video shows how to use the Drag tool to move elements. It shows how to toggle off the connectivity with adjoining entities.

Back to Tutorial Overview

2.4.21 How to use the MEP modeling tools

https://www.youtube-nocookie.com/embed/S4OFhcotTeY

This video shows how to use linear solids to create MEP Flow segments, and how to manipulate these segments using different tools. Back to Tutorial Overview

2.4.22 How to use Layers

https://www.youtube-nocookie.com/embed/flEr6fZfHAs

This video shows how CAD layers can be used in BricsCAD BIM to organize your model and temporarily hide groups of objects. Back to Tutorial Overview

2.4.23 How to use selection windows

https://www.youtube-nocookie.com/embed/IO5W4T0ql_c

This video explains the difference between a green and a blue selection window, and how to use the CTRL key to window select solids, faces or edges. Back to Tutorial Overview

2.4.24 How to use the Components Panel

https://www.youtube-nocookie.com/embed/nomfQh5dB5o This video shows how to use the Components Panel to drag and drop components into your model, and how to create new components from scratch. Back to Tutorial Overview

2.4.25 How to use the Window Creator tool

https://www.youtube-nocookie.com/embed/M7WEU7dUO-E

This tutorial shows how to turn a simple polyline or boundary into a fully parametric window component using the Window Creator Tool. Back to Tutorial Overview

2.4.26 How to use Quickdraw

https://www.youtube-nocookie.com/embed/9g2bhcxPFbo

This video explains the function of the Quickdraw tool. It shows how the magnetic cursor works, how to create a new room and how to edit existing rooms. Back to Tutorial Overview

2.5 Modeling Techniques

2.5.1 BIM Linear Solid

Commands: BimLinearSolid (6.7.29), BimApplyProfile (6.7.10), BimProfiles, (6.7.26) BimAddEccentricity, (6.7.7) BimRecalculateAxis (6.7.51) **Overview:** In this lesson, you learn how to use the Linear Solid tool to create structural members and flow segments. **Lesson Objectives** After completing this lesson, you will be able to:

- Use different structural member profiles and piping profiles in your structural and mechanical modeling.
- Apply and replace profiles of linear solids.
- Add eccentricity to linear solids.
- Recalculate the axis of linear building elements.
- Make structural connections and flow fittings.

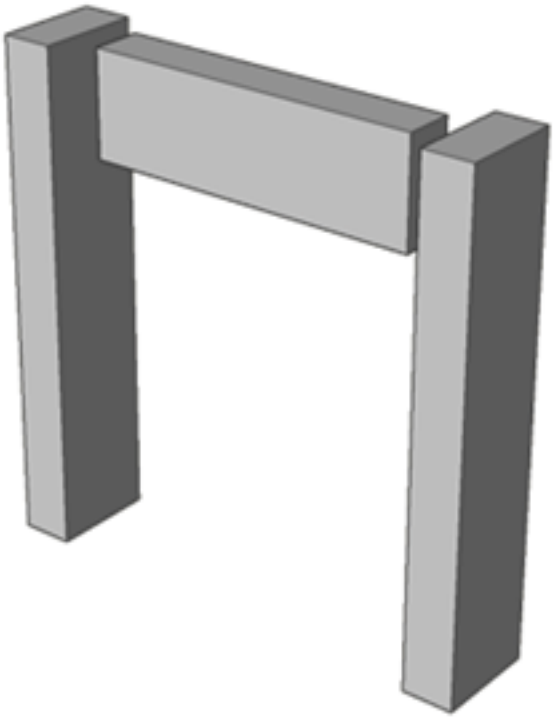
About BIM Linear Solid

The Linear Solid tool allows you to create structural members or flow segments. The tool can be made use of creating a variety of structural member profiles or MEP elements.  For more information about this command, visit the Command Reference article BimLinearSolid (6.7.29).
For more information about **MEP modeling**, visit the help article MEP Modeling (2.5.14) and MEP Flow Connection Points (2.5.16). For more information about **Structural Steel**, visit the help article Structural Steel. (2.5.20)

Tutorial: How to use linear solids Click here (2.4.12) to watch Before starting the process, make sure that Quad is active. Next, follow these steps:

1. Hover over the Model tab in the Quad and select the Linear Solid tool. **Note:** you can also launch the **BimLinearSolid** command you entering it in the commandline. **You are prompted:** Set start point or [Follow/Rectangular/Circular/Dialog/select in Model/adJust profile] <Last point>:
2. Select a start point. **You are prompted:** Set next point or [Angle/Length/Undo/Quarter turn/Rotate/choose other Profile/adJust profile]:
3. Move the mouse cursor to draw the beam or column.
4. Click to specify the endpoint, or enter a value for the distance using the dynamic dimension field.
5. Press Enter key to accept it. The following illustration shows a beam and two columns with the default rectangular profile. (2.127 on the following page)

Figure 2.127



About BIM Profiles

Tutorial: How to use the Profile Library for linear solids Click here (2.6.10) to watch You can access the BIM profiles panel by clicking the I-beam on the right-hand side of your screen. If the BIM Profiles toolbar is not displayed on the right-hand side of your screen, right-click on the **Tool Panel** at the right-hand side of your screen, choose Panels in the context menu, then check BIM Profiles. **Note**: You can also find the BIM Profiles Panel by typing **BIMPROFILES** in the commandline. The following illustration shows the **BIM Profiles Panel**. (2.128 on the next page) The drop-down box at the top (1) acts as a filter. There are different domains on which you can filter: **Generic, Structural Concrete, Structural Steel, HVAC, Piping** and **Electrical**. **Note:** If you don't have any profiles in a certain domain, you will not be able to filter on it. The second drop-down boxes (2) allow you to filter the profiles by the country standards. The search box (3) allows you to filter by name. The menu (4) on the right-hand side allows you to access the BIM Profiles dialog box. Clicking the menu icon displays a context menu with a couple of options. The following illustration shows the BIM Profiles context menu. (2.129 on page 1712) Select **Open profile dialog (5)** on the menu to open the Profiles Dialog box. The following illustration shows the **Profiles** dialog box. (2.130 on page 1712)

Filters (6)	Filters the profiles list by: • **Type**: All, HVAC, Piping or Structural Steel • **Standard**: Localized standards • **Shape**: Profile shape (L, U, circular, ...) • **Name**: Select a character string. Only profiles that contain the selected string are listed.
Tools (7)	: Save the currently edited profile : Create a new profile : Delete the selected profile : Opens the Project Info (6.7.32) dialog box
Custom fields (8)	Set the type, standard, name, and size of a profile
Preselect shape (9)	Select a shape from the drop-down list
Pick profile in model (10)	Select a closed 2D entity or the boundary entities of an enclosed area
Profile properties (11)	Shows the properties of the selected profile

Figure 2.129

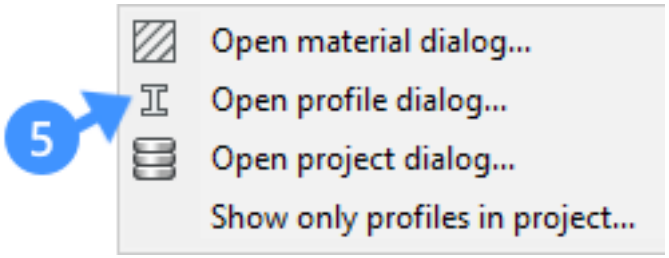

Figure 2.130

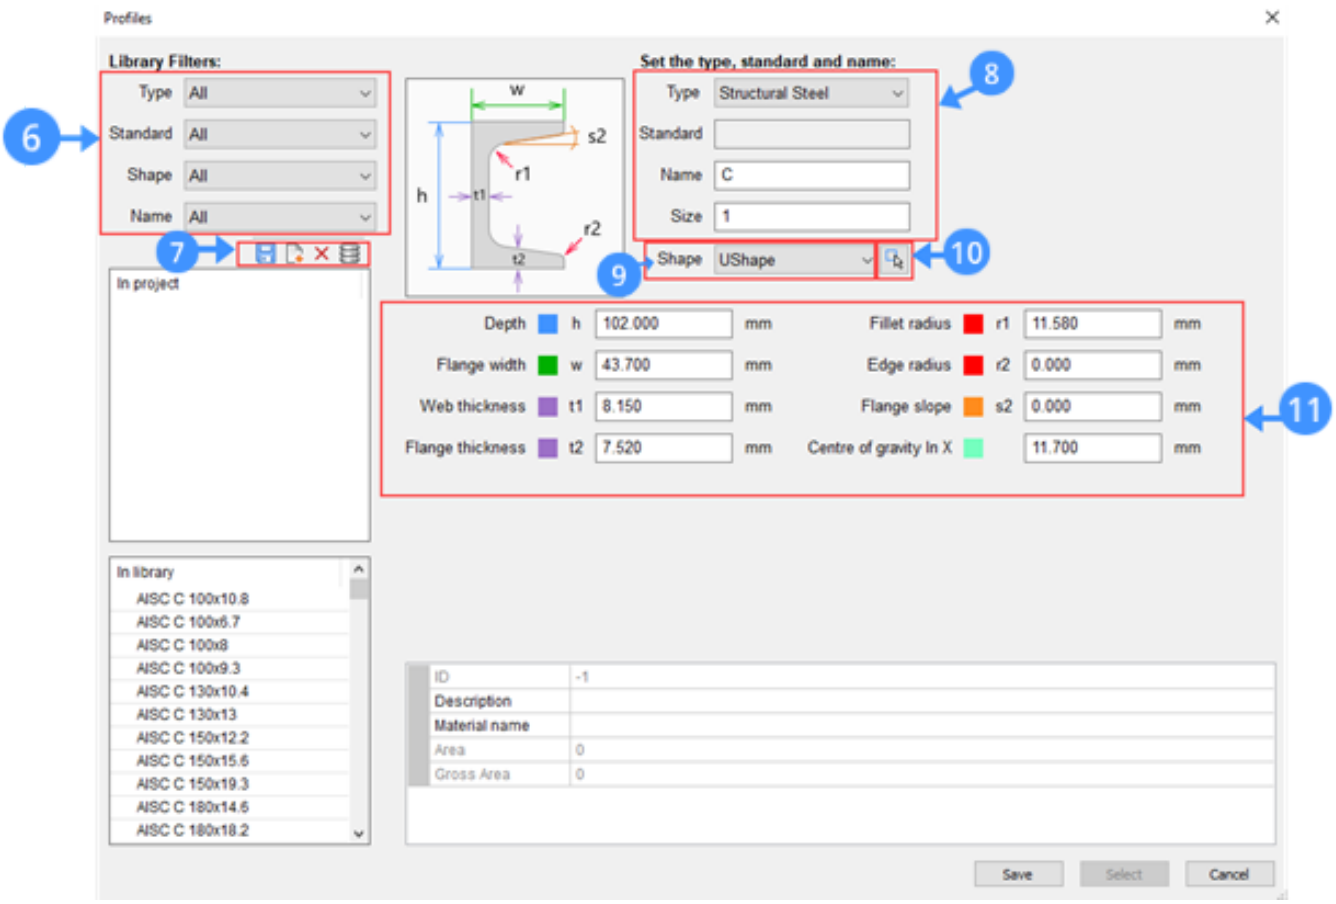
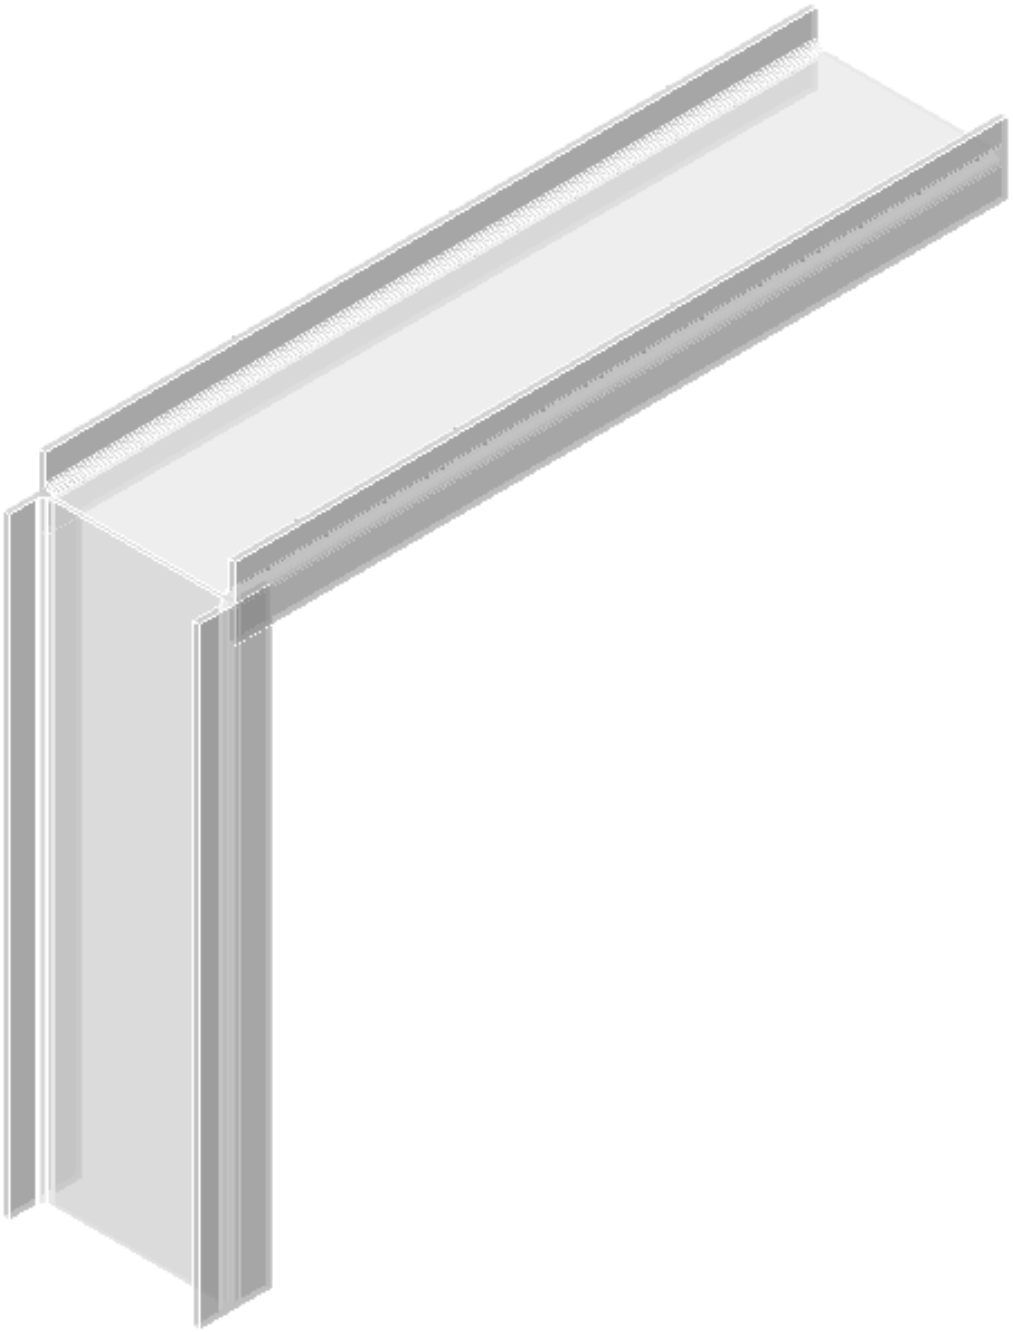


How to use the BIM Profiles Panel

1. Drag and drop the desired profile from the BIM Profiles Panel to the model space. **Note:** This command works in the same way as the Line (6.20.31) command.
2. To define the starting point and the following point(s) click in the model space or use the dynamic dimension fields.
3. Press Enter to end the command.

(2.375 on page 1916) **Note**: BricsCAD doesn't automatically generate the connections between the different segments because the chosen profiles are structural steel.

Figure 2.131



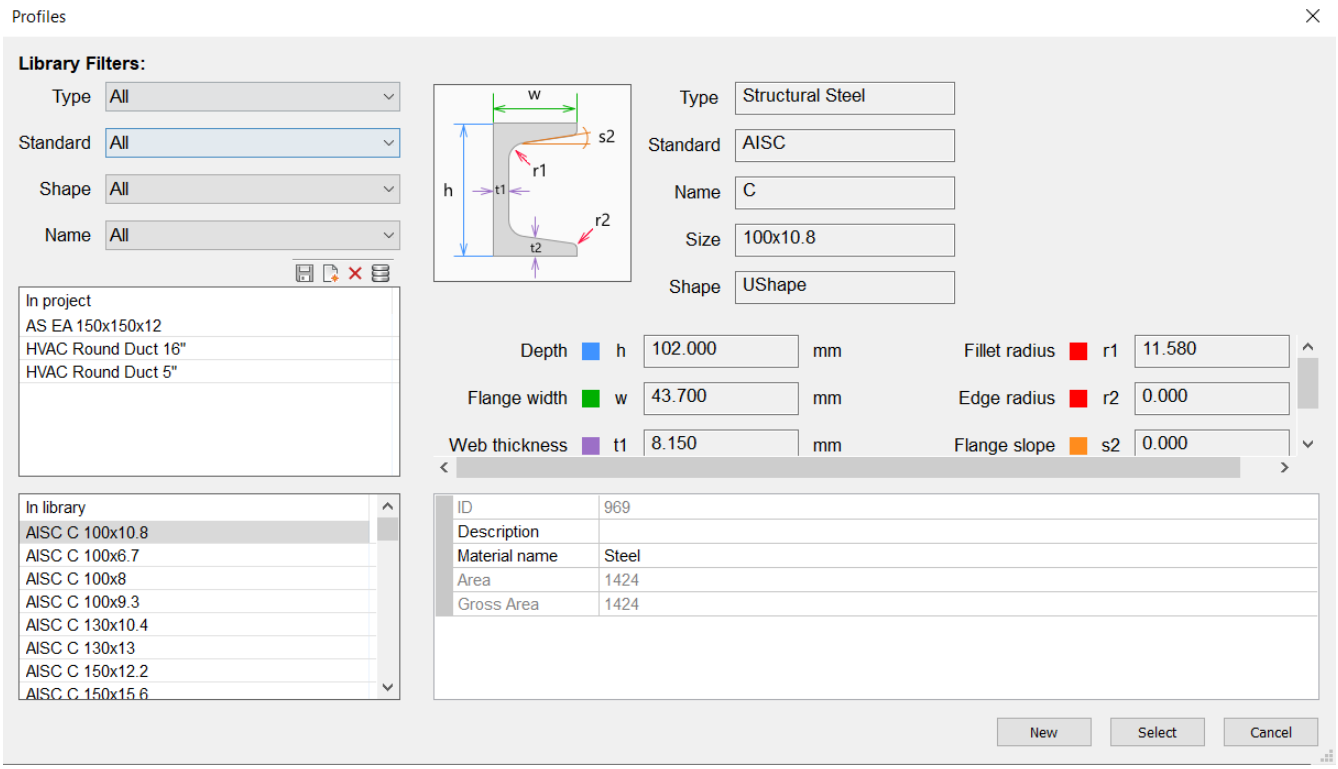
About BimApplyProfile

The Apply Profile tool allows you to change the profile of linear entities and linear solids. Linear solids have a constant cross-section over a linear extrusion path. The tool recognizes clippings and openings. Using the Apply Profile tool, you can create columns, railings, beams, pipes, ducts and more.  For more information about this command, visit the Command Reference article BimApplyProfile (6.7.10).

How to apply profiles to an existing line or solid: with the BimApplyProfile command.

1. Select the line or solid you want to apply a profile to and launch the **BimApplyProfile** command.
2. Press Enter and the Profiles DialogBox, appears.(2.132 on the next page)
3. Choose a profile and press the **Select** button in the bottom-right corner.
4. Press Enter to end the command. The profile is applied to the line or solid in your model.

Figure 2.132



How to apply profiles to an existing line or solid: with the BIM Profiles Panel

1. Open the BIM Profiles Panel. **Note:** You can access the BIM Profiles panel by clicking the I-beam icon on the right-hand side of your screen.
2. Select all the entities you want to apply a profile to.
3. In the BIM Profiles panel, search for the profile you want apply to the selected entities.
4. Drag the chosen profile onto one of the selected entities.
5. The profile is applied to the line or solids in your model. **Note:** By applying a profile to a solid, the solid will be **replaced** by the chosen profile. In case of a line, the line will **not be replaced**, but a profile was added with his axis the same as the selected line.
6. Since the line is no longer needed, you can delete the line.

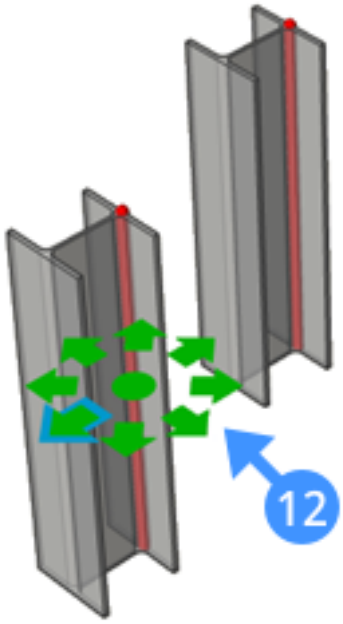
About BIM Add Eccentricity

BIMAddEccentricity allows you to control the relative position of the axis of a linear solid. For more information about this command, visit the Command Reference article BimAddEccentricity (6.7.7).

Tutorial: How to add eccentricities to linear solids Click here (2.4.13) to watch

1. Select an existing linear solid or profile in the drawing area.
2. Launch the **BimAddEccentricity** command by entering it in the command bar, or select the command in the Quad (under the model tab) or in the Ribbon (in the Structural/MEP tab). The eccentricity widget appears
3. To set an eccentricity, click one of the nine locations from the widget, then right-click to confirm.
4. Optionally, type a location in the command line. The options of the locations are: **TR:** Top Right, **TM**: Top Middle, **TL**: Top Left, **MR**: Middle Right, **C**: Center (resets the axes of the selection set to the default location), **ML**: Middle Left, **BR**: Bottom Right, **BM**: Bottom Middle, **BL**: Bottom left
5. Press Enter to accept changes. The following illustration shows the **Eccentricity** widget (12) on the linear solid profile. (2.133 on the facing page)

Figure 2.133



About BIM Recalculate Axis

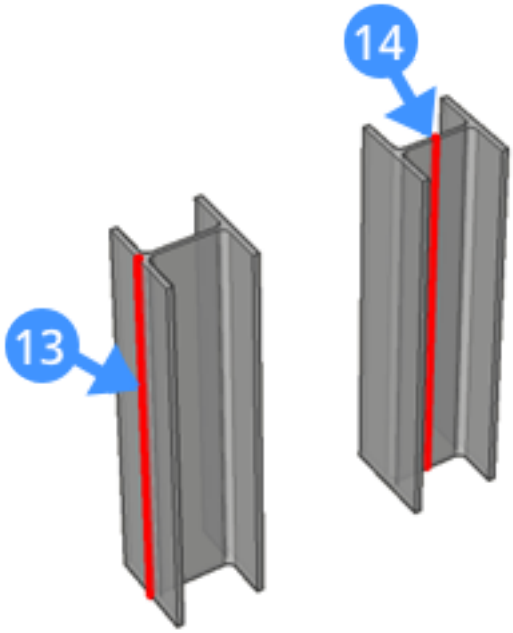
The Recalculate Axis tool recalculates the axis of linear building elements and repositions it back to the centerline of a linear element.  For more information about this command, visit the Command Reference article BimRecalculateAxis (6.7.51).

Recalculate the axis of linear building elements

1. Select any linear building element in your model
2. Launch the **BimRecalculateAxis** command.
3. Press Enter.
4. The axis of the element is moved to the default position.

The following illustration shows the result of using BIM recalculate axis on the linear solid. The axis (13) is moved to the centerline (14) of the linear element. (2.134 on the next page)

Figure 2.134



Helpful settings when modeling Linear Solids

Display Axes The DisplayAxes setting can hide or view the Axes of linear solids in order to edit the structure more easily.  If DisplayAxes is toggled on, the axes of the linear solids are visible as a thick red line. In this case, you will only be able to snap the endpoint of the axis as a starting point to add more linear solids or profiles to your already existing structure. When DisplayAxes is toggled off, no axis is visible in your drawing area and you're able to snap all specific points you have ticked in the context menu of ESNAP.

DisplayAxes OFF	DisplayAxes ON
(2.135 on the facing page)	(2.136 on page 1720)

BIMOSMODE The BIMOSMODE setting gives you the possibility to choose the level of detail you are snapping to.

1. Enter BIMOSMODE in the commandline. **You are prompted**: New current value for BIMOSMODE (0 to 3) <2>:
2. Choose a new value (type a number from 0 to 3)

Value	Snapping detail
0	Turns on all snapping.
1	Turns off all snapping to solids **except** for the axis of the solid.
2	Turns off all snapping to BIM Grid axes **except** for axis intersections.
3	Turns off all snapping to BIM Grid axes **except** for axis intersections. Turns off all snapping to solids **except** for the axis of the solid.

3. Press Enter.

Figure 2.135

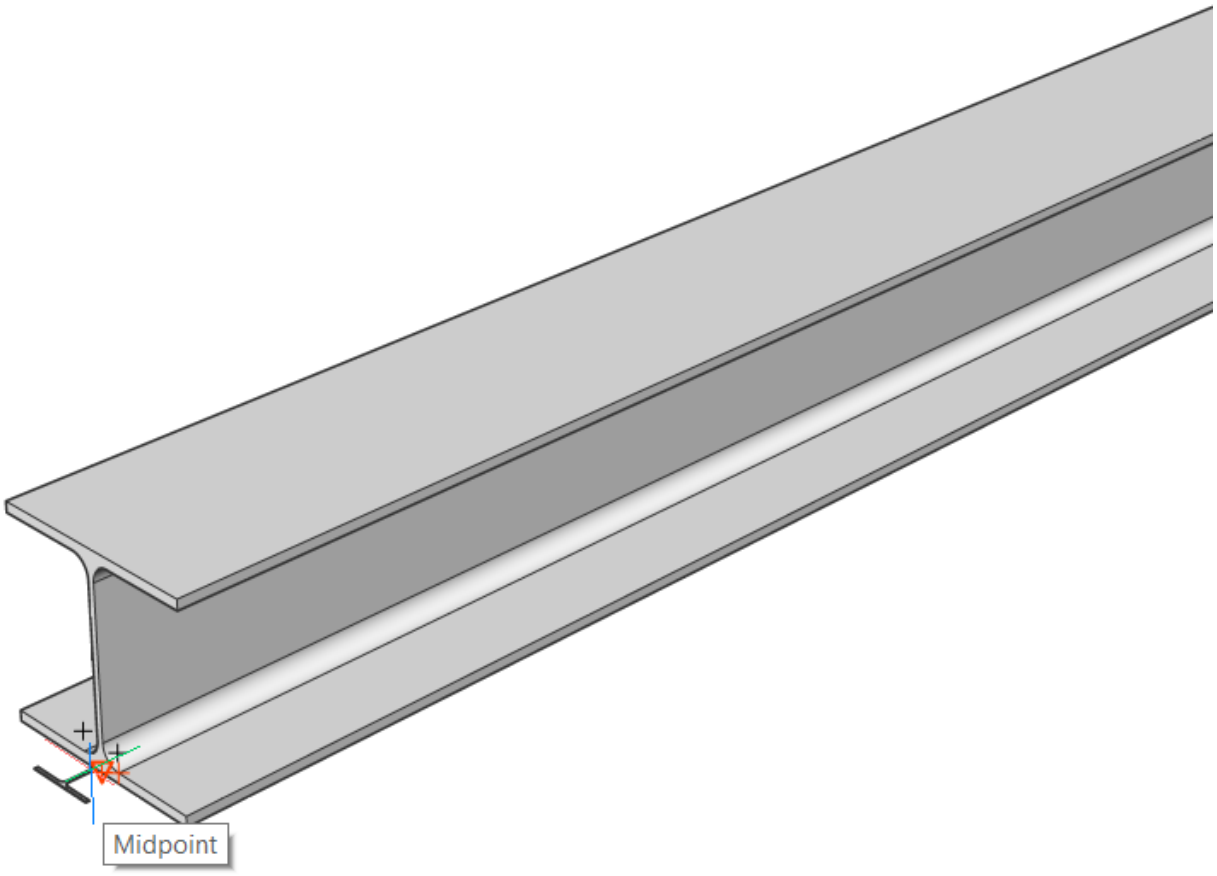


Figure 2.136

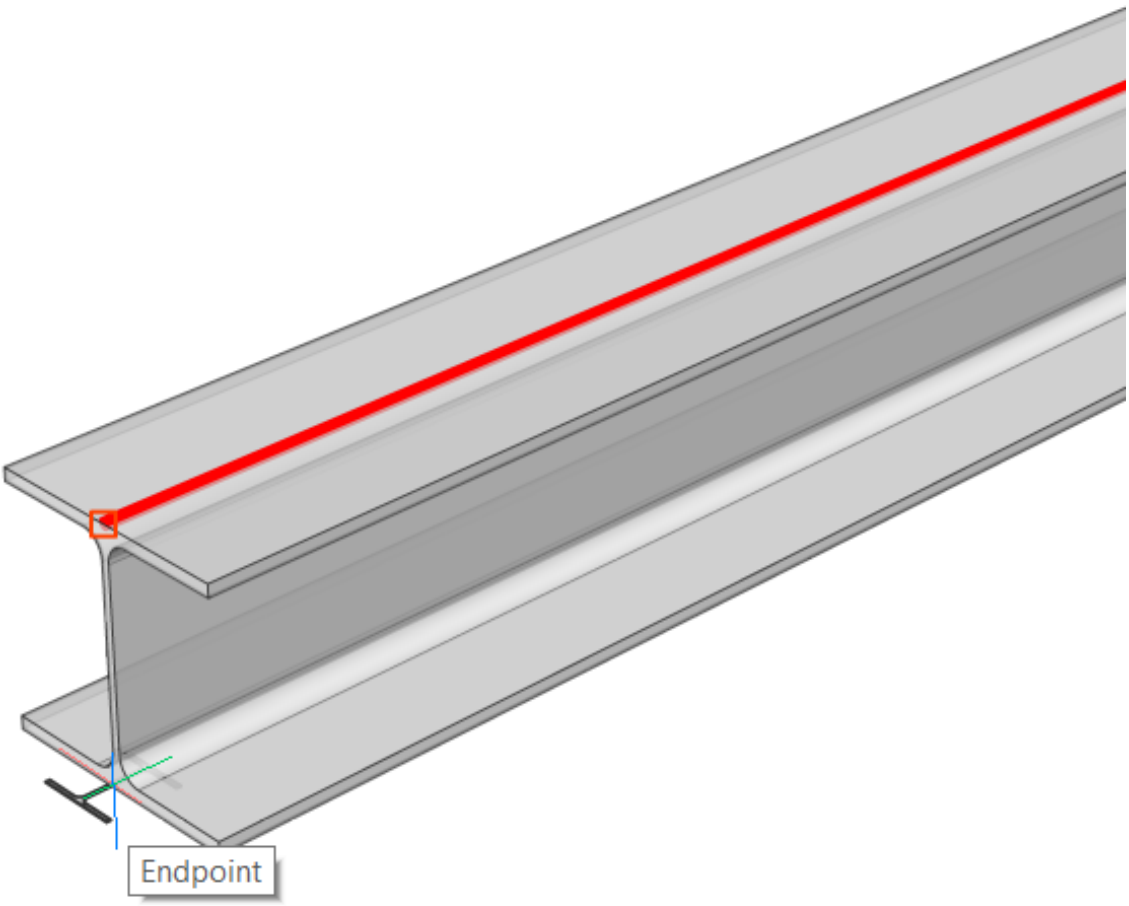

2.5.2 BIM Window Create

Command: BimWindowCreate (6.7.55) **Overview:** In this lesson, you learn how to create a fully parametric window based on a closed contour in your BIM model. **Lesson Objectives** After completing this lesson, you will be able to:

- Create a parametric window from a profile on a wall.
- Change the parameters of the created window.
- Create openings in a wall.

Tutorial: How to use the Window Creator tool Click here (2.4.25) to watch

About

In BricsCAD, the **Window Creator** tool allows you to turn a different set of design ideas into a window. You can use the tool on windows of all shapes and sizes, which enables you to utilize a significant amount of window styles in your BIM project. When you have a closed 2D entity or boundary on the face of a solid (wall), the window creator tool enables you to use these closed entities to make your window. Using the window creator tool, you can select any window styles in the dialog box, and change the properties of this created window in a BIM model.  For more information about this command, visit the Command Reference article BimWindowCreate (6.7.55).

Creating a parametric window using boundaries

1. Draw a polygon on the face of a solid (wall). Based on this base profile, the window opening will be created. (2.137 on the following page)
2. Make sure **Boundary Detection (2.3.5)** is enabled. Hover over the inside of the polygon and select the Create Window tool from the Quad. (2.138 on the next page) A file dialog box displays: (2.139 on page 1723)
3. Select a window style in the dialog box. The window is created on the wall with the selected style. The following illustration shows the double panel vertical window style which was selected to create the windows on the face of the wall. (2.140 on page 1723)
4. **(Optional)** You can refine the window design by changing the default values of the parameters. To do this, select the window and change the desired parameters in the **Properties Panel**. (2.366 on page 1905) To change one of the default parameters of this window, type a new value in the property field.
5. Press **Enter** to accept the new value of the parameter. The window should be updated automatically.

Create windows based on a grid

1. Use BimGrid (6.7.21) to create a Grid on the face of the wall. Choose the basic dimensions in the commandline. Changing the U-line and V-line panel options allows you to specify the desired size and number of panels on the surface. **Note:** To draw on the face, make sure you first highlight the face and then click. Otherwise, the Grid will be created in the XY-plane. (2.142 on the next page)
2. Use Bedit (6.6.7) or RefEdit (6.26.13) to edit the Grid. Use the Manipulator (1.10.7) to change the position of the gridlines on the wall. (2.143 on the facing page)
3. Select the Grid and select Create Window in the Quad. (2.144 on page 1726)
4. The window is generated based on the gridlines. (2.145 on page 1726) **Note:** You can edit the parameters in the Properties Panel. Type a new value in the property field and press Enter. The window will automatically update itself. (2.146 on page 1727)

Creating window openings

BIM Opening Create creates an opening without window geometry. It uses the same command as BimWindowCreate. The command allows to create an opening at the location of the selected base profile. The base profile can be a boundary or a closed polyline.  For more information about this command, visit the Command Reference article BimWindowCreate (6.7.55).

1. Draw one or more closed polylines on the face of a wall.
2. While boundary detection is on, hover over the polygon. **Or** select the closed polyline.
3. Select the Create Opening tool from the Quad. (2.147 on the facing page)
4. The opening is created based on the closed contour. In the Structure Browser (2.7.18), the opening is added as a Block Reference. The block reference is classified as an opening. (2.148 on the next page) (2.149 on page 1730) If you select the opening from the structure browser, you will see a set of properties related to this opening element in the Properties Panel. (2.150 on page 1731) **Note:** If your closed contour has a rectangle shape, the opening element will include Width and Height parameters. **Note:** Opening elements contain subtractor solids. To display the subtractor solid, open the Layers Panel and select the BIM_Subtract layer. **Note:** The associative tags can be generated using the BimTag (6.7.59) command for the opening element in a sectioned drawing. The following animated gif demonstrates how to create an opening based on a closed contour. (2.151 on page 1732)

2.5.3 The Library Panel

Commands: LIBRARYPANELOPEN (6.20.23), LIBRARYPANELCLOSE (6.20.22), CREATELIBRARYBLOCK (6.9.55), -CREATELIBRARYBLOCK (6.9.45) **Overview:** In BricsCAD BIM, the Library panel is used to access your Bricsys BIM library. BricsCAD comes with a standard BIM library, but you can also create your own. **Lesson Objectives:** After completing this lesson you will be able to:

- Create your own libraries.
- Create library blocks, name them and save them in to the required category.
- Manage the display in the Library panel.
- Drag-and-drop a library block into your drawing.

About

The Library panel is a quick way to keep your BIM blocks at your fingertips or access predefined ones. You can add any CAD model to the Library. You can also fully customize the name and category to make it easier to find. You can then insert a library block in your drawing by dragging and dropping. Keep your library clean by deleting the items you no longer need.

Content of the Library panel

You can control the content of the Library panel in the Option menu (6.20.23). **Note:** When the COMPONENTSPATH system variable is empty (all paths deleted), the default **C:\ProgramData\Bricsys\Components** path is added automatically when you close and reopen the Settings dialog.

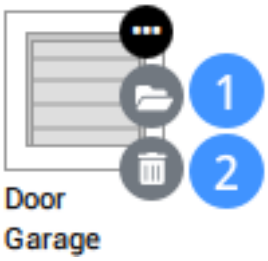
Creating a library block

1. Open or create the drawing which contains the geometry for the new block.
2. Do one of the following:
   - Click the **Home** icon ( ). This allows you to select the destination category; or you can create a new category.
   - Click the **Category** thumbnail. The new item will be created in the selected category or in a subcategory of the selected category.
- Launch the CREATELIBRARYBLOCK (6.9.55) command. The **Add block to library** dialog displays.
- Select the entities or choose the **Entire drawing** option.
- Type a name for the block.
- (Option) Type a new category name or choose a category from the list.
- (Option) Click **Show Options** and set the block creation options.
- Click the **Create** button.

Managing library blocks

1. In the **Grid view** display, hover over the block icon.
2. Click the **Menu** icon (...) (2.152)
3. (option) Click the **File Open** icon (1) to open the block file . Edit the file, then save the changes.
4. (option) Click the **Delete** icon (2) to delete the block file. Click **Yes** to confirm.

Figure 2.152



Searching the block libraries

Type a search string in the search field. Only matching library blocks in the current category display. (2.153 on the facing page)

Inserting a BIM window into your 3D model

1. Click the **Windows** category tile in the Library panel.
2. Click the a window (8).
3. Drag and drop the window onto the wall (9). (2.154 on the next page)
4. **If Dynamic dimensions (DYN) is switched on**, set the window location by entering the dimensions into the DYN fields (9). Press the Tab key to cycle through the DYN fields (10). A DYN field turns red to indicate the distance is locked. (2.155 on the facing page)
5. To edit the dimensions of the window press Ctrl (11) once and then use the Tab-key to cycle through the DYN fields (12). (2.156 on page 1738) (2.157 on page 1738)
6. Press Enter. The window is created. This same technique can be used for most of the blocks in the Library.. (2.158 on page 1739)
7. **(Optional)** Once you have a window you can adjust the position by selecting the window and then clicking on the dimension lines and editing the dimensions (13). (2.159 on page 1739)
8. **(Optional)** To adjust the dimensions of the window after the window has been created, go to the Properties Panel. Scroll down to the **Parameters** section and change the parameters as required. All windows and doors in the Library are parametric. (2.160 on page 1740)

2.5.4 Connecting Solids

Commands: LConnect (6.20.19), TConnect (6.29.9), BimStructuralConnect (6.7.61) **Overview:** In this lesson, you will learn how to use the Connect tool to connect solids in different ways. **Lesson Objectives** After completing this lesson, you will be able to:

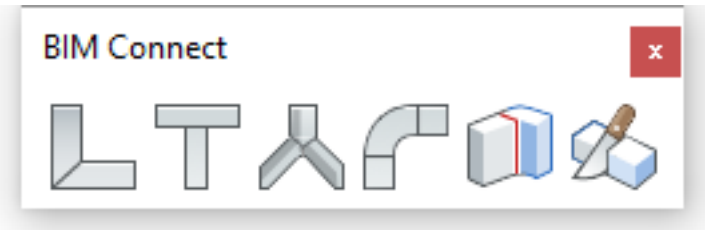
- Make L-connections and T-connections between two solids.
- Modify the height and thickness of a solid.
- Make connections ply-by-ply.
- Disconnect two connected solids.

About

Walls, profiles, plies, etc. are all created as native 3D solids. So any of the 3D Solids Editing commands can be used to modify them. Use BIM Connect commands to connect two solids in different ways. (2.161) The LConnect (6.20.19) command ( ) creates an L-connection (bisector or parallel) between two solids. The TConnect (6.29.9) command ( ) creates a T-connection between two solids. The BimStructuralConnect (6.7.61) command ( ) connects structural profile solids such as beams and columns. The BimFlowConnect (6.7.19) command ( ) creates a connection between flow segments, such as pipes or HVAC ducts. The procedures below use the Quad cursor menu (1.15.5).

Tutorial: How to connect walls Click here (2.4.5) to watch

Figure 2.161



Procedure: Creating L-connections

1. Make sure **SelectionModes** = 0.
2. Type **LConnect** in the commandline or select it via the Quad.
3. Select two solids or faces to connect.
4. The two selected solids are connected: the default connection type is L-bisector. If HKA (1.17.10) is ON, the Hotkey Assistant widget displays. (2.162) Use the CTRL key to cycle between the connection types **or You are prompted: Select base solid [Switch] <Accept>**. Type **A** to use the selected connection, type **S** to switch to the desired connection type. The 3D model updates dynamically when cycling the L-connection types.

Note: L-connections can also be created between non-vertical solids such as roof slabs.

Figure 2.162

Procedure: Creating T-connections

The following procedure allows connecting minor faces of a solid to the major faces of other solids, regardless of what the orientation of the faces is. As a result, you can use **TConnect** command to T-connect solids.

1. Make sure the Select Faces option of the SELECTIONMODES system variable is selected. (2.167 on page 1747)
2. Type **TConnect** in the commandline or select it via the Quad.
3. Move the cursor over the minor face of the first solid at the end that needs to be connected. Press Tab to highlight obscured faces. Click when the face highlights.
4. (2.164 on the next page)
5. **(Optional)** Repeat the previous step to select more faces, then press Enter. Tip: the SelectAlignedFaces (6.27.17) command in the Select command group in the Quad selects all faces in the 3D model that are in the same plane (coplanar) with a selected face.
6. **You are prompted:** Select entities to connect to or [Connect to nearest/Disconnect/selection options (?)] <Connect to nearest>:
7. Do one of the following:
   - Press Enter to connect to the nearest face(s).
   - Select one or more faces. If necessary, press Tab to highlight an obscured face; click when the face is highlighted. Right click to stop selecting faces.(2.165 on page 1745) (2.166 on page 1746)

TIP. Hover over the minor face of the solid and choose **Connect with Nearest** in the Model command group of the Quad.

Figure 2.163

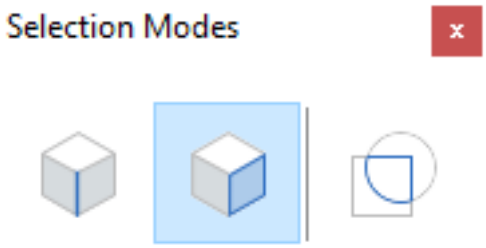


Figure 2.164

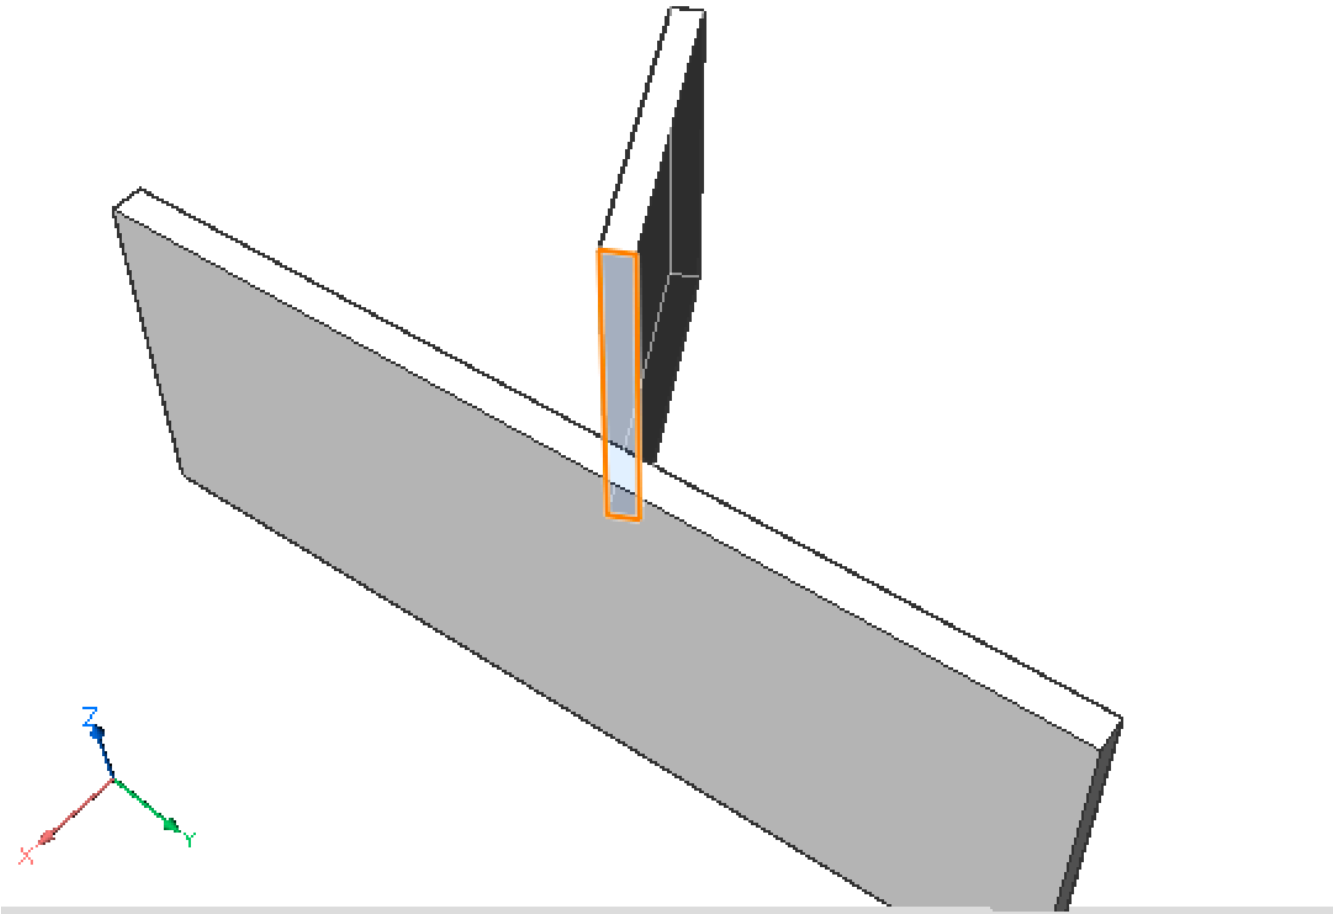

Figure 2.165

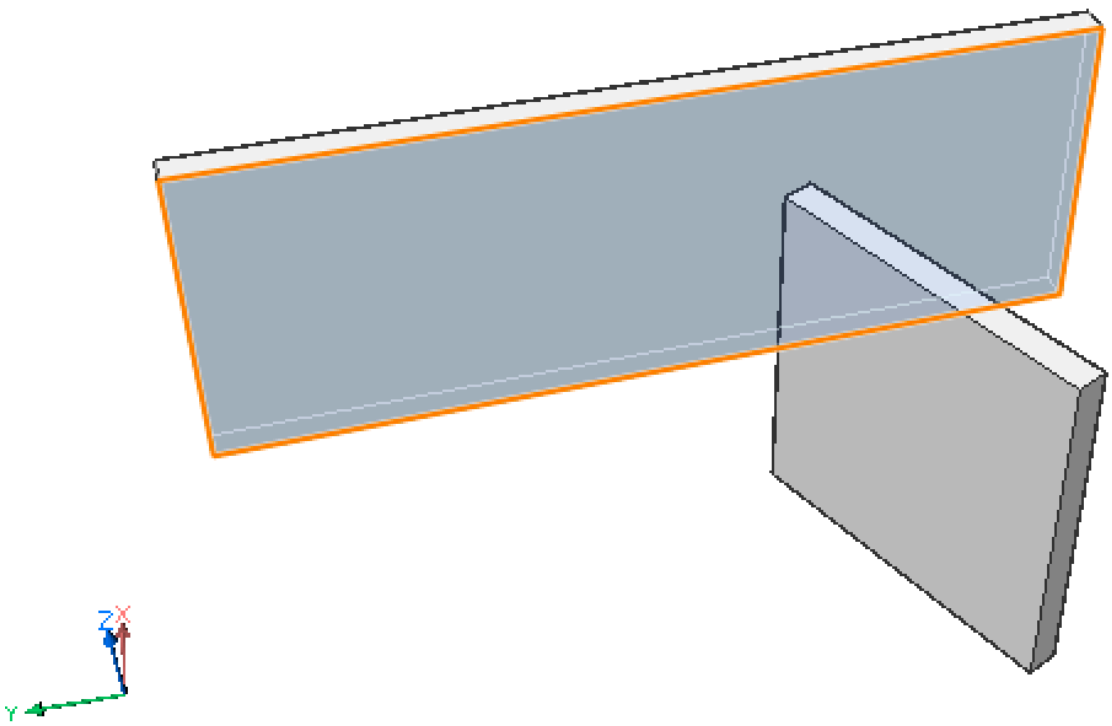

Figure 2.166

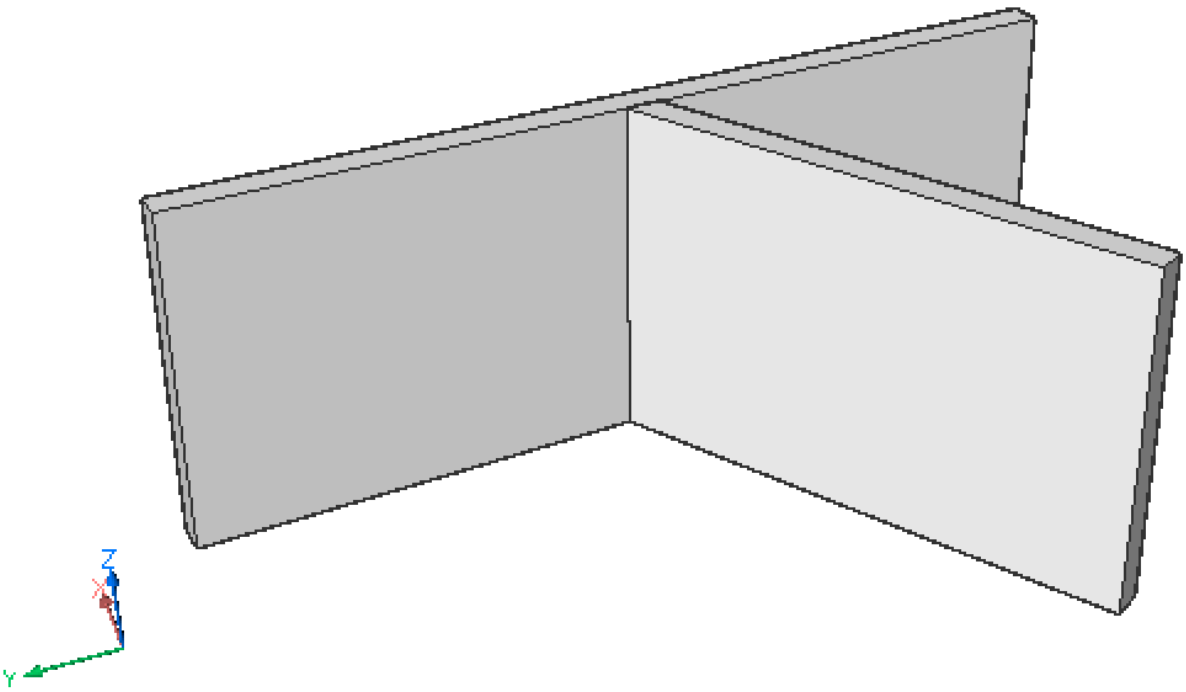


(2.174 on page 1753)	(2.175 on page 1753)
3D Model	**Calculated Section**

Creating T-connections ply-by-ply To control the connection of composition plies between two building elements, you can Push/Pull (6.12.25) a ply in a clipped BimSection (6.7.54) (if Show Composition is ON). For more in-depth information, visit the BIM Ply Editing (2.7.8) article. To create a T-connection ply-by-ply in a section, do the following.

1. Place the cursor over the face of the ply you want to connect. If necessary, repeatedly press Tab to select an obscured face.
2. When the ply face highlights, choose **Push/Pull** in the Quad.
3. Specify to which point the selected ply should reach by moving the cursor or typing in the distance.
4. Right-click or press Enter to confirm. The ply of the first solid is connected to the ply of the second solid. The connected ply is subtracted from the second solid.
5. Optionally, use the BimPropagatePlanar (6.7.36) command to apply the connection to similar locations in the model.

Procedure: Setting the distance between parallel solids

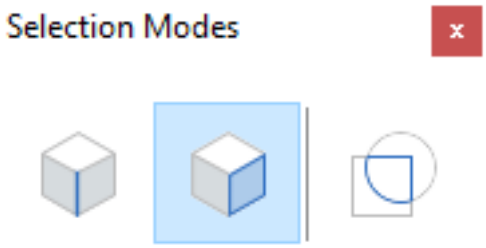
1. Select the solid of which the position must be fixed.
2. Select the solid which will be moved when defining the new distance. The nearest distance (1.21.10) between the solids displays.
3. Type a value in the distance field and press Enter.

Procedure: Creating a copy of a solid

Create a parallel copy of a solid

1. Make sure the Select Faces option of the SELECTIONMODES system variable is selected. (2.167)
2. Move the cursor over a face of the solid to be copied.
3. When the face highlights, choose BimCopy (6.7.13) in the Model command group of the Quad. A copy of the solid displays dynamically. The ruler (1.10.7) indicates the current distance.
4. Type a value in the dynamic entry field and press Enter.

Figure 2.167



Creating a partial copy of a solid

1. Make sure the Enable boundary detection option of the SELECTIONMODES system variable is selected. (2.168)
2. Highlight the part of the boundary for the part of the solid you want to copy.(2.169 on the facing page)
3. When the face highlights, choose BimCopy (6.7.13) in the BIM command group of the Quad. A partial copy of the solid displays dynamically. The ruler (1.10.7) indicates the current distance.
4. Type a value in the dynamic entry field and press Enter. (2.170 on the next page)

Figure 2.168

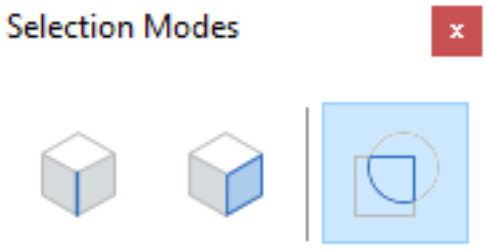


Figure 2.169

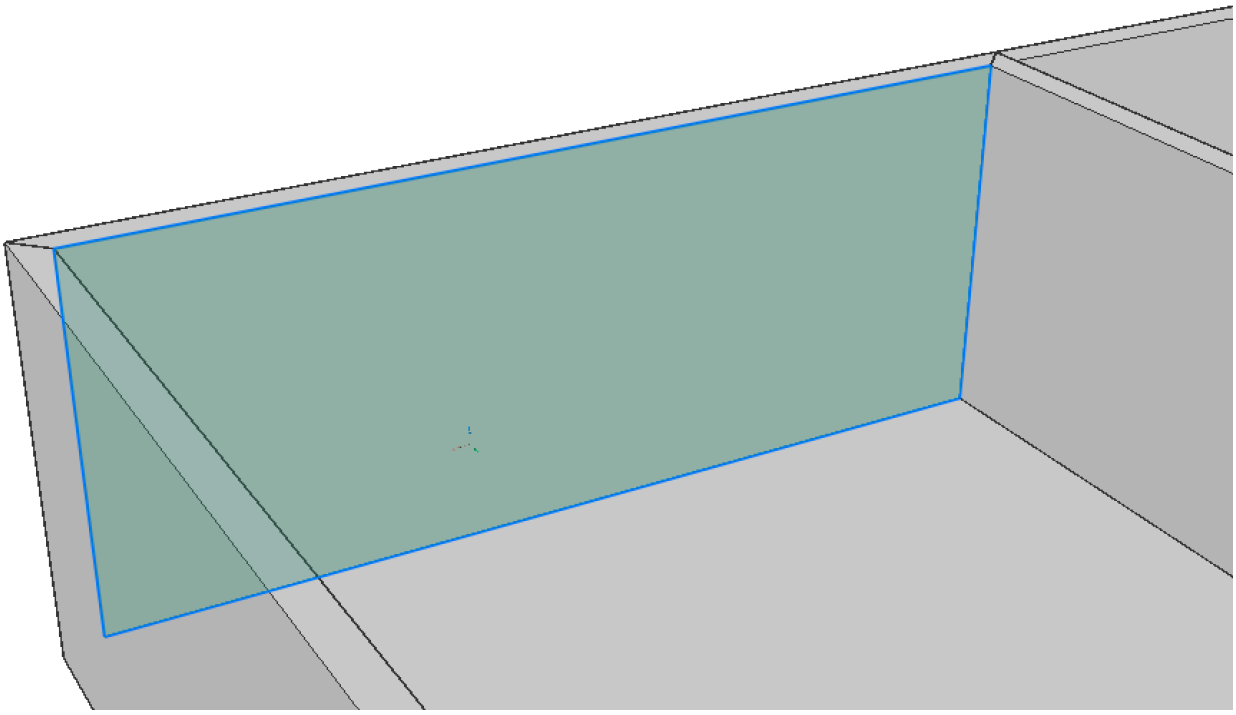

Figure 2.170

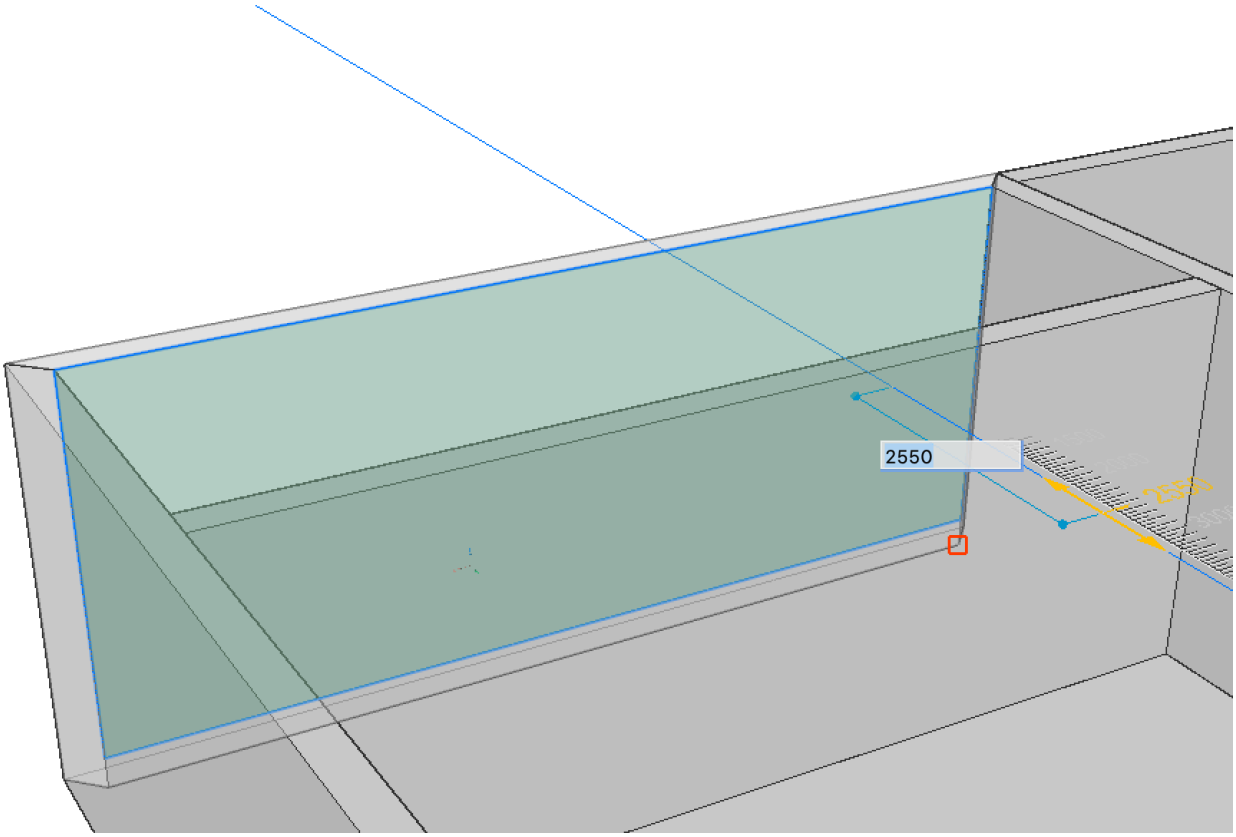

Procedure: Disconnecting two connected solids

In some cases, you need to disconnect 2 solids of a node to do some further direct modeling. You select two solids and it breaks the connection by separating the two solids physically and removes all end clippings at the side of the connection. As such, these solids can direct modeled upon again. (2.171 on the facing page)

1. Type **LConnect** in the commandline.
2. Select the two solids.
3. The connection is automatically made, press CTRL until the disconnect icon is highlighted (2.172 on the next page)
4. Press Enter. (2.173 on page 1752)

Note: You can use Propagate (6.7.30) to disconnect similar nodes.

Figure 2.171

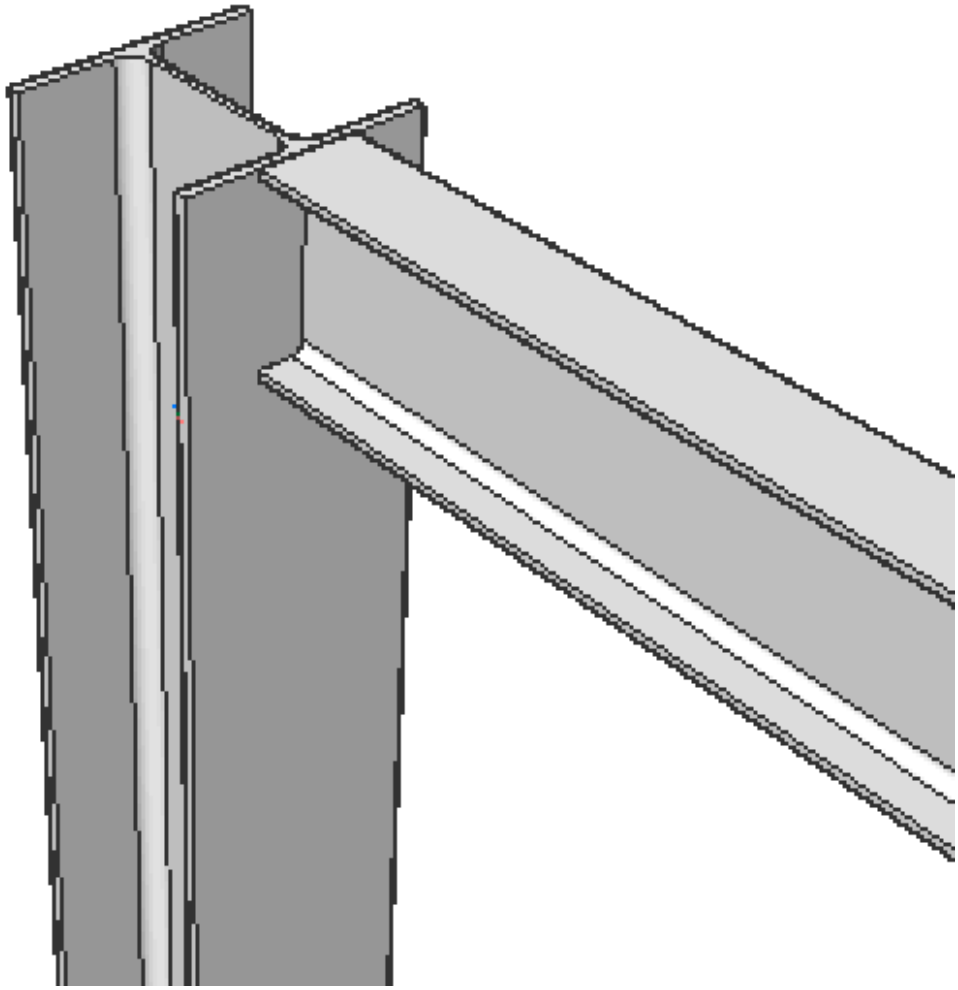

Figure 2.172

Figure 2.173

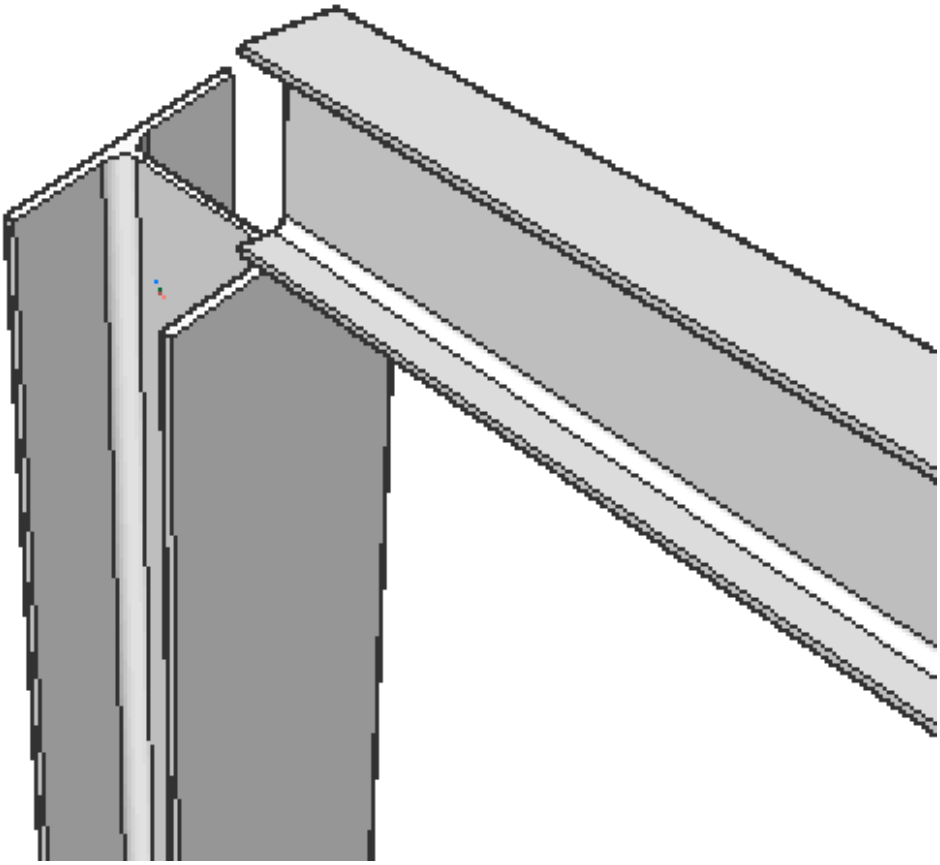

Figure 2.174

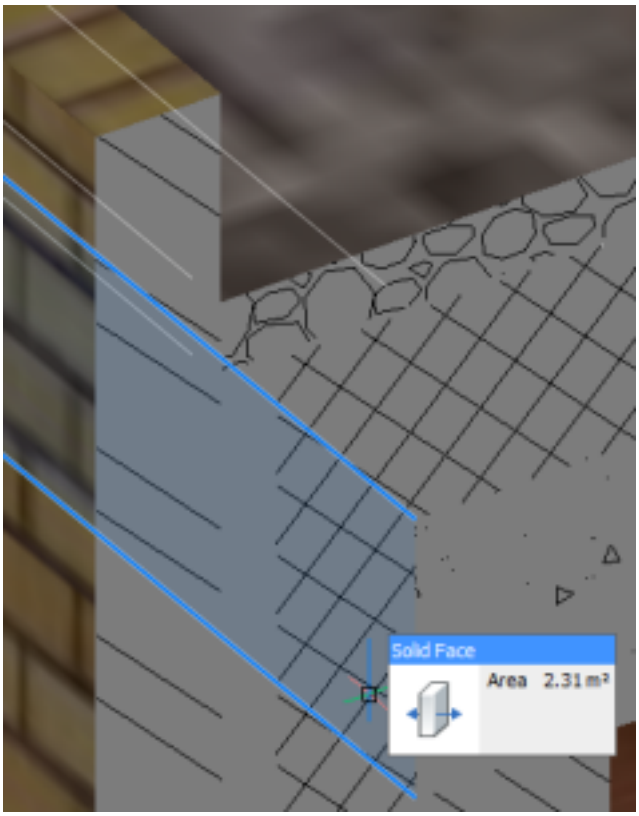

Figure 2.175

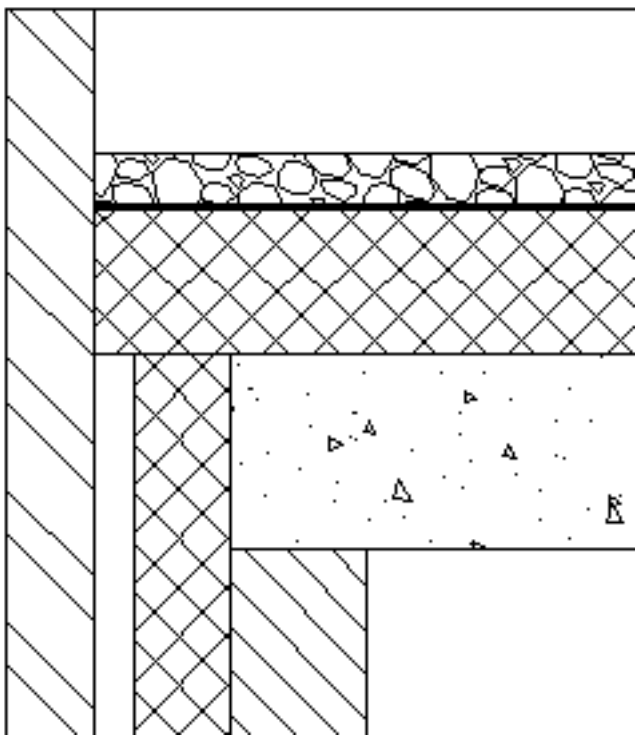


2.5.5 Creating a Custom Window

Overview: In this lesson, you learn how to create a custom window to insert in your drawings. **Lesson Objectives** After completing this lesson, you will be able to:

- Create the 3D geometry of a window element.
- Utilize the pre-defined templates.
- Understand how the subtractor solid can be used in creating an opening for insertion.

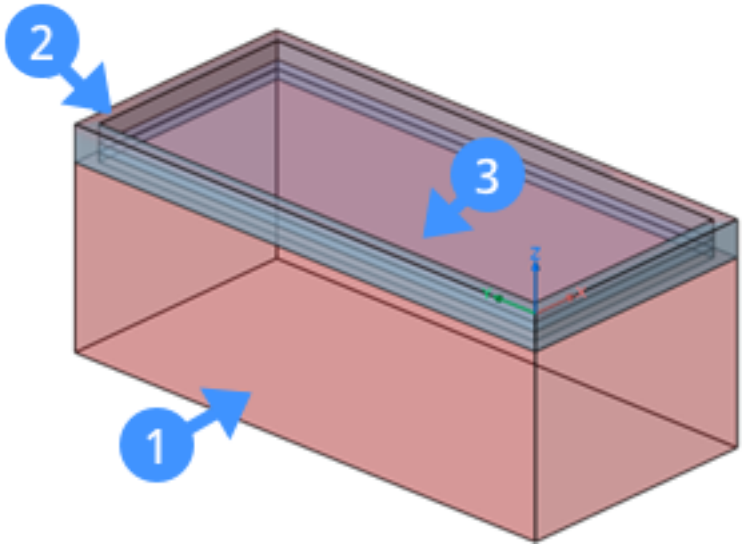
Creating a Custom Window

In BricsCAD, you can create any geometry or component from scratch. Once you have your geometry in 3D you can insert and use it in your BIM model. You can make changes or add more details to your window at any time. This process is explained in 4 parts to make the steps of creating a 3D window geometry straightforward.

- Create the file
- Create the subtractor solid (1)
- Create the window frame (2)
- Create the (Glass) panes (3)

(2.176 on the next page)

Figure 2.176



Step 1: Creating the file

1. Click **New** in the **File** menu
2. Select one of the **pre-defined templates** to create a simple window specifying the unit system of your drawing. **Note:** The pre-defined templates contain the layers needed to create the geometry of the window or door. These .dwt file format templates are BIM-Window-imperial (4) and BIM-Window-metric (5) which assure the required layers and properties are displayed in your drawing. (2.177 on the following page)
3. Set the **BIM_Subtract** layer current (6) either using the drawing explorer or layer field in the properties panel or Layers Panel on the right-hand side. (2.178 on the next page)
4. Create a closed polyline (e.g. a rectangle) that represents the form of the opening for the insert. (2.179 on page 1757)
5. Save the file in any location. The library of predefined windows and doors is located in the support folder. By default this is: **C:\Users<user_name>\AppData\Roaming\Bricsys\BricsCAD\V19x64\en_US\Support\Bim\Component**
This path can also easily be found by typing SUPPORTFOLDER in the command line.

Figure 2.177

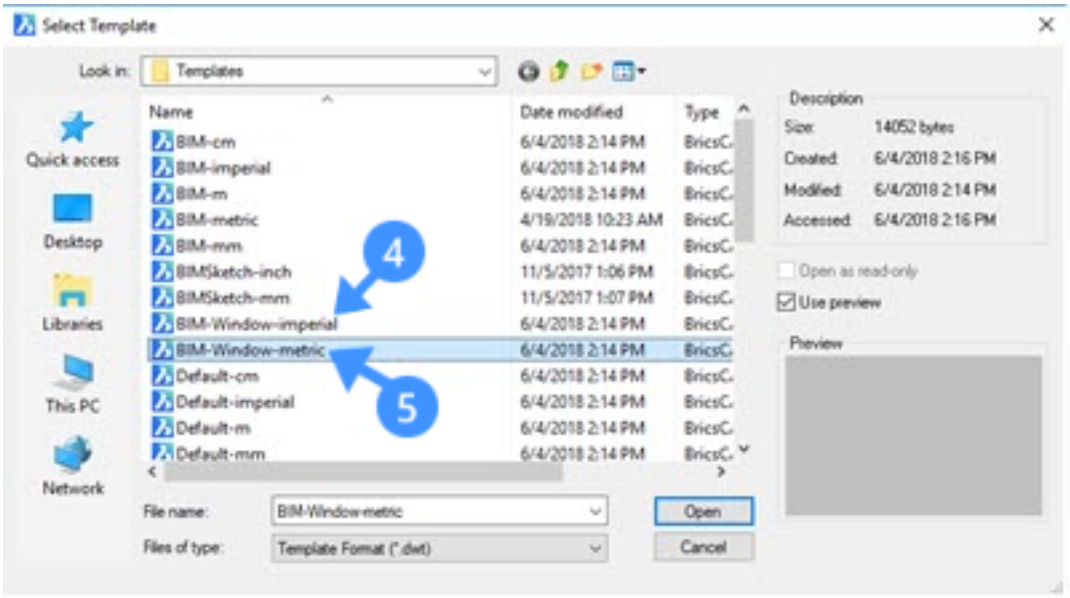


Figure 2.178

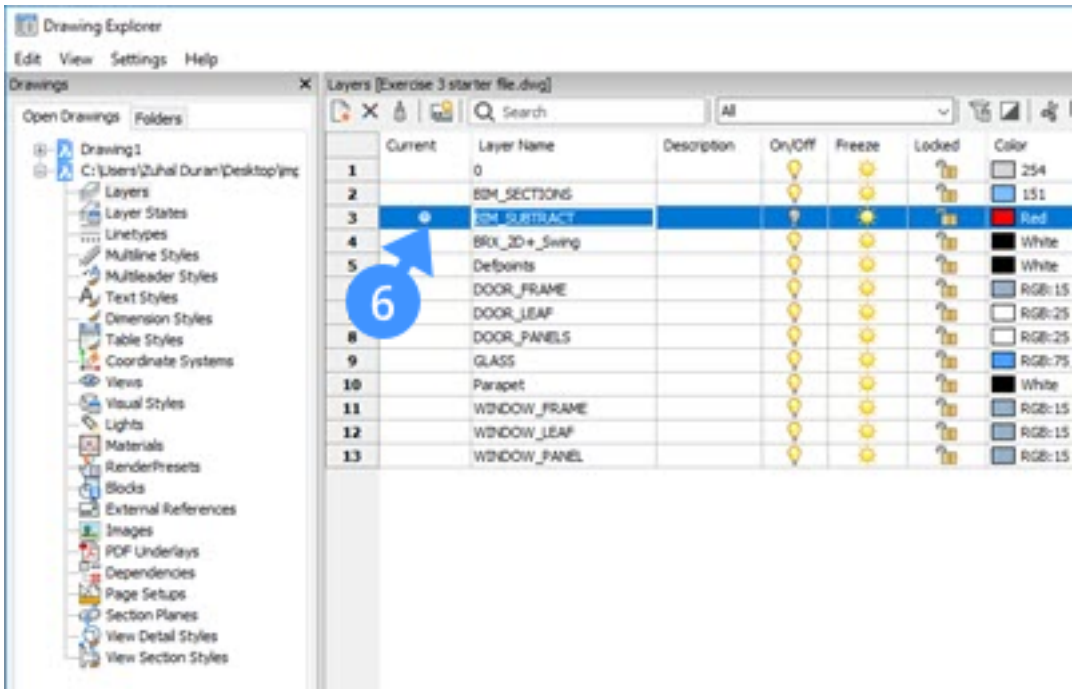

Figure 2.179

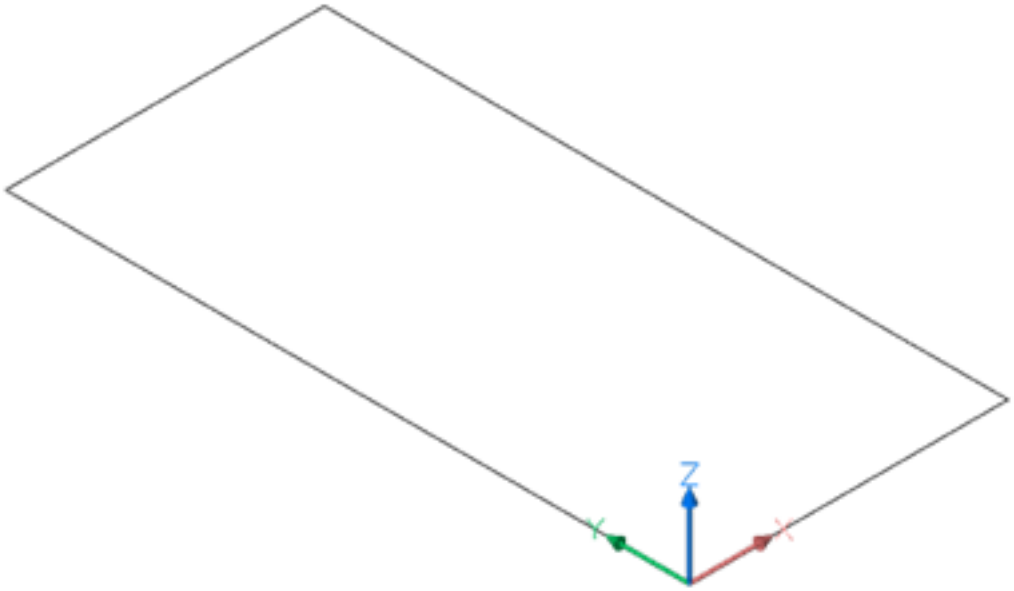

Step 2: Creating the subtractor solid The subtractor solid will be used to create an opening. **Note: BIM Subtract** Layer must be a current layer.

1. Use the outline of the solid which you have previously created (e.g. a rectangle). The outline lies in the first quadrant of the XY plane of the **World Coordinate System** (WCS). (2.180 on the next page) The lower left corner of the rectangle lies at the origin (0,0,0) of the WCS (7).

2. Select the Extrude tool and move the cursor downward (8) to extrude your solid outline in the negative Z direction. (2.181 on the following page)

3. Do one of the following to finish the subtractor solid creation.
   - Click a point
   - Type a value in the dynamic dimension fields, then press Enter.

Figure 2.180

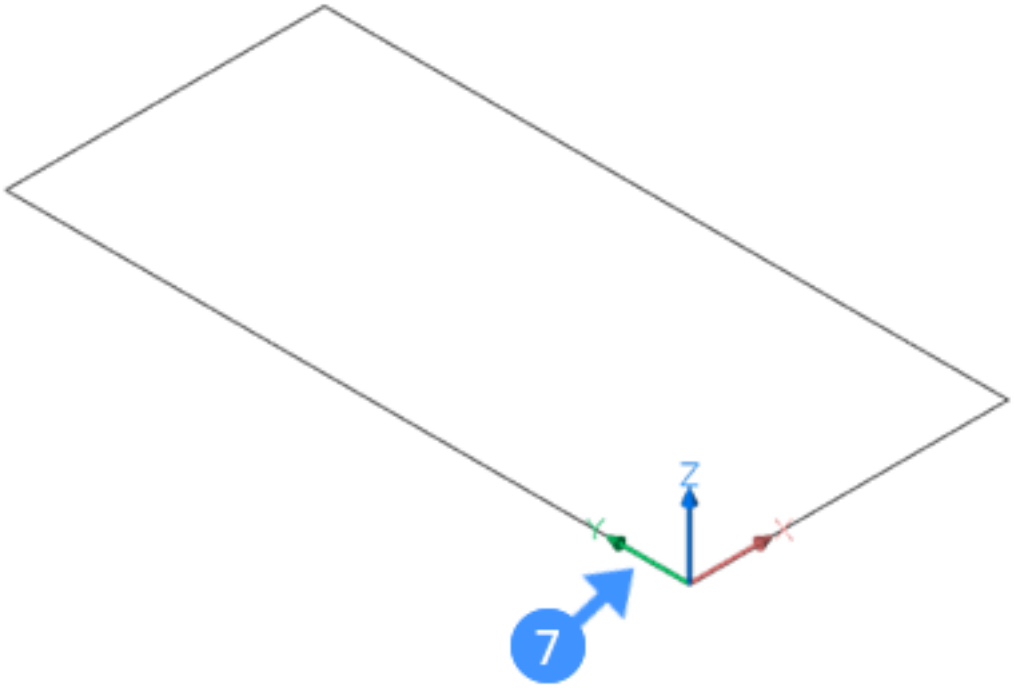

Figure 2.181

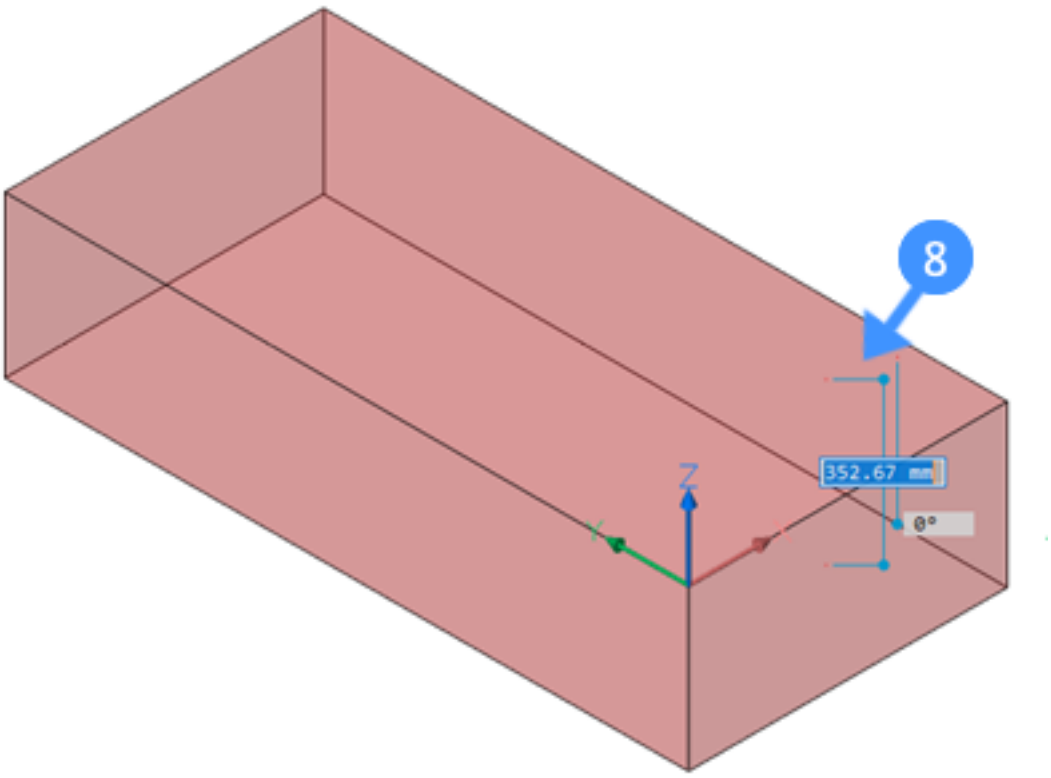

Step 3: Creating the fixed frame The outline of the fixed frame coincides or is parallel (in case of a rebate) with the outline of the subtractor solid.

1. Set the Window_Frame layer current.
2. Highlight the top face of the subtractor solid.
3. Next, extrude the top face of the subtractor solid in the negative Z direction (9) using the **Extrude** tool 'Create' (10) option by pressing the CTRL key once. (2.182 on the next page)
4. Type a value in the dynamic dimension field to specify the height of the fixed frame. **Note:** The height of the extrusion will be the thickness of the fixed frame.
5. Turn off 'BIM_SUBTRACT' layer by clicking the light bulb (11) next to the layer name. (2.183 on the following page)
6. Use the Offset tool to create a parallel offset of the outline of the fixed frame (12). (2.184 on page 1761) **Note:** The distance of the offset equals the width of the frame.
7. Hover over the inside boundary of the parallel offset (13) and select Extrude tool from the Quad. (2.185 on page 1762)

Figure 2.182

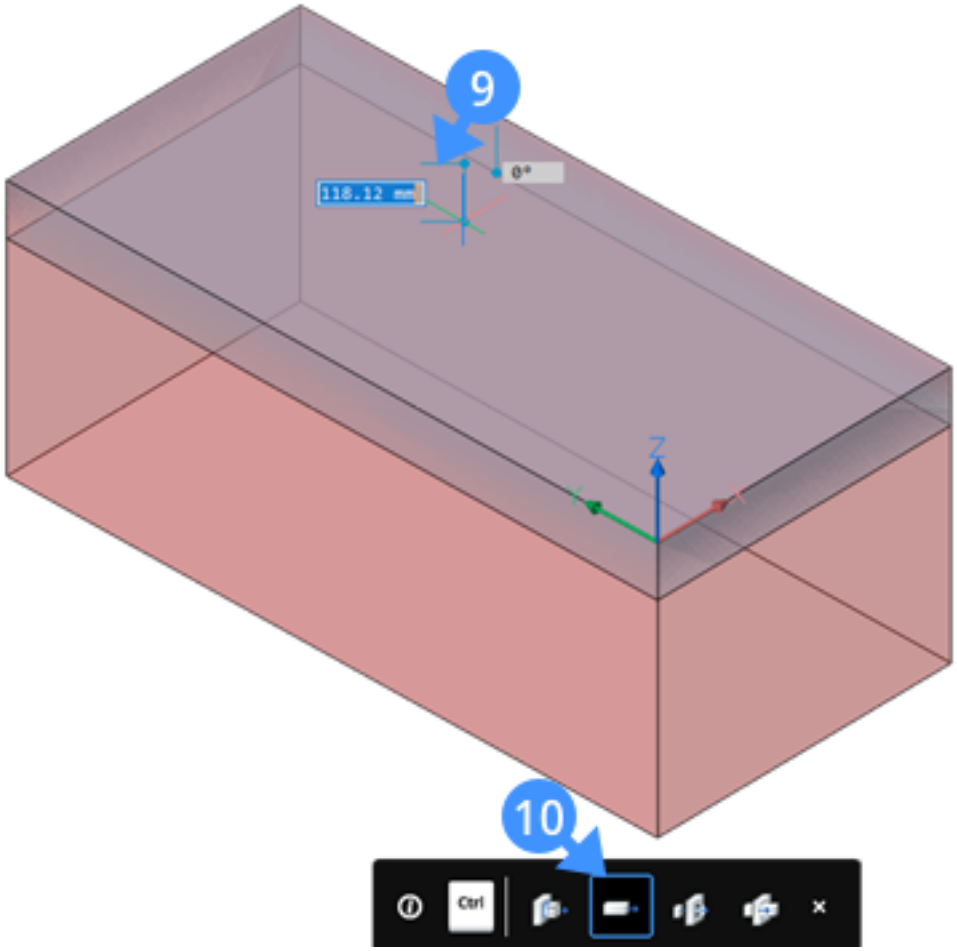

Figure 2.183

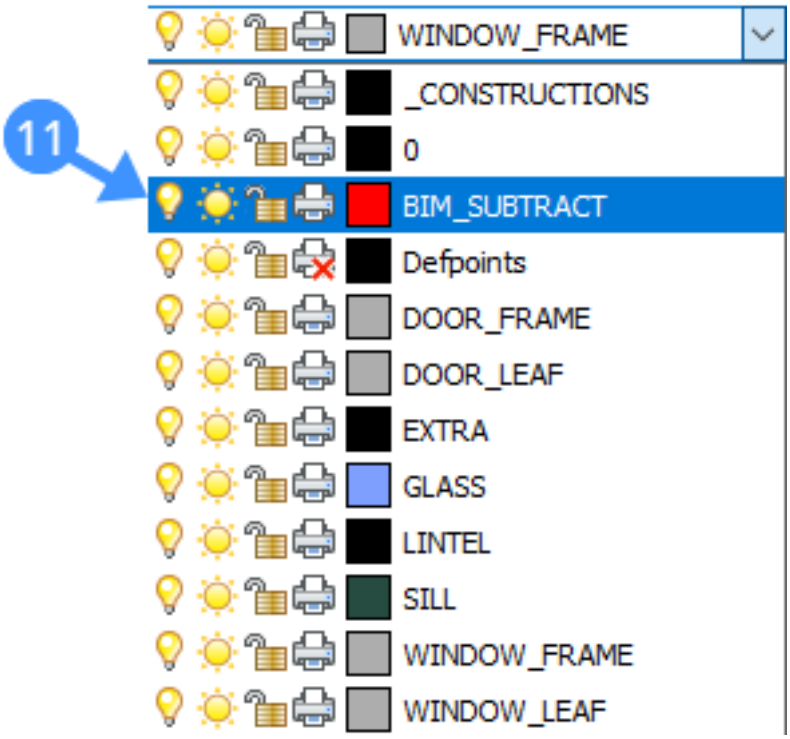

Figure 2.184

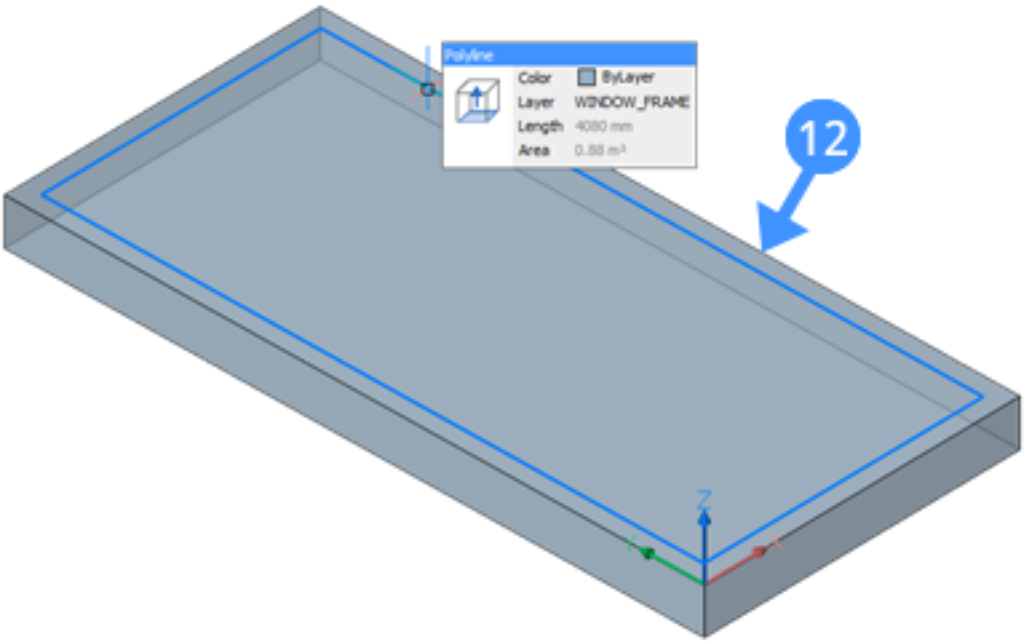

8. When the extrude mode is on the Subtract option (14) move your cursor downward (15) to create an opening in the fixed frame. (2.186 on the next page)

9. Do one of the following to finish the creation of the opening in the fixed frame.
   - Click a point
   - Type a value in the dynamic dimension fields, then press Enter.

Figure 2.185

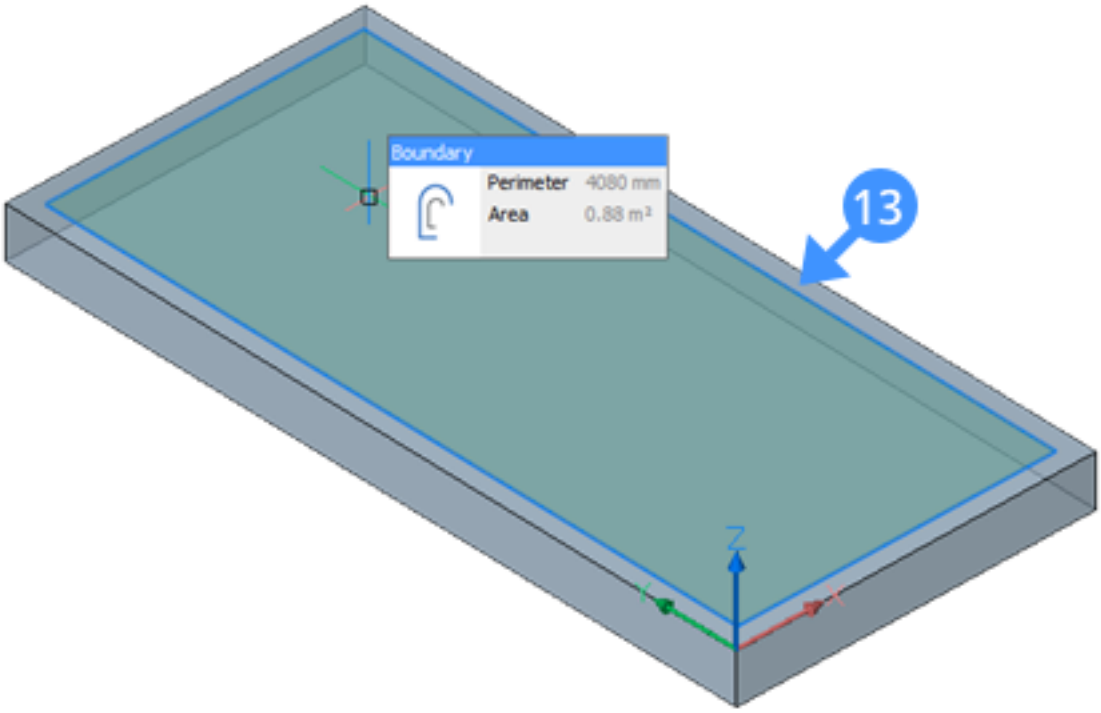

Figure 2.186

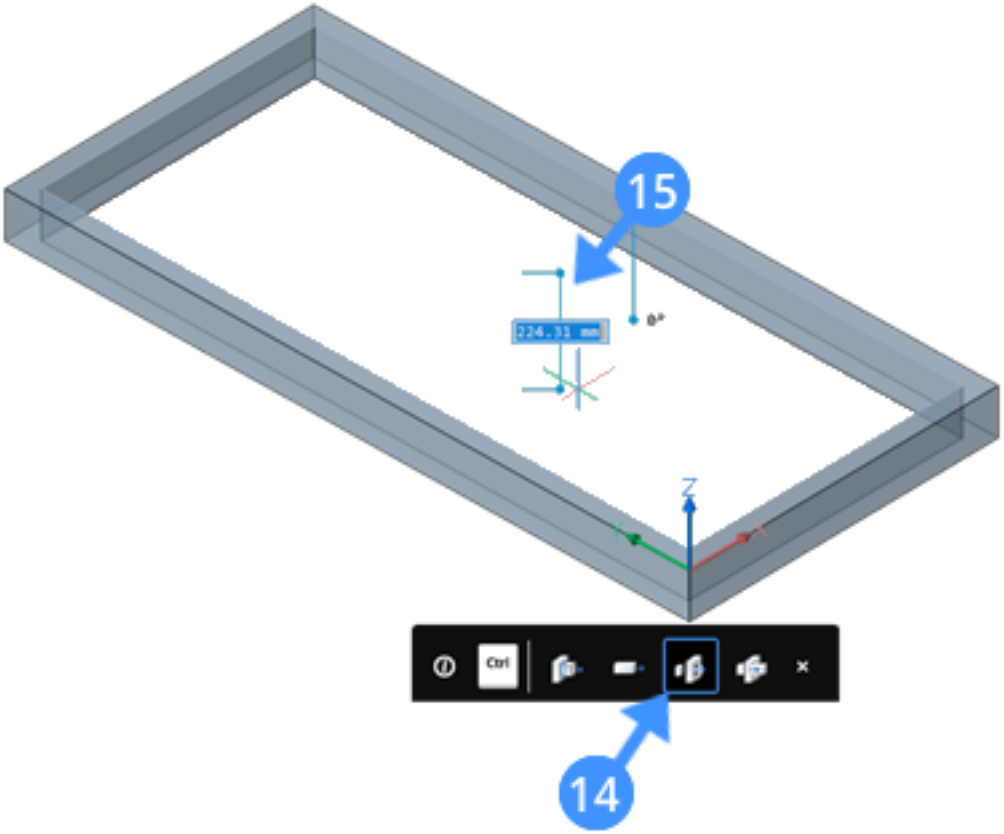

Step 4: Creating the glass panes

1. Set the Glass layer current.
2. Use the DMEXTRUDE command to extrude the inside boundary of the window frame. **Note:** The height of the extrusion equals the thickness of the glass pane. The following illustration shows the inside boundary of the window frame after using DMExtrude to create a window glass pane. (2.187 on the following page) Note that to create a glass pane, the create option should be selected from the Tooltip of DMExtrude.
3. Move the glass pane solid down in the negative Z-direction if the outside face of the fixed frame does not coincide with the outside face of the solid (wall) the insert will be placed in. The following illustrations show the glass pane solid after moving it (17) down. (2.188 on the next page)

Optionally, before saving the drawing, classify the BIM as a window element. To do so, follow these steps:

1. Type BIMCLASSIFY in the command line.
2. Press 'I' for window and press enter to accept it.
3. Next, press 'D' for Drawing and press Enter key until the command is executed.

The drawing is classified as a window. When you insert this block in your drawing, it will automatically be classified as a window.

5. Optionally, when no selection is active, you see a set of BIM properties on the right-hand side of your screen. Here you can assign information about the thermal transmittance coefficient of the window materials, fire rating according to the national fire safety classification, and so on. The following illustration shows the BIM properties of the window in the properties panel. (2.189 on page 1765)
5. Save the drawing.

Figure 2.187

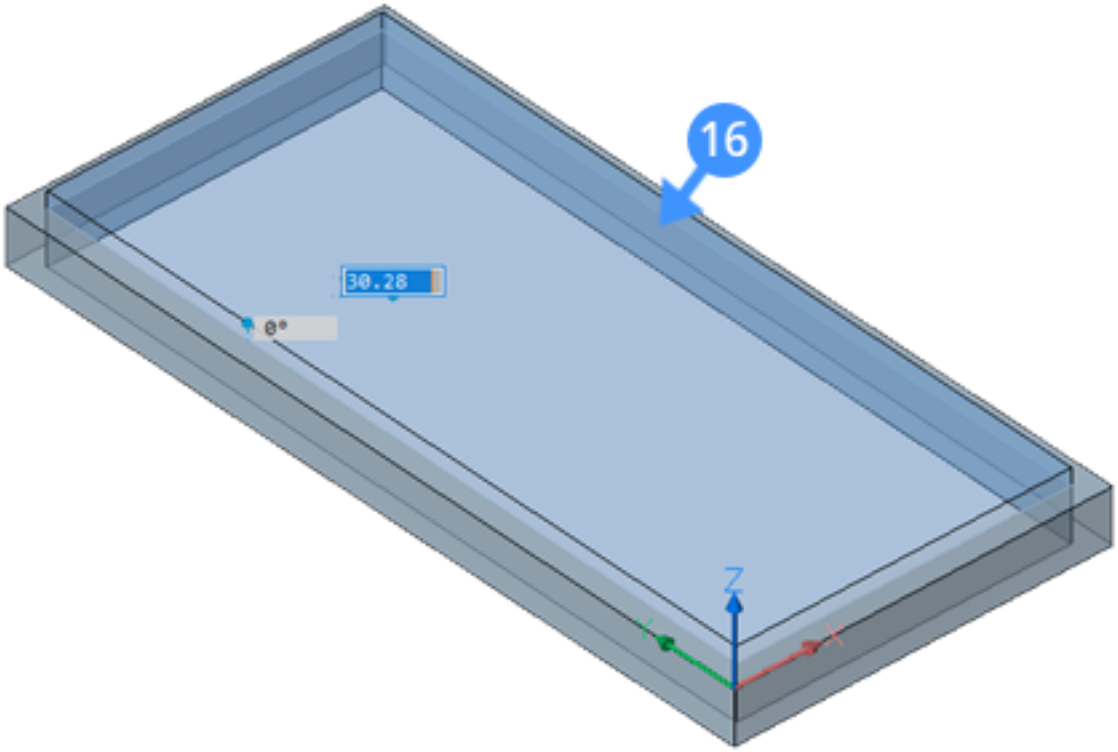

Figure 2.188

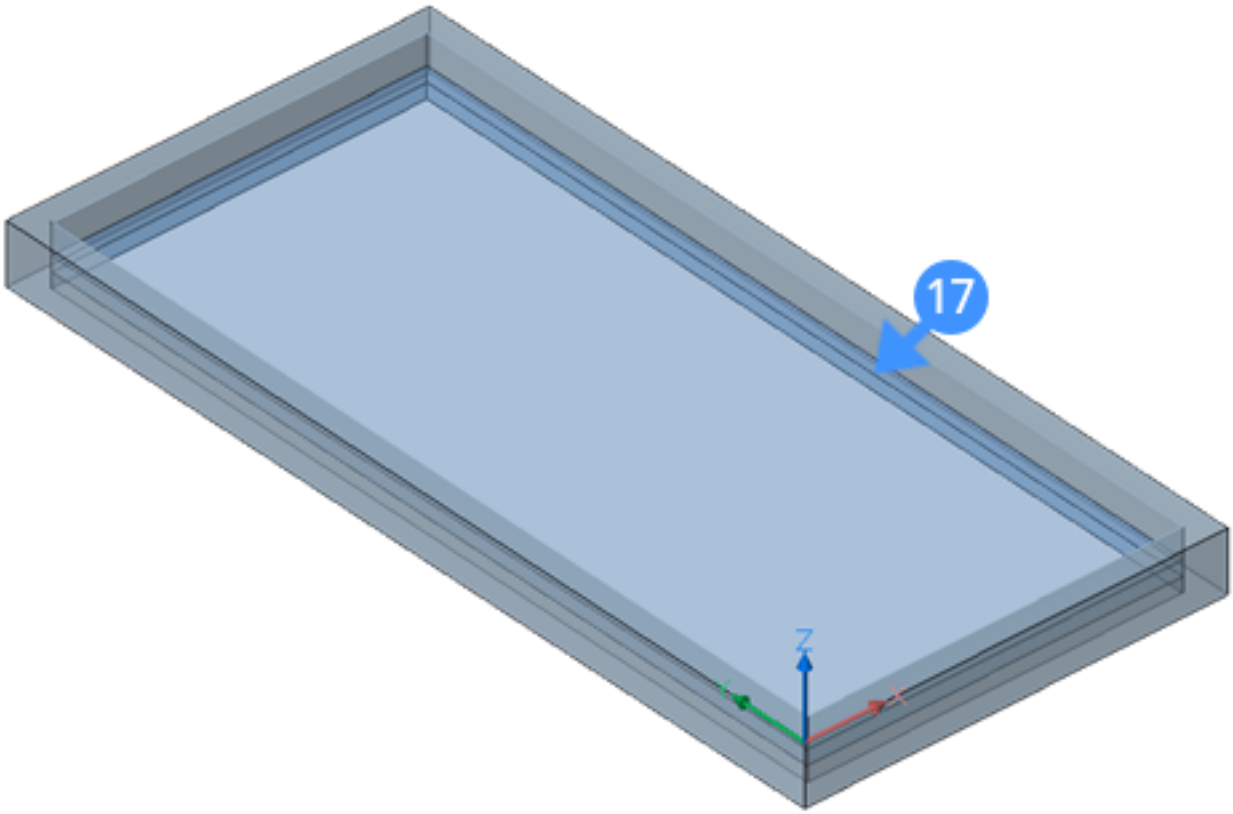

Figure 2.189

Window Common	
Reference	
Fire rating	
Acoustic rating	
Security rating	
Is external	Off
Infiltration	0 m³/s
Thermal transmittance	0 W/m²·K
Glazing area fraction	0
Smoke stop	Off

Adding 2D entities

Optionally, windows and doors drawings can contain 2D symbols. These 2D symbols will either replace the actual 3D Solid section of the window or door or be added to the 3D Solid section, depending on their layer:

- Symbols on a layer with prefix **BRX_2D_**will be used to replace the geometry resulting from the actual section,
- Symbols on a layer with prefix **BRX_2D+_**will be added to the section result. Only those 2D entities in a plane parallel to the section plane are.

2.5.6 Creating Roofs

In BricsCAD BIM roofs are created using default commands and modeling techniques. The roof creation workflow consists of the following steps:

- Creating the roof footprint.
- Extrude the footprint and create a hip roof. (DmExtrude (6.12.14) command)
- Adjust the slope of the roof faces if necessary. (Manipulator (6.21.3) widget)
- Defining the thickness of the roof solid. (Body/Shell option of the SolidEdit (6.27.42) command)
- Create additional roof components.

Tutorial: How to create a pitched roof Click here (2.4.2) to watch

Creating the roof footprint

You can create the roof footprint:

- From the exterior walls boundary.
- Creating a closed polyline by clicking points or other 2D procedures.

To create the roof outline from the exterior walls boundary.

1. Isolate (6.17.22) the exterior walls*.
2. Set the coordinate system to the top face of the exterior walls:
   - Type **UCS** and press Enter. **You are prompted:** Specify origin of UCS or [Face/NAmed/Entity/Previous/View/X/Y/Z/Z Axis/Move/World] <World>:
   - Snap to a top corner of an exterior wall, then press Enter.
3. Set the **Enable boundary detection** ON. (2.190 on the next page)
4. Move the cursor to avoid area inside the exterior walls. The inside boundary highlights.
5. Choose **Offset** in the **Draw** tab of the Quad. (2.191 on the facing page)
6. Do one of the following:
   - Type a value in the dynamic distance field.
   - Click to accept the value.

* Isolating entities is easily done using the Structure Panel. (6.27.54)

Figure 2.190

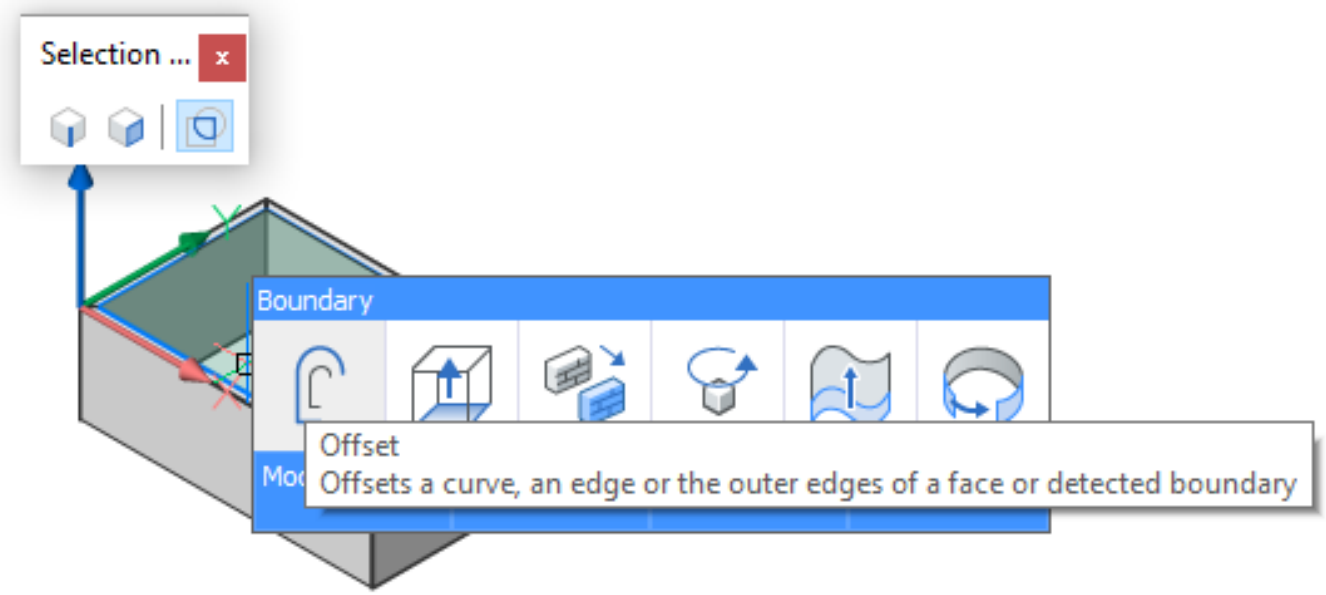

Figure 2.191

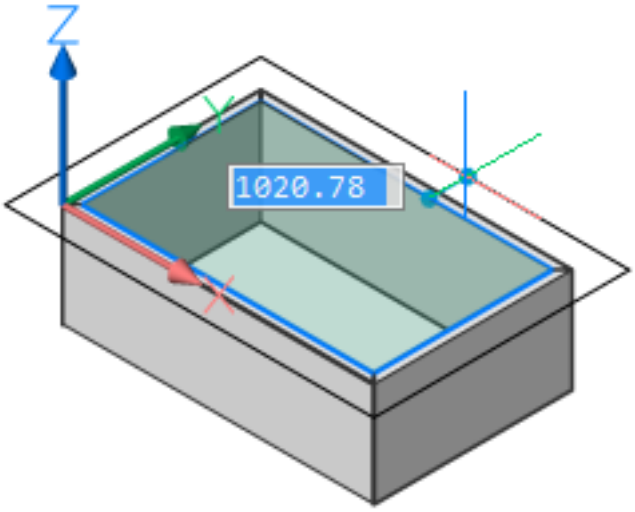

Creating a hip roof

(2.192)

1. Create the roof footprint.
2. Move the cursor over the roof outline and choose **Extrude** in the **Model** tab of the Quad. (2.208 on page 1776)
3. Move the cursor vertically, then hit the Tab key. (2.194 on the next page)
4. Type a value in the **Taper Angle** field and hit the Tab key. (2.195 on page 1770)
5. Do one of the following:
   - Hit the Tab key and type another value in the **Taper Angle** field. The **Taper Angle** field is the complement of the inclination angle of the roof.
   - Press Enter to create the roof.
6. Depending on the shape of the roof outline, the result is:
   - Pyramid roof: (2.196 on page 1770)
   - L-shaped hip roof: (2.197 on page 1770)
   - T-shaped hip roof: (2.198 on page 1771) (2.199 on page 1771)

Figure 2.192

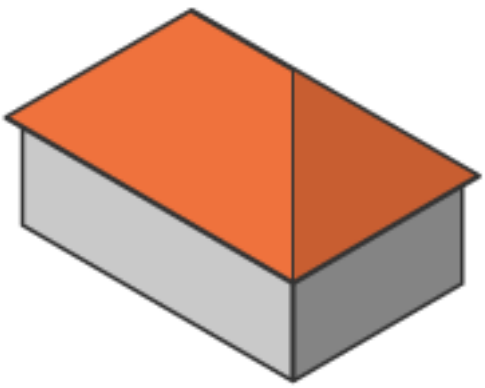

Figure 2.193

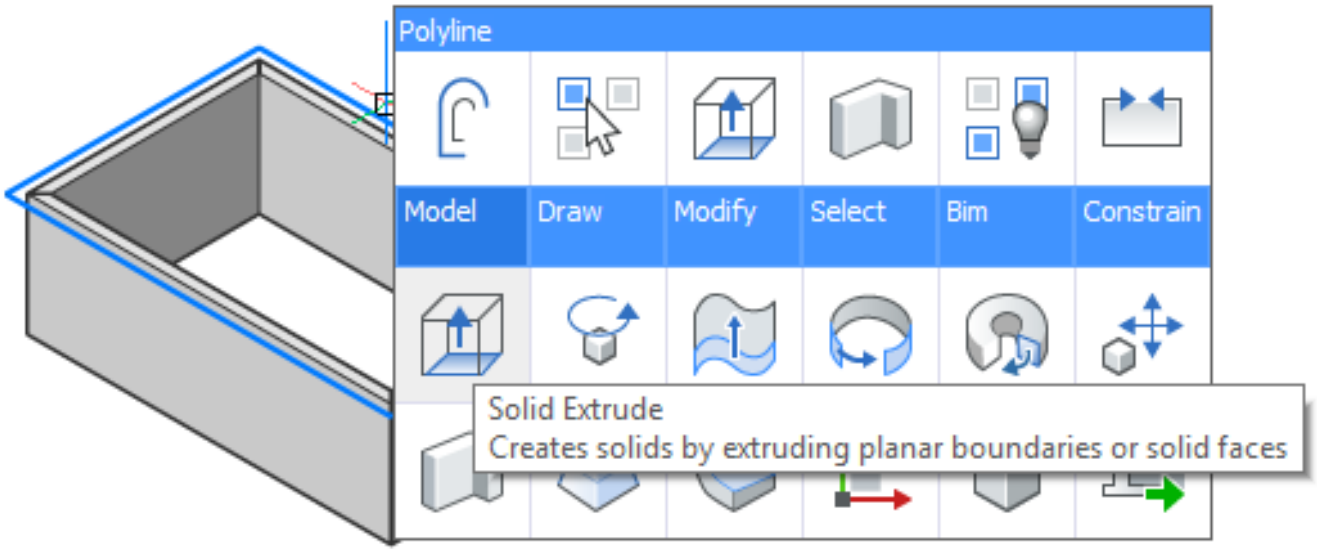

Figure 2.194

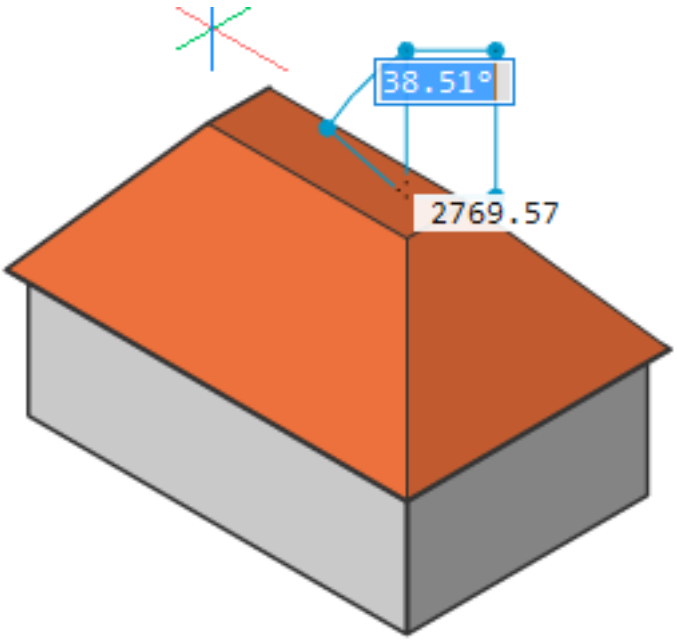

Figure 2.195

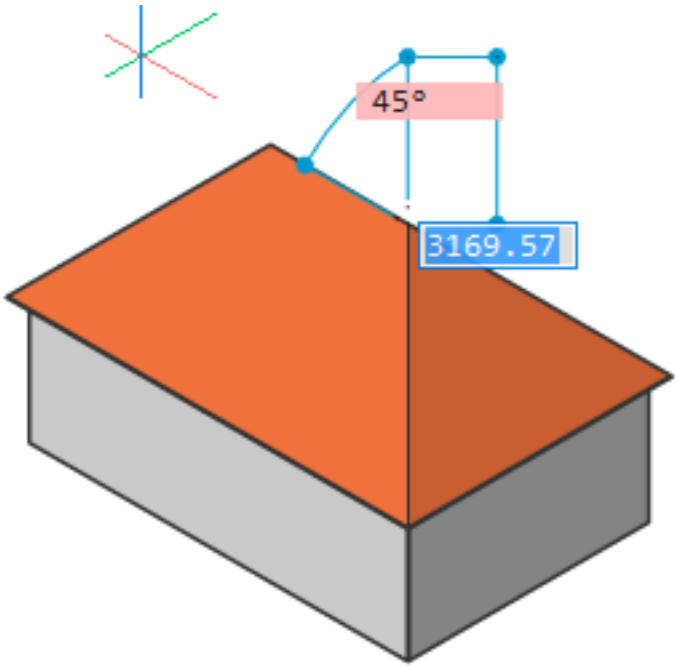

Figure 2.196

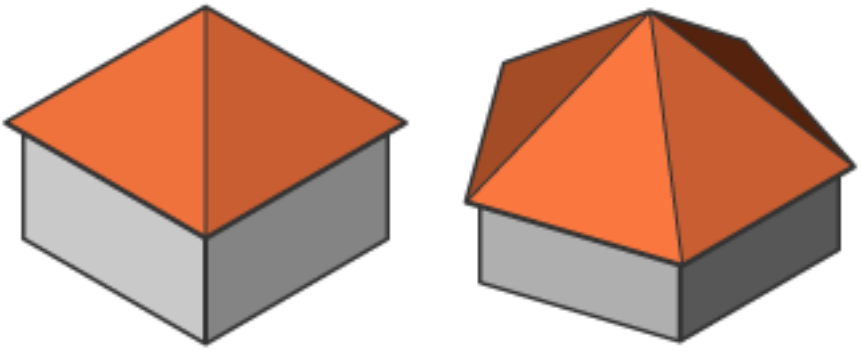

Figure 2.197

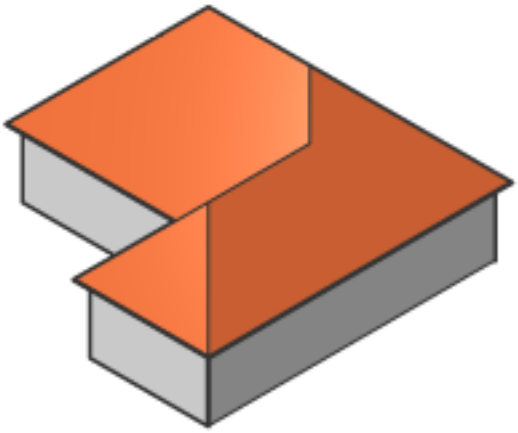

Figure 2.198

(2.200 on the next page)
- U-shaped hip roof: (2.201 on the following page) (2.202 on the next page)
- Complex hip roof: (2.203 on page 1773)

To define the thickness of the roof solid we will use the **Body/Shell** option of the SolidEdit (6.27.42) command. Do one of the following:

1. Choose **Shell** in the **Solid Edit | 3D Solid Editing** ribbon panel. **Or** Choose Shell in the **3D Solid Editing** toolbar.
2. **You are prompted:** Select 3d solid: **Select the roof solid**
3. **You are prompted:** Select face to remove or [Add/Undo/ALL]: **Select the bottom face of the roof solid**
4. **You are prompted**: Enter the shell offset distance: **Type a value to define the thickness of the roof solid**

Figure 2.199

Figure 2.200

Figure 2.201

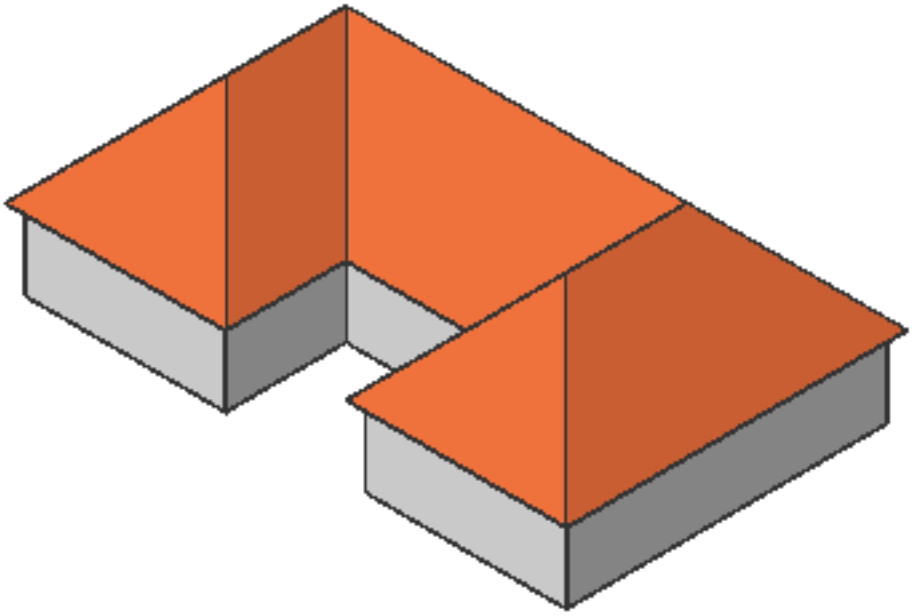

Figure 2.202

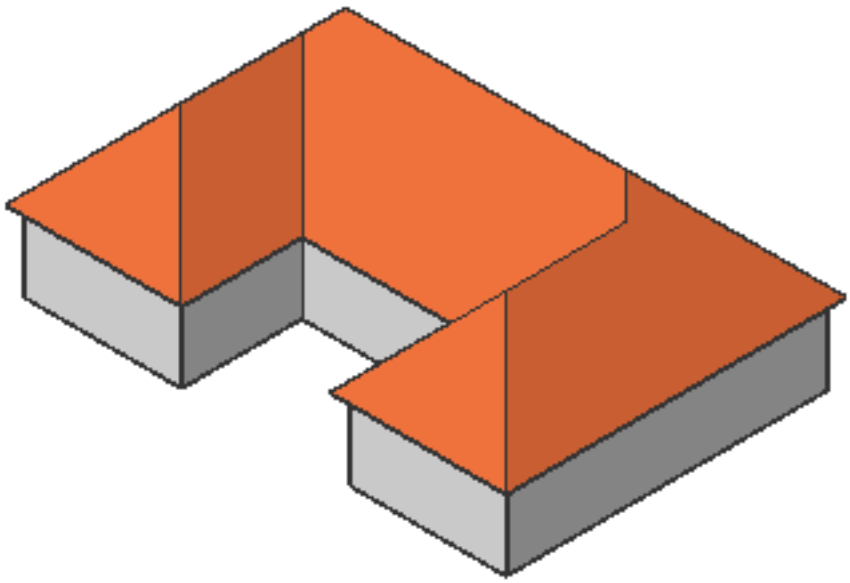

Figure 2.203

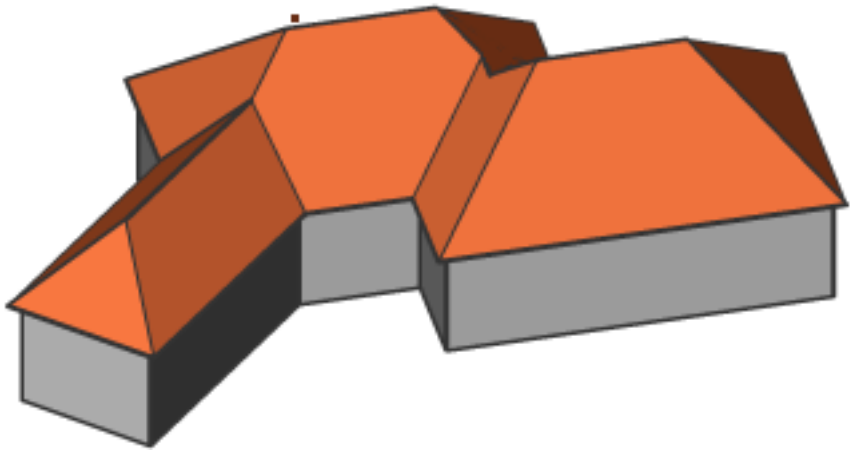

Creating a gable roof

(2.204)

1. Create a hip roof.
2. Make both end faces vertical:
   - Move over the end face then hold down the left mouse button about half a second; the Manipulator widget (1.32.10) displays (set the value of the Manipulator (1.10.7) system variable = 3). (2.205 on the following page)
   - Place the cursor over the vertical rotation arc. When the arc highlights, move the cursor. The selected face rotates dynamically. Click when the face is in a vertical position. (2.206 on the next page)
3. Execute step 7 of the Create a hip roof procedure. Remove the vertical faces of the roof solid.

Figure 2.204

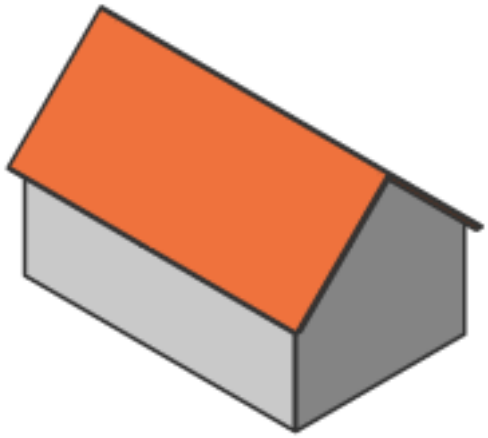

Figure 2.205

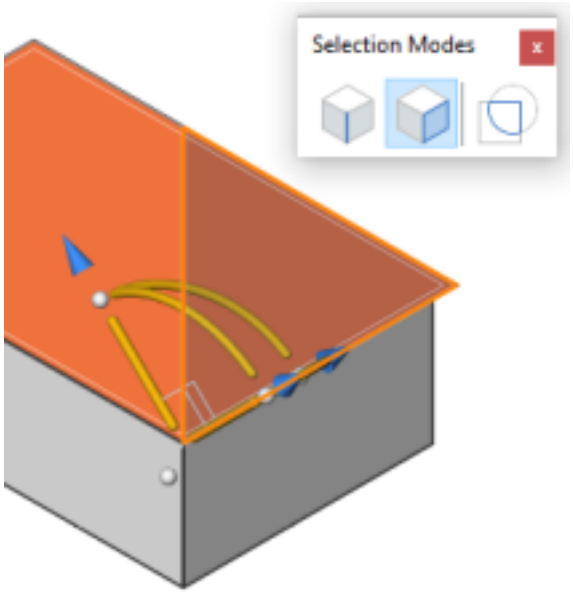

Figure 2.206

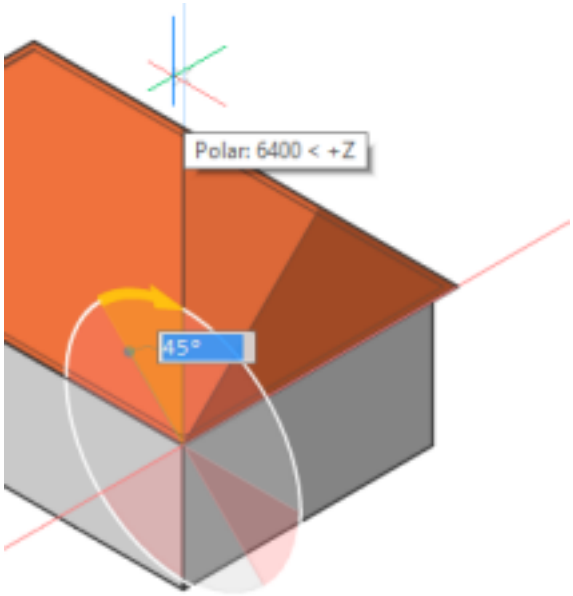

Creating a mansard roof

(2.207) A mansard roof is composed of two solids, which we will create as two separate extrusions.

1. Create a roof footprint.
2. Move the cursor over the roof outline and choose to **Extrude** in the **Model** tab of the Quad. (2.208 on the next page)
3. Move the cursor vertically, then hit the Tab key.
4. Type a value in the **Taper Angle** field then hit the Tab key. The **Taper Angle** field is the complement of the inclination angle of the roof. (2.209 on page 1777)

Figure 2.207

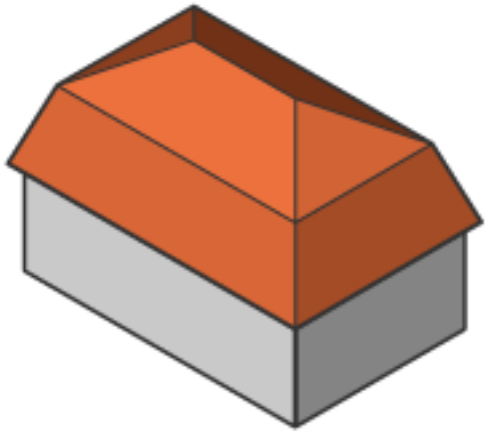

Figure 2.208

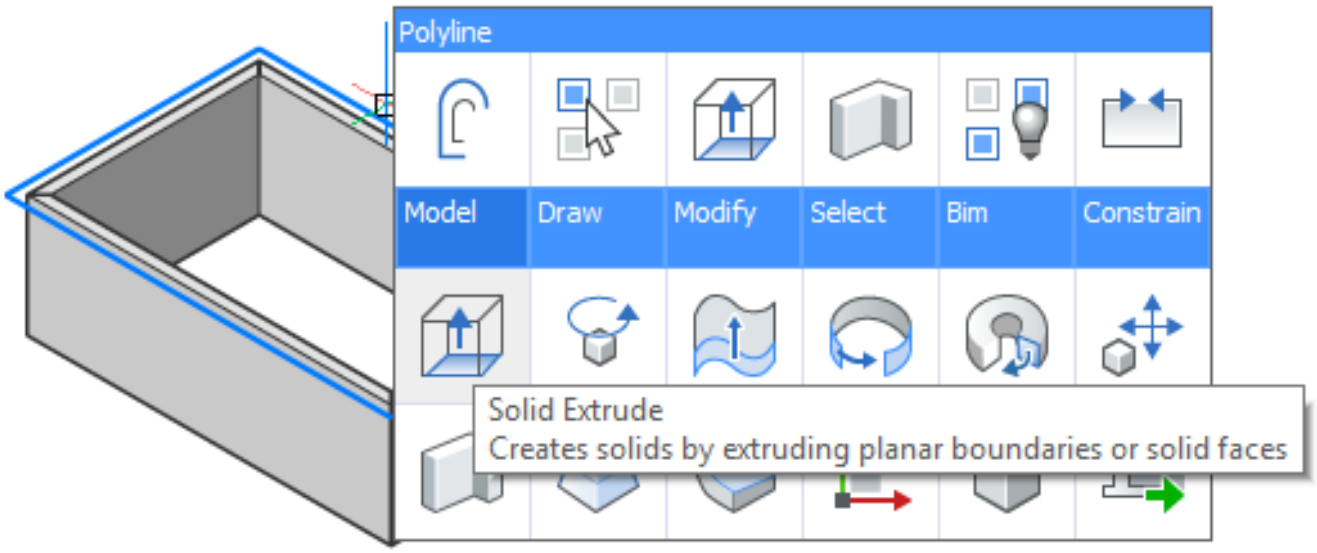

5. Type a value in the extrusion **Height** field, then do one of the following:
   - Hit the Tab key and type another value in the **Taper Angle** field.
   - Press Enter to create the first solid.
6. **Optionally** hit the Tab key to go back and forth between the entry fields and press Enter when you are satisfied with the result.
7. Move the cursor of the top face of the first roof solid and choose **Extrude** in the Quad. (2.210 on the next page)
8. Move the cursor vertically, then hit the Tab key.
9. Type a value in the **Taper Angle** field then hit the Tab key. (2.211 on page 1778)
10. Do one of the following:
    - Hit the Tab key and type another value in the **Taper Angle** field.
    - Press Enter to create the first solid.
11. Select both solids and choose **Union** in the **Model** tab in the Quad. (2.212 on page 1778)
12. Repeat step 7 of the Create a hip roof procedure.

Figure 2.209

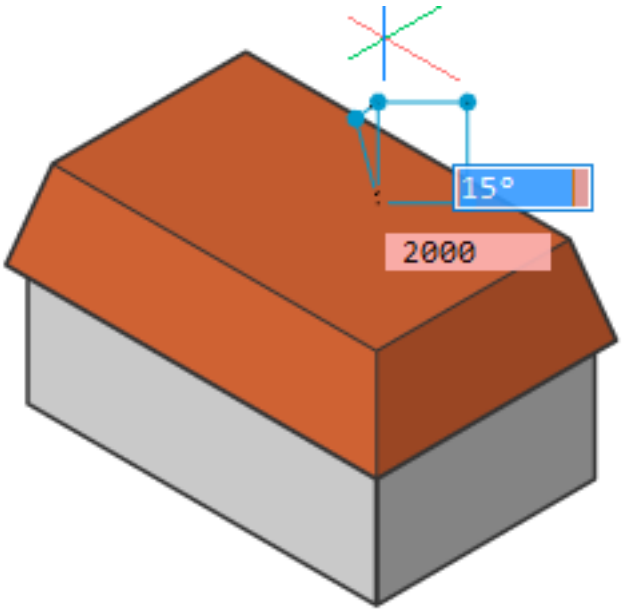

Figure 2.210

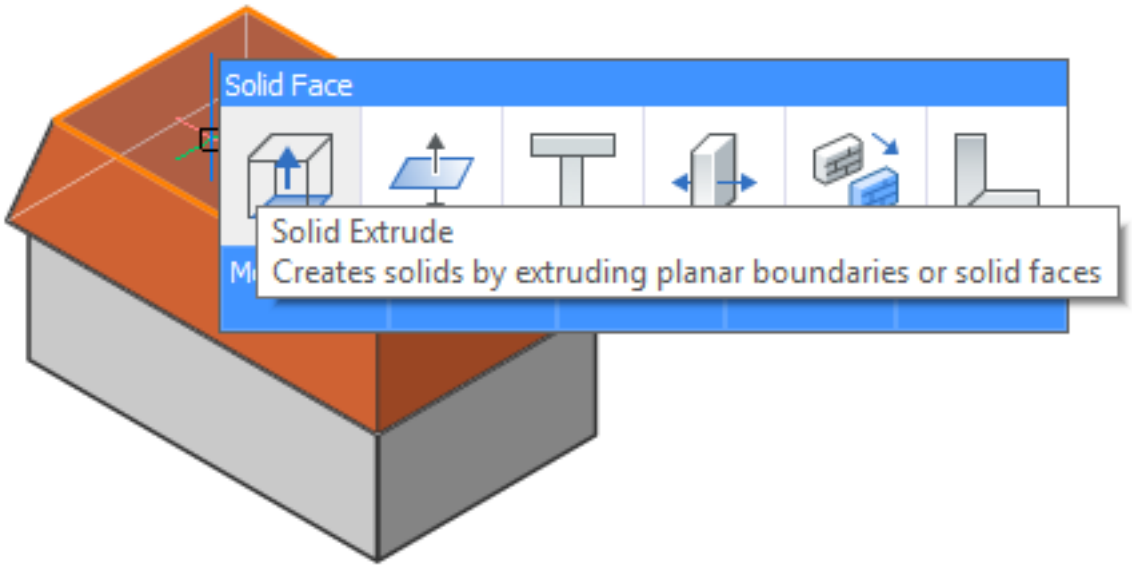

Figure 2.211

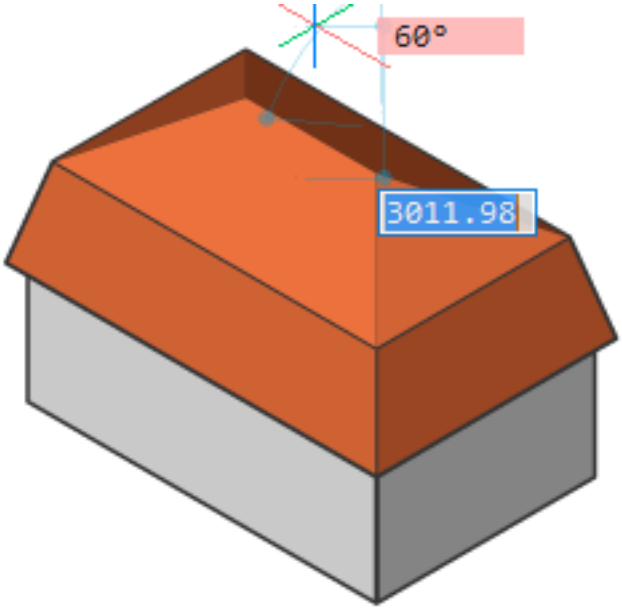

Figure 2.212

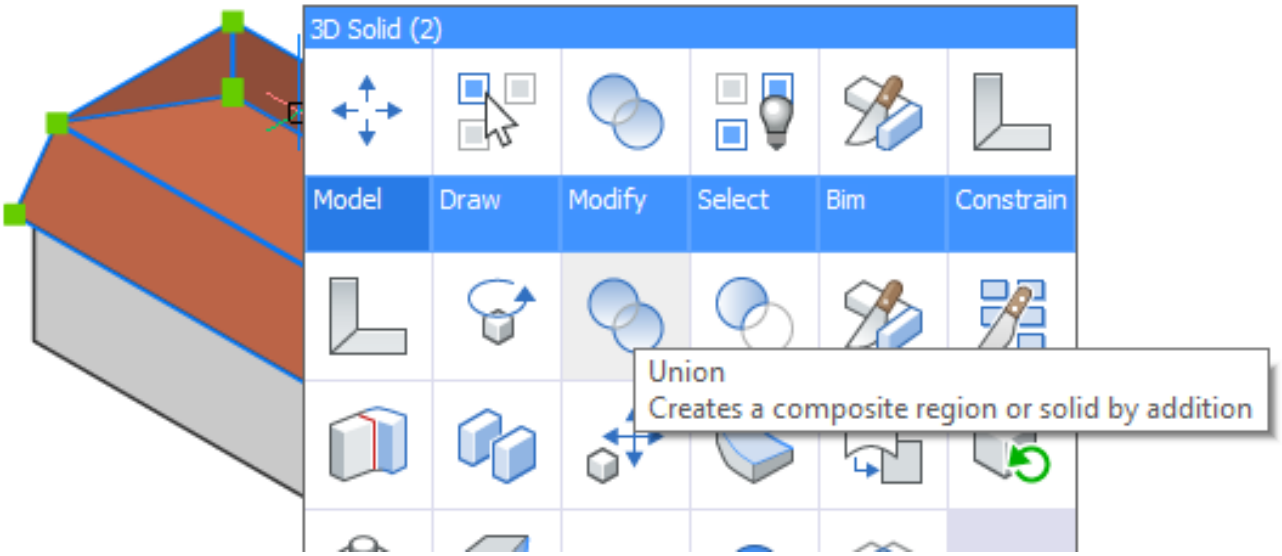
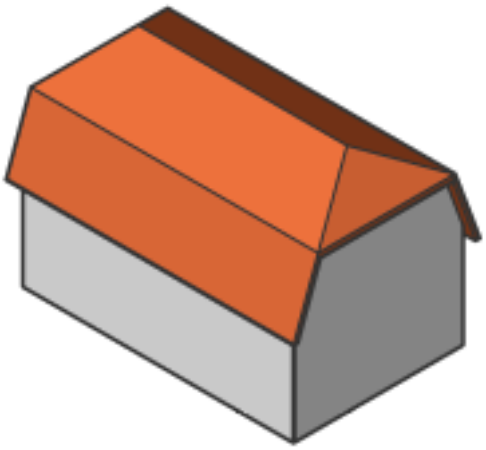


Creating a jerkinhead roof

(2.213) A jerkinhead roof is composed of two solids, which we will create as two separate extrusions.

1. Execute steps 1 to 6 of Creating a mansard roof procedure, to create the first solid.
2. Execute step 2 of Creating a gable roof procedure to set the end faces vertical.
3. Execute steps 7 to 11 of the Creating a mansard roof procedure.
4. Execute step 7 of the Create a hip roof procedure. Move the vertical faces of the roof solid.

Figure 2.213

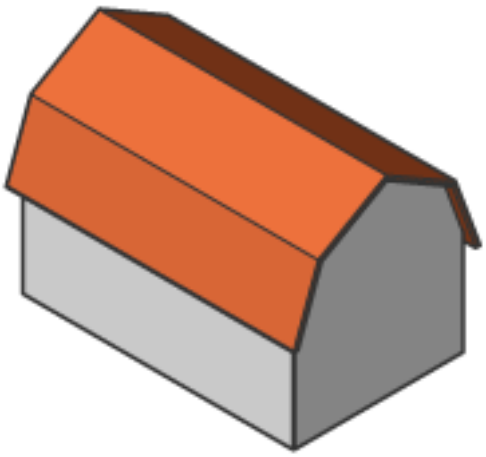


Creating a gambrel roof

A gambrel roof is composed of two solids, which we will create as two separate extrusions. (2.214)

1. Execute steps 1 to 6 of Creating a mansard roof procedure, to create the first solid.
2. Execute step 2 of Creating a gable roof procedure to set the end faces vertical.
3. Execute steps 7 to 10 of Creating a mansard roof procedure to create the second solid.
4. Execute step 2 of Creating a gable roof procedure to set the end faces vertical.
5. Execute step 11 of Creating a mansard roof procedure.
6. Execute step 7 of the Create a hip roof procedure. Remove the vertical faces of the roof solid.

Figure 2.214



Creating a dutch gable roof

(2.215) A Dutch gable roof is based on a hip roof.

1. Create a hip roof.
2. Set the **Select Edges** option of the **Selection Modes** system variable ON.
3. Move the cursor over the bottom edge of the roof face, then choose **Offset** in the **Draw** tab in the Quad. (2.216 on the next page)
4. Move the cursor and type a value in the dynamic distance field or click a point. (2.217 on the following page)
5. Do one of the following:
   - Choose **Imprint** in the **3D Solid Editing** toolbar
   - Choose Imprint in the **Solid Edit | Solid Editing** ribbon panel.
6. **You are prompted:** Select 3d solid, surface or region: Select the roof solid.
7. **You are prompted:** Select an entity to imprint: Select the offset roof edge.
8. **You are prompted:** Delete the source object[Yes/No] <No>: Choose Yes. A triangular face is created.
9. Execute step 2 of Creating a gable roof procedure to set the triangular face vertical. (2.218 on page 1783) (2.219 on page 1784)

Figure 2.215

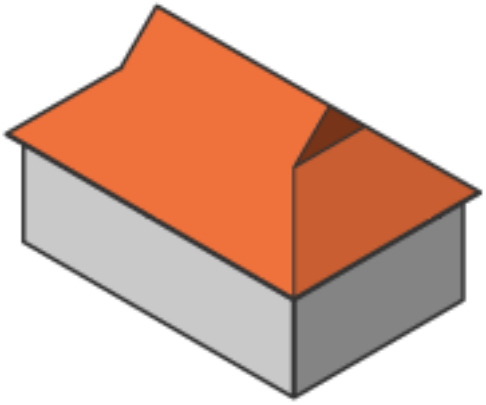


Figure 2.216

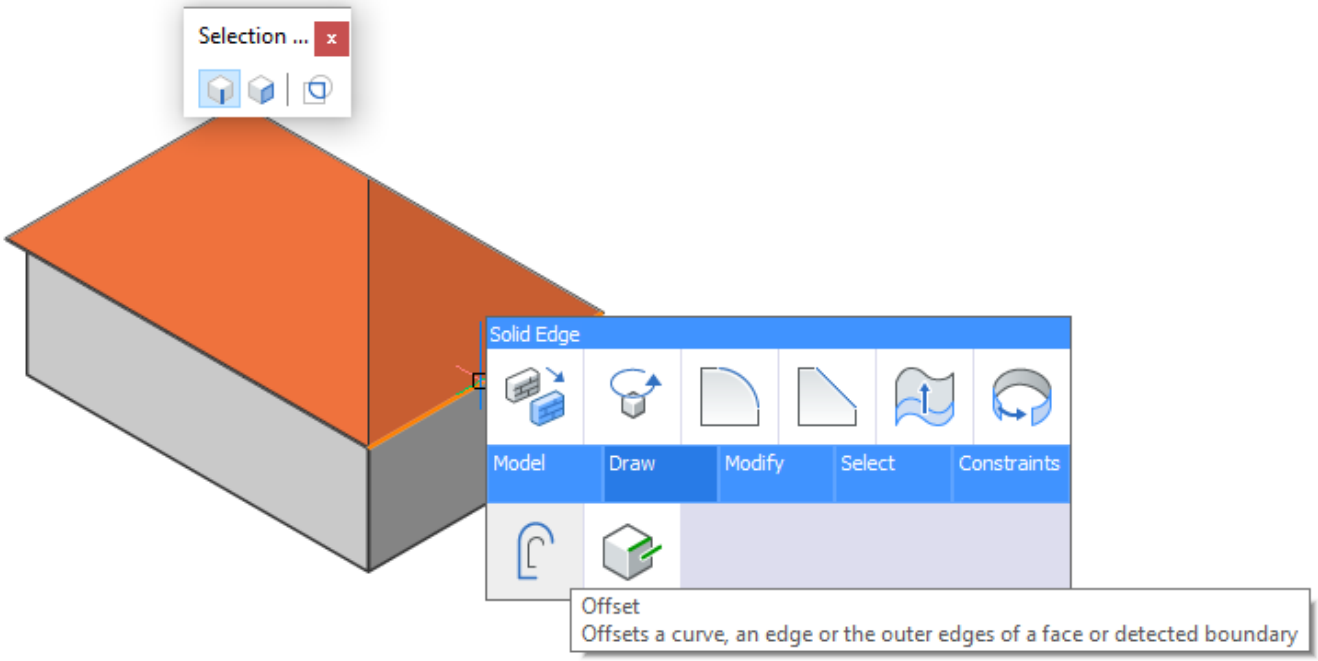

Figure 2.217

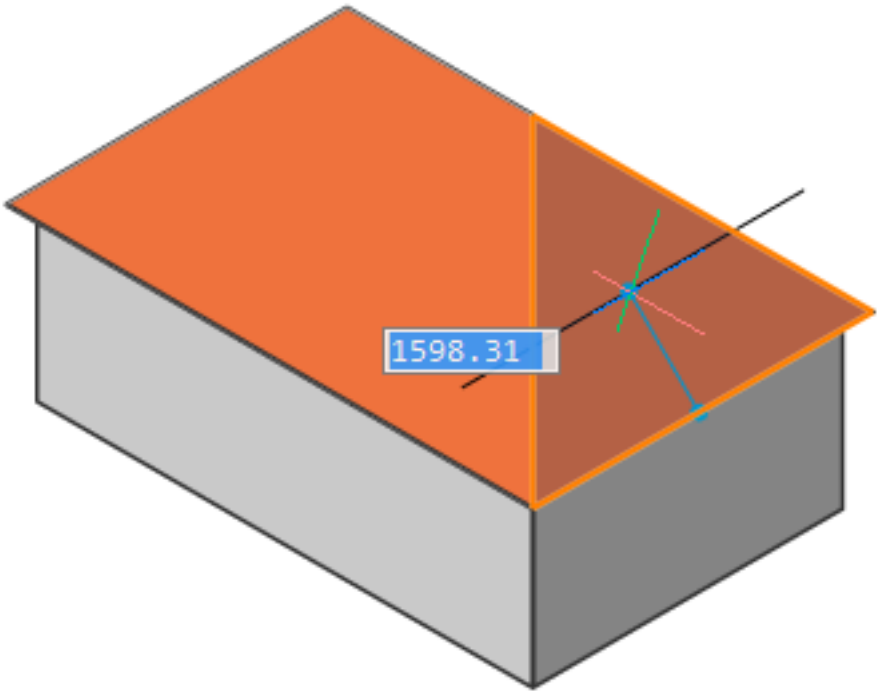

Figure 2.218

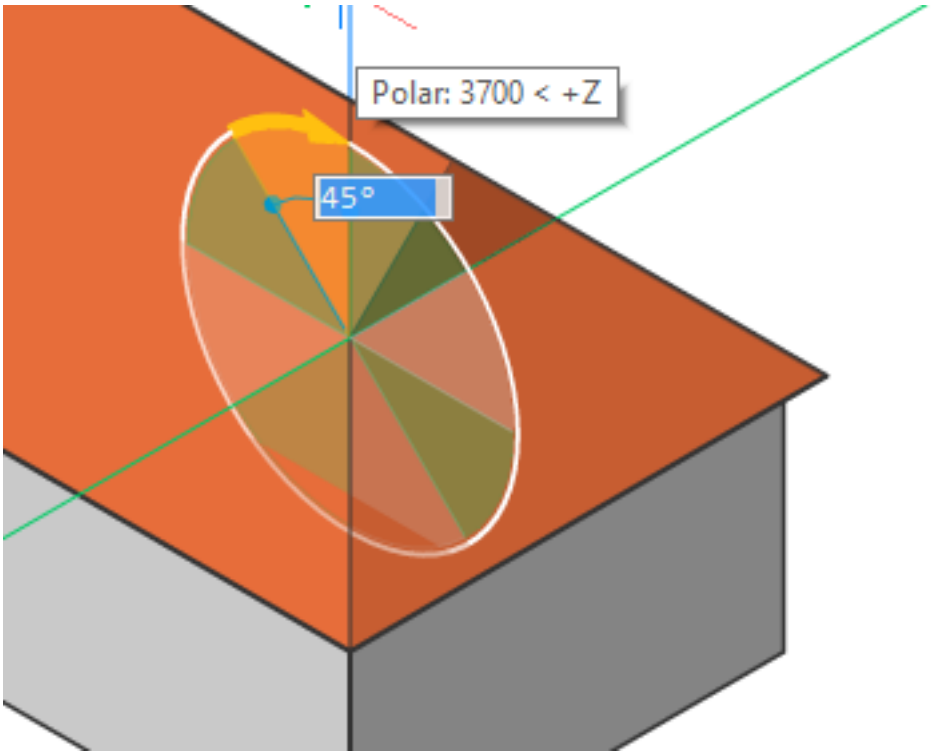
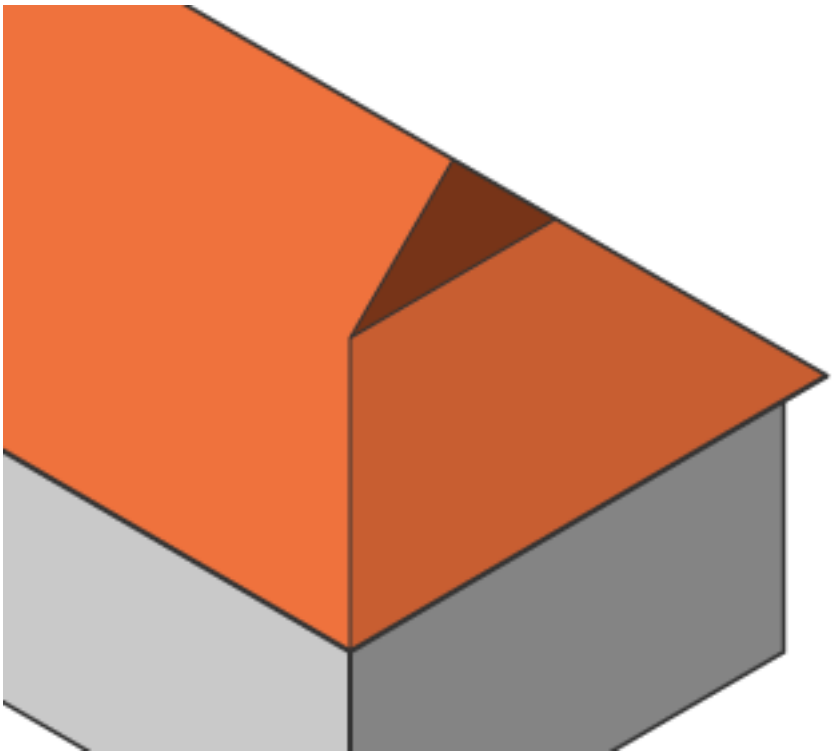


10. Execute step 7 of the Create a hip roof procedure to set the thickness of the roof solid.

Figure 2.219

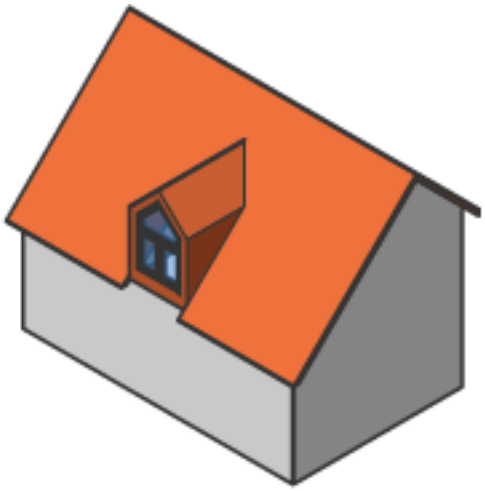


Creating dormers

(2.220) The procedure to create a dormer consists of the following steps:

- Create a box solid at the bottom edge of the roof plane and connect the box to the roof.
- Define the position and dimensions of the dormer.
- Create a dormer roof.

Figure 2.220



Create a box solid

1. Right-click, then choose **Box** in the **Model** tab of the Quad. **You are prompted:** Set corner of box or [Center] <0.00,0.00,0.00>:
2. Click a point at the bottom edge of the roof plan. **You are prompted:** Set opposite corner or [Cube/Length of side]:
3. Click a point, then define the height of the cube: either click a point or type value. (2.221 on the following page)
4. Select the back face of the cube: move the cursor over the cube at the location of the back face, then hit the Tab key until the face highlights (Selection Modes: Select Faces = ON).
5. Choose Connect with nearest in the Model tab in the Quad.
(2.222 on the next page) (2.223 on page 1787)
6. Select the front face of the box, choose **PushPull** in the **Model** tab in the Quad and move the face to the roof plane.
7. Use **PushPull** on the front, top and side face of the dormer solid to define the dimensions and the position of the dormer on the roof:
   - Select a side face, then hit the Tab key to define the width. (2.224 on page 1787)
   - Select both side faces, then choose to **Add rigid set** in the Constraints tab in the Quad to fix the width. (2.225 on page 1788)
   - Drag one of the side faces to position the dormer. Do one of the following:
     - Type a distance in the dynamic entry field.
     - Click to accept the value.
     - Move the cursor over a face that is parallel to the face being dragged and hit the Tab key. The distance field now shows the distance to this face.
   - Drag the top face to define the height of the dormer.
   - Drag the front face to set the distance from the roof eave. Move the cursor over the exterior face of the wall beneath the dormer, then hit the Tab key. The distance field now shows the distance to this face.
8. Modify the shape of the dormer:
   - Add a hip roof.
   - Add a hip roof, then rotate the front face vertical to create a gable roof.
   - Add a vault.
   - Rotate top and side faces.
   - Starting from a gable roof move the front face of the dormer backward until the front face is triangular.

(2.226 on page 1788) Hip	(2.227 on page 1788) Flat	(2.228 on page 1789) Vault
(2.229 on page 1789) Special	(2.230 on page 1789) Triangle	(2.231 on page 1789) Eyebrow

2.5.7 Creating Walls

Command: Polysolid (6.24.65), LConnect (6.20.19), TConnect (6.29.9), BimQuickDraw (6.7.41) **Overview:** In this lesson, you will learn how to create and modify a basic wall element. **Lesson Objectives** After completing this lesson, you will be able to: Use the Polysolid tool or the QuickDraw tool to create a basic wall.

- Create walls using an existing 2D plan.
- Create a connection between the two walls.
- Connect walls to other elements.

Tutorial: How to create walls Click here (2.4.7) to watch There are two ways to create a simple wall: with the PolySolid tool or by using BimQuickdraw. For a detailed explanation about Quickdraw, read the articles BimQuick-Draw (6.7.41) and Using BIM Quickdraw (2.5.22).

About the Polysolid Tool

The Polysolid tool allows you to create wall solids by selecting a start point, an endpoint and entering a height. Note that, in BricsCAD BIM, you always start by creating the geometry first and adding materials or compositions later. This way there is no need to worry about details when modeling a preliminary design. The use of Dynamic Dimensions (1.21.9) and Polar Tracking (1.21.18) is recommended. Dynamic Dimensions (1.21.9) can be used to specify the length of the wall and Polar Tracking (1.21.18) controls the direction.  For more information about this command, visit the Command Reference article PolySolid (6.24.65).

Procedure: Create a simple wall

1. Launch the Polysolid tool.
2. Select a start point, the footprint (1) of the wall is displayed automatically. Move the cursor in the desired direction, the current length value is displayed in the length dynamic entry field (2).

(2.232 on the next page)

3. Select an endpoint **or** enter a value in the dynamic input field and press Enter. The footprint (3) of the adjacent wall is displayed. Select a new endpoint **or** enter values in the dynamic input field to create adjoining wall segments.

(2.233 on the facing page)

4. Press Enter once more **or** right-click. The height of the wall is displayed dynamically in the height field (4). Here, you can change the default height of the wall. To change the width of the wall, use the width field (5). You can switch between the two dynamic input fields by pressing **Tab**.

(2.234 on the next page)

5. To change the justification of the wall hit CTRL while the 'Polysolid justification **Hotkey Assistant** widget' appears at the bottom of the screen. (2.235 on page 1792) **Note** The width and height of the previous wall will be the new default values of the next Polysolid.

Figure 2.232

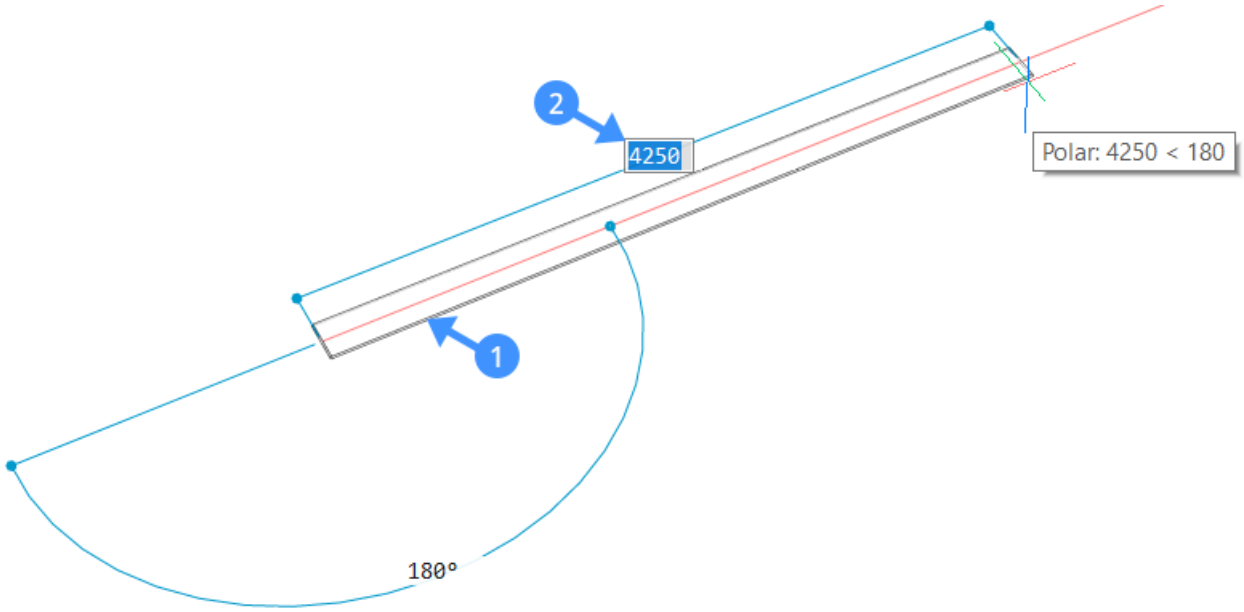

Figure 2.233

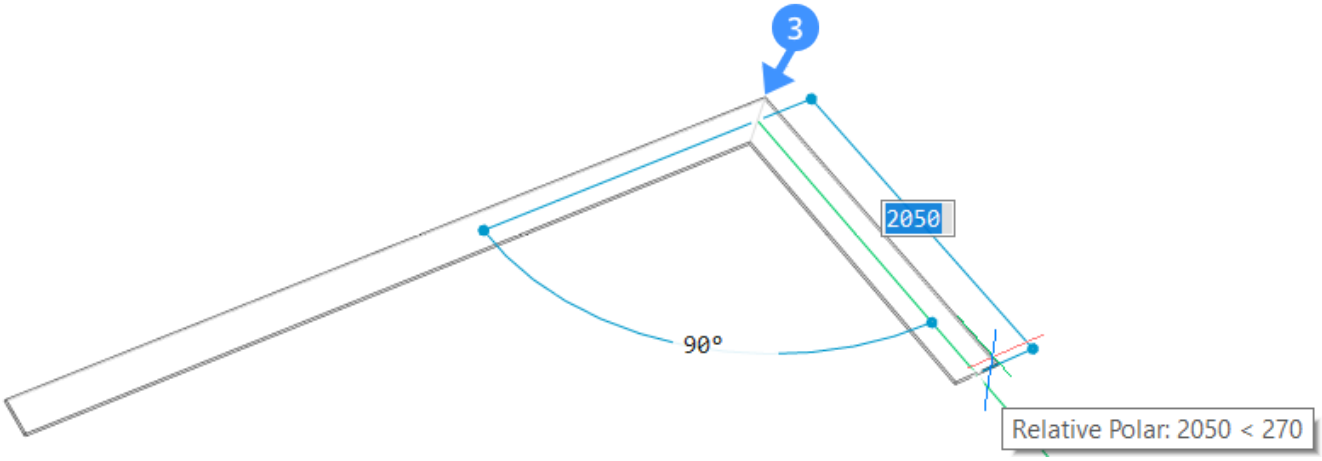

Figure 2.234

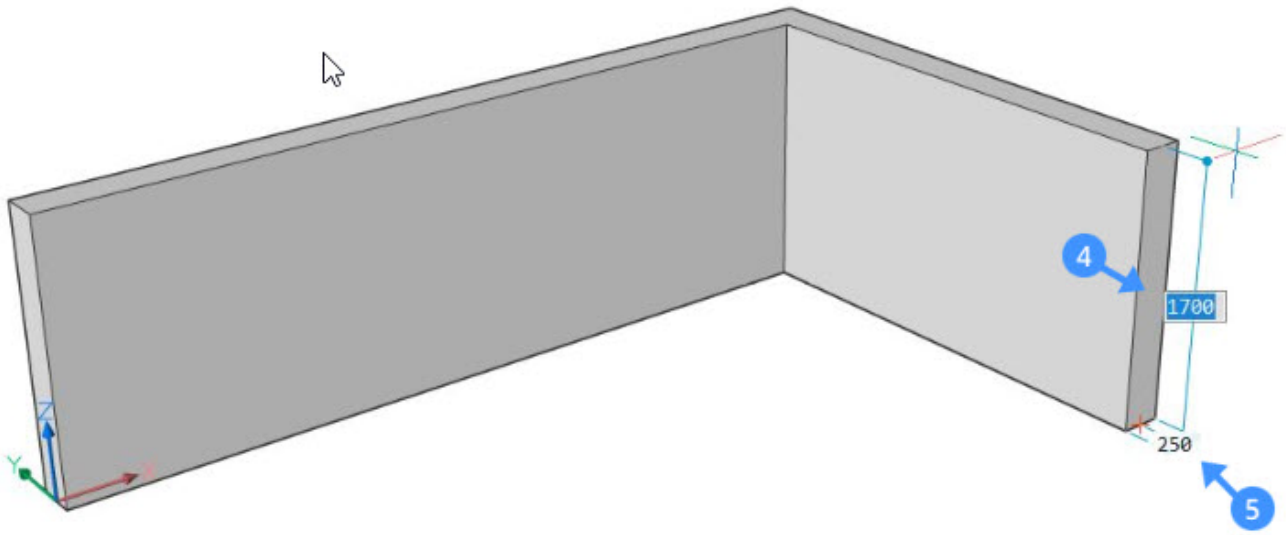

Figure 2.235

Procedure: Creating a curved wall

1. Launch the **Polysolid** tool.
2. Select a start point and move the cursor to set the length **or** click to set the endpoint.
3. To create a curved wall, type **A** and press Enter to choose Draw arcs or select **Draw arcs** in the prompts menu.
4. Now move the cursor in the desired direction to curve the wall. Enter a value in the dynamic input field to set the degree and length of the arc. Press Enter. (2.236)
5. You can continue creating curved, adjoining wall segments by clicking or by entering values in the dynamic input fields. To go back to drawing straight wall segments, type **L** and press Enter or select **Draw lines** in the options dialog. (2.237 on the facing page)
6. Press Enter once more or right-click. The height of the wall is displayed dynamically in the height field. Type a value to change the default height of the wall. To change the width of the wall, use the width field. You can switch between the two dynamic input fields by pressing **Tab**. (2.238 on the next page)

Figure 2.236

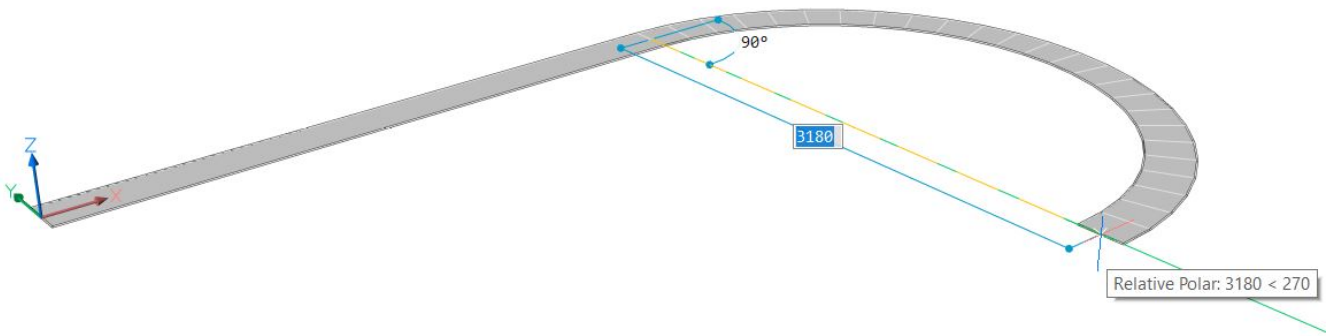

Figure 2.237

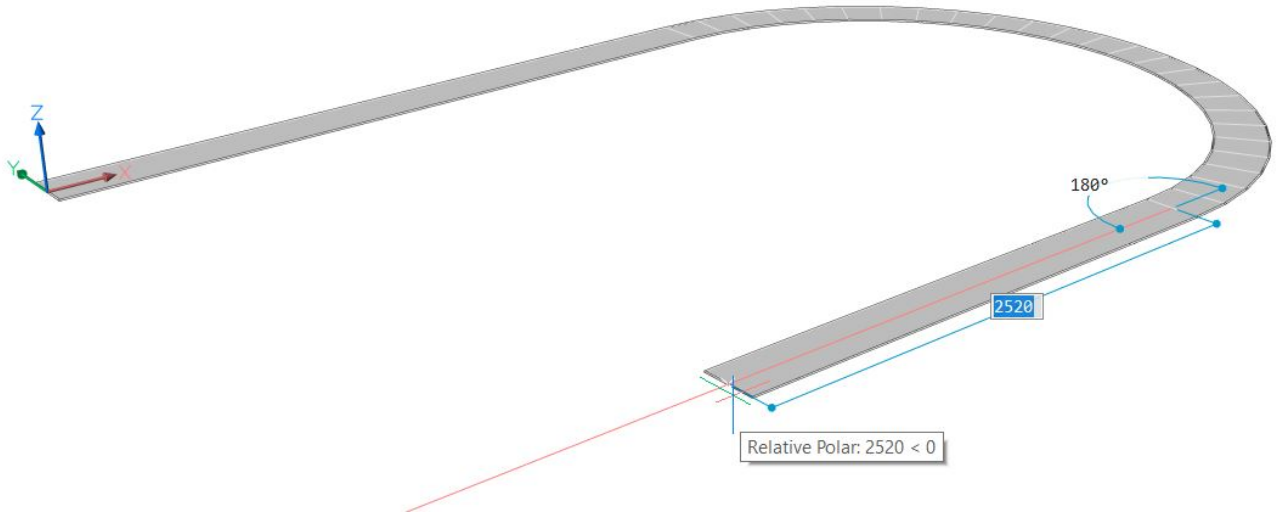

Figure 2.238

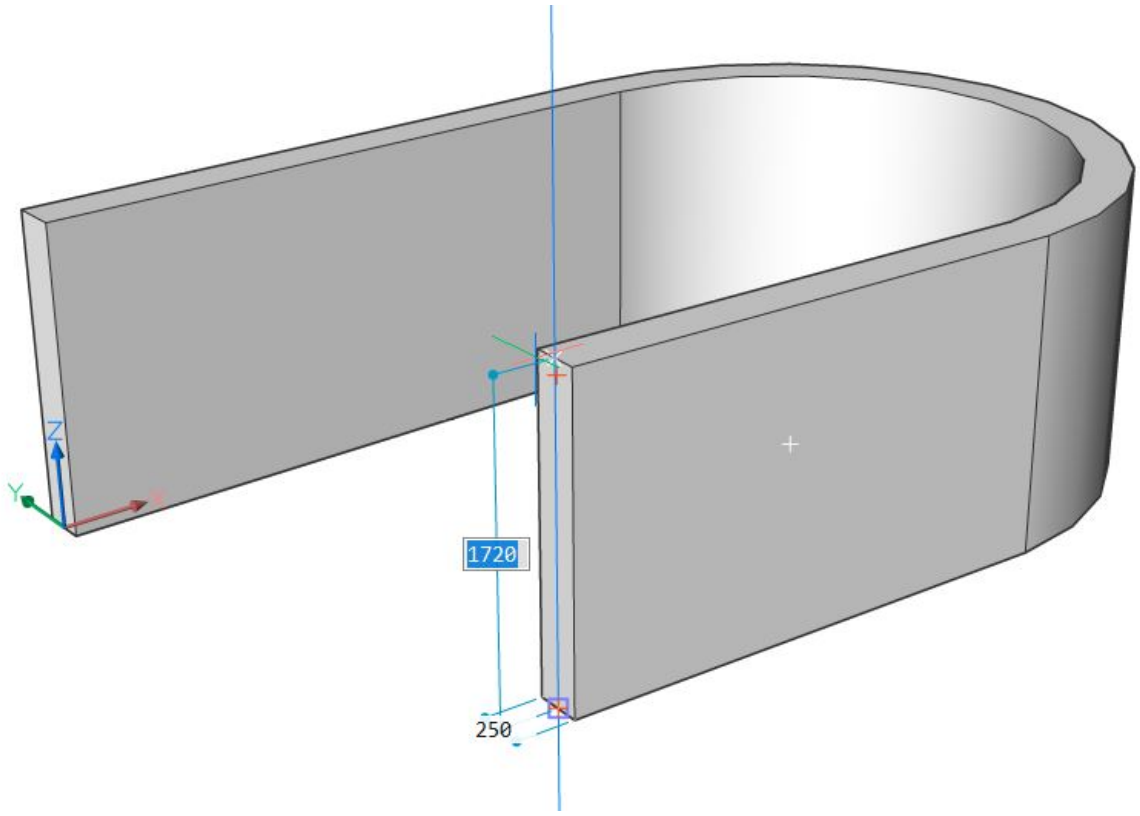

Procedure: Using an existing 2D plan to create walls

Tutorial: How to create wall layouts Click here (2.4.3) to watch

Using an existing 2D plan view enables you to create a wall element in 3D.

1. Click the **Polysolid** tool from the Quad and type **E** on the commandline **or** select **Entity** in the prompts menu. Using the Entity option in Polysolid enables you to create 3D geometry from a 2D layout.
2. Choose a 2D linear entity which will be the Polysolid base. Lines, open and closed polylines, arcs, circles, ellipses, elliptical arcs, and splines are accepted as a polysolid base.
3. Move the solid up or down and left-click to set the height of the wall, enter a value in the dynamic input field or right-click to accept the default value.
4. The current width of the wall appears in the **Width Field**. Press Tab switch between the Height and the Width field.
5. The **Hotkey Assistant** appears and displays the possible justification options. Press **CTRL** to cycle through the wall justification options. (2.239 on the facing page)

It is also possible to use an existing 2D plan to create walls using the BimQuickDraw (6.7.41) tool:

1. Open the **Quickdraw** tool from the Quad **or** type **Quickdraw** in the commandline.
2. The cursor automatically snaps to the lines of your 2D drawing. Place your cursor where you want to place your first corner and left-click. (2.240 on the next page)
3. Hover your mouse to the opposite corner and left click again **or** type the values of the lengths of the sides in the respective fields and press Enter. (2.241 on page 1797)

Figure 2.239

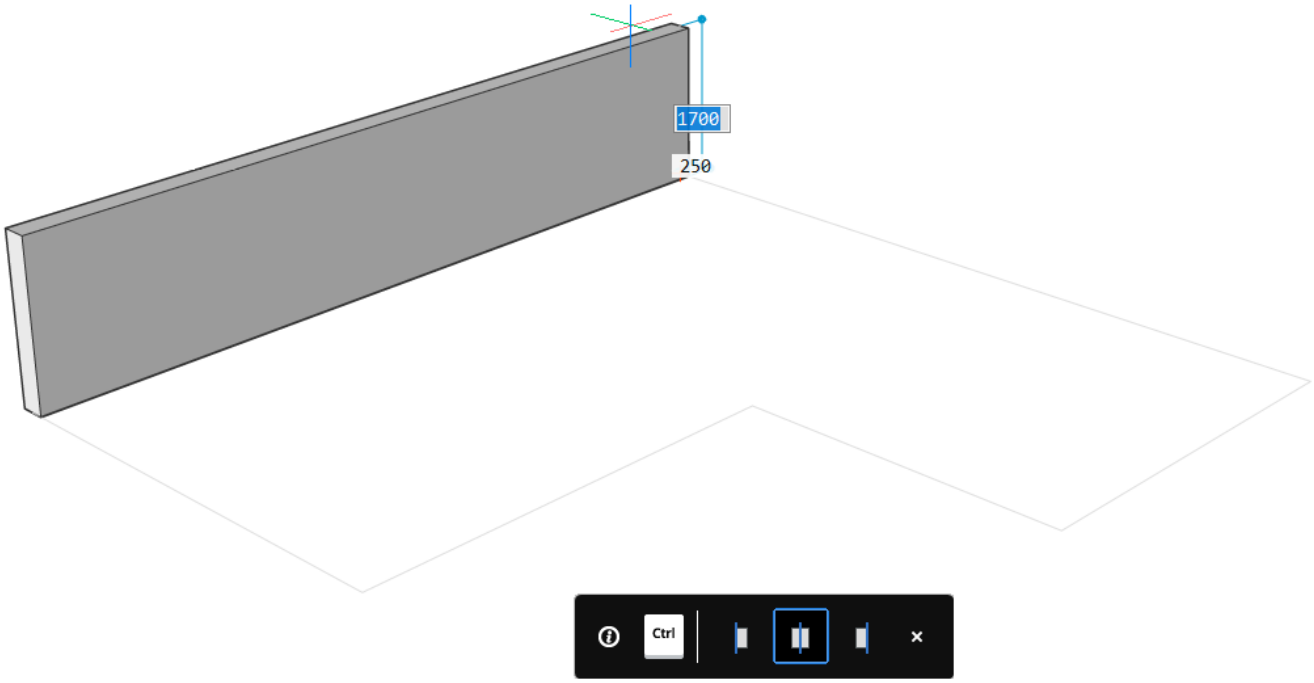

Figure 2.240

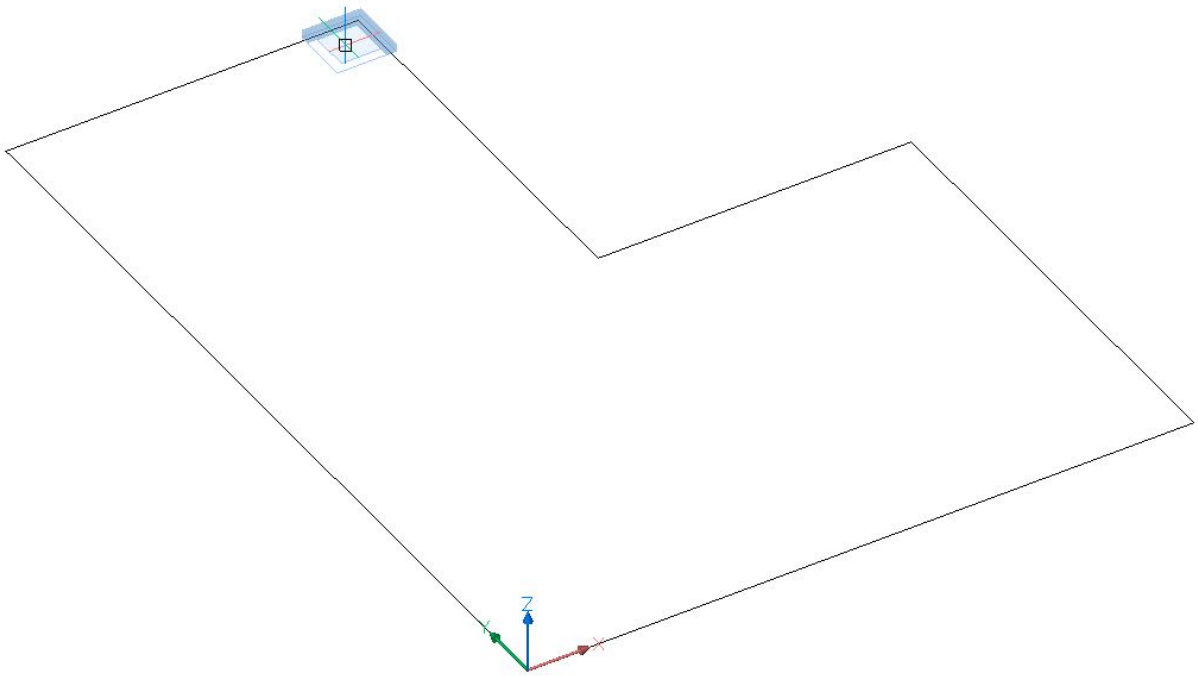

4. The Quickdraw tool always uses the default height and width settings. To change these values type **S** and press Enter to open the Quickdraw Settings. Change the values in this menu.
5. To finish the L-shaped form, you can draw a new rectangular on the second part of the figure. The common wall of the two rectangles will automatically be removed if you draw a second rectangular starting from the interior side of the first rectangular as indicated below: (2.242 on the next page)
6. While drawing the second rectangular, you can see the wall that will be deleted is displayed in red. (2.243 on page 1798) (2.244 on page 1798) For more info about Quickdraw, please read the article Using BIM Quickdraw (2.5.22).

Figure 2.241

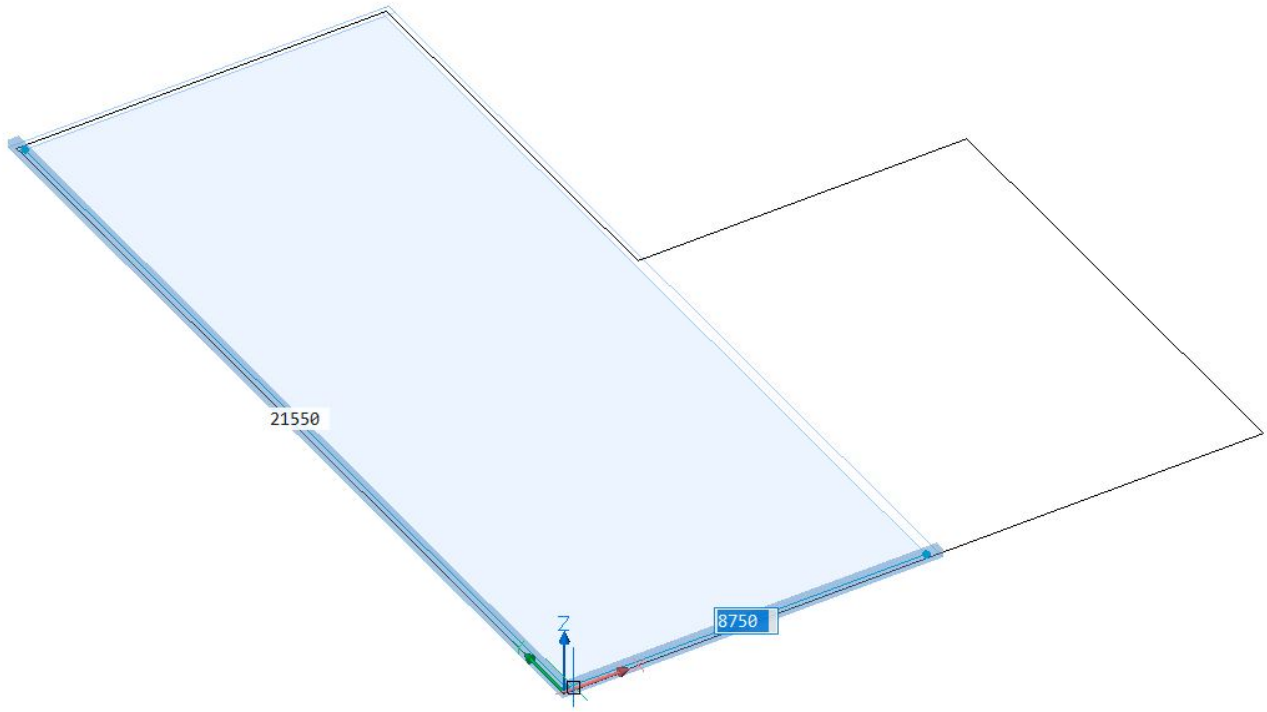

Figure 2.242

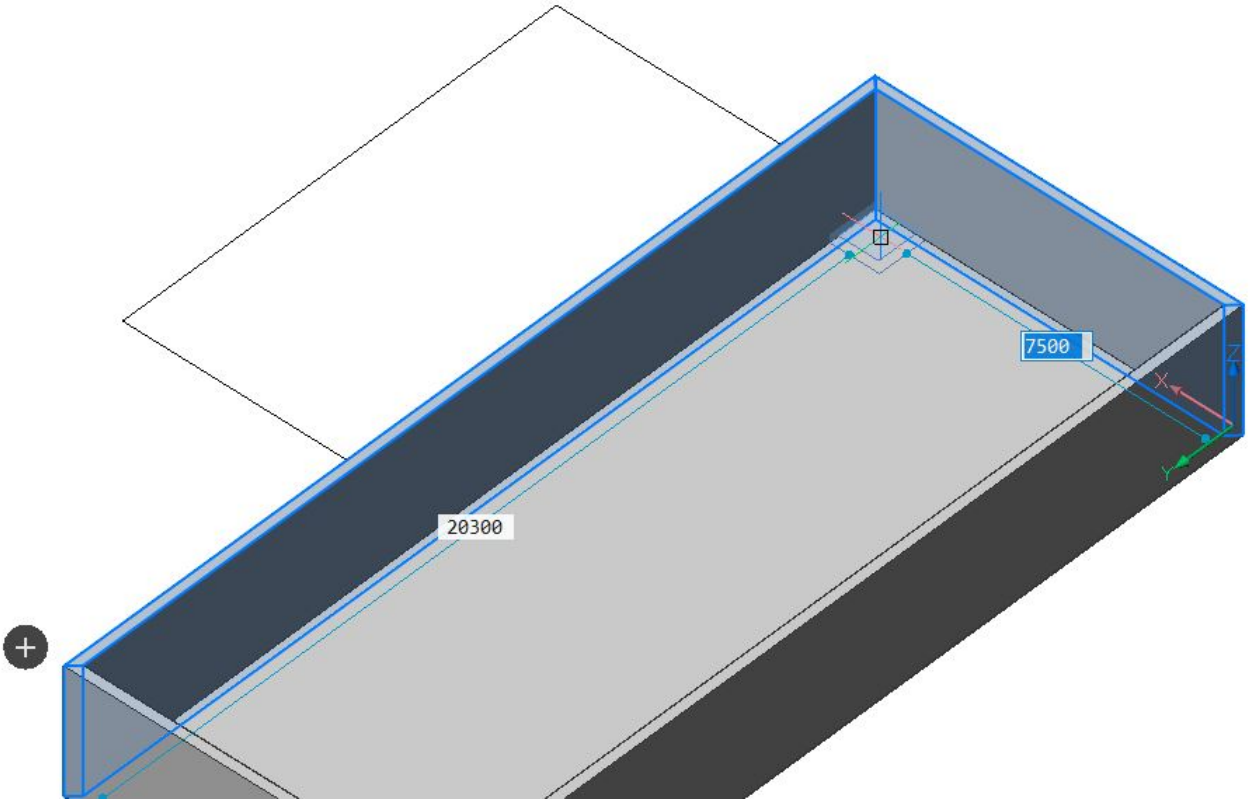

Figure 2.243

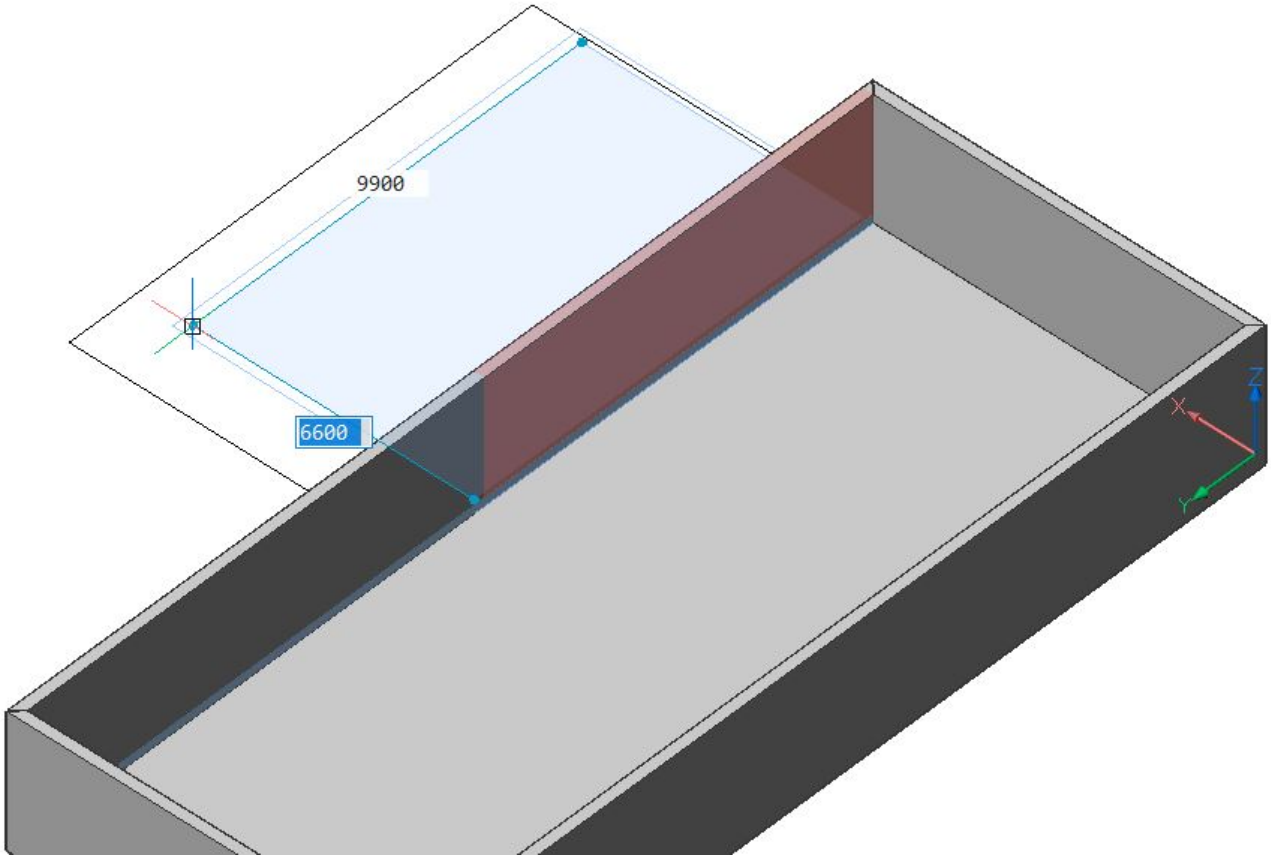

Figure 2.244

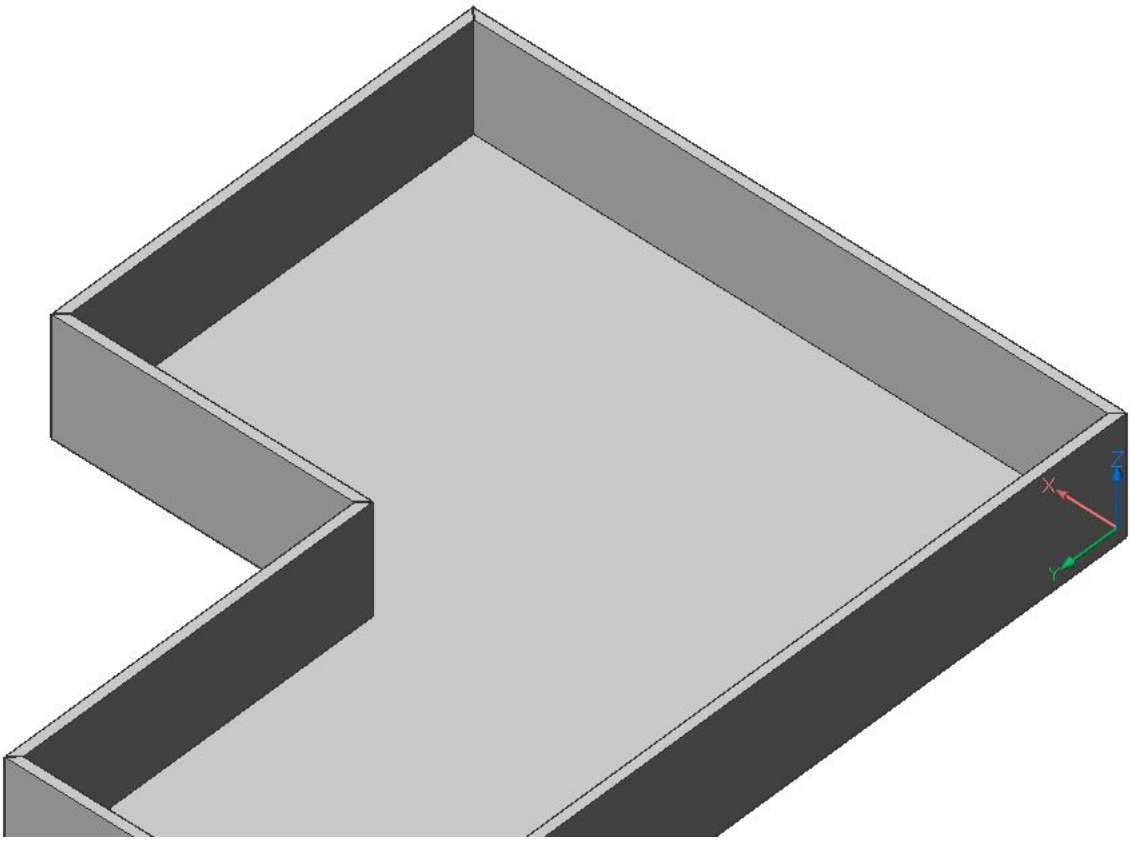

About the BimConnect Tool

The BimConnect tool allows you to connect one wall to another element.  For more information about this command, visit the Command Reference article LConnect (6.20.19).

Procedure: Connecting two walls

Tutorial: How to connect walls Click here (2.4.5) to watch

1. Select two wall elements and apply the LConnect tool.

When two walls intersect, a mitered connection will be created by default. (2.245 on the following page) (2.246 on page 1801)

2. Change the layout of the wall connections using the 'LConnect HotKeyAssistant widget'.

The selected connection type is indicated by a blue frame. (2.247 on page 1801) The connection can be (from left to right) a bisector L-connection , L parallel type 1 , L parallel type 2 or a disconnection. Switch between the options by pressing CTRL.

- **Bisector L-connection (miter)** When the bisector L-connection is selected, the walls are connected at an angle of 45°. (2.248 on page 1801)
- **Parallel L-connection 1 Parallel L-connection 2** When the L parallel type 1 or type 2 connections are selected, the walls are connected at an angle of 90°. (2.249 on page 1802) (2.250 on page 1802)
- **Disconnection** When the disconnected option is selected, the existing connection between the walls is removed. (2.251 on page 1803)

Figure 2.245

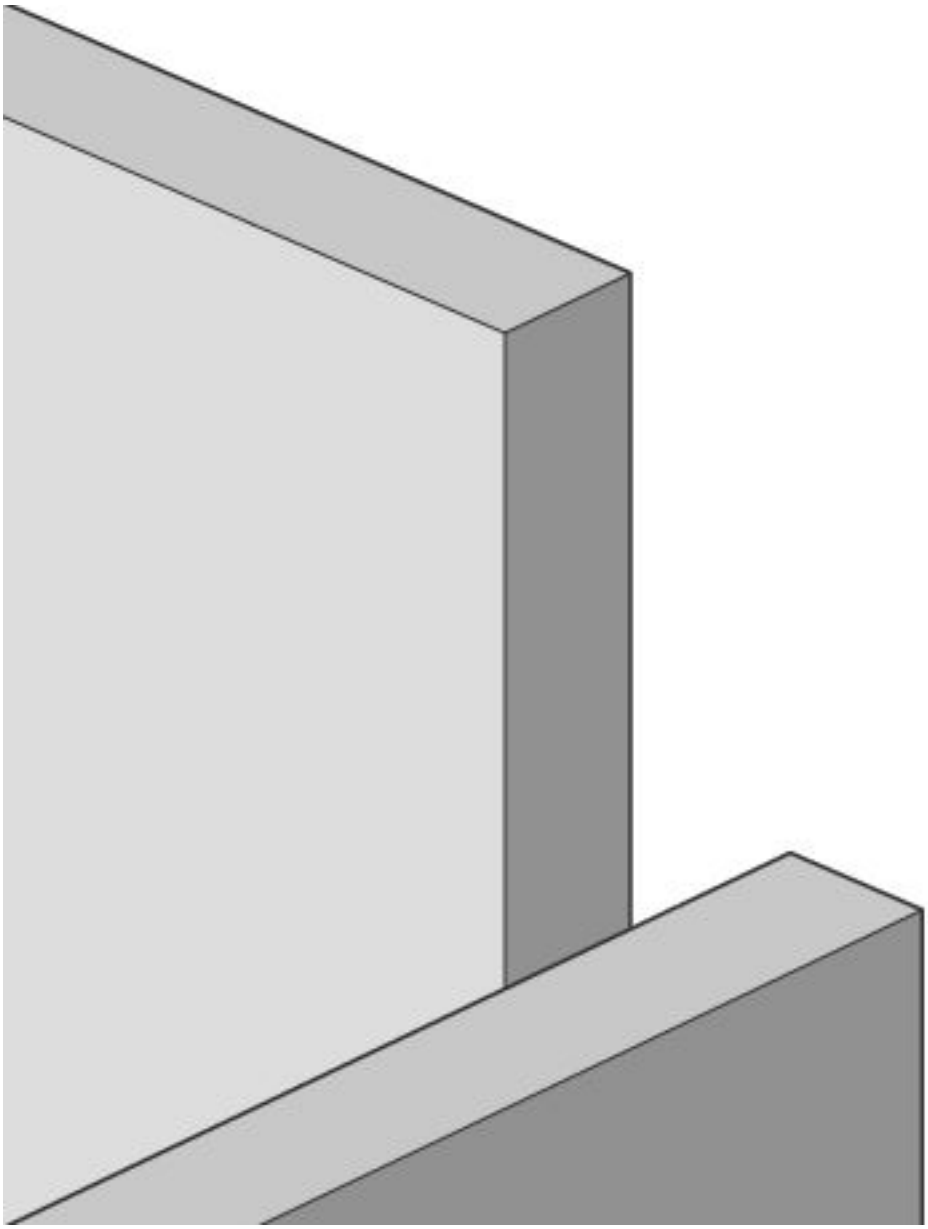

Figure 2.246

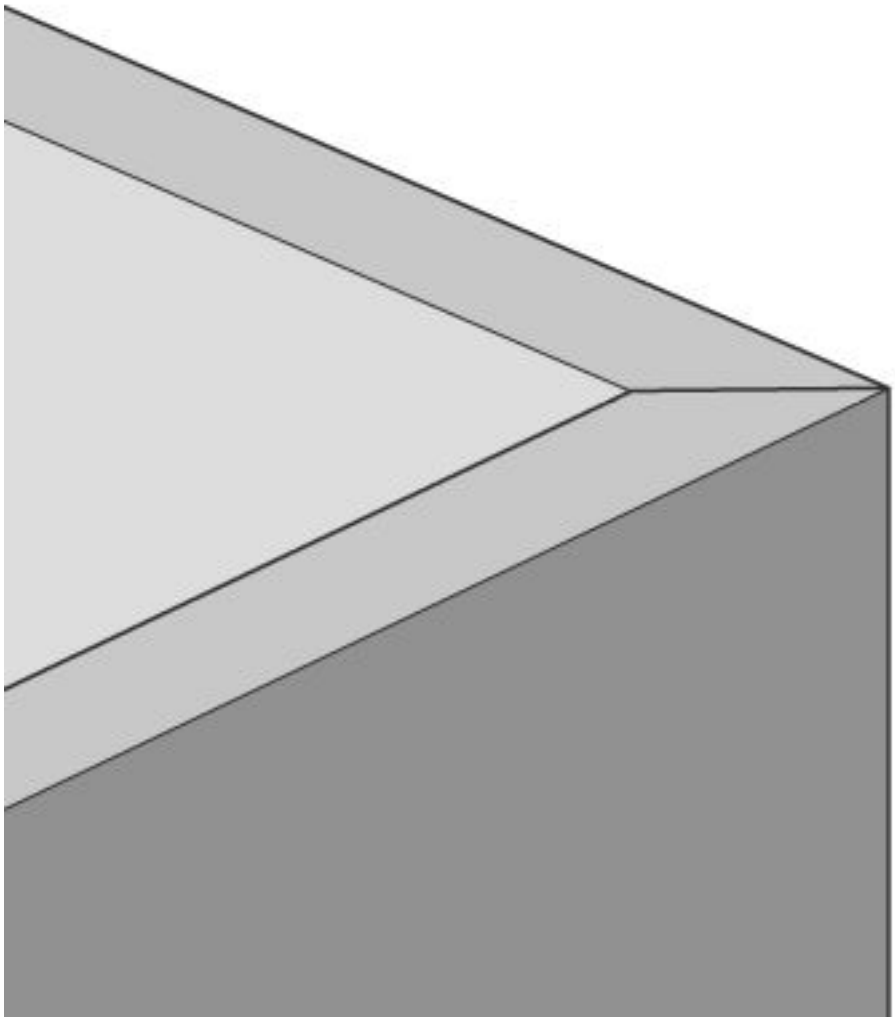

Figure 2.247

Figure 2.248

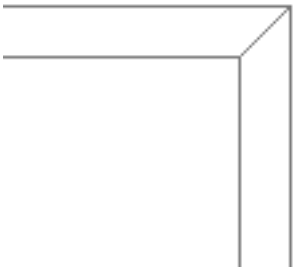

Figure 2.249

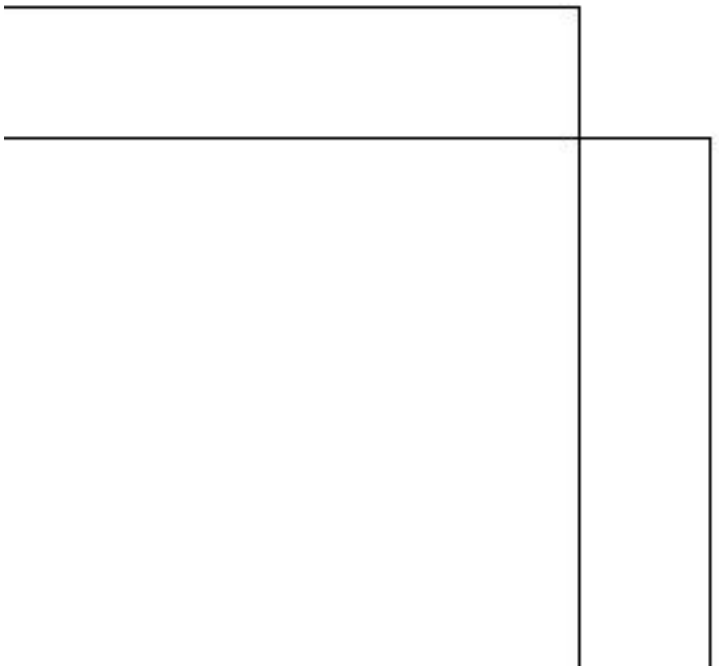
Figure 2.250

Press Enter to accept the current connection type or press CTRL to cycle through the possible connection options.

Figure 2.251



Connecting walls to other elements

The **Connect with Nearest** tool allows you to connect the minor face of a wall to the major face of another element, regardless of the orientation of the faces. This tool can be used to connect the top face of a wall to a roof, the bottom face to a slab or the side face of a slab to a wall. To connect the face to the nearest object, select the face of the object that you would like to connect with the nearest object and choose the **Connect With Nearest** tool in the Quad. **Note:** Before using the **Connect with Nearest** tool, make sure the Select Faces option is enabled in the selection mode settings.  For more information about this command, visit the Command Reference article TConnect (6.29.9).

Procedure: Creating T- connections between two walls

1. In the drawing area, highlight the face you want to connect to another wall. (2.252 on the next page)
2. Use the **Connect with Nearest** tool from the Quad.

The **Connect with Nearest** tool automatically makes a T-connection between the two walls by extruding the face of the first wall to the face of the other wall. (2.253 on page 1805)

Figure 2.252

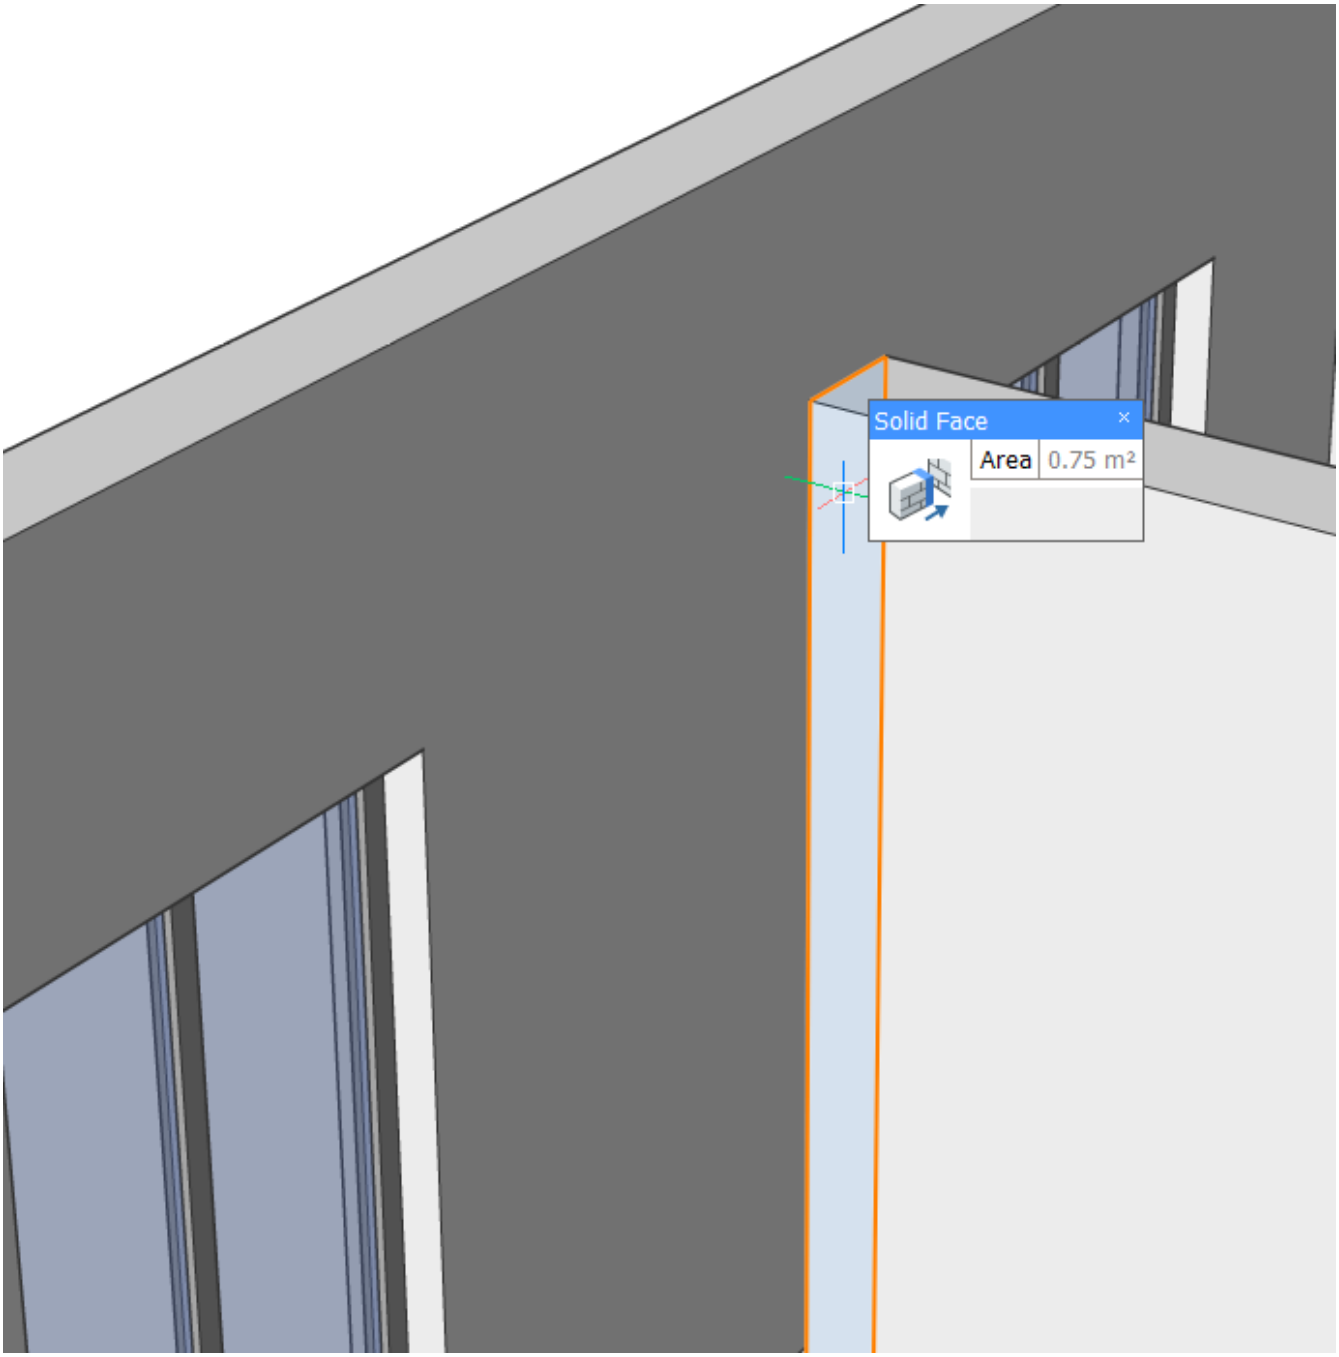


Figure 2.253

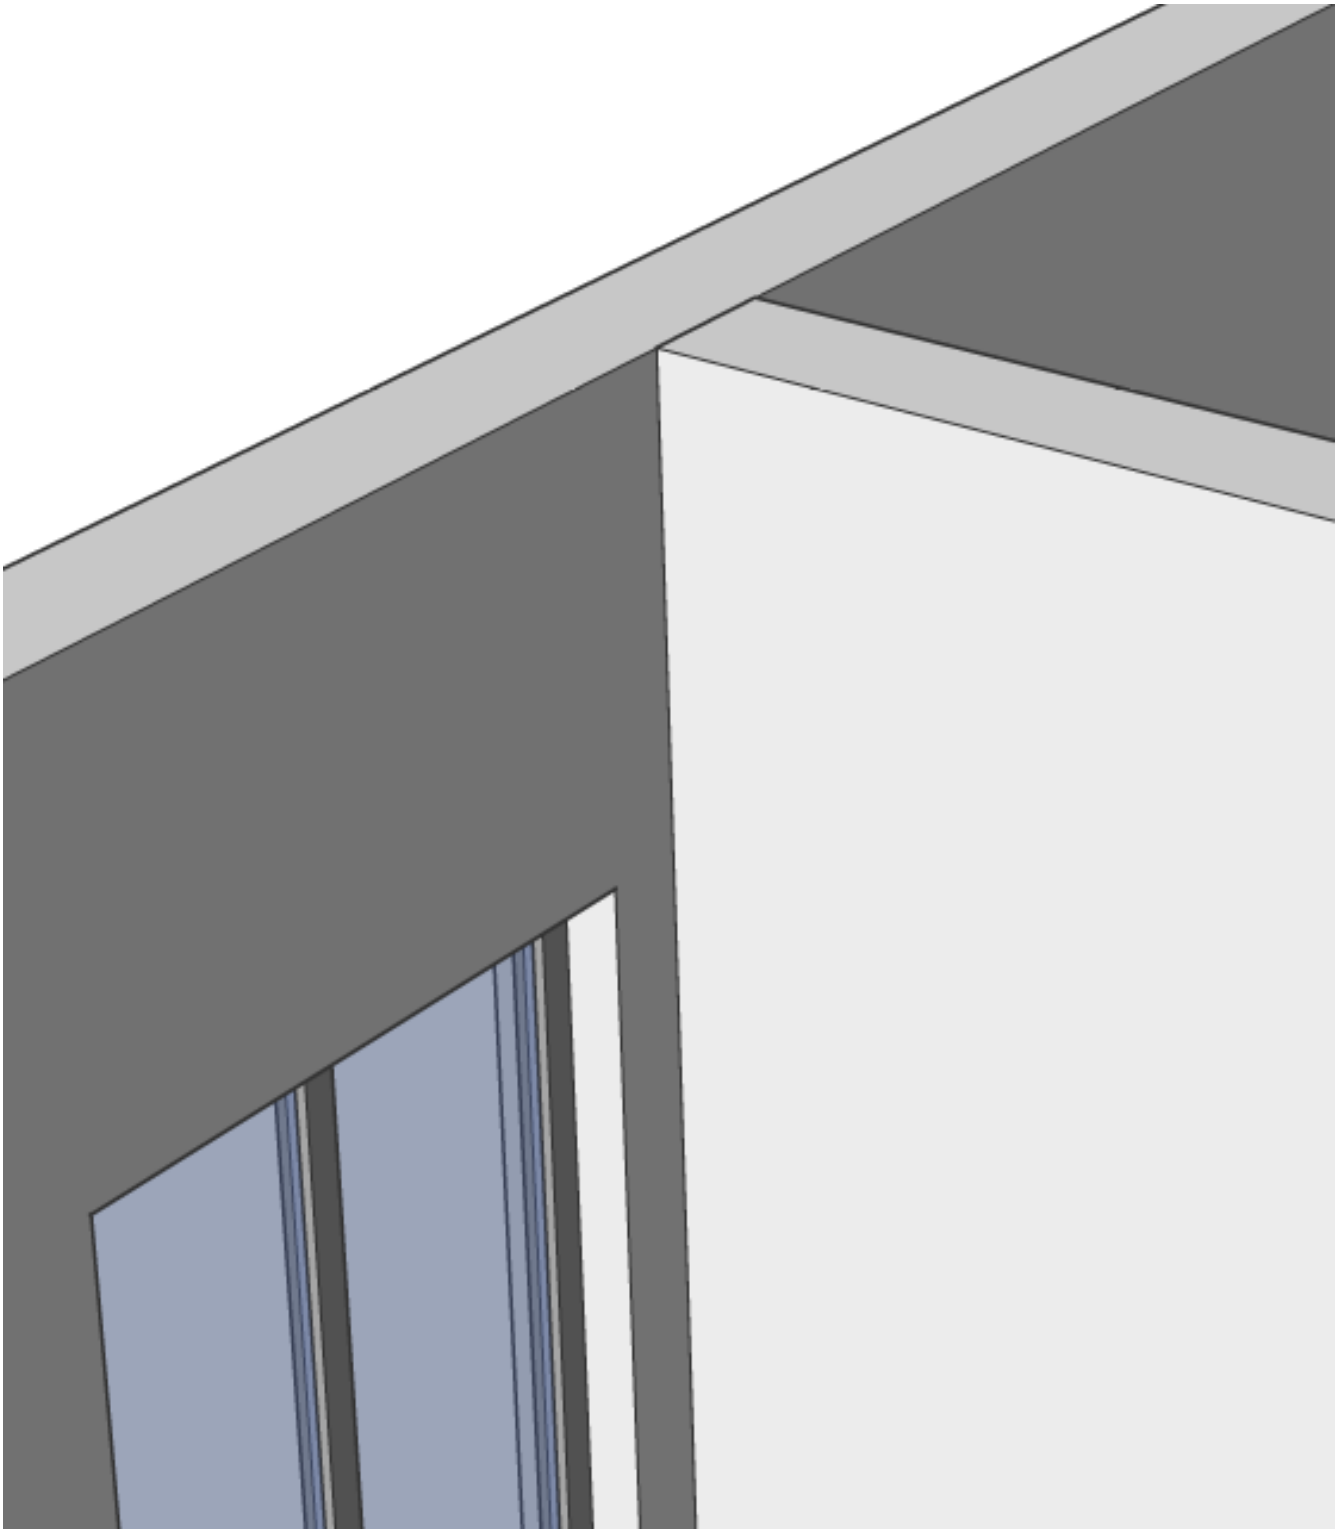

About the Select Aligned Faces Tool

The **Connect with Nearest** tool can also be used to connect multiple faces of a wall to the nearest face of another element. To do this use the **Select aligned faces** tool. This tool enables you to highlight all faces that are coplanar with the current selection.  For more information about this command, visit the Command Reference article SelectAlignedFaces (6.27.17).

Procedure: Connecting multiple faces of the wall to the roof slab

1. To select all faces aligned to the current selection, highlight the top face of one of the walls and click the **Select aligned faces** tool in the Select tab of the Quad. (2.254 on the next page)
2. Launch the **Connect with Nearest** tool. The top faces of the wall are attached to the roof. (2.255 on page 1808)

Figure 2.254

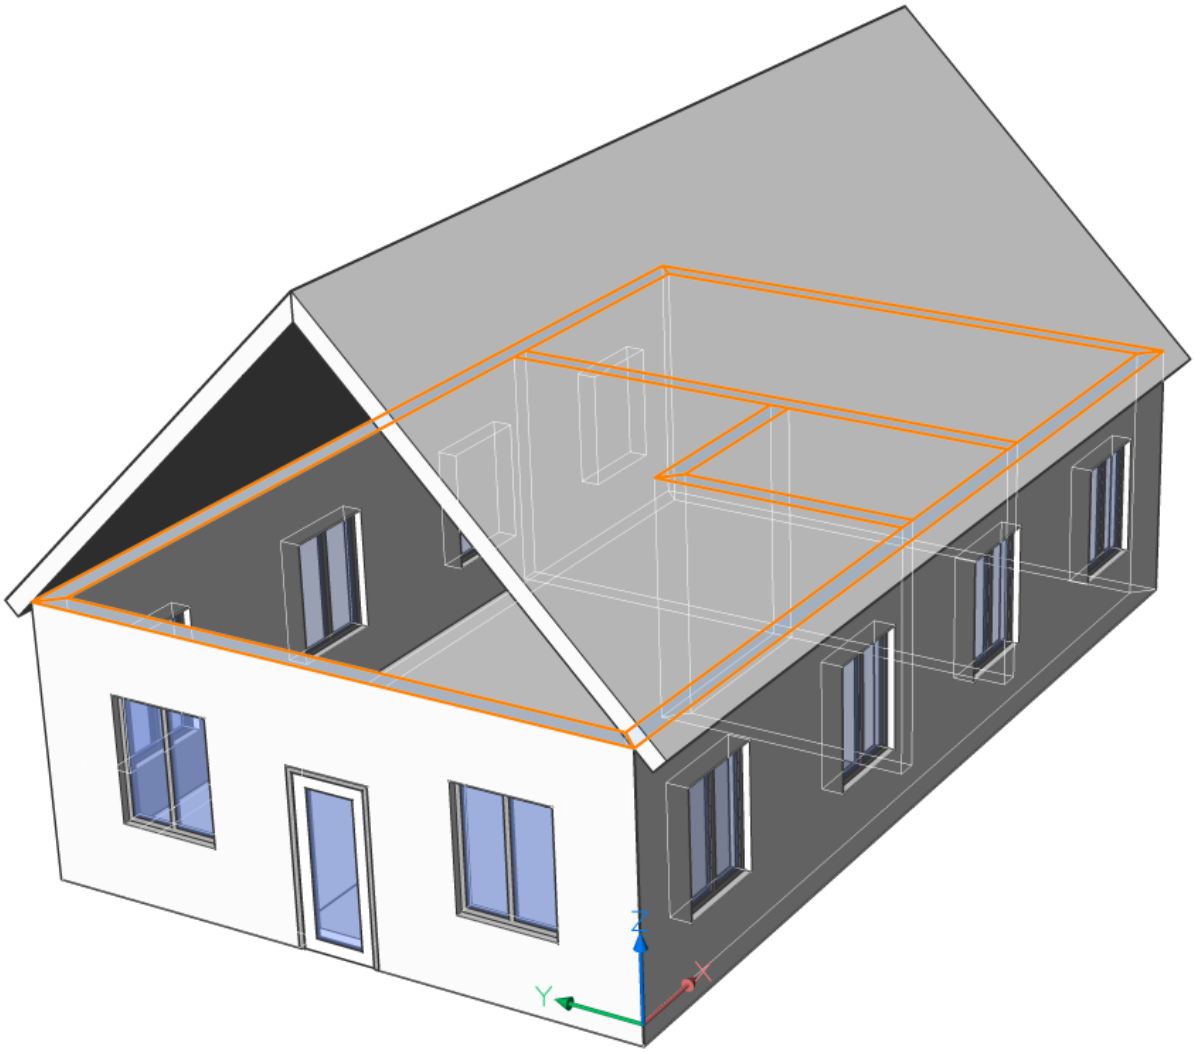

Figure 2.255

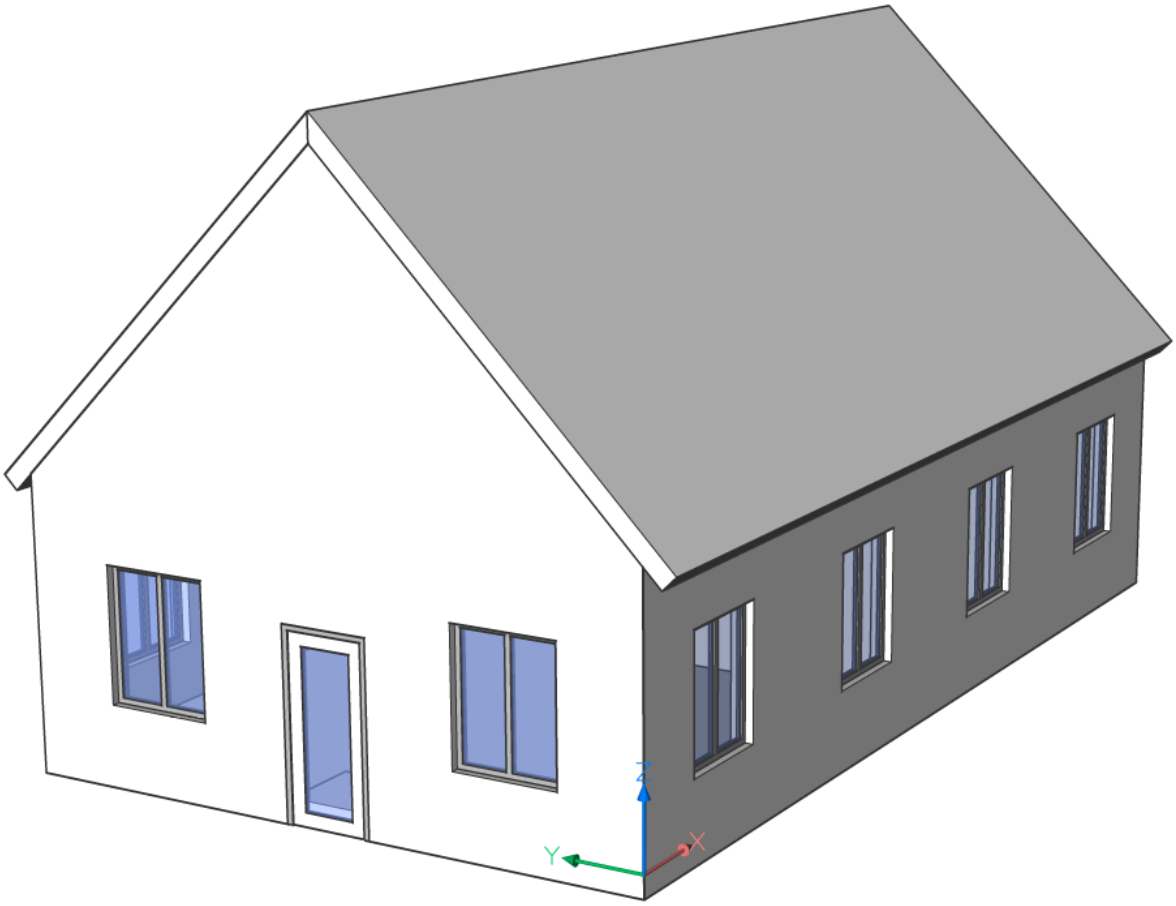

2.5.8 Creating Slabs

Commands: DmExtrude (6.12.14), Polysolid (6.24.65) The DmExtrude command allows to extrude a closed 2D entity such as polylines, circles, ellipses and extrude a detected boundary, enclosed by walls and/or 2D entities. The PolySolid command allows to create pitched roofs.

Creating floor slabs between walls

Make sure that:

- The Enable Boundary Detection option of the Selectionmodes (1.32.4) system variable is ON.
- The bottom faces of the surrounding walls are in the XY-plane of the current coordinate system. If necessary move the origin of the coordinate system (1.21.21).
- Dynamic dimensions (1.21.9) are ON.

1. Move the cursor inside the surrounding walls.
2. When the boundary highlights, choose Extrude in the Model command group in the Quad. The slab is extruded dynamically.
3. Do one of the following:

- Type the thickness of the slab in the dynamic dimension field.
- Pick a point.

Creating a pitched roof slab

Make sure that:

- Dynamic UCS (1.21.21) is ON.
- Dynamic dimensions (1.21.9) (DYN) is ON; it is recommended to have the Tracking dynamic dimensions option of the DYNMODE system variable set.
- Entity Snap Tracking (1.21.17) (STRACK) is ON.
- Endpoint (6.13.7) entity snap is ON.

1. Launch the Polysolid (6.24.65) command. **You are prompted:** Start point or [Height/Width/Justification/Entity/Separate solids/Dynamic] <Entity>:
2. Move the cursor over the outside face of a wall which is perpendicular to the roof slab you want to create.
3. When the face highlights, hit the Shift key to lock the dynamic UCS.
4. Do one of the following: To create the roof at the top edge of the wall, snap to the exterior top corner of the wall. To create a roof overhang (eave):
    - Move the cursor over the exterior top corner of the wall to require a snap tracking point.
    - When a small red cross indicates the tracking point is acquired, move the cursor to the outside and type the overhang distance in the dynamic entry field. (2.256 on the next page)
5. Hit the TAB key to activate the Angle field, then type the pitch angle and hit the TAB key again to jump to the Distance field. (2.257 on the following page)
6. Specify the height of the roof slab, then press Enter twice: the first Enter creates the footprint of the roof slab, the second Enter interrupts the creation of a second solid. The roof slab is extruded dynamically.
7. Specify a point to define the length of the extrusion. (2.258 on page 1811)
8. Repeat the previous steps to create more roof slabs.
9. Use ConnectWithNearest to connect the walls to the roof slabs.

Figure 2.256

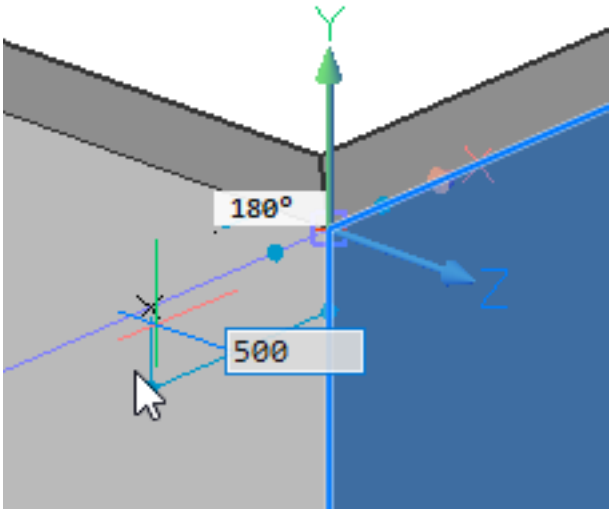

Figure 2.257

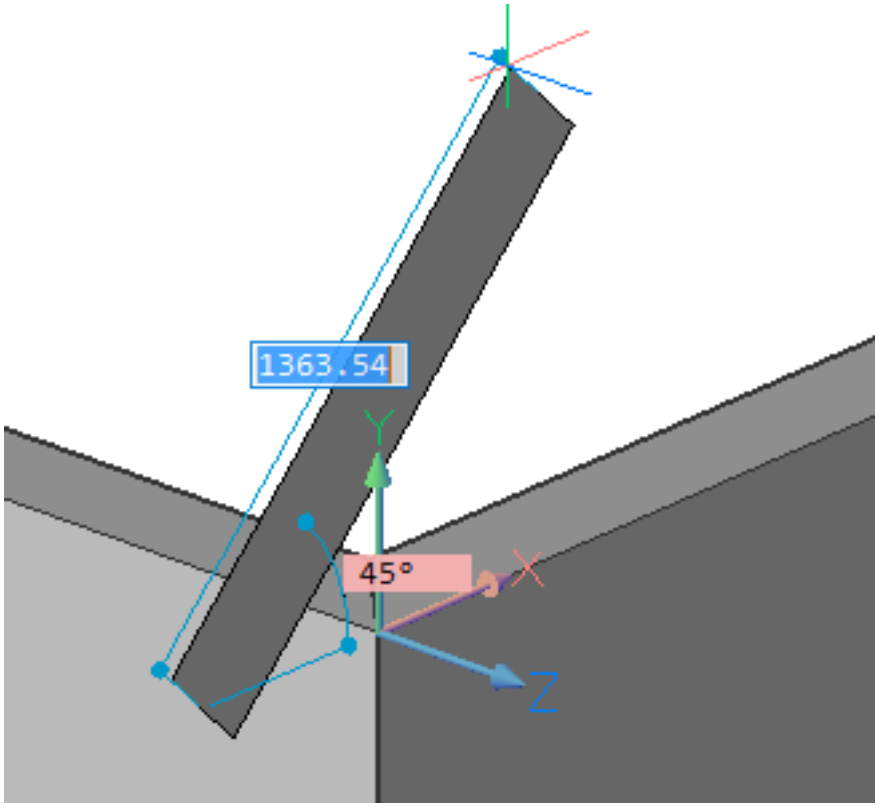

Figure 2.258

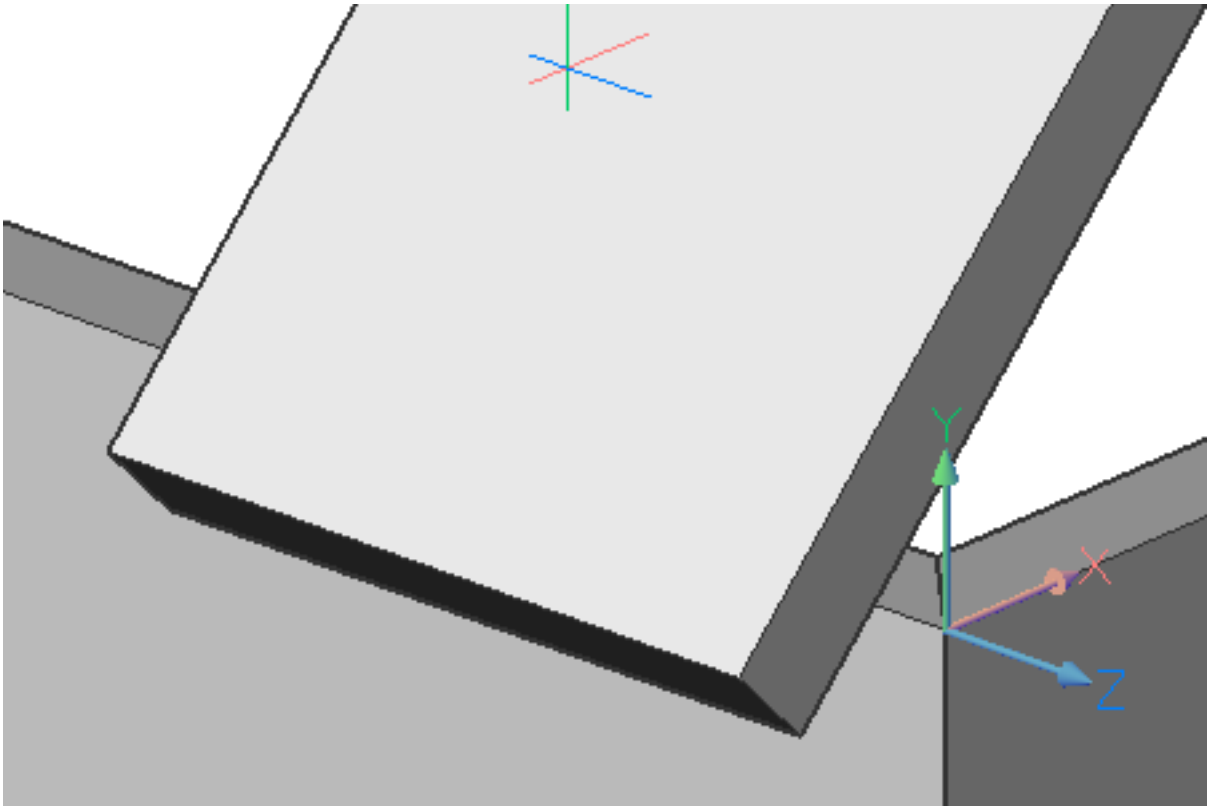

2.5.9 Curtain Wall

Command: BimCurtainWall (6.7.15) **Overview:** In this lesson, you will learn how to create a curtain wall in BricsCAD. **Lesson objectives:** After completing this lesson, you will be able to:

- Create a curtain wall
- Planarize the grid cells of the curtain wall
- Change the dimensions and the number of panels
- Change the connection type

Tutorial: How to create Curtain Walls Click here (2.4.15) to watch

About

In BricsCAD, curtain walls are created from the face of a 3D solid or surface as a block by using the **Curtain Wall** tool.  For more information about this command, visit the Command Reference article BimCurtainWall (6.7.15).

- Curtain walls can be created from any planar and curved surface.
- Window Frames are placed on a BIM Grid when creating a Curtain Wall.
- Changing the U-line and V-line panel options allows you to specify the desired size and number of panels on the planar or curved surface. (2.259 on the facing page) (2.260 on the next page) **Figure 1, Curtainwall grid (1). Figure 2, Curtainwall with glazing (2).** The curtain wall system consists of panels of glass. This is a panel infill for a curtain wall. (2.261 on page 1814) **Figure 3, A curtain wall. The frame that coincides with the grid vertical (U) panels (3), the frame that coincides with the grid horizontal (V) panels (4), and glass in-fill (5) are shown. By default, the straight connection (6) is made between the beams.**
- Curtain walls are automatically classified as a Curtain wall in the Structure browser (2.7.18). If you explode the Curtain wall, the sub-entities are classified as windows and as frames. The frames are linear solids. This allows you to calculate the length of a curtain wall.

(2.277 on page 1824) Classified as Curtain Wall	(2.278 on page 1825) Classified as window and frames

Figure 2.259

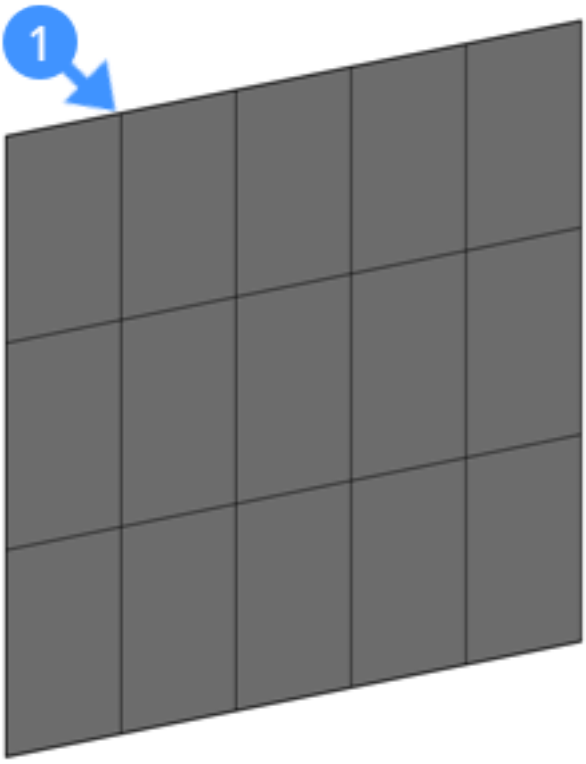

Figure 2.260

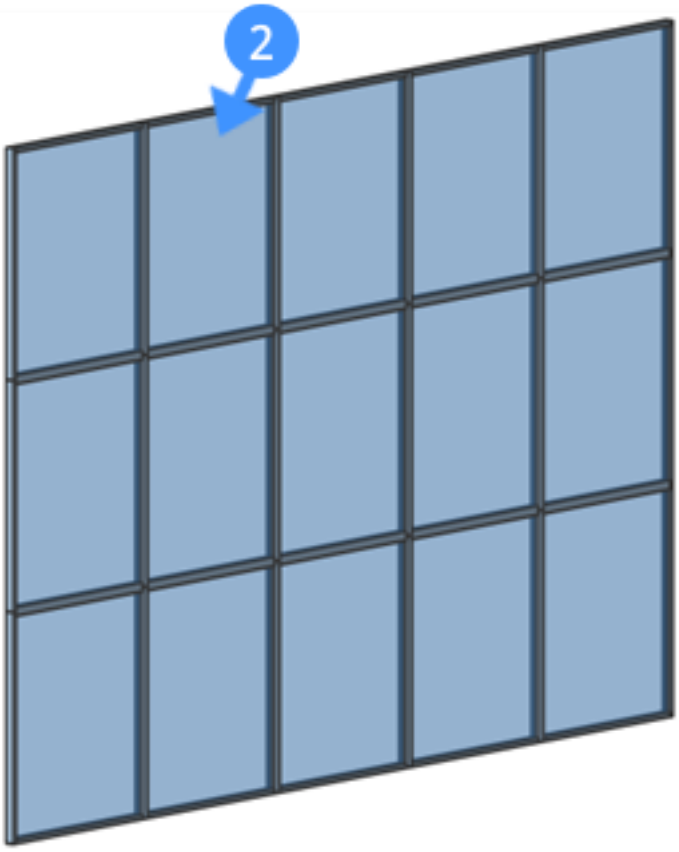

Figure 2.261

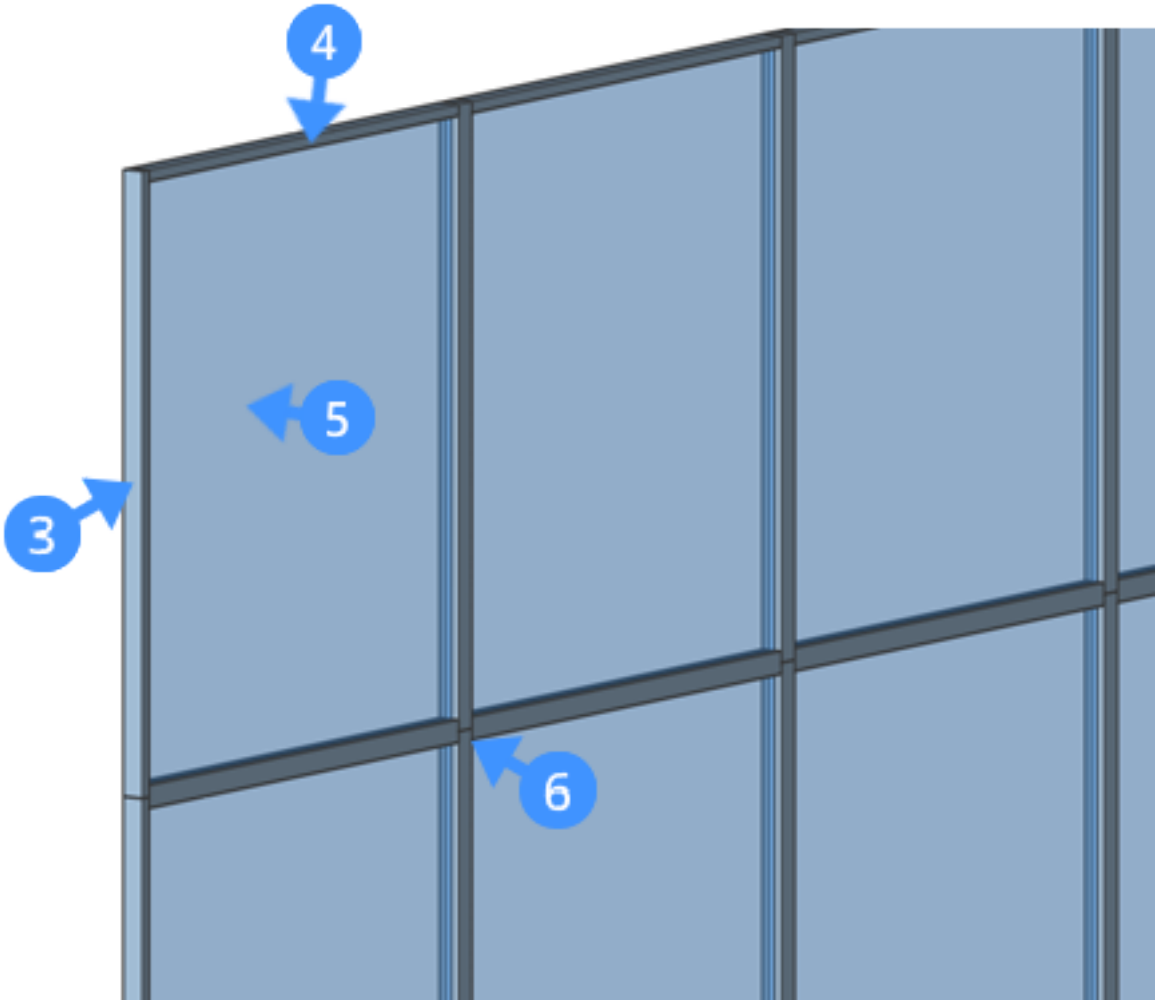

Procedure: Creating a curtain wall

1. Launch the **BimCurtainWall** command in the command line. **You are prompted:** Select a face:

2. Select a face in the drawing area to create a curtain wall. The curtain wall grid is automatically generated on this face. **You are prompted:** Create grid or [Lenght U panels/Length V panels/Number U panels/Number V panels]:

3. Change the length of the U or V panels and number of U or V panels using the prompt menu and command line. (2.262) **Or** if **Dynamic dimension (DYN)** is on, the length of the panels can be changed using the DYN fields (7). (2.263 on the following page)

4. Hit the **TAB** key to switch between dynamic dimension boxes. **Or** Press **Enter** to accept the current value. **Note:** The maximum deviation from planarity is displayed in the command line. **Optional:** If the value of the max deviation from planarity is different to "0", the prompt menu (8) will appear and the command line prompts a message (9). (2.264 on the next page) (2.265 on the following page) The prompt menu and command line allows you to planarize the grid cells. Click "Yes" to planarize the grid cells. By default, the target deviation from planarity is set to "0.00001".

5. Press **Enter** to accept the default value. **You are prompted:** Change parameters or accept [Accept/Width/Depth/Glass thickness/Connections type] <Accept>: The prompt menu: (2.266 on page 1817) **Optional** To change the frame width, select the 'Width' option in the prompt menu or type "W" in the command line. Default frame width = 60.000000 **Optional** To change the frame depth, select the 'Depth' option in the prompt menu or type "D" in the command line. Default frame depth = 60.000000 **Optional** To change the glass thickness, select the 'Glass thickness' option in the prompt menu or type "G" in the command line. Default glass thickness = 20.000000 **Optional** To choose a connection type between, select the 'Connections type' option in the prompt menu or type "C" in the command line. For smooth connections, select the 'Smooth connection' option or type "S" in the command line. For nodes connection, select the 'Nodes connection' option or type "N" in the command line. The default connection is straight. (2.267 on page 1817) (2.268 on page 1818)

Figure 2.262

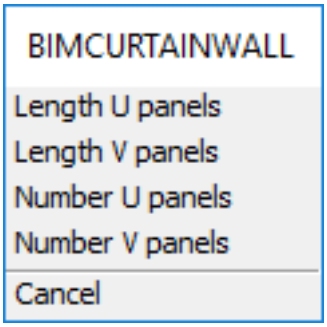

Figure 2.263

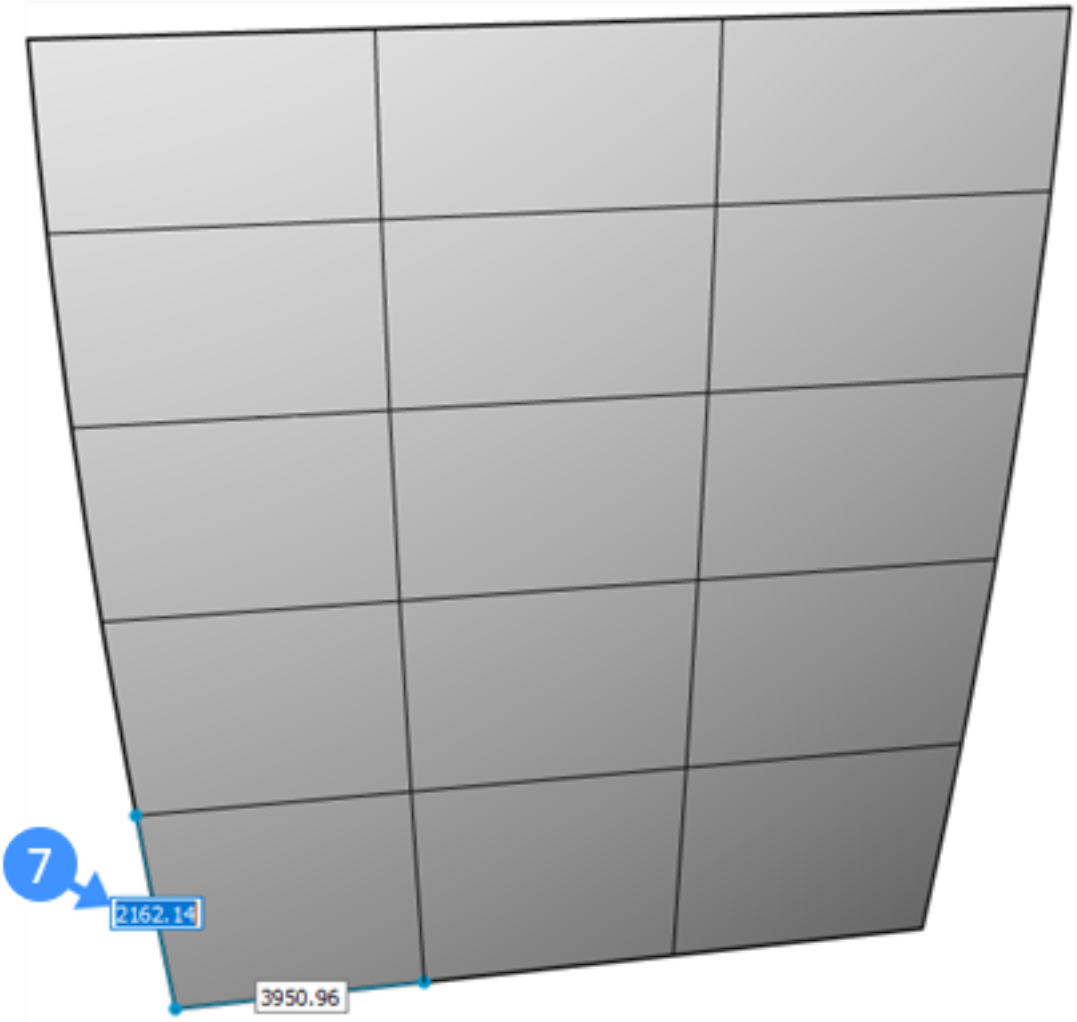

Figure 2.264

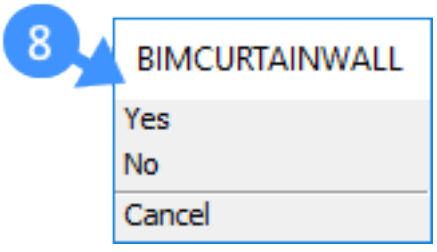

Figure 2.265

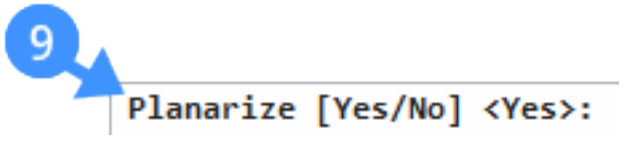

Figure 2.266

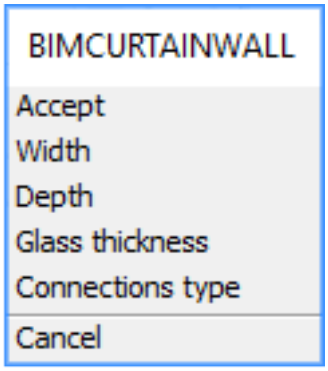

Figure 2.267

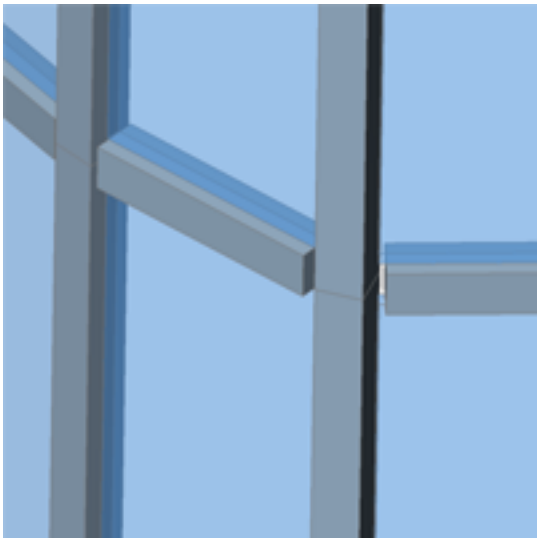

(2.269 on the facing page) **There are three types of connection. From left to right: Straight - Smooth - Nodes.**

6. Blue lines (10) appear on the face to show the side a curtain wall will be created. (2.270 on the next page) **Note:** Step 6 and step 7 are skipped when the face is selected from a solid. In this case the inside normal is chosen by default.
7. Use the widget (11) to flip the curtain wall. (2.271 on page 1820)
8. Press Enter to accept. **Note:** The surface or solid used to create the curtain wall will be deleted by default. If you don't want this, set the DELOBJ value to '0' in Settings.

Figure 2.268

Figure 2.269

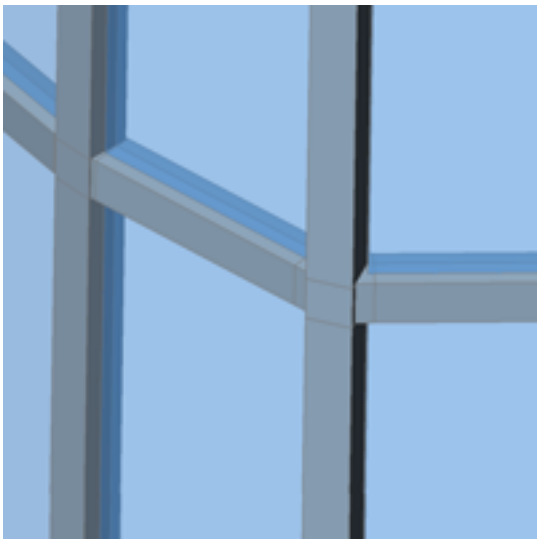

Figure 2.270

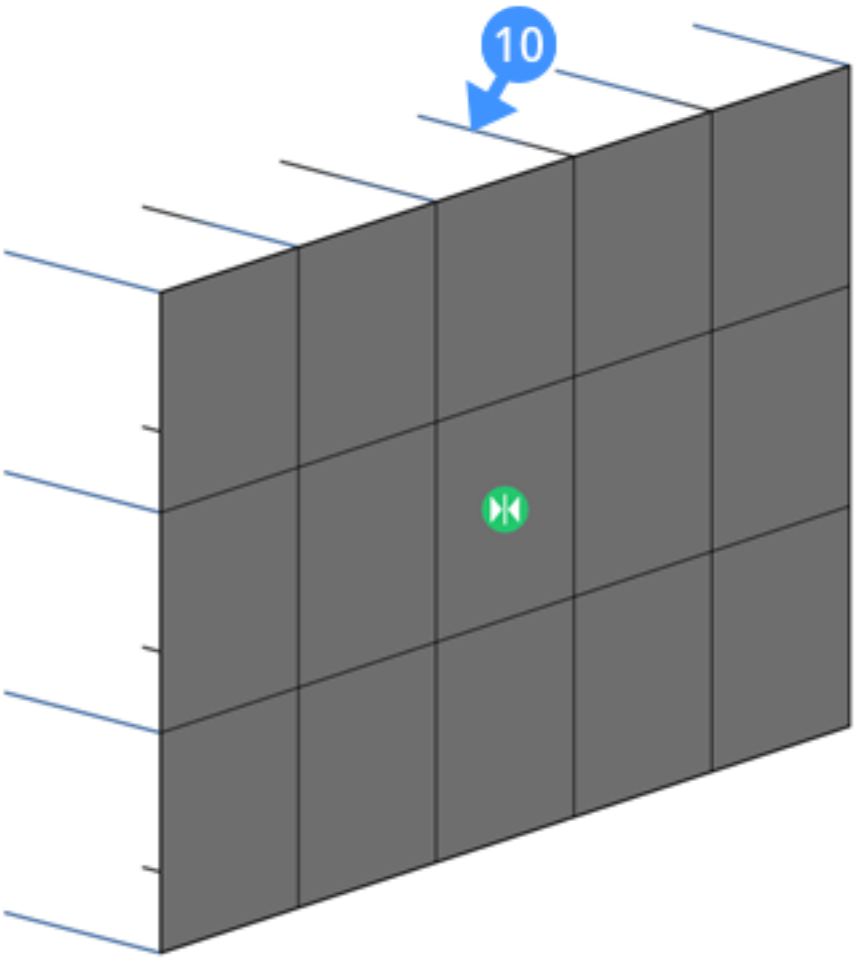

Figure 2.271

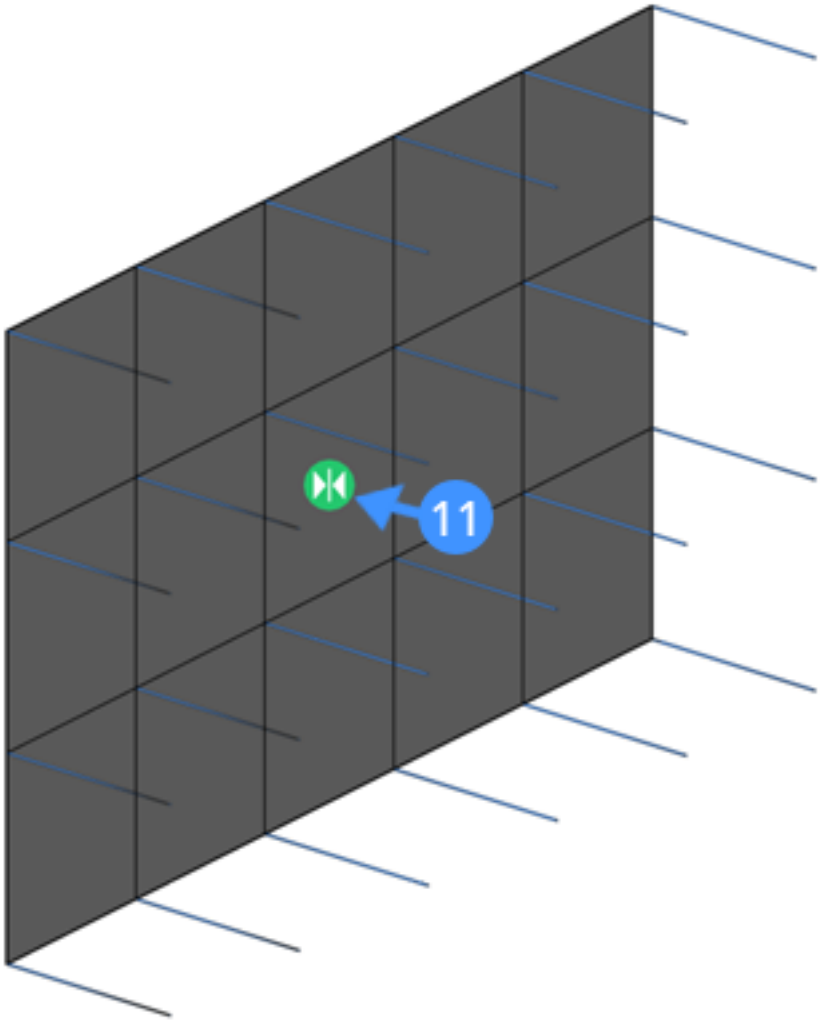

Procedure: Creating a curtain wall from a free form surface

1. Start with 4 splines. (2.272 on the next page)
2. Launch the **Loft (6.20.37)** command in the command line. **You are prompted:** Select cross-sections in lofting order [MOde]: Select the 4 splines in lofting order. (2.273 on the following page)
3. Press **Enter** twice to end the command. (2.274 on page 1823)
4. Launch the **BimCurtainWall** command in the command line. **You are prompted:** Select a face Select the lofted surface. (2.275 on page 1823)
5. A curtain wall grid is automatically generated from this surface. **You are prompted:** Create grid or [Lenght U panels/ /Length V panels/Number U panels/Number V panels].
   Change the number of the U and V panels in the prompt menu or command line. In this example: U = 20 and V = 8.
6. **You are prompted:** Planarize [Yes/No] <Yes> Click "Yes" to planarize the grid cells.
7. **You are prompted:** Enter target deviation <0.00001>: By default, the target deviation from planarity is set to "0.00001". Press **Enter** to accept it.
8. **You are prompted:** Change parameters or accept [Accept/Width/Depth/Glass thickness/Connections type] <Accept>: Change the parameters to:
   - Width: 150
   - Depth: 300
   - Glass thickness: 20
   - Connection type: Smooth
9. Press **Enter** to accept. A curtain wall is created. (2.276 on page 1824)

2.5.10 DmExtrude

Command: DmExtrude (6.13.25) **Overview:** In this lesson, you learn how to use the Extrude tool to create Solids and Surfaces. **Lesson Objectives** After completing this lesson, you will be able to:

- Create solids and surfaces from existing 2D entities or boundary.
- Understand the Extrude tool options: Auto, Create, Subtract, Unite, Both sides.

Tutorial: How to extrude Click here (2.4.6) to watch

About

The Extrude tool allows you to create 3D solid(s) by extruding closed 2D entities, faces of 3D solid(s), regions or closed boundaries. The Extrude tool enables you to cut the solid model partially by removing the volume from the main solid and it can also create new solid(s) by adding volume to the main solid model.  For more information about this command, visit the Command Reference article DmExtrude (6.13.25). The following illustration shows the selected entity, entities or boundary to be extruded. Closed entities (1) (2) are shown. A region object (3) is shown in the figure. (2.279) (2.280 on the next page) (2.281 on the facing page) The following illustration shows a closed boundary in the XY-plane of the current coordinate system (4) and the closed boundary on the face of the solid (5) is highlighted while hovering over it. (2.282 on the next page) (2.283 on the facing page) The closed boundaries are recognized automatically in BricsCAD, unless the **Select detected boundaries** option on the **Selection modes** toolbar is inactive. **Note:** As a closed entity only closed polylines, circles, and ellipses are accepted.

Figure 2.279

Figure 2.280

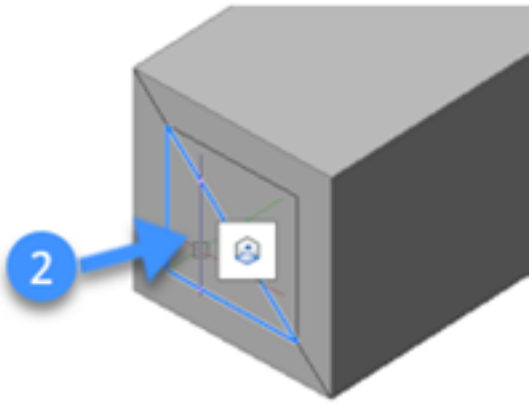

Figure 2.281

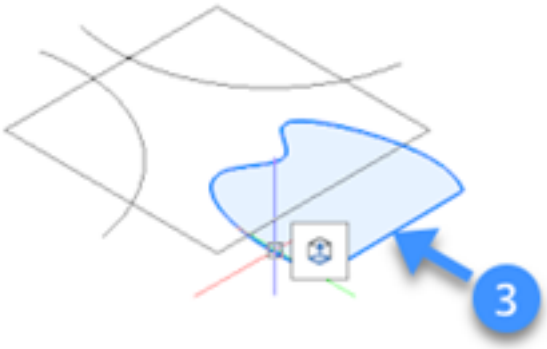

Figure 2.282

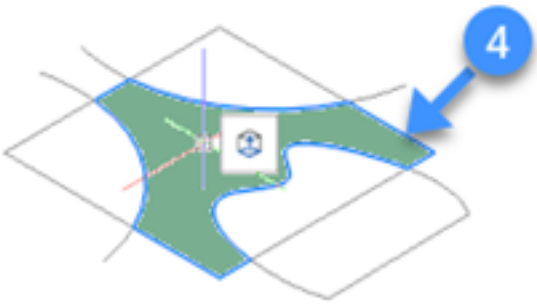

Figure 2.283

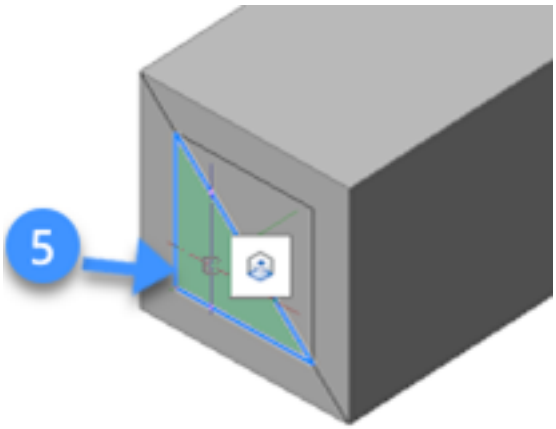

Procedure: Using DmExtrude in Solid Mode

The following are general steps to add and remove volume from the solid(s) using the Extrude tool.

1. Hover the cursor over an entity or sub-entity in the drawing area.
2. Select the Extrude tool in the Model tab from the Quad. **You are prompted:** Specify height of extrusion or set [Auto(subtract or create)/Create/Subtract/Unite/Both sides/Taper angle/Direction/Limit] <Auto>
3. The "DmExtrude Hotkey Assistant" appears at the bottom of the screen with a set of extrusion options. **Note:** The default mode is indicated by a blue frame. (2.284)

- **Auto (6):** The result of the auto option depends on the extrusion direction of the 3D solid and the value of the DMEXTRUDEMODE setting value. **Note:** By default, the value of the DMExtrude mode is set to "8". The following illustration shows the extruded entity from the main solid while the default value is set to "3". When you highlight an entity (10) and extrude it to the **outward** (11), a new volume is added (12) to the main solid model. (2.285 on the facing page) (2.286 on the next page) (2.287 on the facing page) The following illustration shows the subtracted entity from the main solid. When you highlight an entity (13) and extrude it to the **inward** (14), a volume is subtracted (15) from the main solid. (2.288 on page 1830)

Figure 2.284

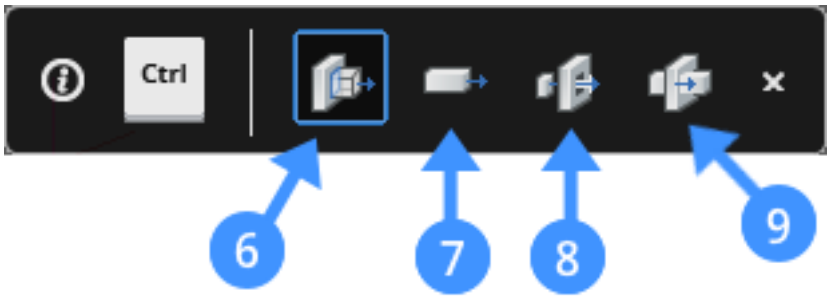

Figure 2.285

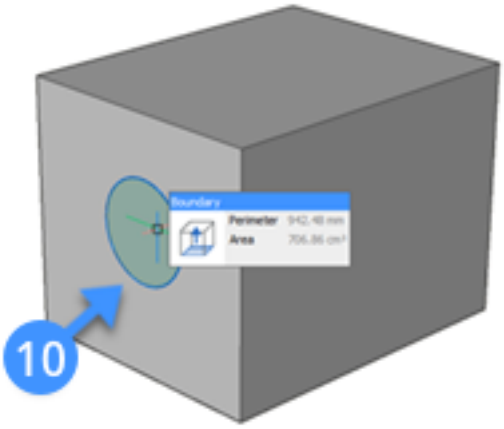

Figure 2.286

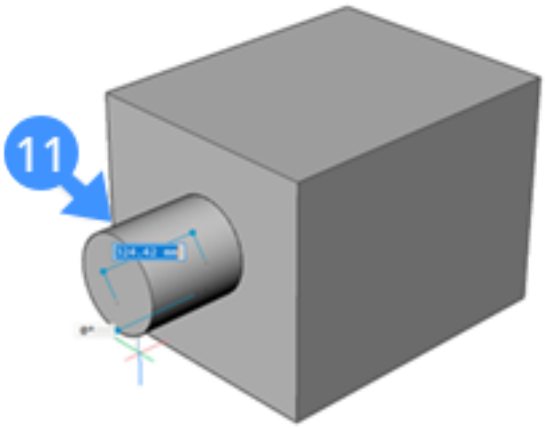

Figure 2.287

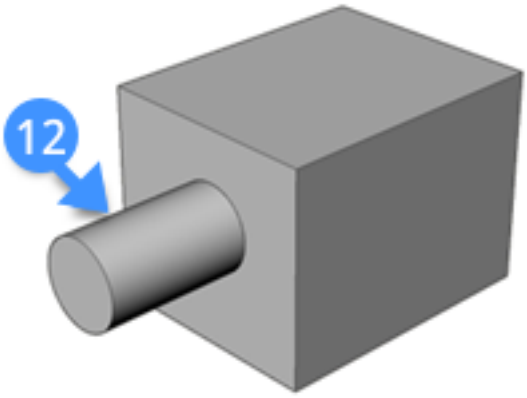

(2.289 on the facing page) (2.290 on the next page)

- **Create (7):** Regardless of the extrusion direction, a new volume is created (16) from the existing solid. (2.291 on the facing page)
- **Subtract (8):** The 3D solid is subtracted from each interfering existing solid. The following illustration shows the subtracted solids (18,19) using the highlighted boundary (17). (2.292 on page 1832) (2.293 on page 1833)
- **Unite (9):** The new volume is unified with each interfering existing solid. The following illustration shows the before and after when using the extrusion tool unite option. The solid surface is highlighted (20) and the distance between the left and right face is shown with the aligned line (21). The new volume is unified (22) with the first solid. (2.294 on page 1833) (2.295 on page 1834)
- **Both sides:** New symmetric volumes are created (23), (24) in both directions from the main solid. (2.296 on page 1834) To create symmetric volumes from the existing solid, type “B” on the command line which corresponds to Both sides option of the Extrusion tool.

Select one of the available options to operate the extrusion function on your solid. Next, move the cursor in the desired direction to specify the extrusion direction. The selected entity or sub-entity is extruded dynamically. Define the height of extrusion by specifying a point in the drawing, entering a value in the dynamic dimension field or choose the limit option. Press enter or right-click to accept the extrusion from your existing solid.

Figure 2.288

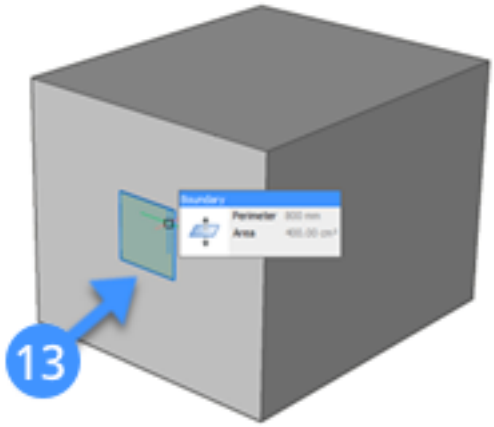

Figure 2.289

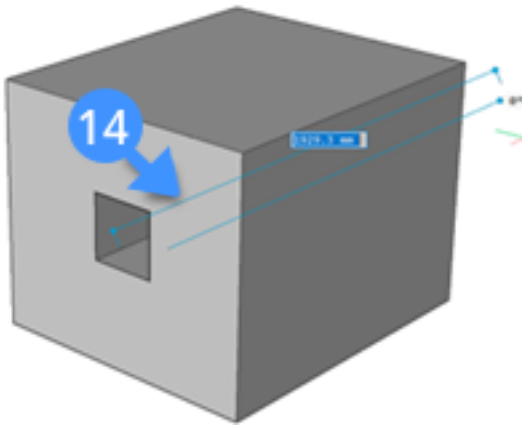

Figure 2.290

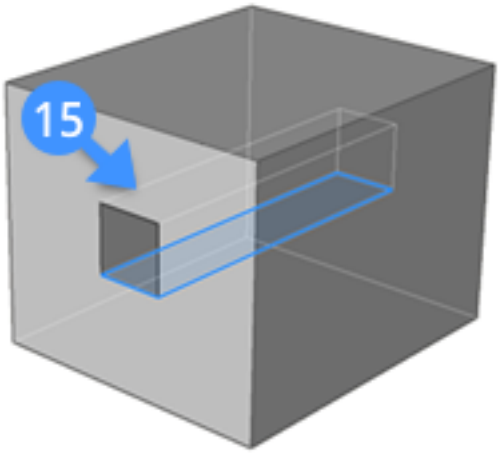

Figure 2.291

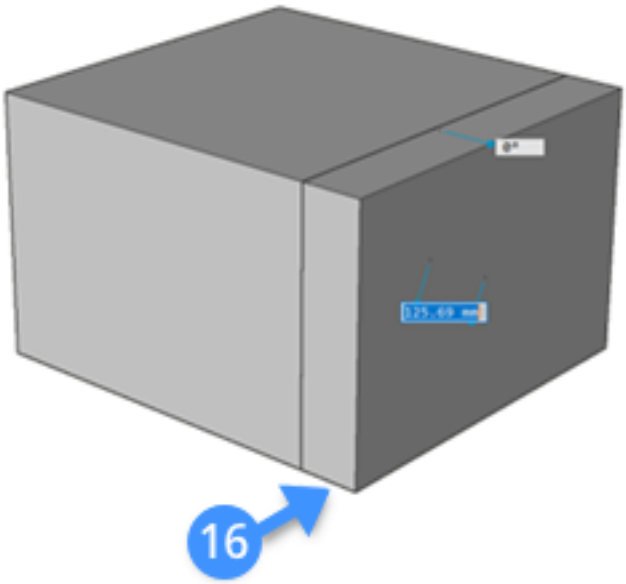

Figure 2.292

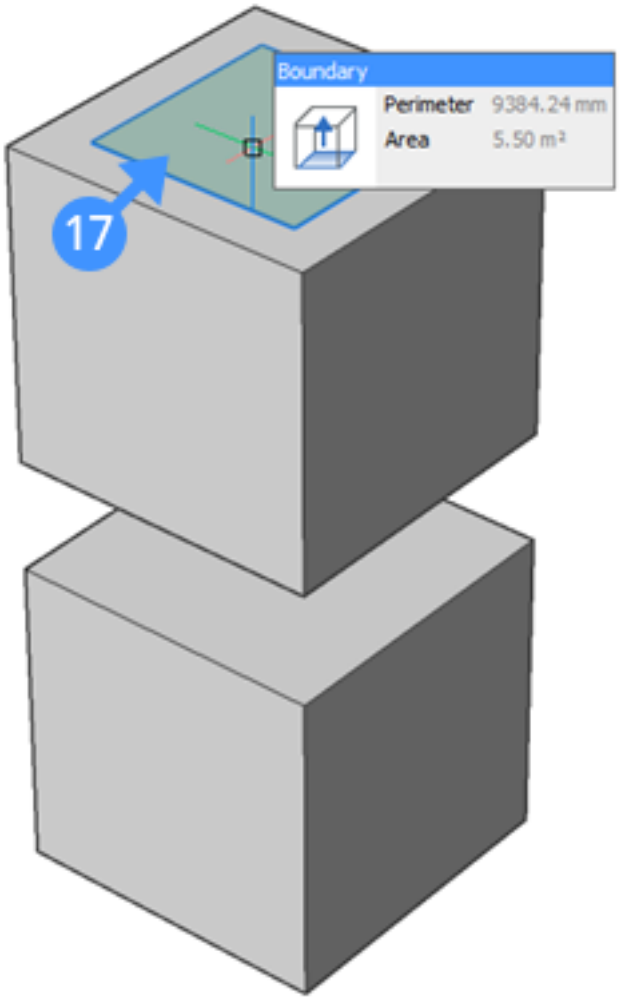

Figure 2.293

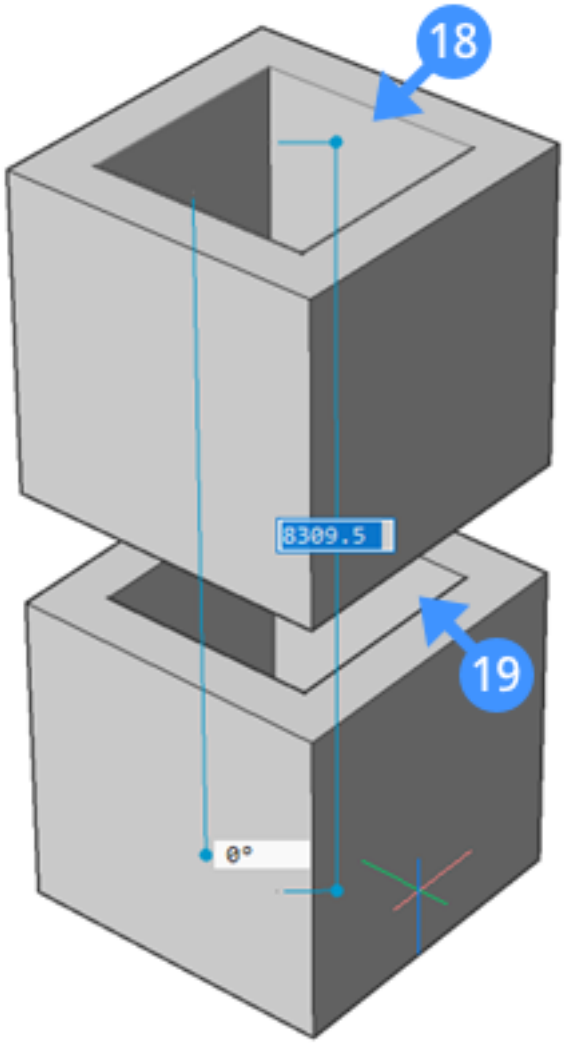

Figure 2.294

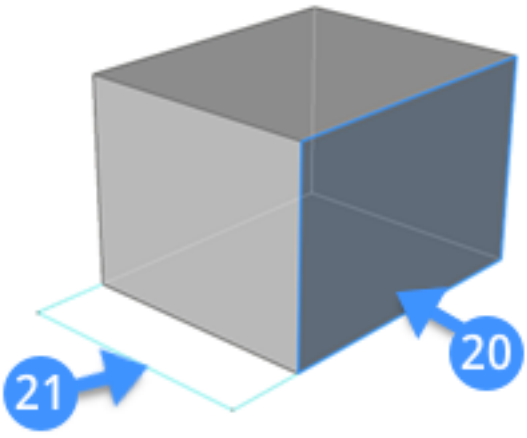

Figure 2.295

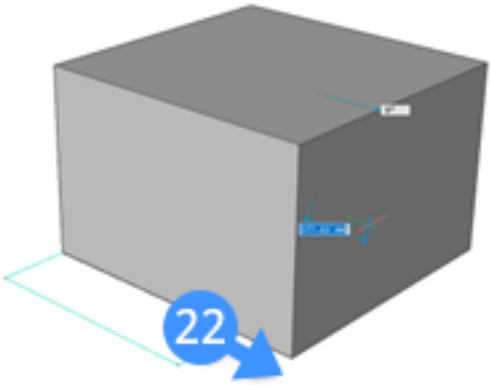

Figure 2.296

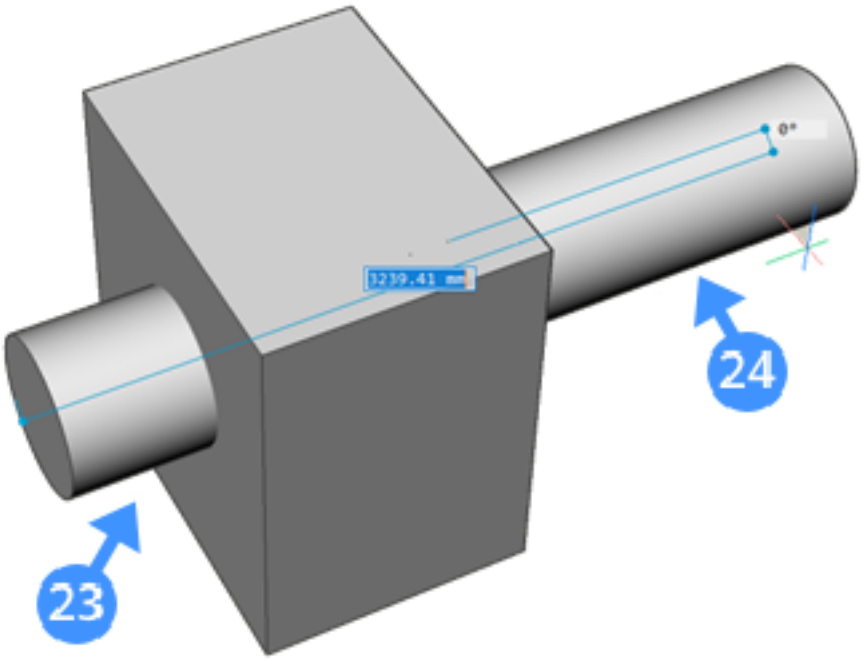


DmExtrude in Surface Mode

The extrude tool allows you to create 3D surface(s) by extruding 2D entities such as lines or polylines. For more information about this command, visit the Command Reference article DmExtrude (6.13.25).

Procedure: Using the Extrude tool in Surface Mode

The following are general steps to create 3D surface(s) using the Extrude tool in the Surface mode.

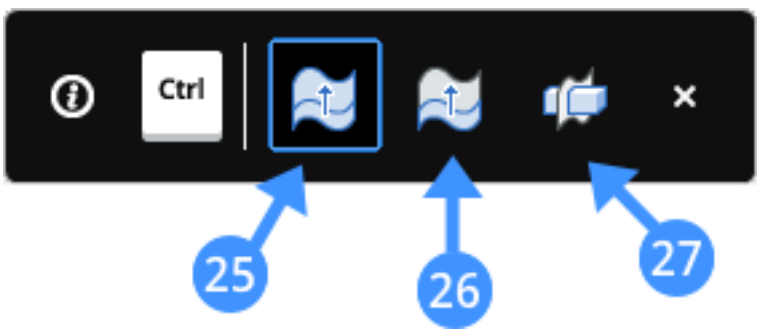
1. Move the cursor over an entity or sub-entity in the drawing area.
2. Select the Surface Extrude tool in the Model tab from the Quad. **You are prompted:** Specify height of extrusion or set [Auto(subtract or create)/Create/Subtract/Unite/Both sides/Taper angle/Direction/Limit] <Auto>
3. The "DM Extrude Surface Hotkey Assistant" appears at the bottom of the screen with a set of surface extrusion options. (2.297) **NOTE:** The default mode is indicated by a blue frame.

Auto (25)	Select either a surface or the face of a solid element. When the surface's edge is used as a contour for extrusion, the created surface is stitched with **the base** surface. When the surface's face is used for extrusion, the surface results in not stitched with the base surface.
Create (26)	Create new surfaces
Slice (27)	Cut through solids with the extruded surface. This option is much like the Slice command.

- Select one of the options and move the mouse to give the extrusion direction, entering a value in the dynamic dimension field.
- Press enter or right-click to accept the extrusion for the surface.

The following illustrations show the created surface (29) by extruding the selected 2D entity (28) in the drawing. (2.298 on page 1837)

Figure 2.297



(2.299 on the facing page)

Figure 2.298

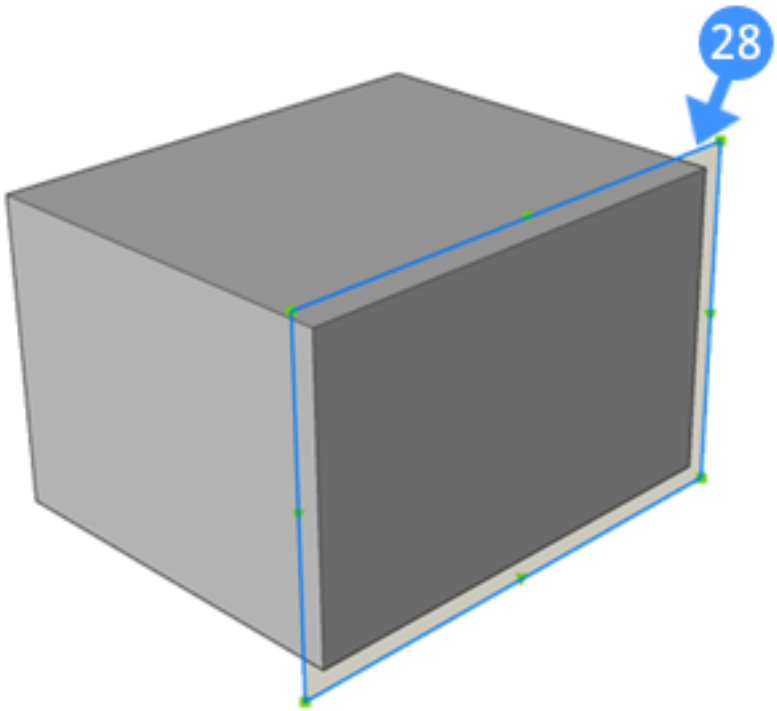


Figure 2.299

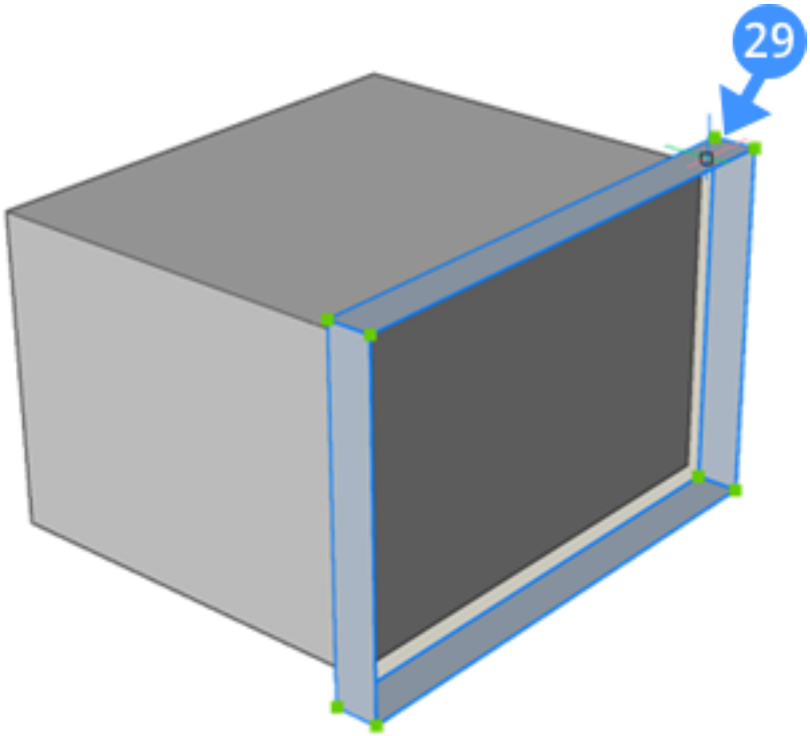


2.5.11 DmPushPull

Command: DmPushPull (6.12.25) **Overview:** In this lesson, you learn how to make use of the Push/pull tool in your drawings. **Lesson Objectives** After completing this lesson, you will be able to:

- Add a volume to a solid.
- Remove a volume from a solid.

Tutorial: How to push or pull solids Click here (2.4.9) to watch

About

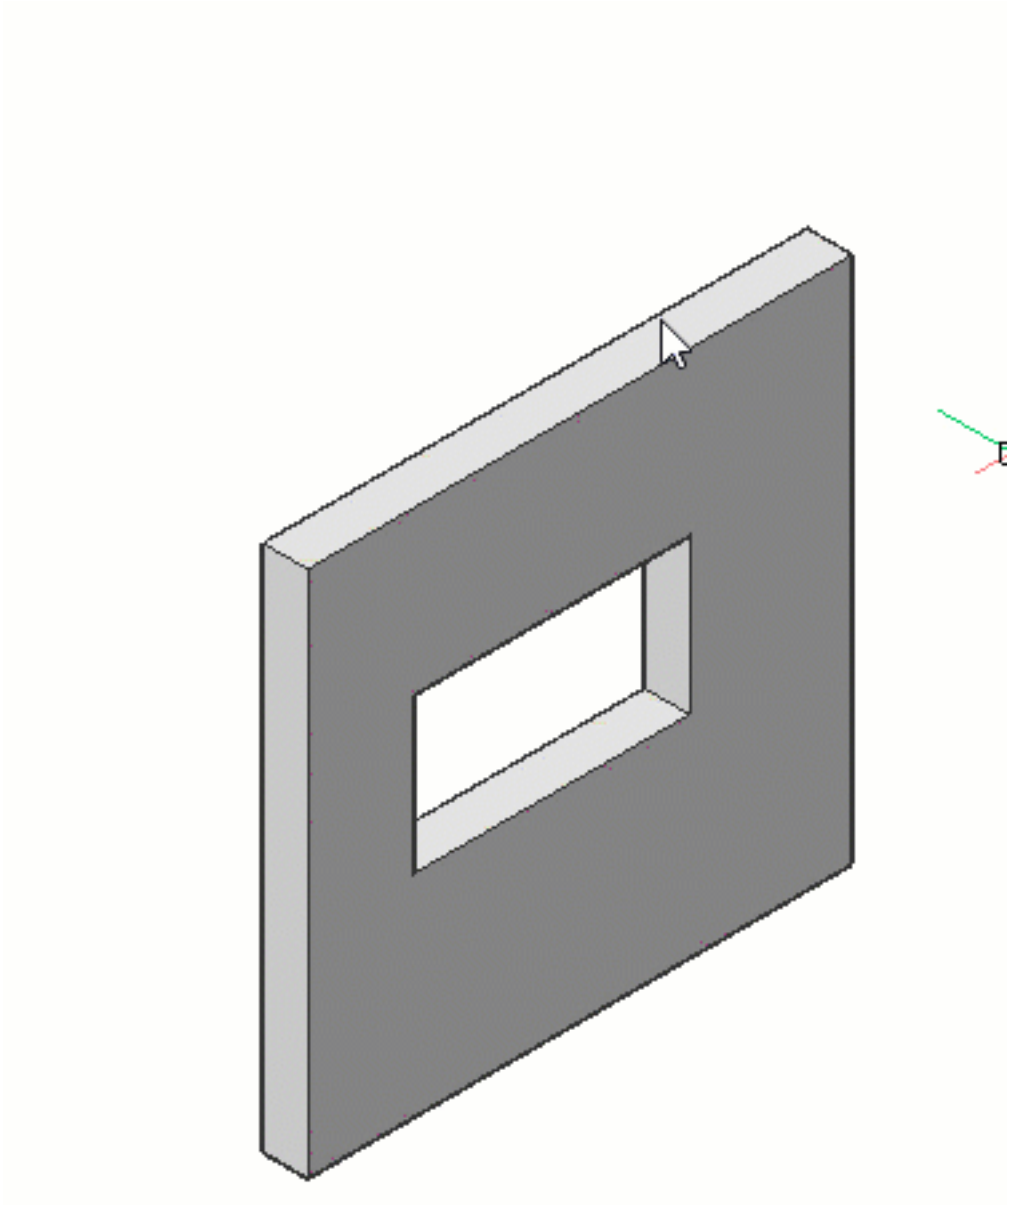
The Push/pull tool allows you to add and remove volume from solids by moving highlighted faces. **Note:** Push/pull tool applies to Planar, cylindrical, spherical, conical and toroidal faces of a solid.  For more information about this command, visit the Command Reference article DmPushPull (6.12.25).

Procedure: Using Push/Pull tool to add or remove volume to the solid

The following are general steps to add or remove volume from a solid(s) using the Push/Pull tool.

1. Highlight any face(s) of the solid(s) in the drawing.
2. Select the **Push/pull** tool in the **Model** tab from the Quad.
3. Move the cursor to pull the highlighted face. The following movie shows the highlighted face behavior. The selected face moves dynamically, adding or removing volume. (2.300 on the next page)
4. Specify a point in the drawing or enter a value in the dynamic dimension field, then right click to accept changes.

Figure 2.300



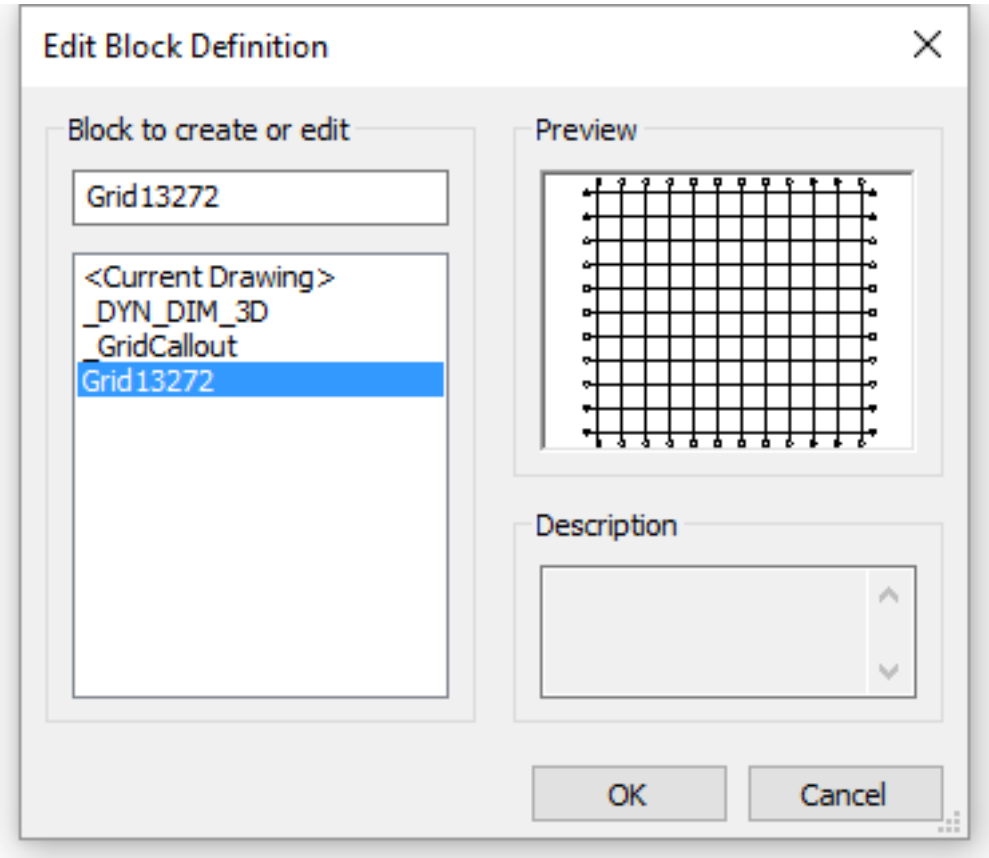
2.5.12 Editing Grids

Command: BimGrid (6.7.21), BEdit (6.6.7), Number (6.22.9), Properties (6.24.54) BIm grids are created as a block. The BEdit (6.6.7) (Block Edit) command allows to edit a BIM grids

Editing a rectangular grid

1. Double click the grid. The **Edit Block Definition** dialog displays. (2.301 on the facing page)
2. Select the grid, then double click or click the OK button. A Block Edit session is started.
3. Edit the grid axes. You can move, rotate, copy, stretch, grip-edit or delete grid axes.
4. Renumber grid axes or edit axis labels if necessary (see the procedures below).
5. Click the **Bclose and Save** icon () on the **Block Edit** toolbar.

Figure 2.301



Renumbering the grid labels

Renumbering grid labels is needed:

- If you want a different numbering style.
- When grid axes are added (copied) or deleted.

Do the following:

1. Double click the grid to start a Block Edit session.
2. Select all vertical axes. Use the window overlap procedure and avoid touching horizontal lines.
3. Start the Number (6.22.9) command and choose the appropriate number style. Make sure to overwrite the existing numbers.
4. Repeat the previous steps for the horizontal axes. Use the window overlap procedure and avoid touching vertical lines.
5. Click the **Bclose and Save** icon ( ) on the **Block Edit** toolbar.

Editing a grid label

1. Double click the grid to start a Block Edit session.
2. Double click an axis. The properties of the axis entity (line or arc) display in the **Properties** panel.
3. Select the **BIM/Axis number** property.
4. Type a value or name.
5. Click the **Bclose and Save** icon ( ) on the **Block Edit** toolbar.

2.5.13 Mass modeling with Quickbuilding

Command: BimQuickBuilding (6.7.40), BimSpatialLocations (6.7.63) **Overview:** In this lesson, you will learn how to use the QuickBuilding tool to easily create initial 3D BIM models.

About

The QuickBuilding tool allows you to generate a BIM building just from one or more massing solids. BricsCAD creates a separate drawing and in this drawing walls, slabs and roofs, as well as spatial elements such as floors and spaces will be automatically created It's useful in early design stages, volume studies and conceptual designs.

The tool will assign BIM properties and spatial information to each part of the new building.  For more information about this command, please visit the Command Reference article BimQuickBuilding (6.7.40).

Procedure: Top-Down workflow

1. Draw one or more solids in your model space. **Note:** The solids don't need to be unioned (6.30.6), the command will do it automatically. (2.302 on the next page)
2. Type the command **BimQuickBuilding** in the command line **Or** select from the Quad, select the solids and press Enter. (2.309 on page 1849)
3. **You are prompted:** Do the selected solids represent [Buildings/Spaces]: Type **B** to continue with the top-down workflow and press Enter.
4. **You are prompted:** Enter desired story height (mm) or [BuildingRequirementFile/Spatialallocations]: Enter the desired story height. Press Enter and the building will be generated. (2.304 on page 1845) **Note:** To generate different floor heights, type (2x4000,*3000,1x5000) which stands for two stories of 4000mm, the rest 3000mm and the top floor has a story height of 5000mm. **Or** import the story height values from a .txt file. Enter **BimQuickbuilding** in the commandline, Type BuildingRequirementFile and press Enter. Then search for the text file in the file folder and click open. (2.305 on page 1845) Now the properties of the text file are applied to the building.

   ```
    Example of a text file with parameters for your building:
   Space:Name='Bricsys Tower',Area=15000
   Space:Name='Level 0 - Reception',Area=6%,'Floor-to-Floor Height'=5000
   Space:Name='Level 1-10',Area=5%,'Floor-to-Floor Height'=4000,Count=10
   Space:Name='Level 11-17',Area=4%,'Floor-to-Floor Height'=3000,Count=7
   Space:Name='Level 18-19',Area=4%,'Floor-to-Floor Height'=4000,Count=2
   Space:Name='Level 20-21',Area=1.5%,'Floor-to-Floor Height'=4000,Count=2
   ```

   The area and area ratios that are specified in the file are requirements. If the result of Quickbuilding does not satisfy the required areas this will be printed in the command line, see also the section about Command Line Output later in this article.
5. If you make a section, you can see the newly formed slabs and walls which each have individual BIM properties. (2.306 on page 1846) Select the roof and navigate to the Properties Panel (1.15.4) - BIM tab. You will see that this entity has Roof type property, as well as some other properties such as spatial locations, quantities or a GUID. (2.307 on page 1846) **Note:** All the elements are categorized, in the Structure Browser (2.7.18) you will see a list of building elements, sorted by floors and building element. The different buildings elements will be placed in different layers according to their building type (External wall/slab, Flat/pitched roof, Internal wall/slab). (2.308 on page 1847)

Procedure: Bottom-up workflow

The bottom-up workflow creates a building out of solids that represent spaces. This approach allows you to first shape the spaces, then use QuickBuilding to create the shell and the new spaces.

1. Type **QuickBuilding** in the commandline.
2. Select the solids and press Enter (2.309 on the facing page)
3. **You are prompted:** Do the selected solids represent [Buildings/Spaces]: Type Spaces to create a building from the selected massing solids. **Note:** BricsCAD takes these defined solids and converts them to BIM Spaces with walls and slabs.
4. Press Enter to create the building.
5. **(Optional)** make a section to see the newly created spaces. (2.310 on page 1850) **Note:** The original solids are kept, Quickbuilding just creates a Building from it with the information that these input solids represent spaces, so it knows that inner walls and slabs should be created based on those input spaces. (2.311 on page 1851)

Figure 2.309

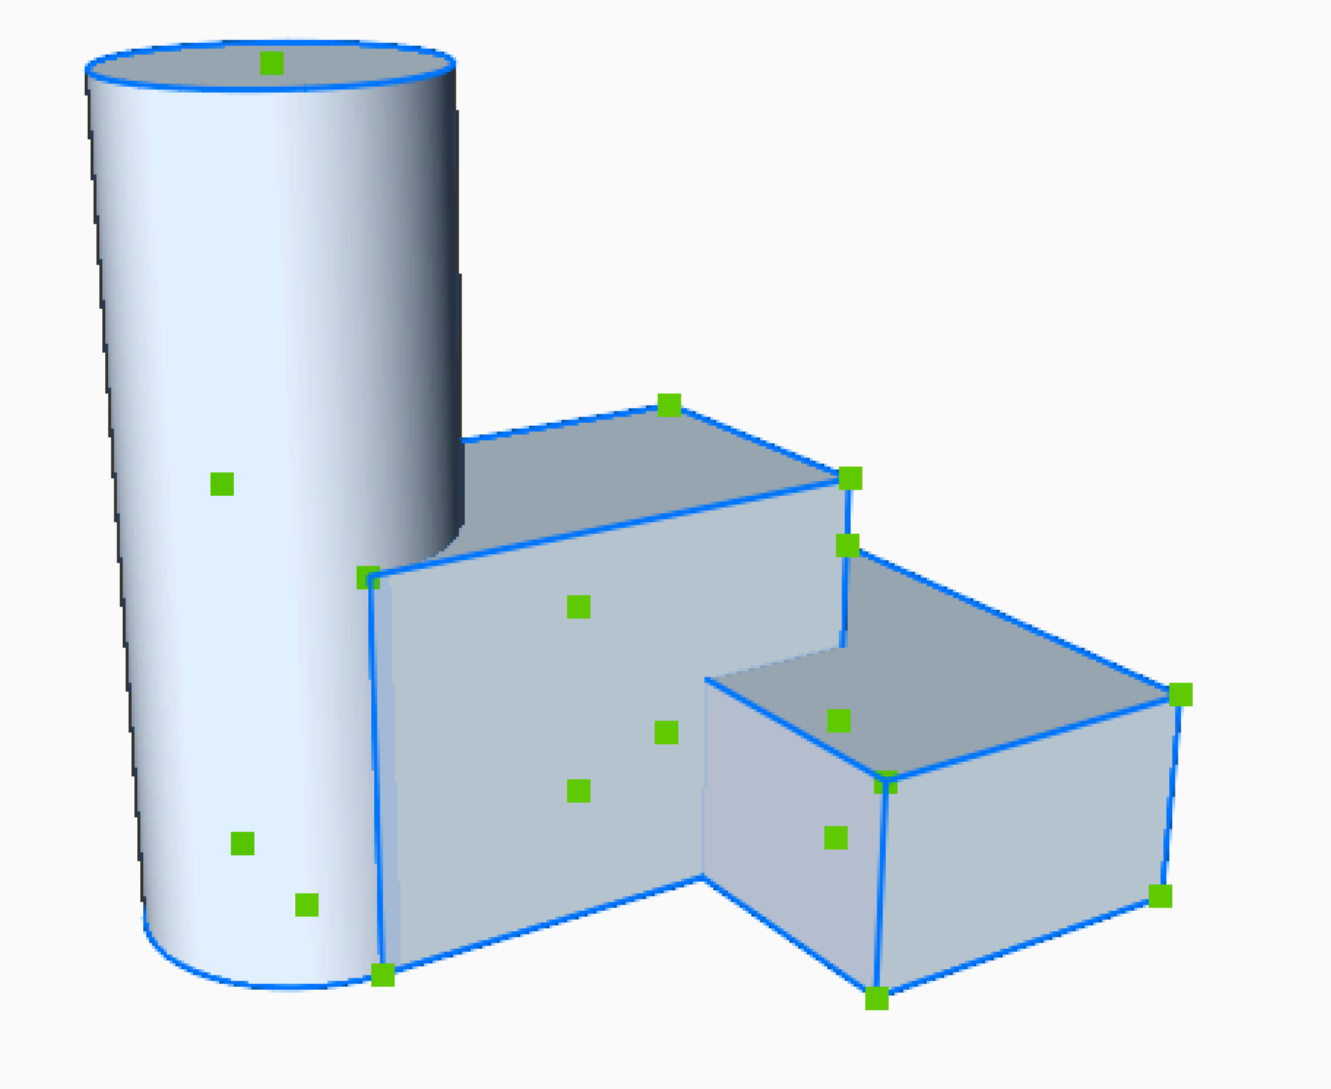

Figure 2.310

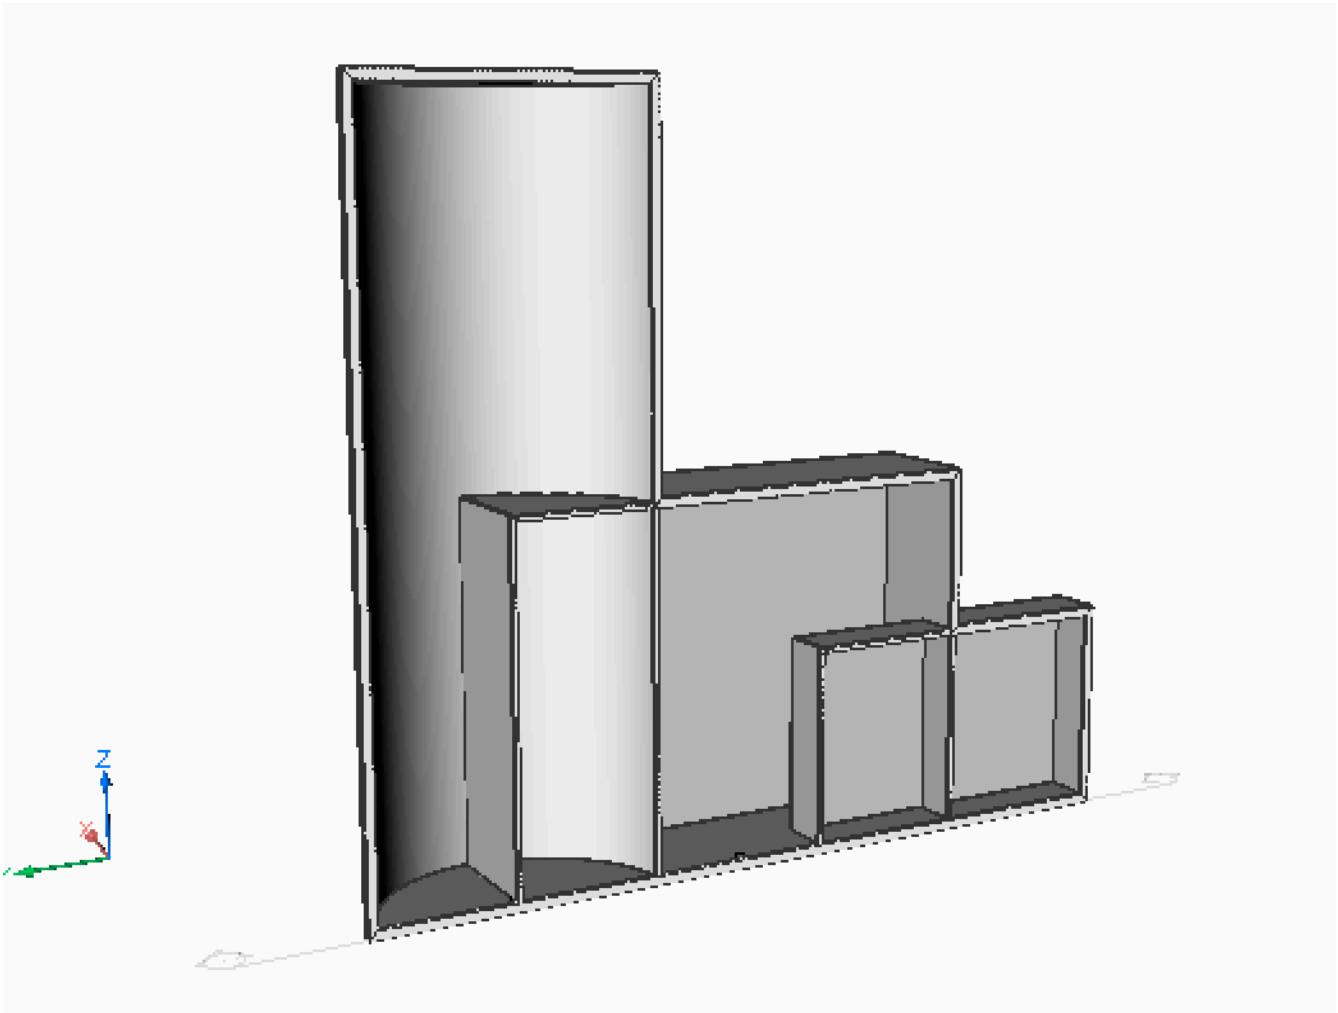

Figure 2.311

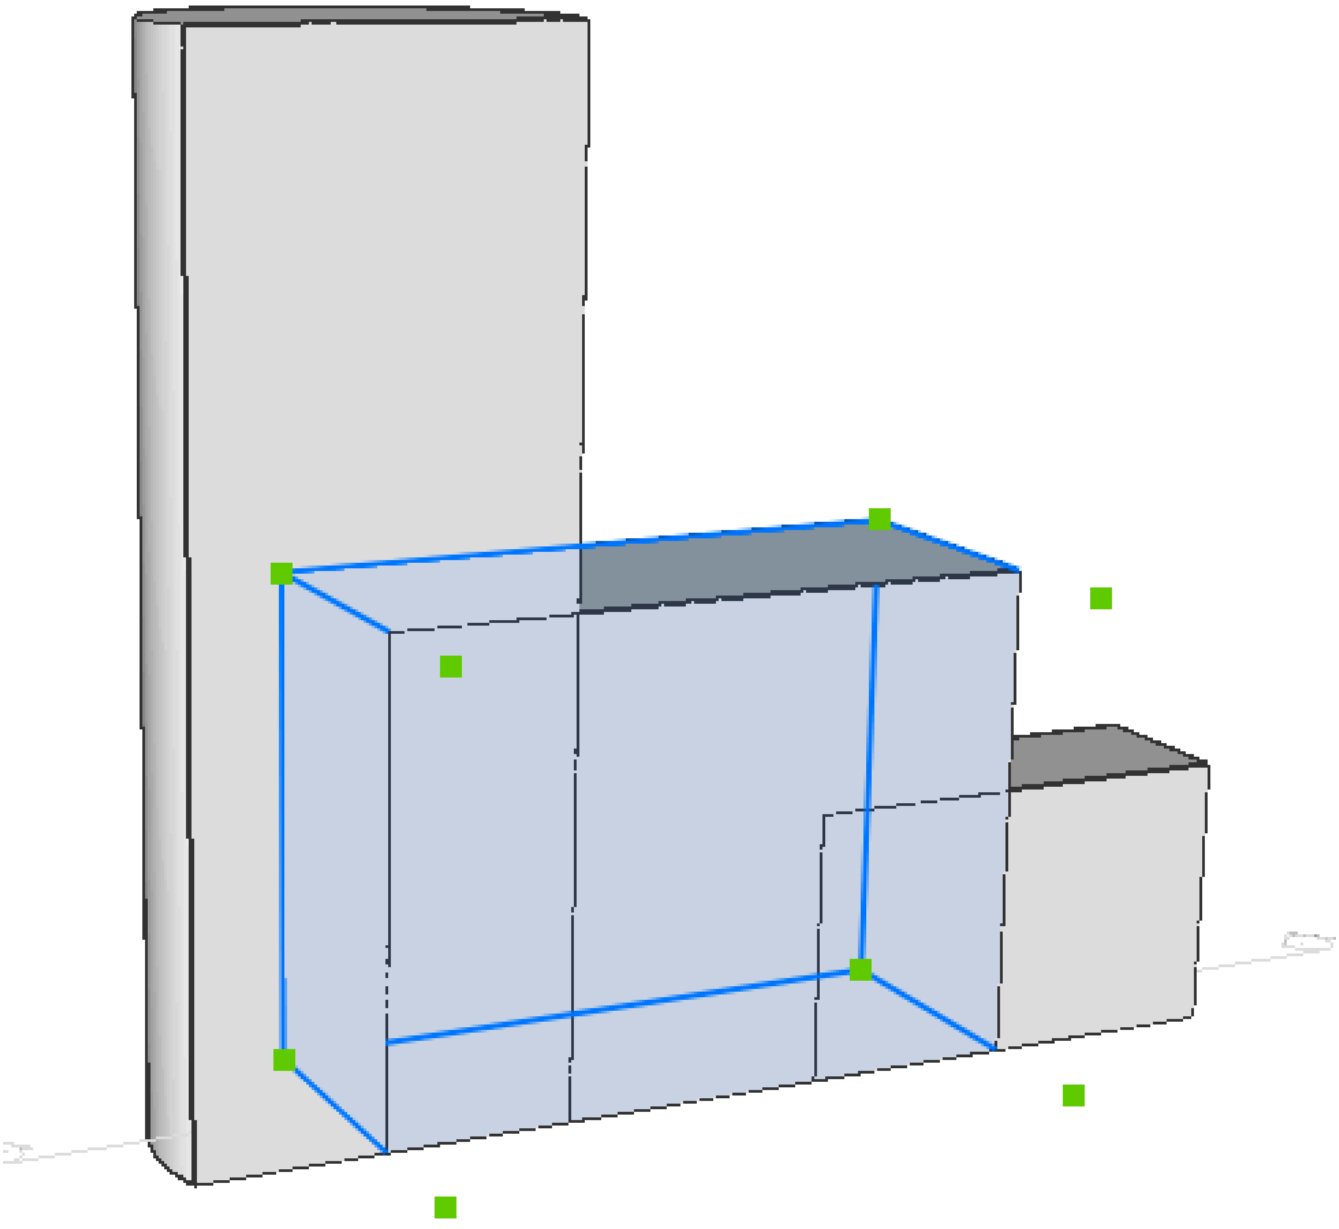

Procedure: SpatialLocations as input

It is also possible to use a Spatial Structure as input for Quickbuilding. So you can import a Spatial Hierarchy and use that data to subdivide the building.

1. Import or Edit the Spatial Locations. For more information about this command, please visit the help center article Spatial Locations (2.7.16). (2.312 on the next page)
2. Make sure that the solid(s) you wish to use for Quickbuilding are:
   - classified as a Building (under Spatial Structure Elements in BimClassify (6.7.12)), and
   - are assigned the correct 'building' in its BIM properties
3. Type QuickBuilding in the commandline
4. Select the building and press Enter.
5. **You are prompted:** Enter desired story height (mm) or [BuildingRequirementFile/Spatiallocations]: Type **Spatiallocations** to use the Spatial Structure as input.

Note: If you add more than one building in the Spatial Locations manager and then assign the building to the solids, QuickBuilding will use the different story heights on the different buildings.

Commandline output

After you run the BimQuickBuilding command, BricsCAD will create an overview with information on some basic building information. For instance, the total floor area of the building or other information for each floor. (2.313)
Note: If you used a Building Requirement File, and some requirements are not passed (e.g. not enough total area or floor area), you can see the problems in the output. (2.314 on the next page)

```

2.5.14 MEP Modeling

Commands: BimApplyProfile (6.7.10), BimLinearSolid (6.7.29), BimFlowConnect (6.7.19), Drag (6.10.38), BimStretch (6.7.48) **Overview:** In this lesson, you will learn how to create HVAC and piping segments, and how to manipulate these segments using different tools. **Lesson objectives** After completing this lesson, you will be able to:

- Insert profiles into your BIM model.
- Apply a profile to an existing line or solid in your model.
- Connect different flow segments to each other.
- Alter the positioning of segments without losing their connection.

Tutorial: How to use MEP modeling tools Click here (2.4.21) to watch

About BimFlowConnect

It's also possible to connect different segments using the **BimFlowConnect** command.  For more information about this command, visit the Command Reference article BimFlowConnect (6.7.19).

Connecting different segments to each other Select the segments you want to connect and launch the **BimFlowConnect** command. When the Hot Key Assistant is switched on (**HKA** on the status bar), the following widget appears on the screen press the CTRL-key to cycle through the different options. (2.315 on the facing page) (2.316 on page 1858) End the command by pressing Enter, the segments are now connected.

Figure 2.315

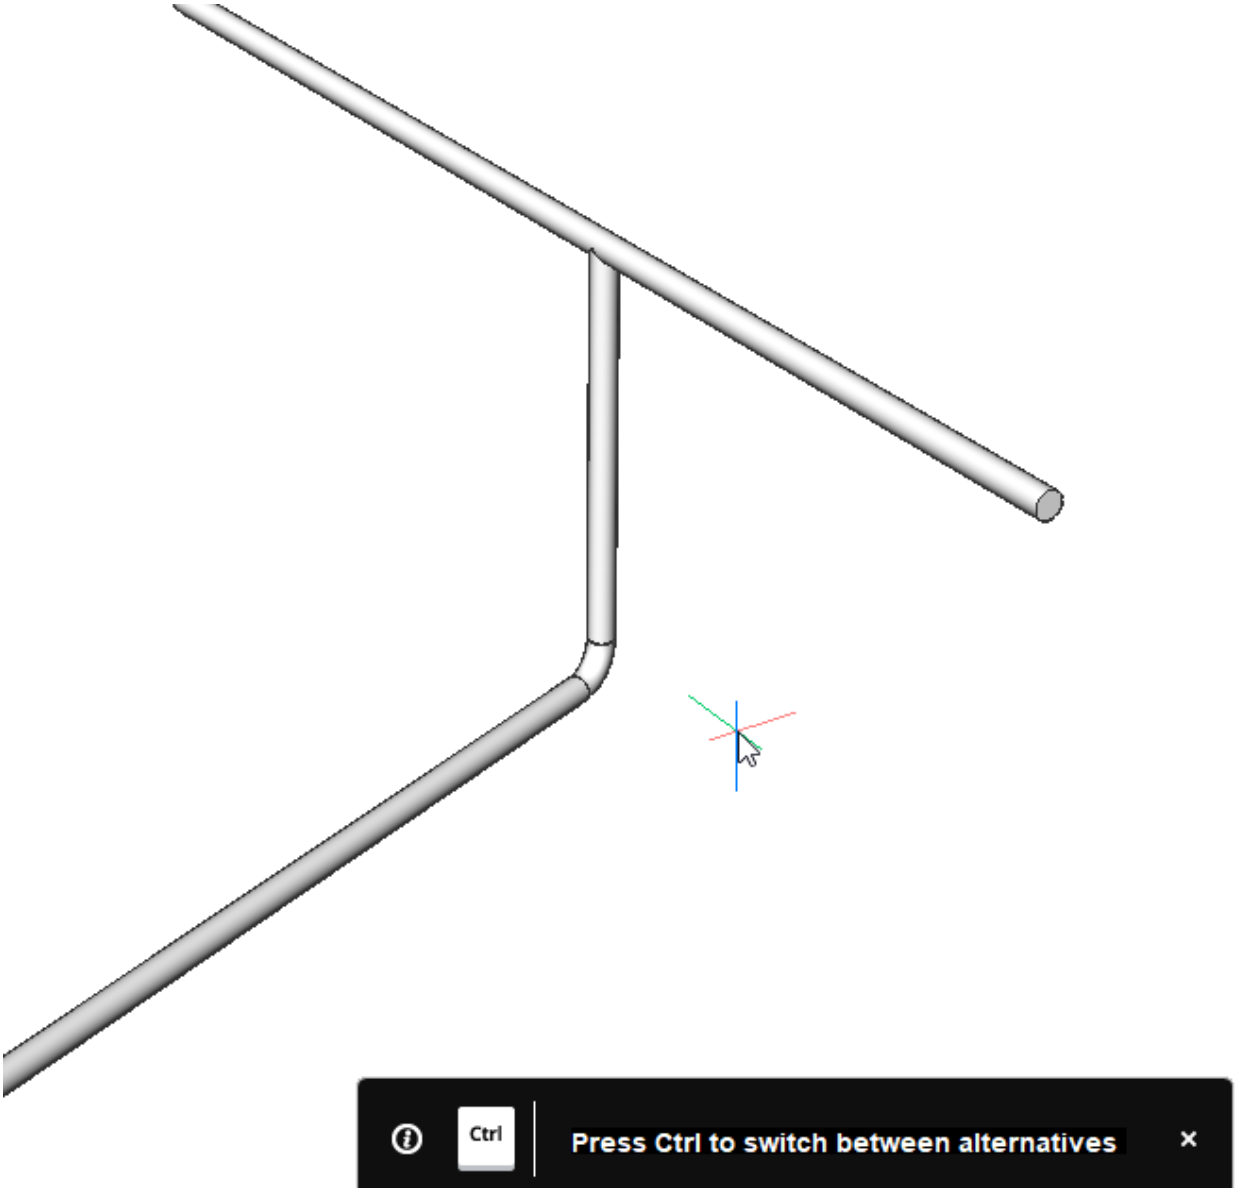

Figure 2.316

Procedure: Altering the position of segments

Before starting with the procedures: enable the selection (2.3.5) of sides and ends: 

1. Click the icon on the **BIM** toolbar.
2. Type **DisplaySidesAndEnds,** then type **1** or **ON.**

Drag The **Drag** command makes it possible to alter a segment of a drawn profile without losing its connection to the other segments.  For more information about this command, visit the Command Reference article Drag (6.10.38).

1. Hover over a segment, select a face perpendicular to the section of the profile. (2.317 on the following page)
2. Launch the **Drag** command.
3. Choose a new position for the segment **or** use the dynamic dimension field to enter a value for the displacement. **Note:** The software automatically regenerates the connection between the segments. (2.318 on the next page)

Figure 2.317

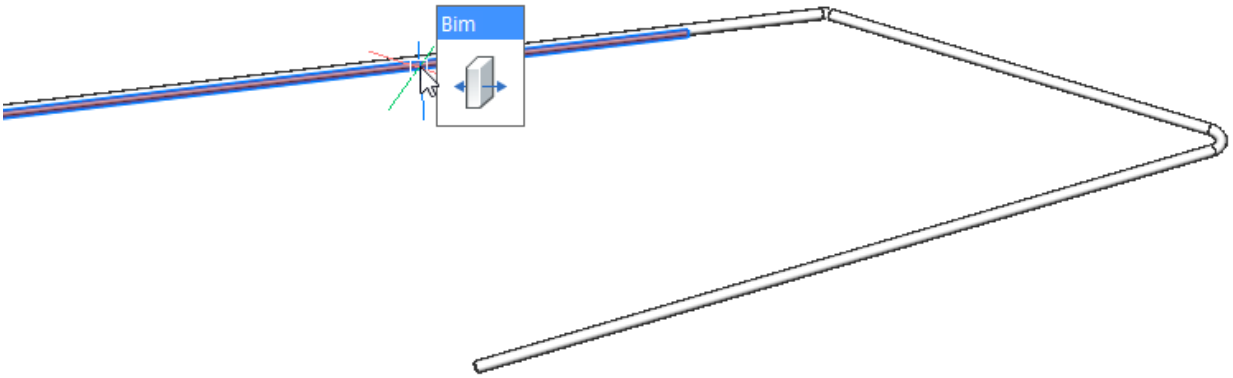

Figure 2.318

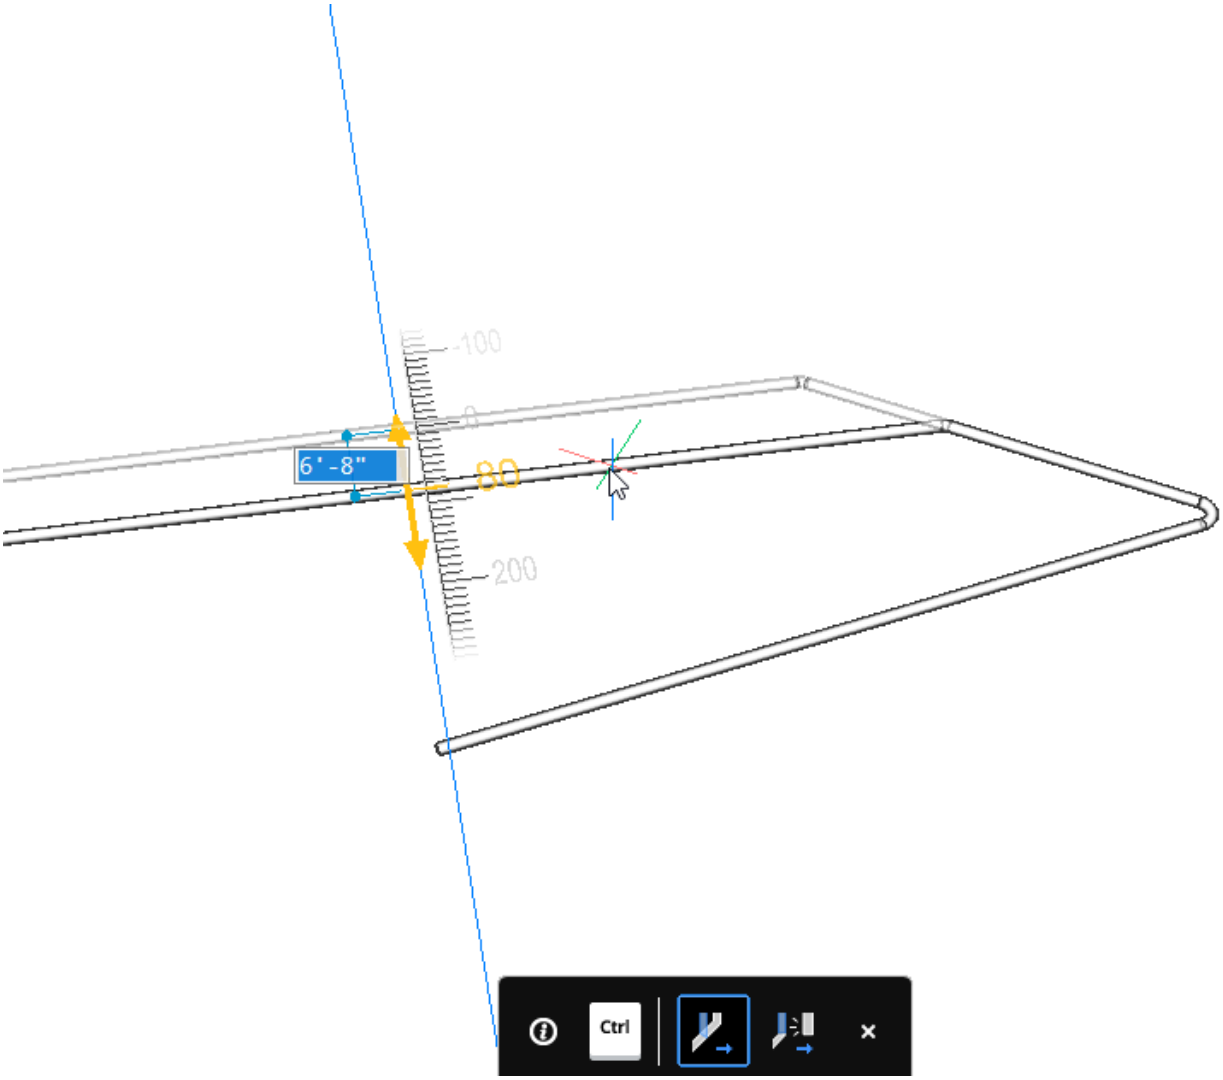

Manipulator

1. Hover over a segment, select a face perpendicular to the section of the profile.
2. Select **Manipulate (1.32.10)**. (2.320 on the following page)
3. Choose a new position for the segment **or** use the dynamic dimension field to enter a value for the rotation. (2.320 on the next page)
4. Click on the new position **or** enter the rotation angle and hit enter. (2.321 on page 1863)

Figure 2.319

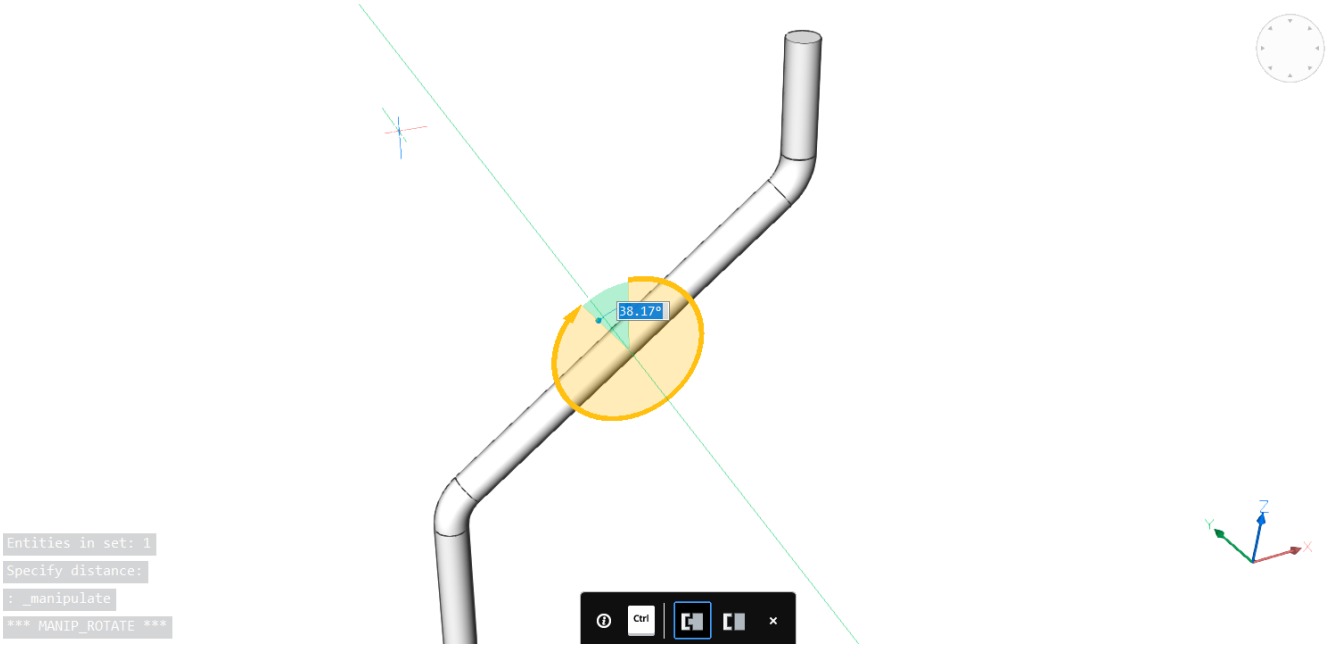

Figure 2.320

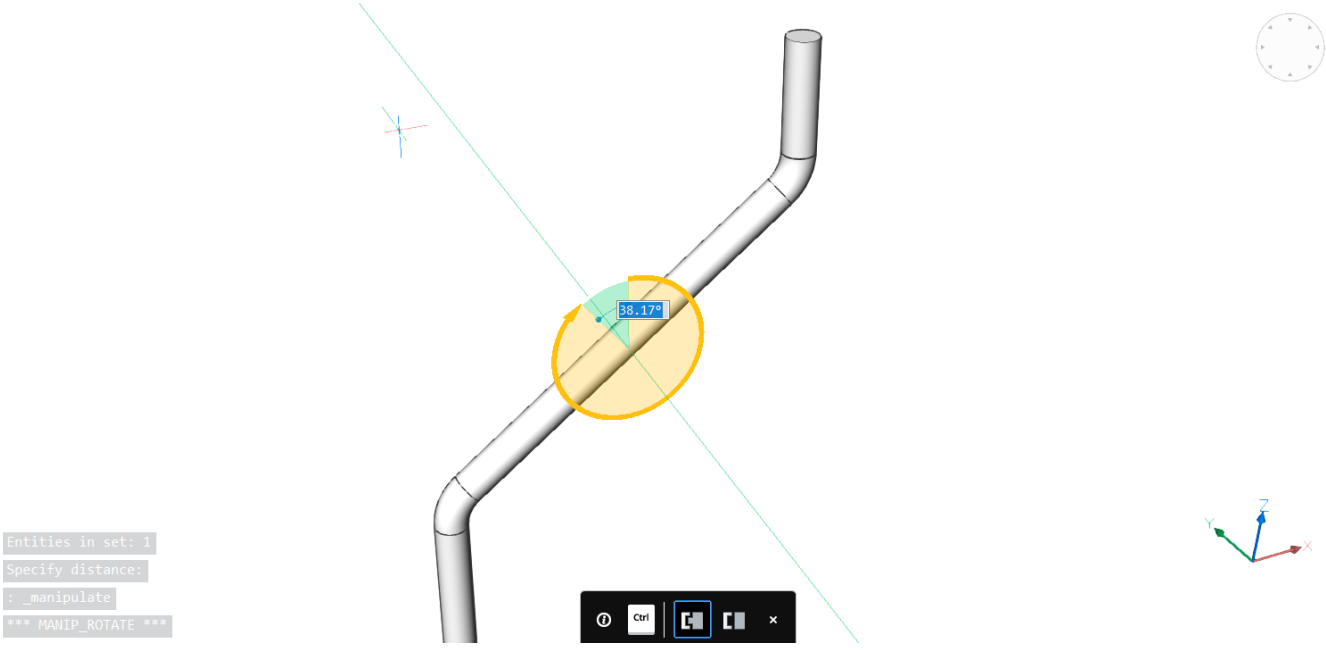

Figure 2.321

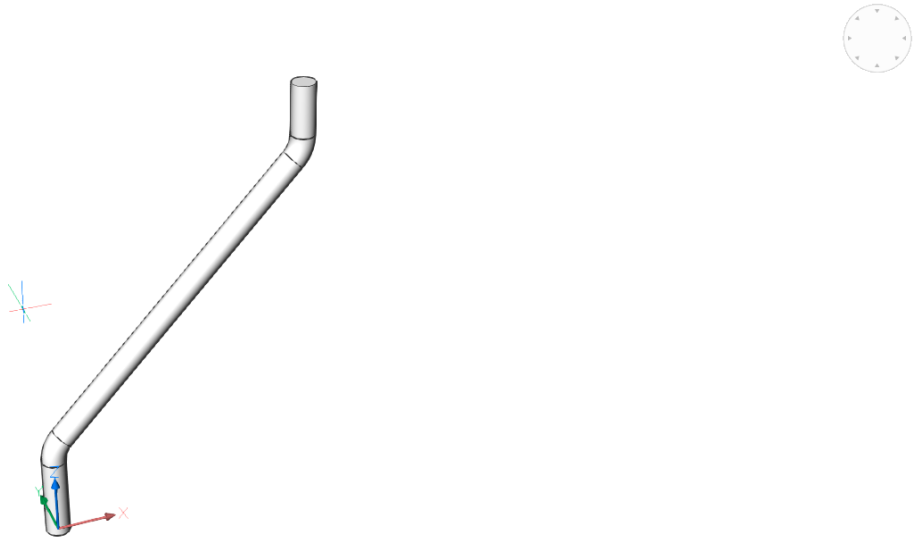

Procedure: Using the MEP Modeling tools to draw and connect profiles

1. Open the drawing that contains the MEP model. You can download this **MEP.zip**-file containing the drawings at the end of this article. (2.322 on the next page)

4. Open the BIM Profiles panel on the right-hand side of your screen (see Dockable Panels (1.15.7)). Filter on HVAC and select the **Rectangular 12"x 8"** profile, drag it to the model space. (2.323 on page 1865)

5. Define the starting point of the profile. Snap to the geometric center of the yellow rectangle. (2.324 on page 1867)

HVAC Rectangular Duct 1200x300
HVAC Rectangular Duct 1200x400
HVAC Rectangular Duct 1200x500
HVAC Rectangular Duct 1200x600

6. Turn **Ortho** on and define the next points of the profiles by using the dynamic dimension field. Quarter turn the profile by entering **Q** in the commandline. Go up **3.5**, go **3.5** to the left and go **21** horizontally. (2.325 on page 1868)
7. Connect the other rectangular ducts on the side to the one we have just created. Select the ducts together with the main duct and launch the **BimFlowConnect** command. Your connection should look like the image below. (2.326 on page 1869)
8. Create a duct from the flow terminal. Launch the **BimLinearSolid** command and select the flow connection point (2.5.16). This connection point contains profile information, so the software automatically creates the predefined circular duct. Give the duct a length of **1**. (2.327 on page 1870)
9. Connect the ducts from the flow terminal to the rectangular main duct. Select the main duct and the duct from the flow terminal and launch the **BimFlowConnect** command. (2.328 on page 1871)
10. Connect all the other flow terminals to the rectangular duct at once. Select the other flow terminals and the rectangular duct and launch the **BimFlowConnect** command. (2.329 on page 1872)
11. BricsCAD uses the information from the flow connection point (2.5.16) to determine the type of duct used to connect with the main duct. **Note:** The flow terminal on the back is connected to the back of the rectangular duct. (2.330 on page 1873)

Figure 2.324

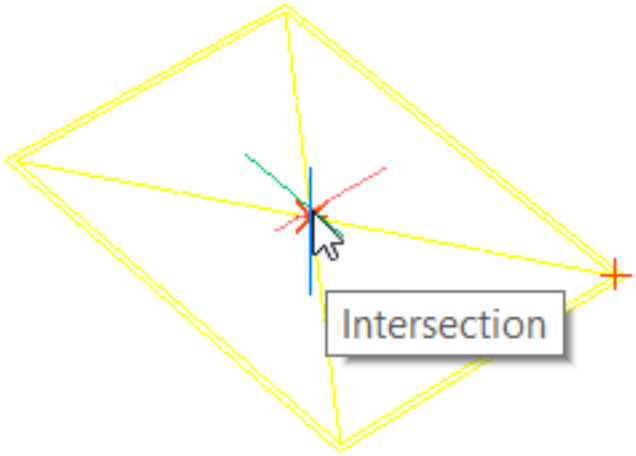

Figure 2.325

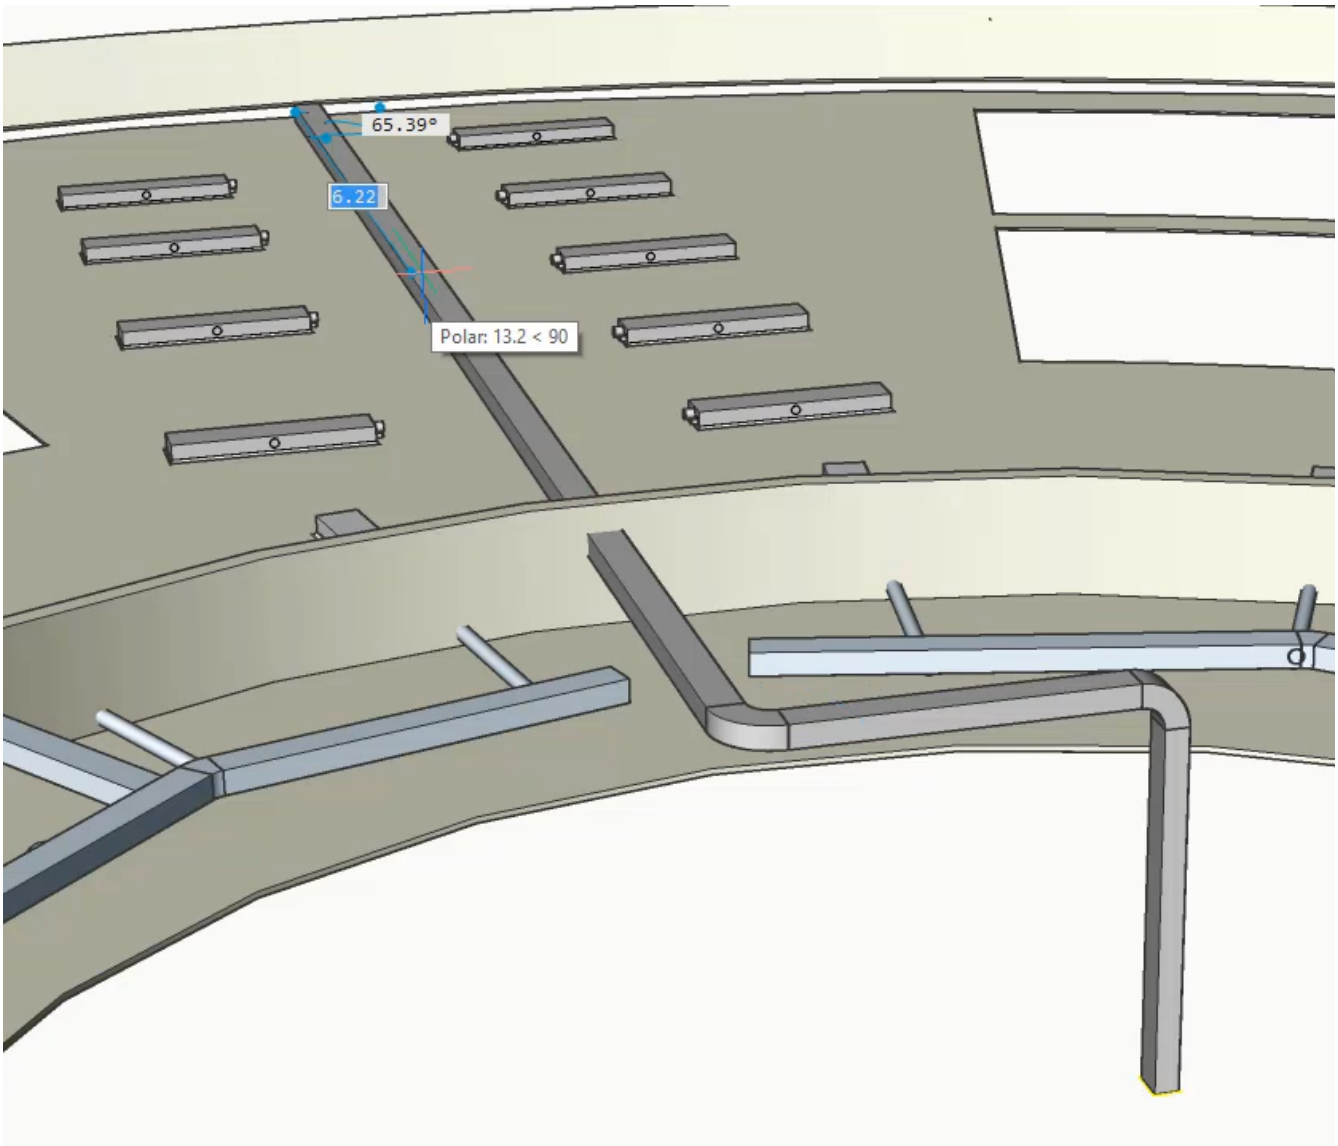

Figure 2.326

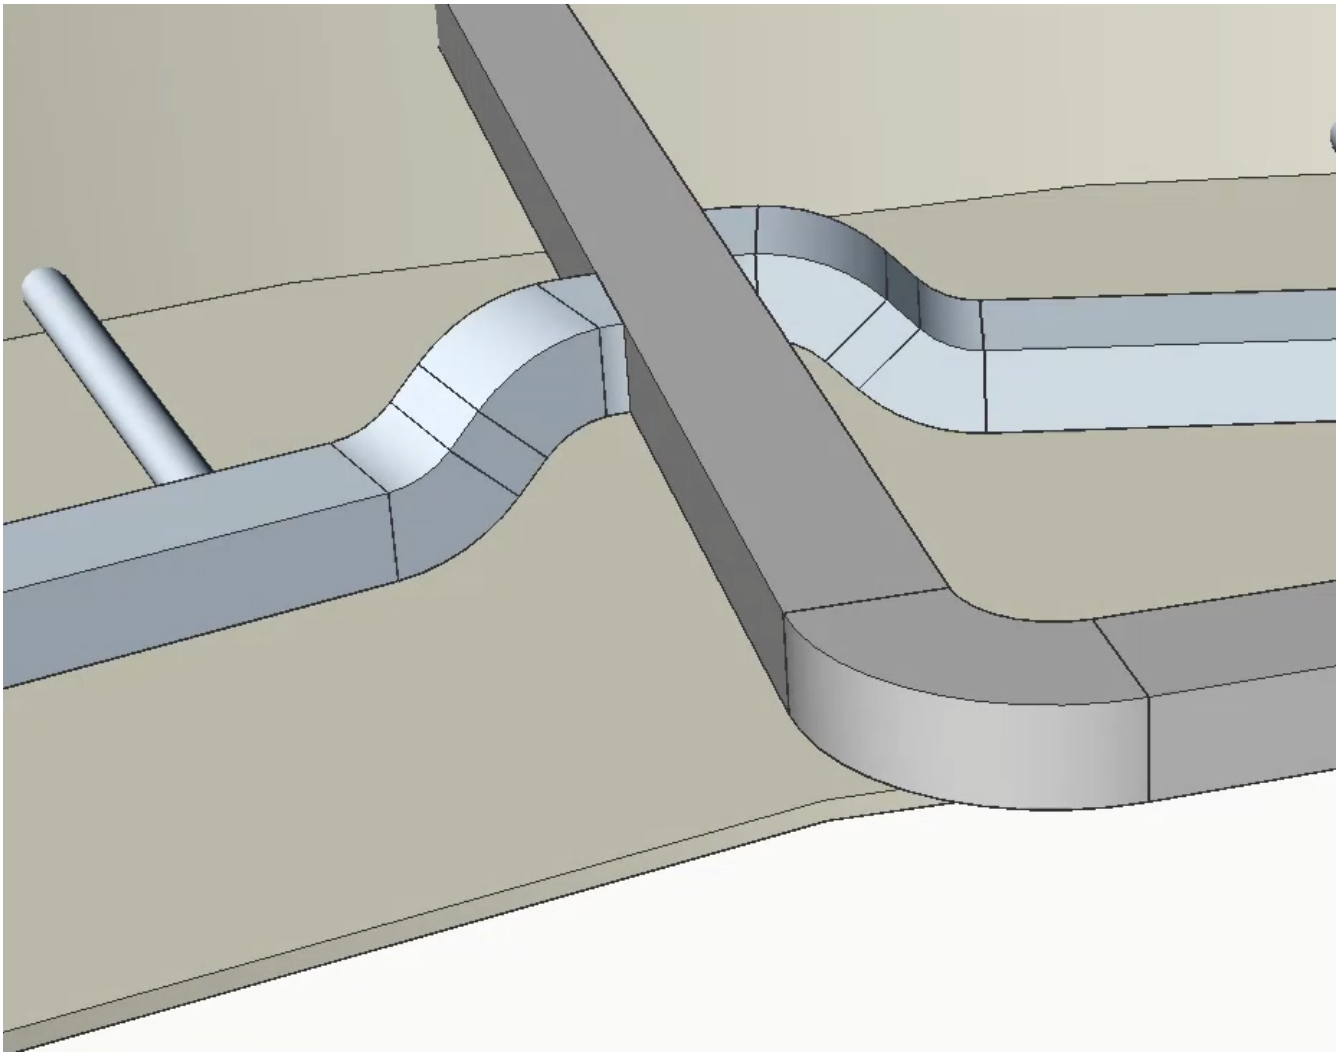

Figure 2.327

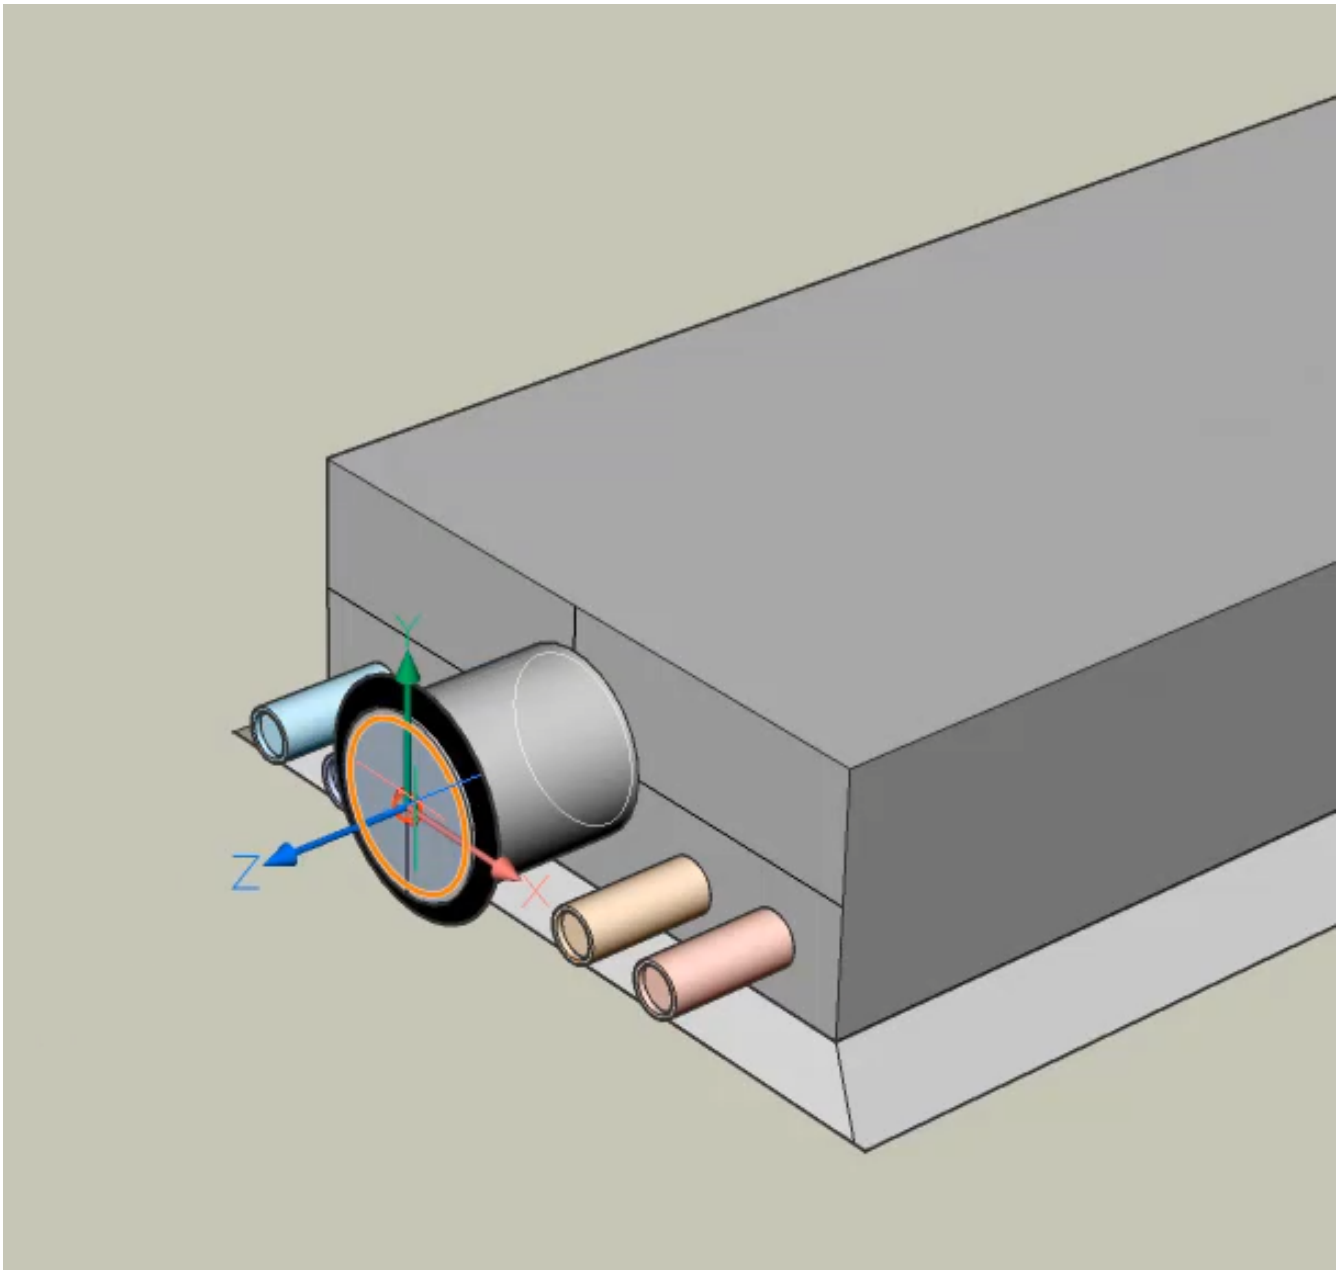

Figure 2.328

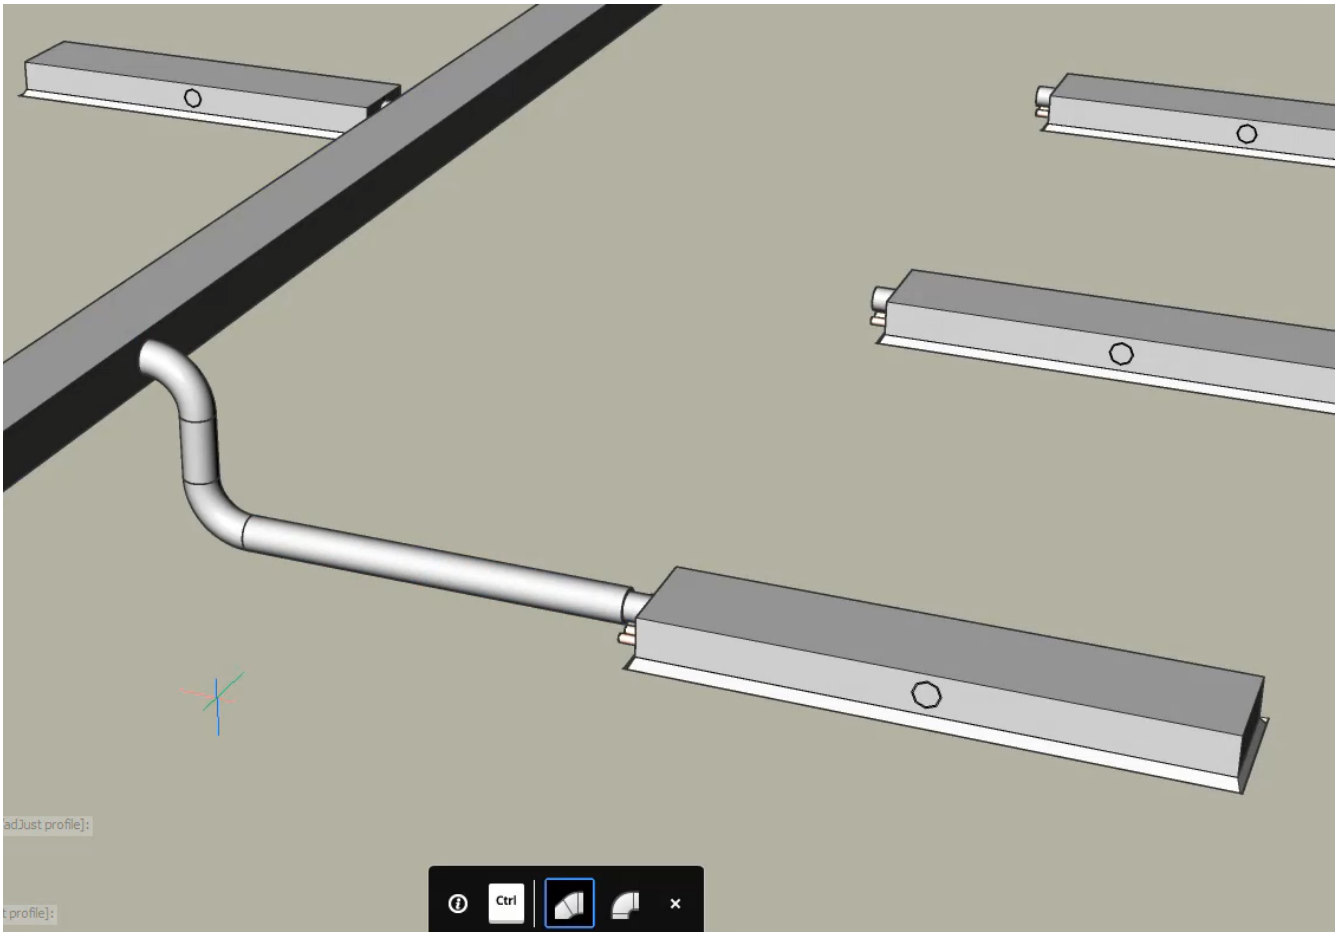

Figure 2.329

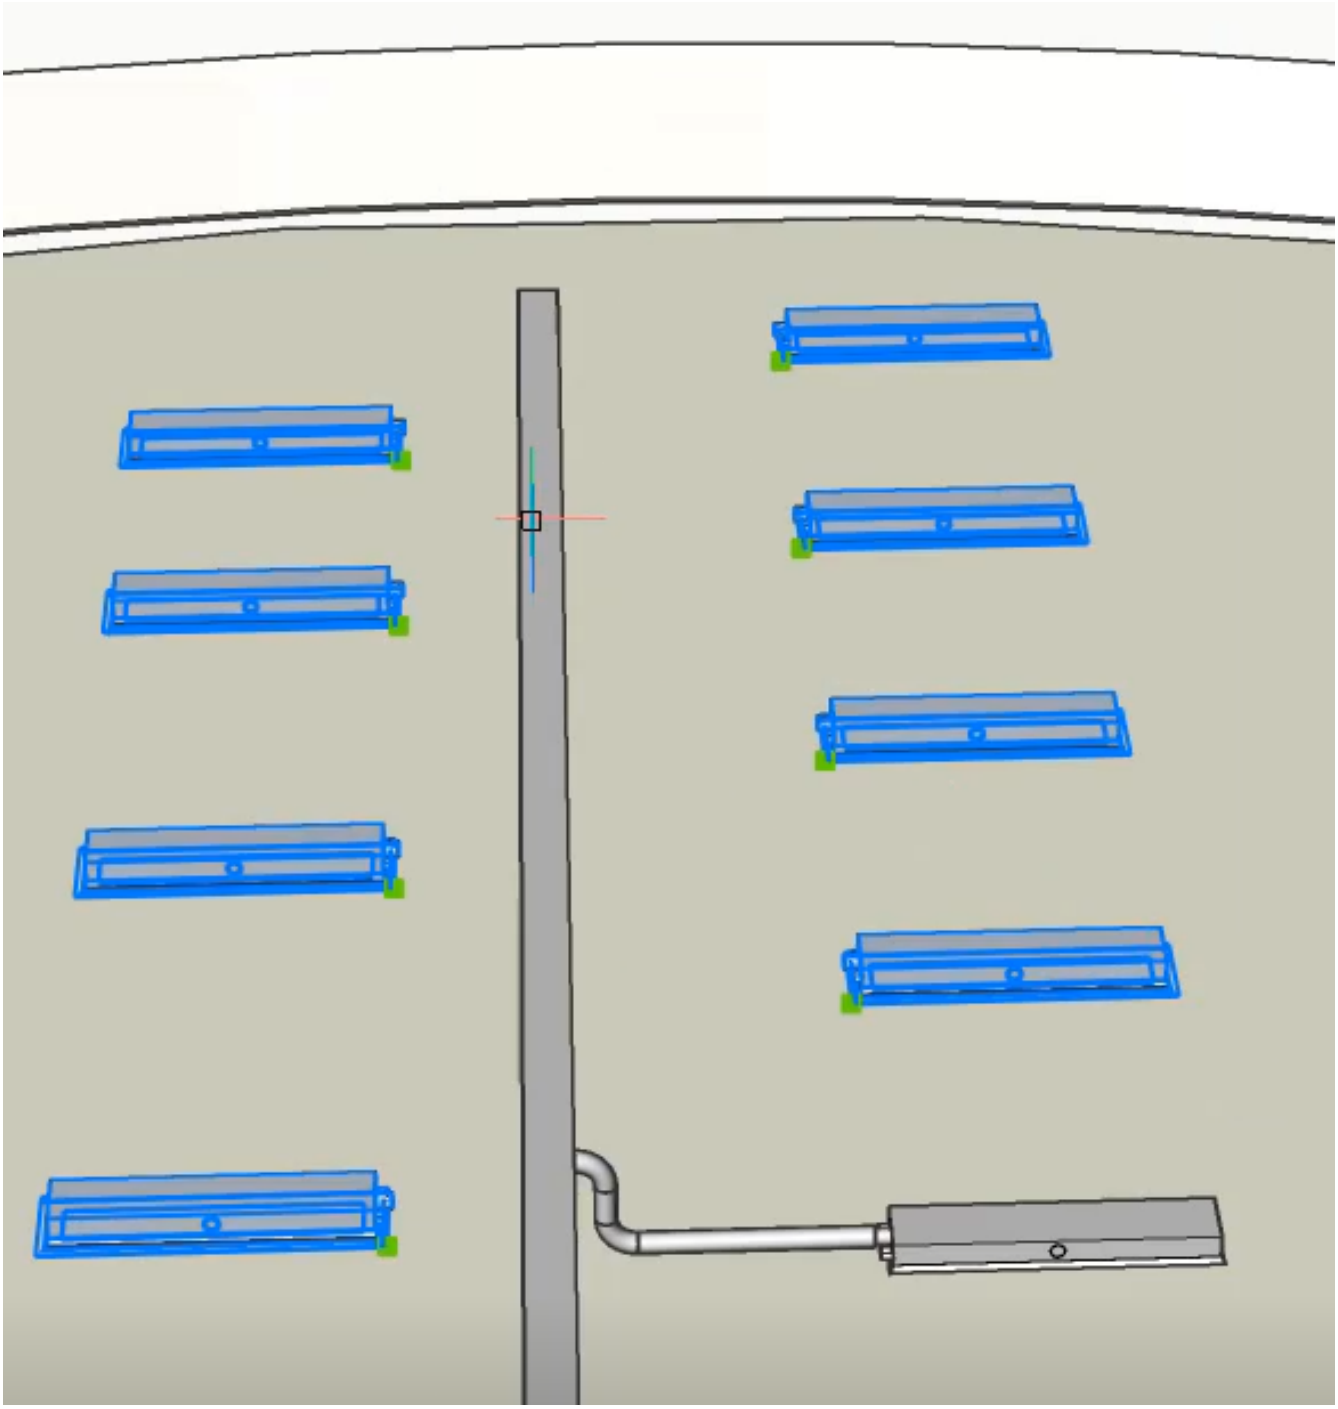

Figure 2.330

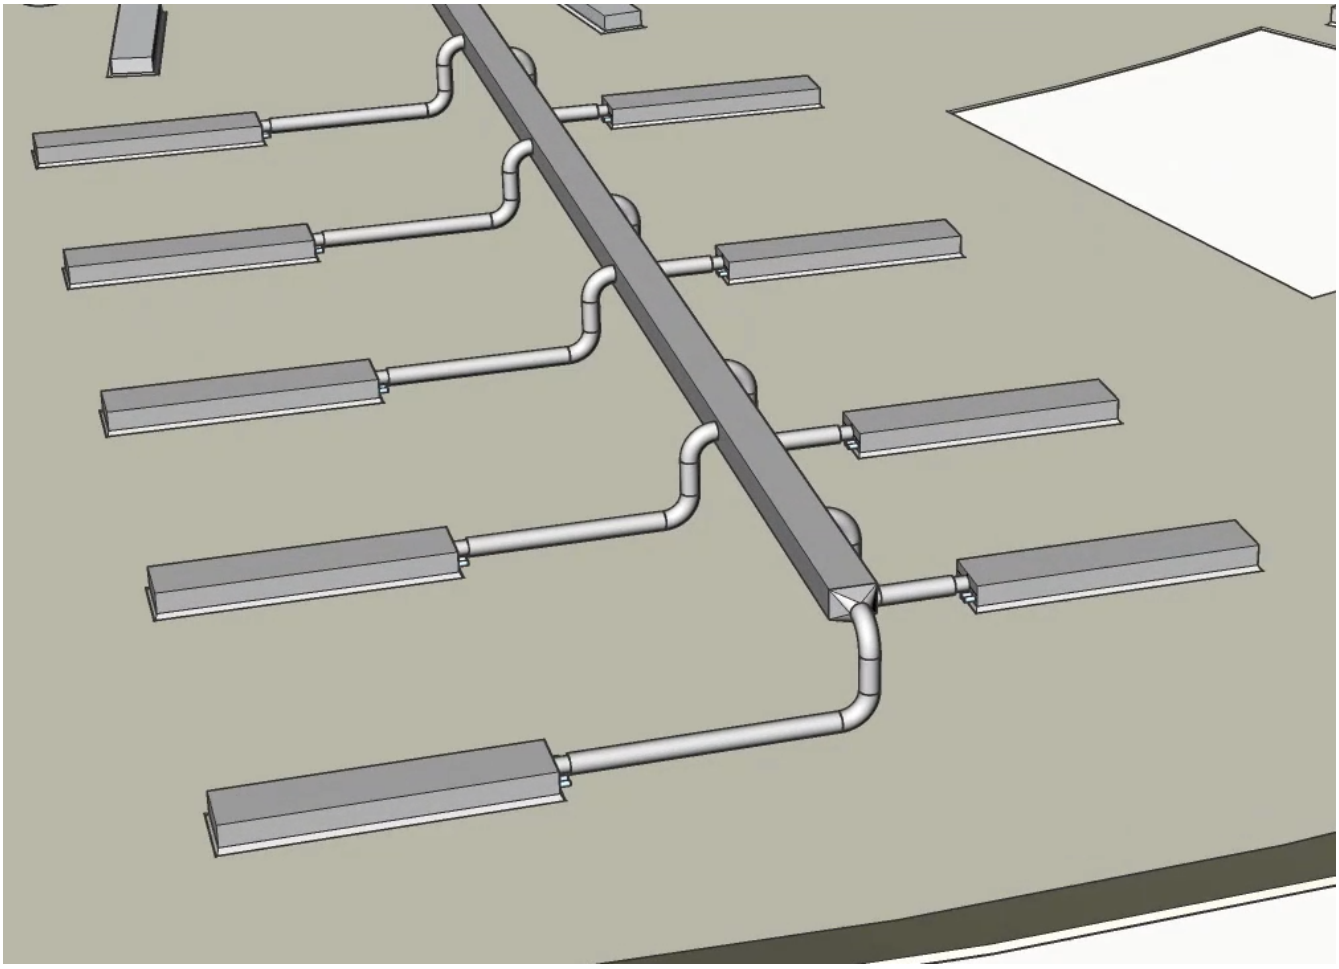

Procedure: Using the MEP Modeling tools to alter profiles

1. Type **XRef** in the commandline and check the load box next to the structural model to load the structural drawing. (2.331 on the facing page)
2. Use **MultiSlice** to divide the rectangular duct. Enter **3** in the dynamic dimensions field and press Enter to end the command.
3. Alter the positioning of the rectangular duct, so it doesn't interfere with the structural model. Select the upper face of the duct and launch the **Drag** command. **Note:** BricsCAD preserves the connections with the circular ducts. You can change this by pressing the CTRL-key if you want to disconnect the ducts. (2.332 on the next page) Move the duct down by **0.23**.
4. The structural model no longer interferes with the MEP Model, while the connections between the ducts of the flow terminals and the main rectangular duct were preserved. (2.333 on page 1876)

Figure 2.331

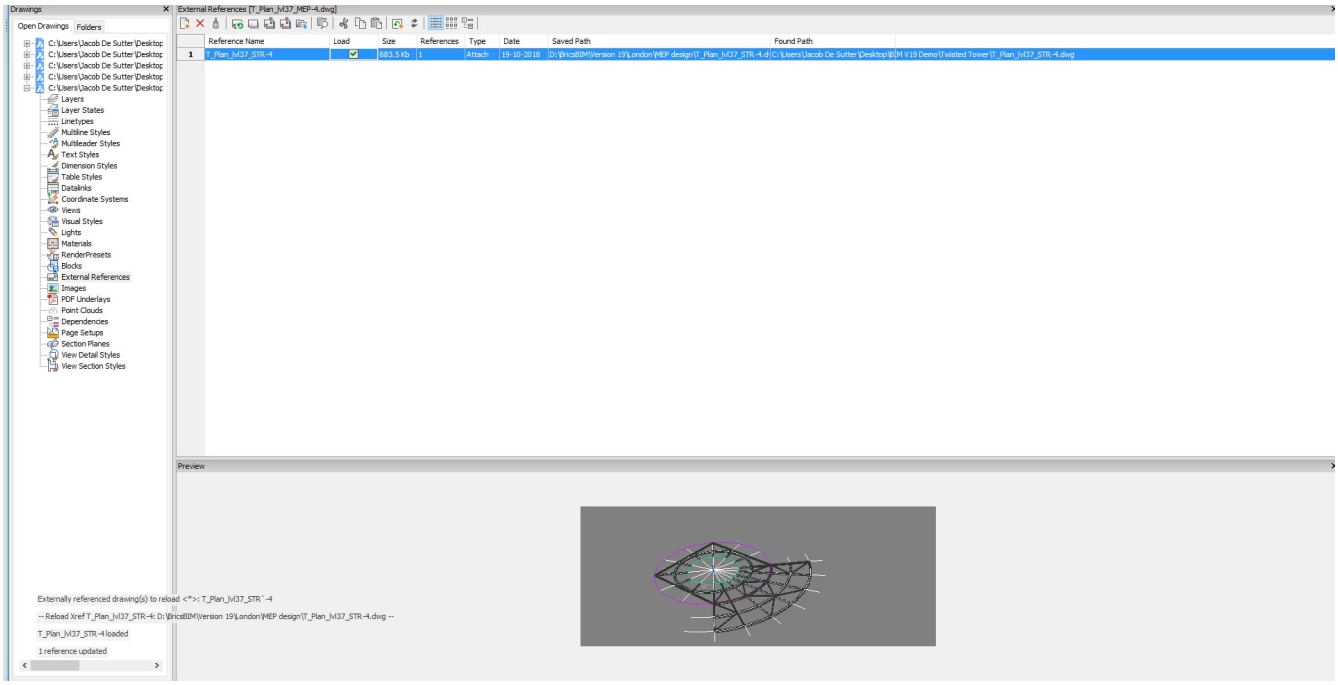

Figure 2.332

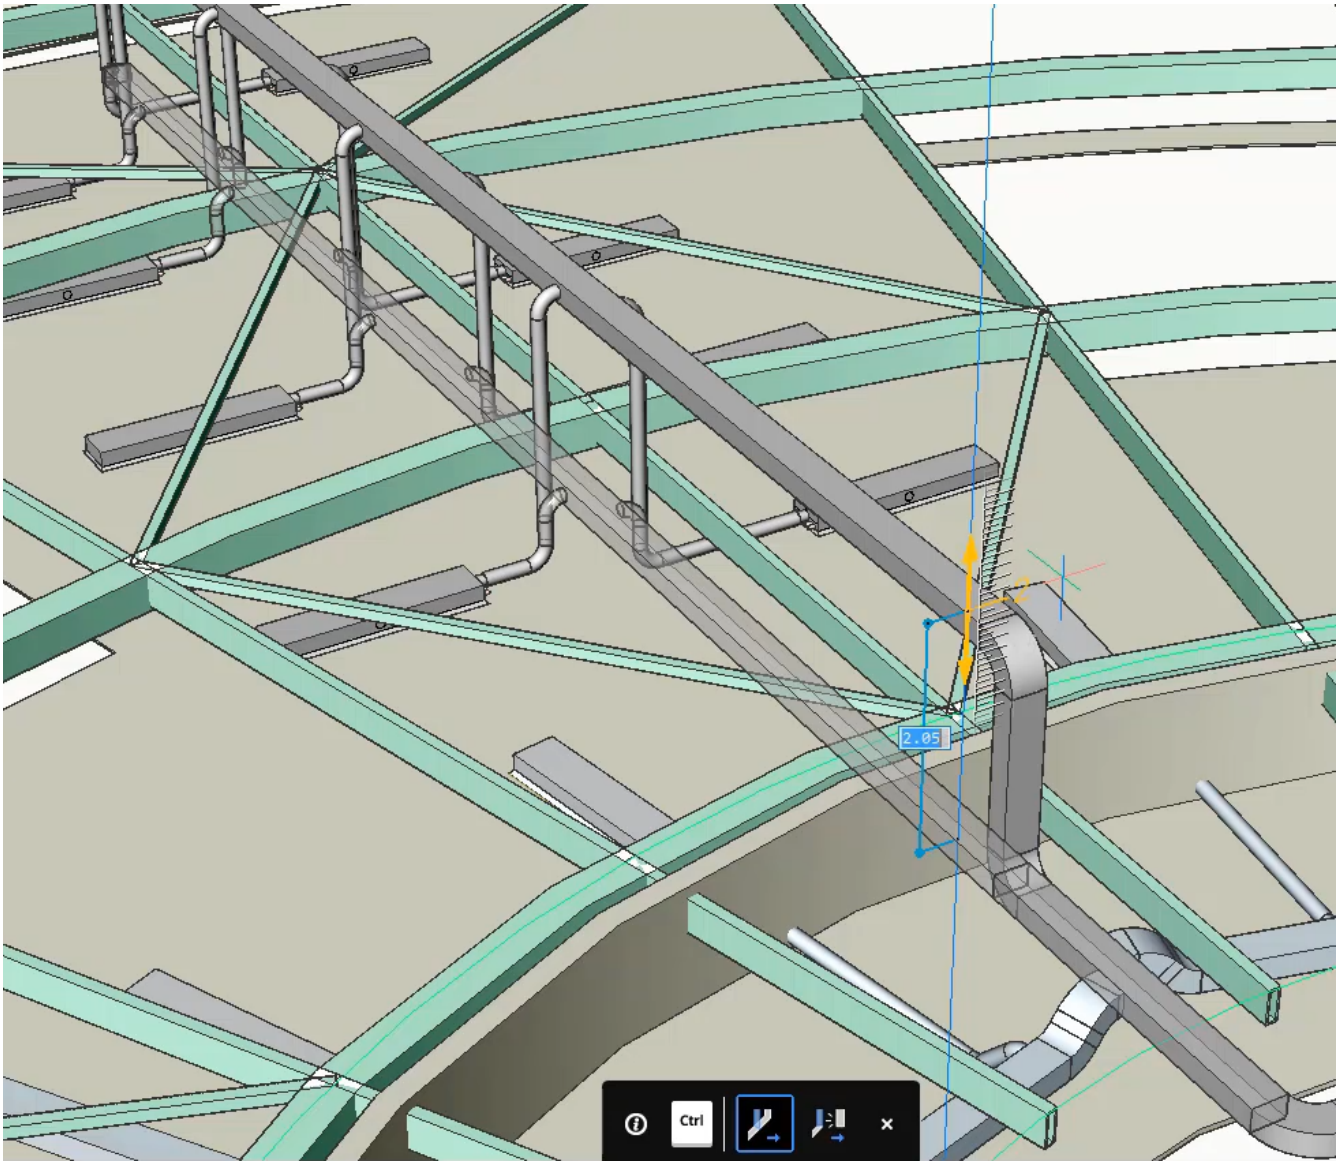

Figure 2.333

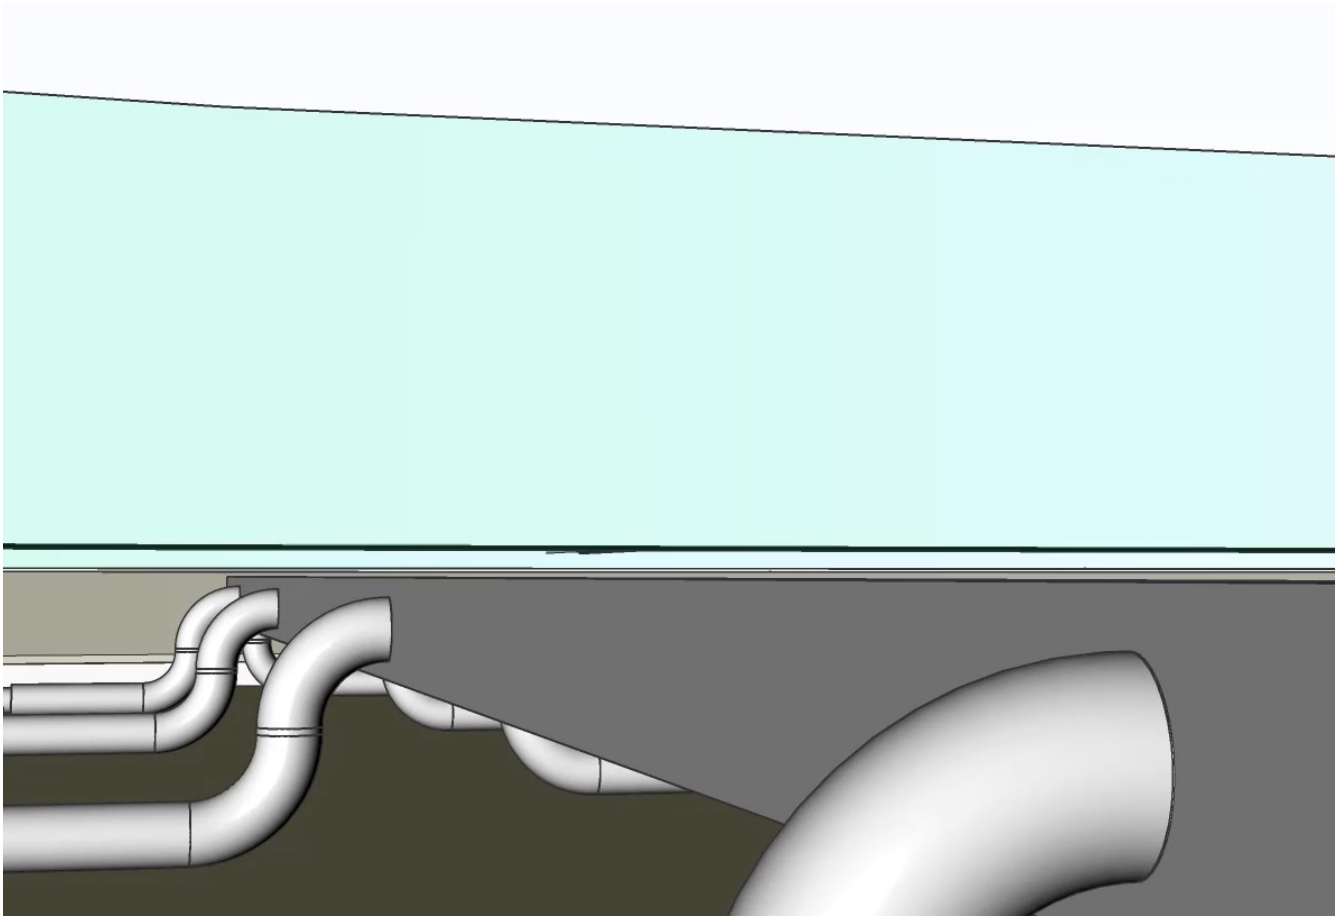

Procedure: Using Bimstretch to modify Flow segments

1. Open a **New drawing**.
2. Open the **Profiles Panel** by clicking on it on the right-hand side of your screen. **Note:** If the Profile Panel icon isn't visible yet, right-click on the ribbon and check Profiles in the context menu under
3. Filter on the HVAC standard. These profiles will be automatically classified as flow segments once they are dragged into the model space.
4. Search for the profile **HVAC Rectangular Duct 10"x10"** in the Profiles panel and drag the profile in the model space.
5. Select a starting point and draw a profile. Press enter to stop drawing with this profile. Your model should look like this: (2.334 on the next page)
6. Search for the profile **HVAC Round Duct 8"** in the Profiles Panel and drag the profile in the model space.
7. Click on the end of the Rectangular profile, after hovering on its profile face. **Note**: To easily snap on the end of the rectangular profile, turn on the **Display Axes** setting.
8. Make sure to draw the circular profile along the same axis as the rectangular one. After accepting the last point of the circular profile, it will be connected to the rectangular profile through an automatically generated reducer. (2.335 on the facing page) **Note:** If you had chosen to draw with a non-HVAC profile, you will not get the automatic classification as Flow Segment and the connection will not be made immediately. You can still manually classify the profiles through the BimClassify (6.7.12) command and then use BimFlowConnect (6.7.19) to connect the two through a reducer. **Note:** Make sure the **Display Sides and End**s and **Display Axes** is enabled.
9. Select the connecting ends of both segments. (2.336 on the next page)
10. Launch the BimStretch (6.7.48) tool.

Figure 2.334

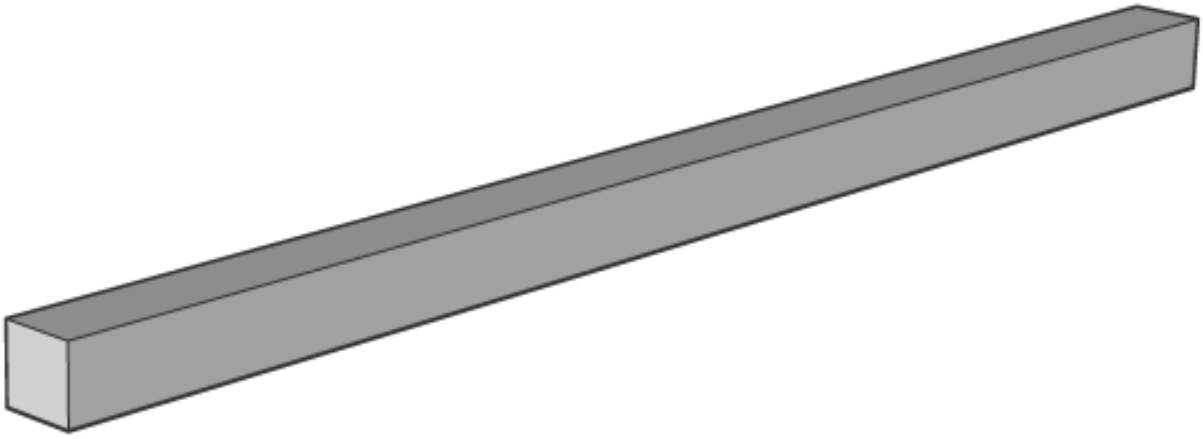

Figure 2.335

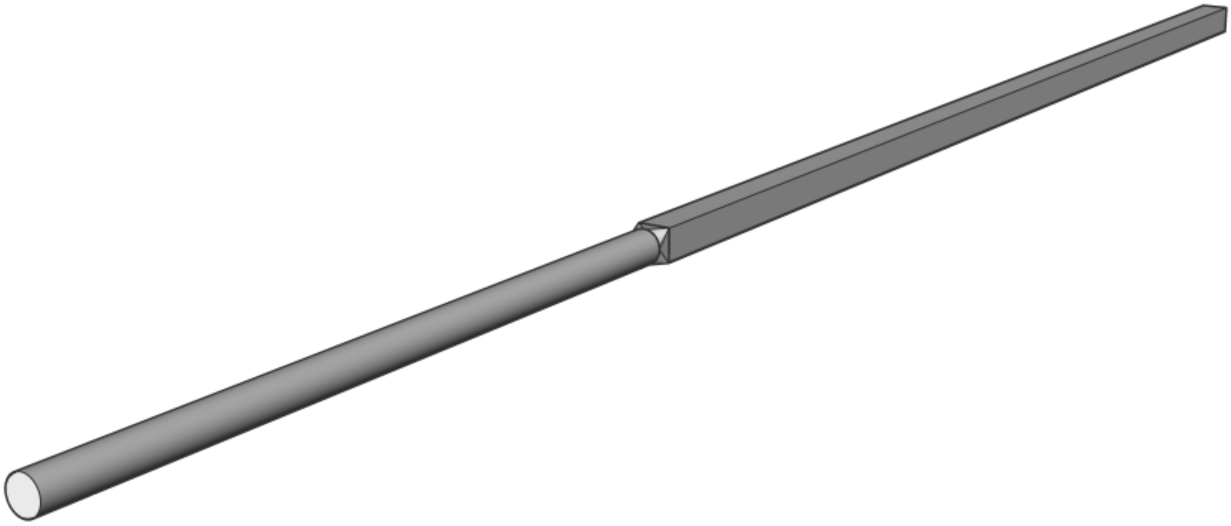

Figure 2.336

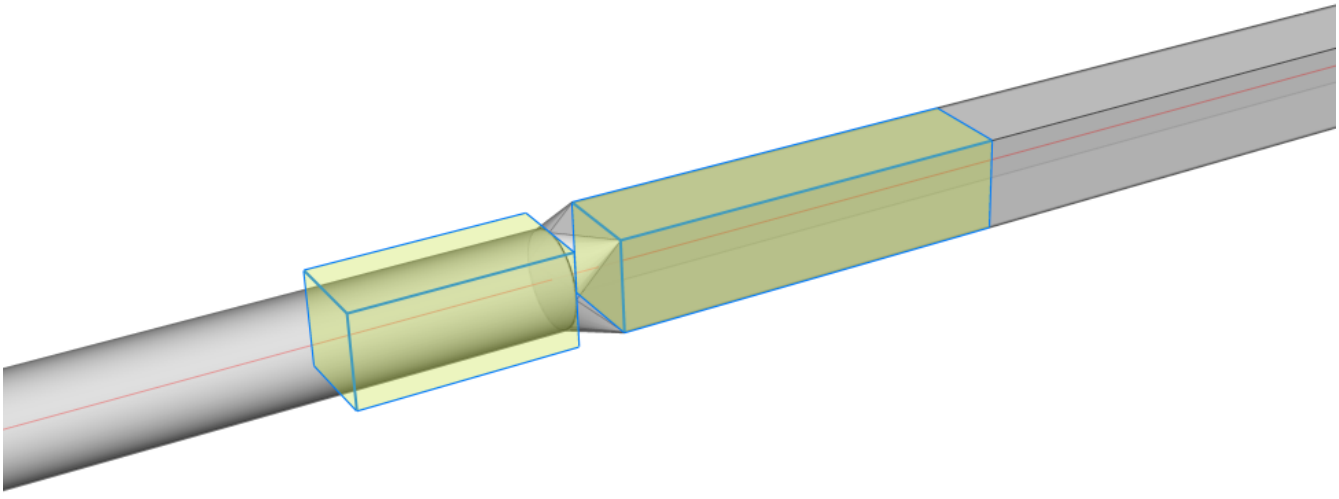

Figure 2.337

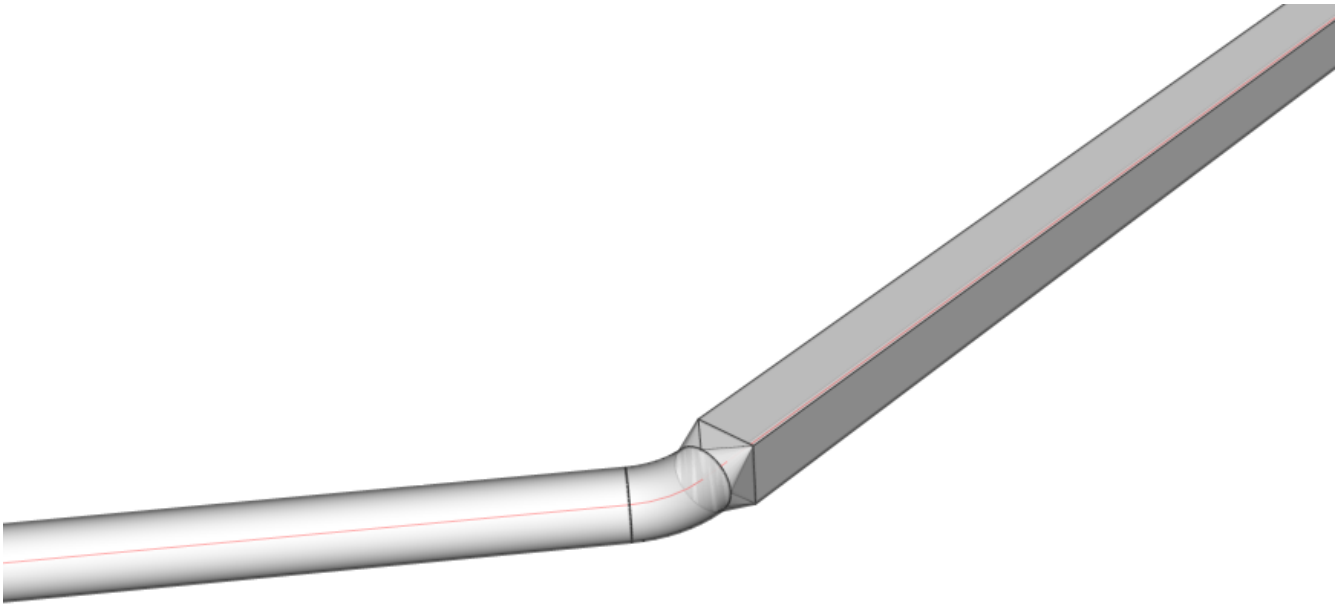


11. Hover your cursor to one of the sides and click on the desired location. BricsCAD automatically stretches the 2 Flow Segments in their new position and adds an extra curved Flow Fitting in the middle. (2.337)

2.5.15 Offset

Command: Offset (6.23.3) **Overview:** In this lesson, you learn how to use the Offset tool to create parallel copies of entities. **Lesson Objectives** After completing this lesson, you will be able to:

- Make an offset of a 3D solid face.
- Make an offset of a 3D solid edge.
- Make an offset of a detected boundary.

Tutorial: How to offset Click here (2.4.14) to watch

About

The Offset tool allows you to create copies of linear entities and align them parallel to the original entities at a specified distance.  Depending on the selected options in the Selection Modes toolbar, the Offset tool allows to create a parallel copy of:

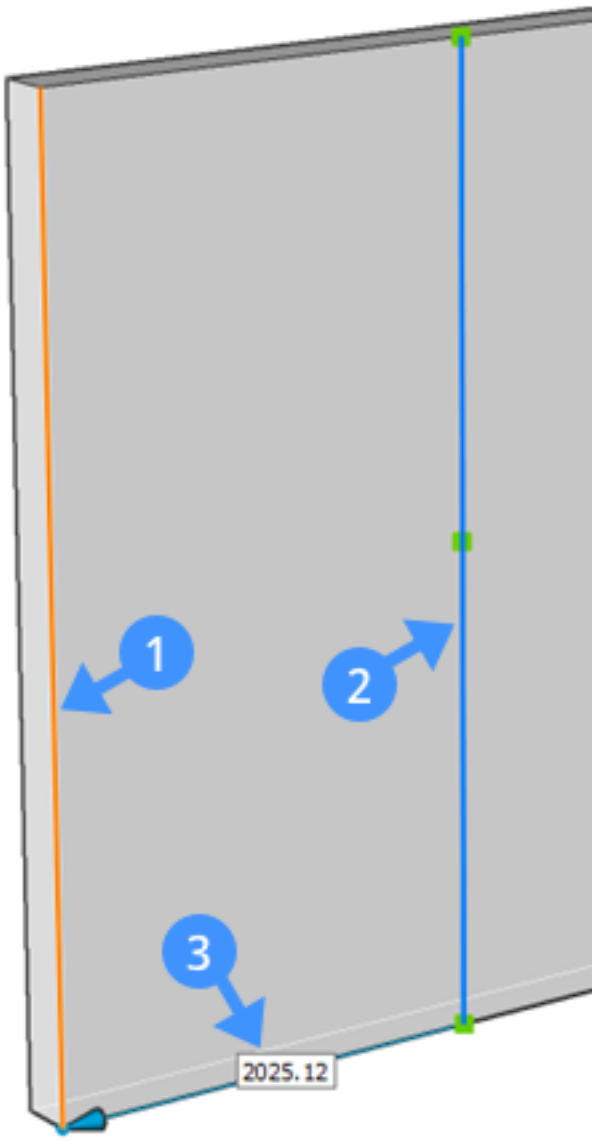
- An edge of a 3D solid if the Select Edges option () is enabled.
- The edges of a 3D solid face if the Select Faces option () is enabled.
- Detected boundaries if the Select Detected Boundaries option () is enabled.

Procedure: Make a parallel copy of a 3D solid edge

Before starting the process, make sure that Quad is active and the Select Edges option in the Selection Modes toolbar is on. Next, follow these steps:

1. Move the cursor over the edge of the solid to highlight the edge.
2. Choose the Offset tool from the Quad.
3. Specify the offset distance by dragging the edge of the solid face. **Note:** The distance of the offset displays in the dynamic dimension field The parallel copy of the edge is created dynamically.
4. While dragging the edge to set a precise offset distance, type a distance in the dynamic entry field and press Enter, or left-click to accept the offset. The following illustration shows the offset edge on the 3D solid. The edge highlights in orange is the original edge (1) of the 3D solid, whereas the blue highlighted line with grips (2) is the offset copy of the original one. The line (3) between the original edge and copied edge gives the offset distance. (2.338 on the next page)

Figure 2.338

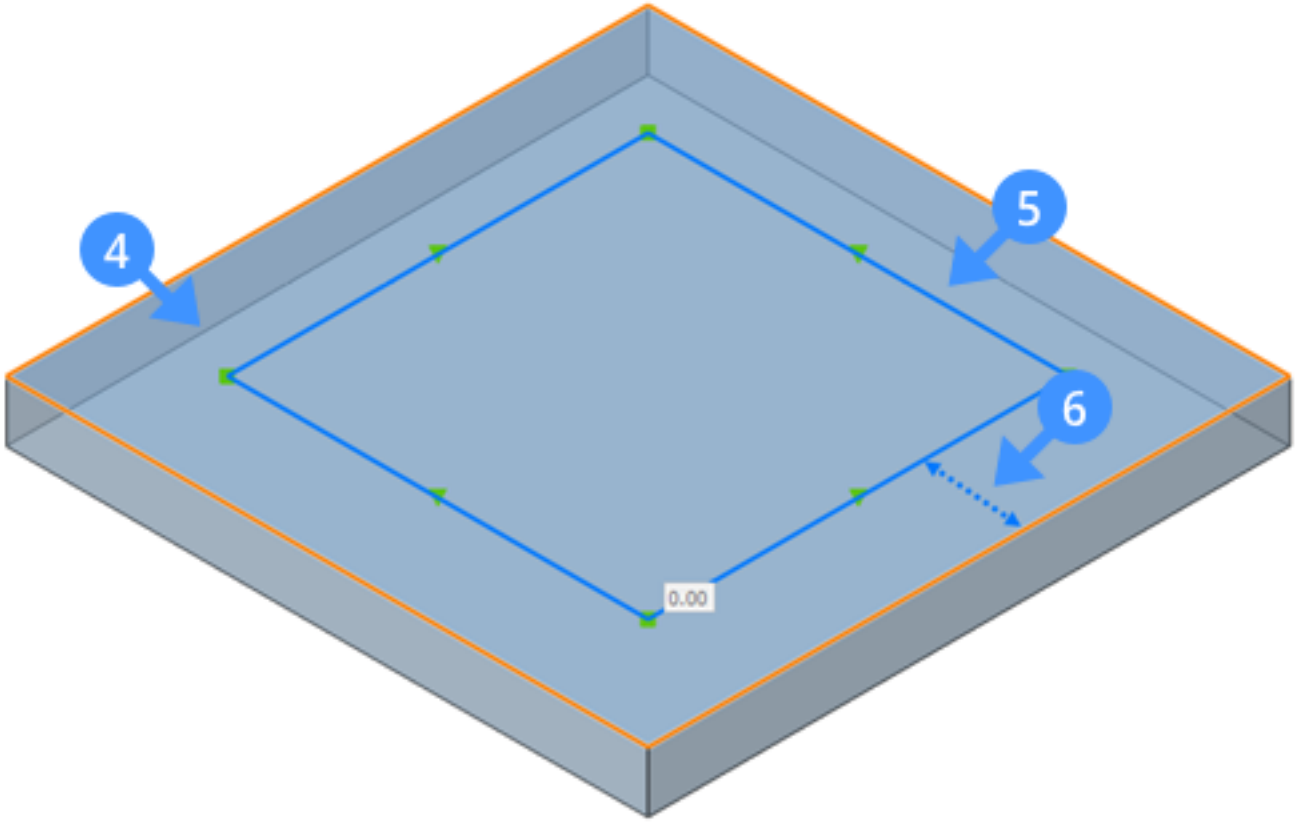


Procedure: Make a parallel copy of a 3D solid face

Before starting the process, make sure that Quad is active and the Select Faces option in the Selection Modes toolbar is on. Next, follow these steps:

1. Move the cursor over the face of the solid to highlight the solid face.
2. Choose the Offset tool from the Quad.
3. Specify the offset distance by moving the cursor outside or inside of the solid. The parallel copy of the face is created dynamically.
4. Enter a distance in the dynamic entry field and press Enter, or left-click to finish the offset. The following illustration shows the offset of the 3D solid face. The highlighted face is the original 3D solid face (4), whereas the created polyline (5) is the offset from the original one. The line (6) between the original 3D solid face and copied polyline gives the offset distance. (2.339 on the following page)

Figure 2.339

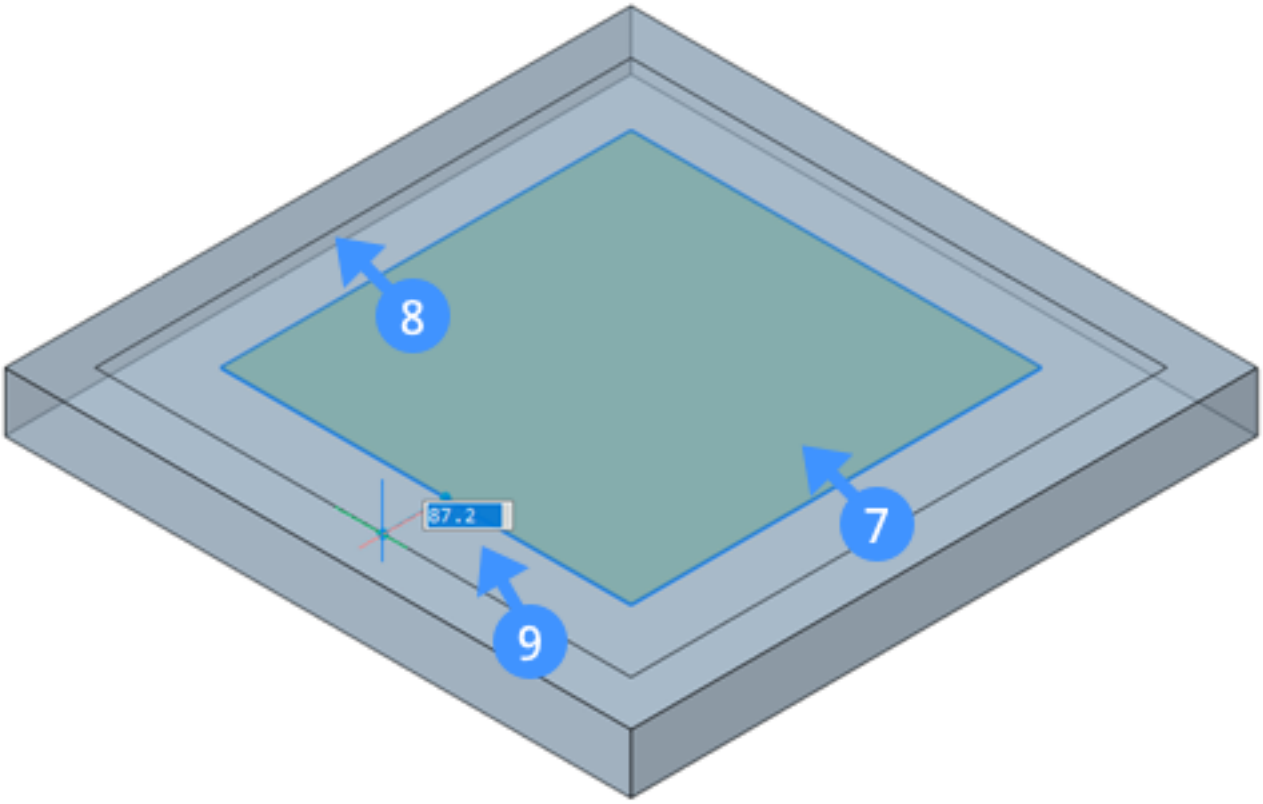


Procedure: Make a parallel copy of a detected boundary

Before starting the process, make sure that Quad is active and the Select Detected Boundaries option in the Selection Modes toolbar is on. Next, follow these steps:

1. Move the cursor inside the boundary to highlight the detected boundary.
2. Choose the offset tool from the Quad.
3. Move the cursor to define the offset distance and left-click. The parallel copy of a detected boundary is created dynamically.
4. Enter a distance in the dynamic entry field to set a precise offset distance and press enter, or left-click to accept the offset. The following illustration shows the offset boundary on the face of a 3D solid. The highlighted face is the detected boundary (7), whereas the created polyline (8) is the copy from the original one. The line (9) between the detected boundary and copied polyline gives the offset distance. (2.340 on the next page)

Figure 2.340



2.5.16 MEP Flow Connection Points

Commands: BimLinearSolid (6.7.29), BimFlowConnect (6.7.19) **Overview:** In this lesson, you will learn how to create Flow Connection Points for HVAC and piping components, and how to manipulate these segments using different tools.

About

When creating flow elements like Flow Terminals and Flow Segments, you can add a 2D symbol and classify it as a Flow Connection Point. A flow connection point contains BIM data where you can predefine the profile you want to use with this flow component. When you select the flow connection point and use the commands BimLinearSolid (6.7.29) or BimFlowConnect (6.7.19), BricsCAD will automatically use a BIM Profile based on the given information. Click here (2.5.1) for more information about Linear Solids. Click here (2.5.14) for more information about MEP modeling.

Creating a Flow Connection Point

In this procedure, you will learn how to create your own HVAC components with flow connection points. As an example, we will create an air heat pump unit.

Creating a Flow Connection Point in the Library Panel

1. Draw a box with the desired dimensions (80x40x80 cm) representing the heat pump.
2. Select the box and launch **BimClassify (6.7.12)** with the <Other> option or hover over the box and select **Classify Manually** in the **BIM** tab of the Quad.
3. Classify the box as **Building Service Elements>Flow Terminal** and click **OK**.
4. Open the Library Panel (2.5.3).
5. Go to the **MEP Flow Connection Points**. (2.341 on the facing page)
6. Place **HVAC Outlets Round** on the heat pump box. (2.342 on the next page)
7. Select the Outlet and click the **BIM/Profile** property in the Properties Panel (1.15.4). (2.343 on page 1886)
8. Click the browse (…) button. The **Profiles** dialog box displays.
9. Set **Type** and **Standard** = HVAC.
10. Choose the desired profile and click the **Select** button.
11. Go back to the Library panel and click **Create Component**.
12. Choose a name and category and click the **OK** button. See the Components Panel (2.5.3) article for more information about adding a component to the library. (2.344 on page 1887) The drawing is now saved as a component and can be used in other drawings.

Creating a Flow Connection Point from scratch

1. Draw a box with the desired dimensions (80x40x80 cm) representing the heat pump.
2. Select the box and do one of the following:
   - – Launch **BimClassify** with the **Other** option.
   - – Hover over the box and select **Classify Manually** in the **BIM** tab of the Quad.
3. Classify the box as **Building Service Elements > Flow Terminal** and click **OK**.
4. Draw a circle (6.9.12) on the top face of the box. (2.345 on the facing page)
5. Select the circle and launch **BimClassify** with the **Other** option.
6. Classify the circle as **Building Service Elements>Flow Connection Point** and click **OK**.
7. Select the circle.
8. In the **Properties** panel, select the **BIM/Profile**, property and click the Browse (…) button. (2.346 on page 1890) The **Profiles dialog** displays.
9. Select the desired profile and click **Select**.
10. On the **Library** panel and click **Create Component**.
11. Choose a name and category and click **OK**. The drawing is now saved as a component and can be used in other drawings.

Creating an HVAC System

In this procedure, we will use flow connection points to create a ventilation system.

1. Let's start from a file with a series of flow terminals and a ventilation unit. (2.347 on the facing page)
2. Select the flow terminals and the ventilation unit.
3. Select **FlowConnect (6.7.19)** in the Quad or in the **Structural/MEP** ribbon tab.
4. Press the CTRL-key to switch between the alternative setups and press Enter. (2.348 on the next page)
5. Click the **Tune** option or enter **T** in the command line to modify the chosen setup.
6. Select **Topology** in the toolbar or enter **T** and press Enter.
7. Select the check icons to modify the layout of the system. (2.349 on page 1892)
8. Press Enter 3 times to exit the command. **Note:** BricsCAD automatically uses the profiles that were assigned to the ventilation units. This information is stored in the Flow Connection Points.

(2.350 on page 1892)

2.5.17 Splitting Solids

Command: BimSplit (6.7.52) The BimSplit command either splits segmented solids into separated solids automatically or allows to split a solid using a selection of cutting faces.

To split a solid automatically

Make sure that the value of SelectionPreview (1.17.10) is 2 or 3.

1. Do one of the following:

   - Click the BimSplit tool button () on the Model tab of the ribbon.
   - Choose Split in the BIM menu.
   - Type BIMSPLIT in the command bar, then press Enter. You are prompted: Select solid for auto-splitting or cutting faces for manual splitting:

2. Place the cursor over a face of the solid. The face highlights.
3. Without moving the mouse, hit the TAB key until the complete solid highlights, then click. **You are prompted:** Entities in set: 1 Select solid for auto-splitting or cutting faces for manual splitting:
4. Right click. The selected solid is split. The number of parts is reported in the command window.

Using the Quad Make sure the Select Faces option () of the SelectionModes (1.17.10) system variable is switched off. Place the cursor over a face of the solid. When the solid highlights, choose Split () in the BIM command group of the Quad. The solid is split. The number of parts is reported in the command window.

To split a solid using cutting faces

Make sure that the value of SelectionPreview (1.17.10) is 2 or 3.

1. Do one of the following:

   - Click the BimSplit tool button on Model tab of the ribbon.
   - Choose Split in the BIM menu.
   - Type bimsplit in the command bar, then press Enter. You are prompted: Select solid for auto splitting or cutting faces for manual splitting:

2. Place the cursor over a face of the solid. Hit the TAB key to highlight an obscured face. When the face highlights, click to select the face. **You are prompted:** Entities in set: 1 Select solid for auto splitting or cutting faces for manual splitting:
3. (option) Repeat step 4 to select more faces.
4. Right-click to stop selecting faces. The solid is split using the selected faces as cutting planes. The number of parts is reported in the command window.

Using the Quad Make sure the Select Faces option of the SelectionModes (1.17.10) system variable is set.

1. Place the cursor over a face you want to use as a cutting plane. When the face highlights, do one of the following:
2. Go to step 3.
3. Go to step 2 to select more faces.
4. (option) Place the cursor over a face you want to use as a cutting plane. When the face highlights, do one of the following:
5. Go to step 3.
6. Repeat this step to select more faces.
7. Choose Split in the BIM command group of the Quad. The solid is split using the selected faces as cutting planes. The number of parts is reported in the command window.

2.5.18 Using Drag

Command: Drag (6.10.38) **Overview:** In this lesson, you learn how to move a 3D solid that is perpendicular to the selected face using the Drag tool. Furthermore, you learn how to preserve connections between solids when Drag is executed on a face. **Lesson Objectives** After completing this lesson, you will be able to:

- Move 3D solids along the normal of their selected face.
- Preserve connections between solids while dragging a single solid or multiple solids.
- Increase or decrease the geometry of the solid in size according to the process you use.
- Disable the connection between solids using the CTRL-key.

Tutorial: How to use Drag Click here (2.4.20) to watch

About

The Drag tool allows you to move walls, slabs or linear elements on the highlighted face of a solid. For instance, the Drag tool can be used to move linear solids by highlighting/selecting the end or side face of a linear solid. Depending on the modeling operation, the connection between solids can be either preserved while dragging one or more solids at a time or solid (s) can be moved independently by disjoining the connectivity to other solid(s).

Procedure: Using Drag on a 3D Solid

1. Highlight/select any faces of the solid and select Drag (6.10.38) from the Quad | Model tab. (2.351 on the facing page)
2. Move the cursor to adjust the position of the moving solid in the dynamic dimension field, then click or enter a precise value in the dynamic dimension field and press Enter. (2.352 on the next page) **Note:** A ruler appears to visually represent the distance over which you will move the entity.
3. The Hotkey Assistant appears at the bottom of the screen showing the available options. (6.893 on page 4153) **Note:** The current mode is indicated by a blue frame. Hit the CTRL-key to toggle the connectivity mode. Alternatively, type **D+Enter** to disable connectivity or type **E+Enter** to enable connectivity.

- Select the **Enable connectivity mode** option, to move the solid while preserving the connections between solids. In the following illustration, the solid behavior is shown before and after applying the DRAG in **"Enable connectivity mode"**. The connectivity between walls, i.e. T- (3) and mitered (4) connections are preserved after dragging an inner wall surface (5). (2.354 on page 1896) (2.355 on page 1896) (2.356 on page 1897)
- Select the **Disable connectivity mode** (default) option to move the solid while breaking the connections between solids. In the following illustration, the solid behavior is shown before and after applying the Drag in **"Disable connectivity mode".** The connectivity between walls, i.e. T- (3) and L- (6) connections are disjointed after dragging an inner wall surface (5). **(2.357 on page 1897) (2.358 on page 1898) (2.359 on page 1898)**

Figure 2.351

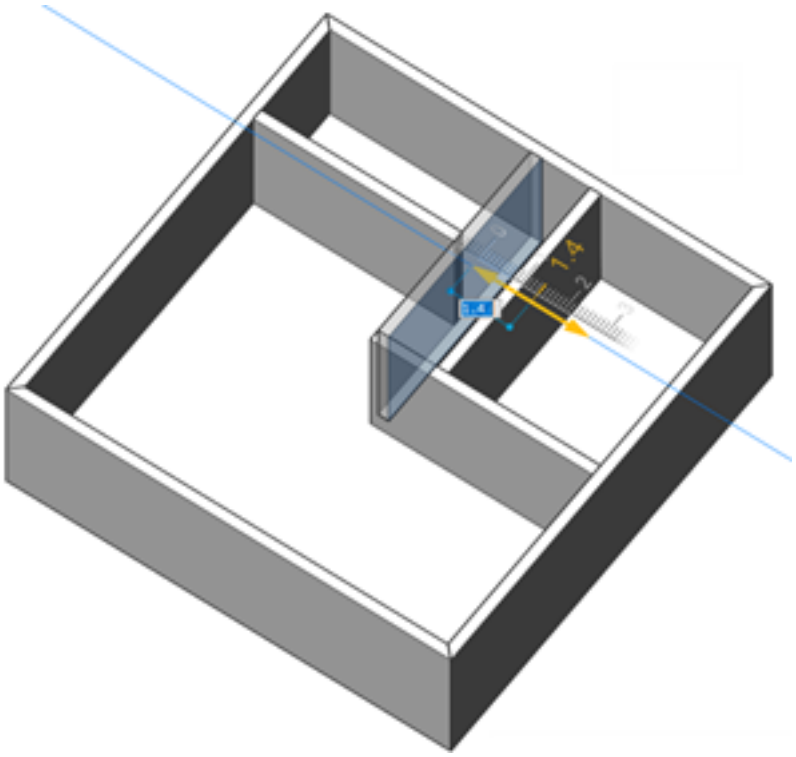

Figure 2.359

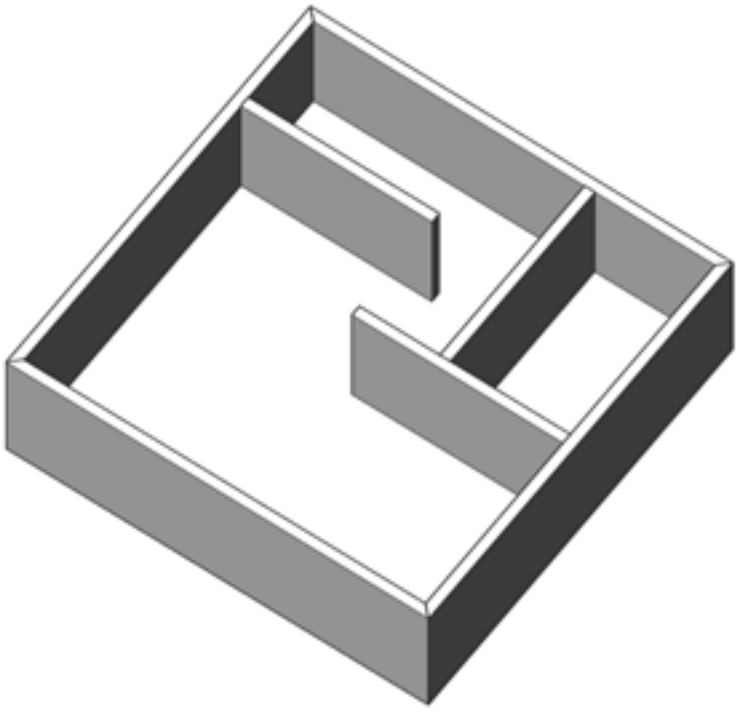

2.5.19 Inserting and editing Windows and Doors

Command: BmInsert (6.8.16) **Overview:** In this lesson, you learn how to insert, manipulate and edit windows and doors in a solid. **Lesson Objectives:** After completing this lesson, you will be able to:

- Insert a window or door as a block reference into your 3D model.
- Edit the parameters of a window or door.
- Move the inserted door or window in the face of a 3D solid.
- Place copies of an insert in the same 3D solid.
- Replace an existing insert with another.

Tutorial: How to use the BIM Insert tool Click here (2.4.16) to watch

About

In BricsCAD, the **Insert BIM Component** tool allows you to insert windows, doors and other components, such as furniture, sanitary equipment, plants, ..., in any face of a 3D solid and is typically used to insert windows and doors.  For more information about this command, visit the Command Reference article BmInsert (6.8.16).

Controlling the position of the window or door

To control the position of the window in the face of the solid (wall), you can use the following drawing aids:

- Dynamic Dimensions (1.21.9): During placement of a window or door on a 3D Solid face, dynamic dimensions are created, starting from the middle of each edge of the bounding rectangle of the opening to the nearest parallel edge on the face of the 3D Solid. Make sure Dynamic Dimensions are active by checking the DYN field in the status bar and Dynamic UCS is active by checking the DUCS field in the status bar. The Dynamic UCS aligns the window to the face of the solid. The edge of the face by which the cursor enters the face defines the orientation of the X-axis. Hit the Shift key to temporarily lock the UCS, which allows to use reference points outside the face of the solid. Hit the shift key again to unlock.
- Temporary Tracking points (1.21.15): Click the mouse wheel or press the Temporary Tracking Points tool button () on the Entity Snaps toolbar to start specifying temporary points.
- **OSNAPZ:** If this system variable is ON, the Z-value of any entity snapping point is replaced by the current value of the ELEVATION system variable. If ELEVATION=0, entity snapping points are forced to lie in the face of the solid. OSNAPZ is toggled by the **Ignore entity snap elevation** tool button () on the **Entity Snaps** toolbar. The state of the tool button (pressed or not) indicates the current value of OSNAPZ.
- **Entity snap to negative Z-values:** Press the Entity snap to negative-z tool button () on the **Entity Snaps** toolbar to enable entity snaps on points that lie behind the selected face. If OSNAPZ is ON, the point is projected onto the selected face.

Procedure: Inserting windows or doors

Note: Make sure Dynamic UCS (DUCS) and Dynamic Dimensions (DYN) are active.

Using the BmInsert command

1. Select **Insert BIM Component** from the **Model** tab of the **No Selection** Quad. The file explorer opens, displaying the content of the most recently used folder to insert a BIM component. The default folders for BIM components sit in the following subfolder of the BricsCAD installation folder: ...\UserDataCache\Support\en_US\Bim\Comp
2. Select the Windows (1) or Doors folder.(2.360 on the next page)

2. Select a window or door you want to insert in your drawing, then double click or click the **Open** button. The selected insert is attached to the cursor (2). (2.361 on the following page) The parameters of the insert display in the Properties panel. Prompts you: **Select insertion point or [Edit inserted entity/Rotate component/set Base point/Name/insertion Type/Flip/mUltiple/Change target 3d solids] <0, 0, 0>:**

3. Optionally, edit the parameters in the Properties panel or choose an option (see Command Options (6.8.16) of the BmInsert command).

Figure 2.360

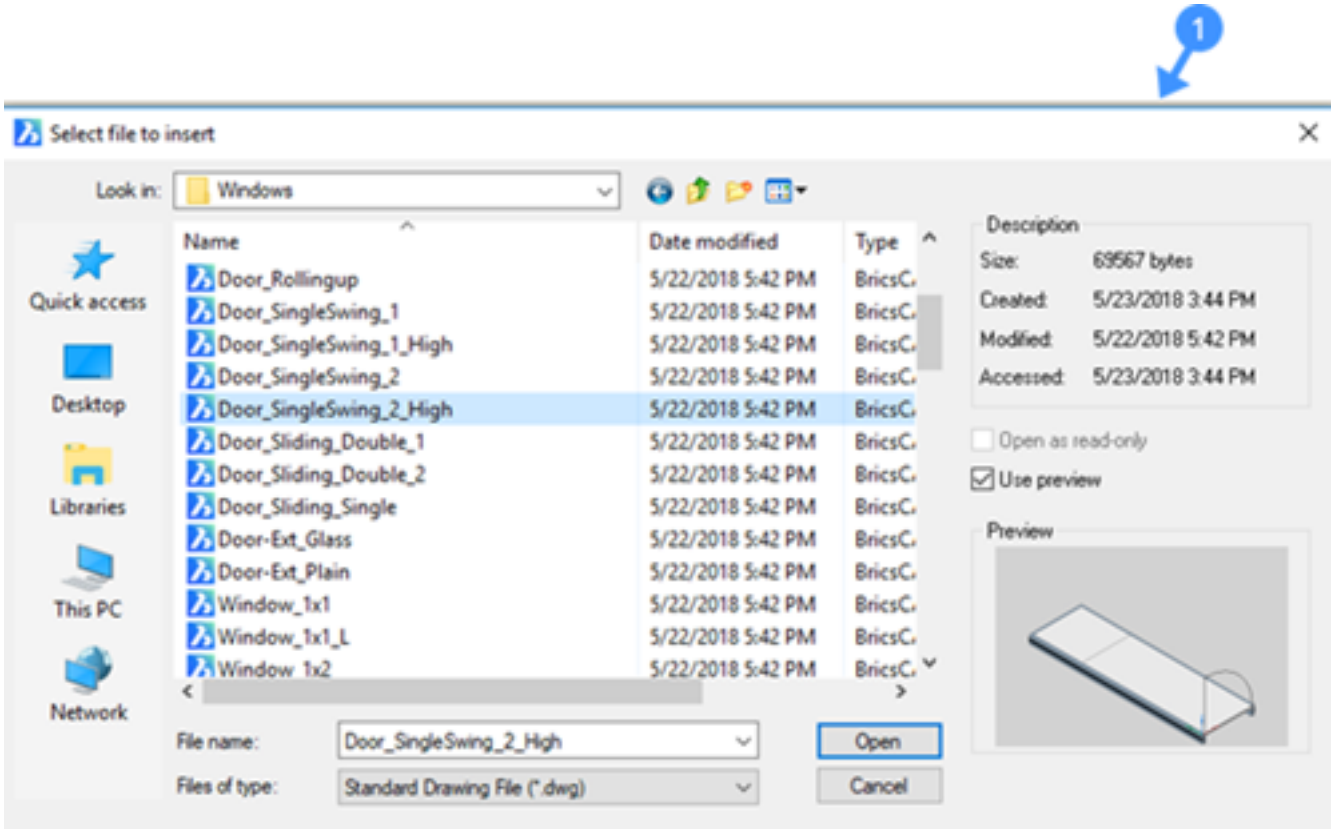

Figure 2.361

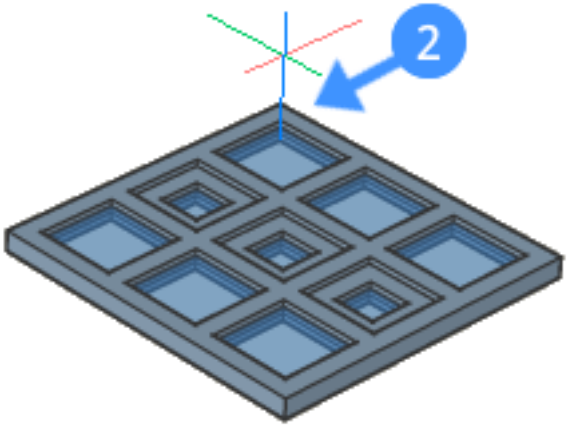

Figure 2.362

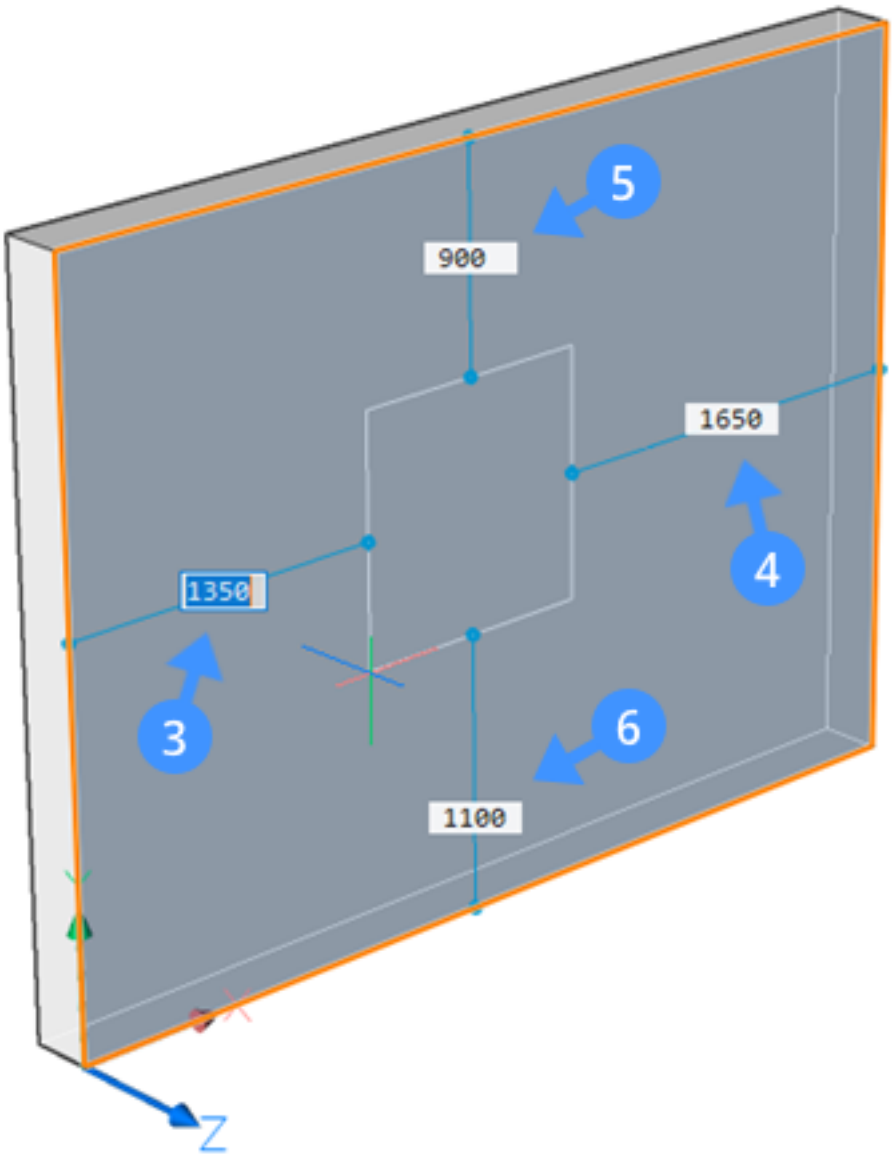

Figure 2.363

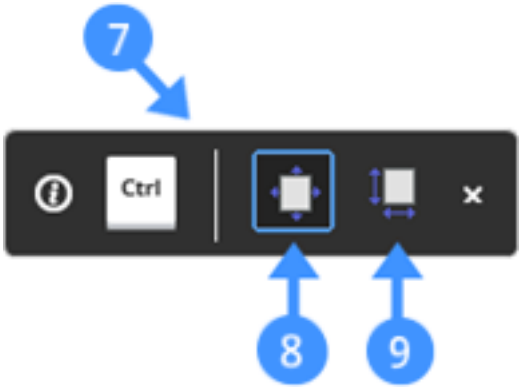

Figure 2.364

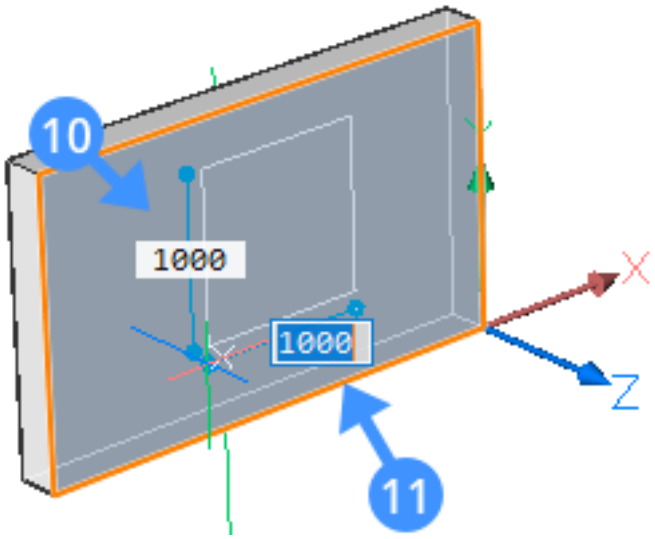


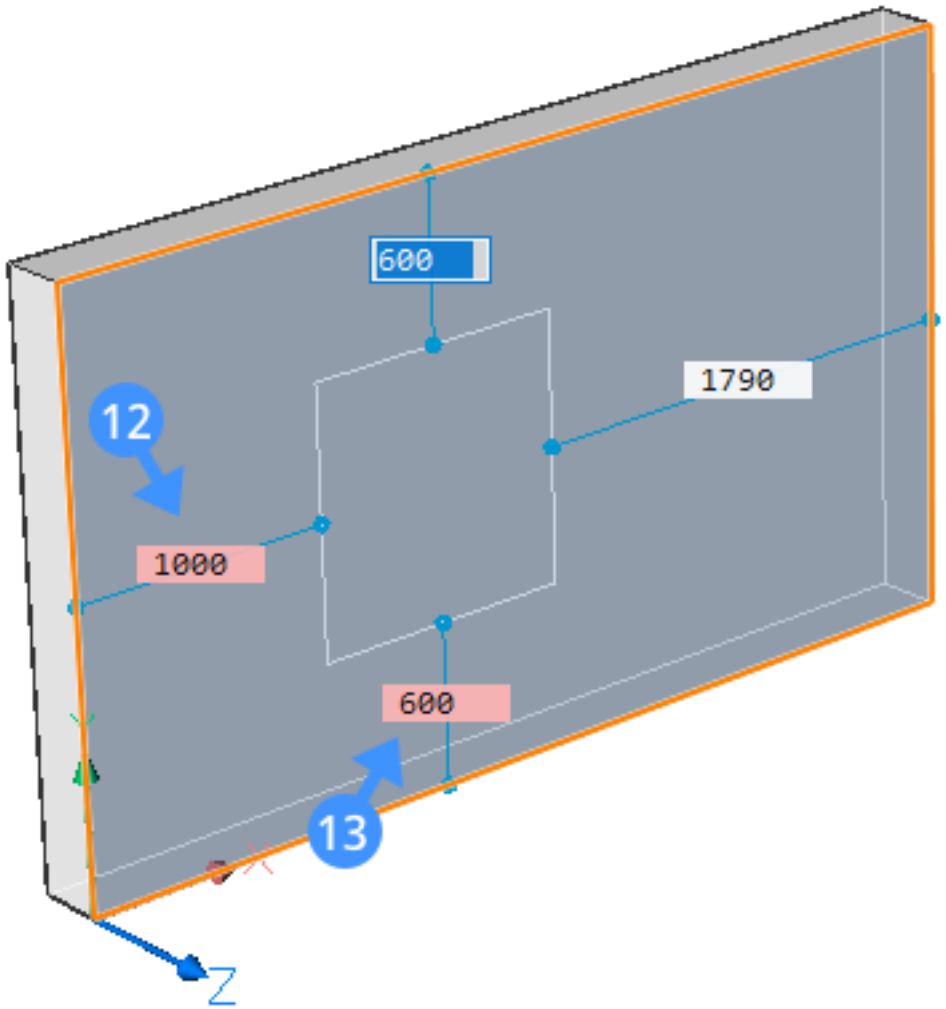
4. When you move over a face of the solid, the insert aligns with the face under the cursor. The distances from the start (3), end (4), top (5) and bottom (6) face of the wall to the placement rectangle of the insert display dynamically. (2.362 on the previous page) If the HKA (Hot Key Assistent)* is ON, the HKA Widget (7) displays at the bottom of the screen to show you the available options. Use 'pick position' (8) option to adjust the insertion point of the wall or door. Use the 'update size' option (9) by hitting the CTRL key to specify the width and height of the insert. The Width (10) and Height (11) field will indicate the current dimensions of the insert. (2.363) (2.364) * Click the HKA field in the Status bar (1.15.2) to toggle the display of the Hot Key Assistent.

5. Do one of the following to place the selected window or door using the dynamic dimension fields:

- Hit the TAB key to select one of the dynamic dimension fields, then type a value and hit the TAB key to lock the dimension. The locked dimension turns red (12).
- Hit the TAB key to select one of the other dynamic dimension fields, then type a value and hit the TAB key to lock the dimension. The locked dimension turns red (13).

(2.365 on the facing page)

Figure 2.365



Using the Components panel See: Insert a window from the Components Panel into your drawing (2.5.3)

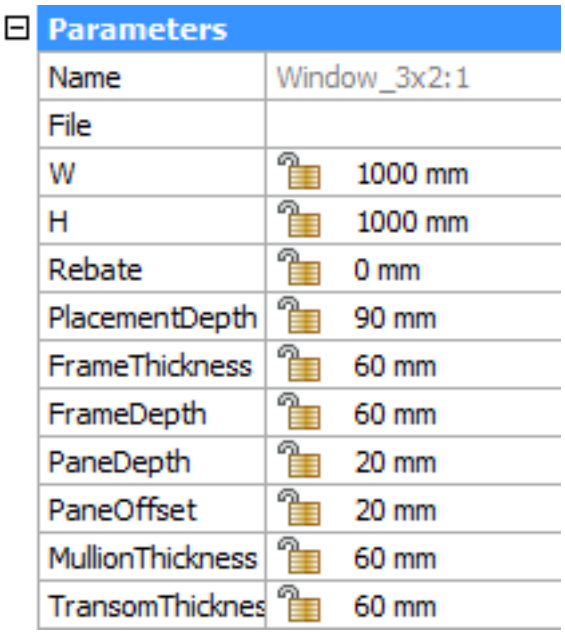
Procedure: Editing the parameters of an insert

If parameters are defined in the window or door source drawing, these parameters can be used to edit each detail of a window/door separately.

1. Select any door or window in the drawing. The current values of the various parameters display in the parameters section of the **Properties Panel**. In the following illustration, window parameters are shown in the properties panel. (2.366 on the next page)

2. Select a parameter you want to change, then type a value in the settings field.

Figure 2.366



Moving an Insert

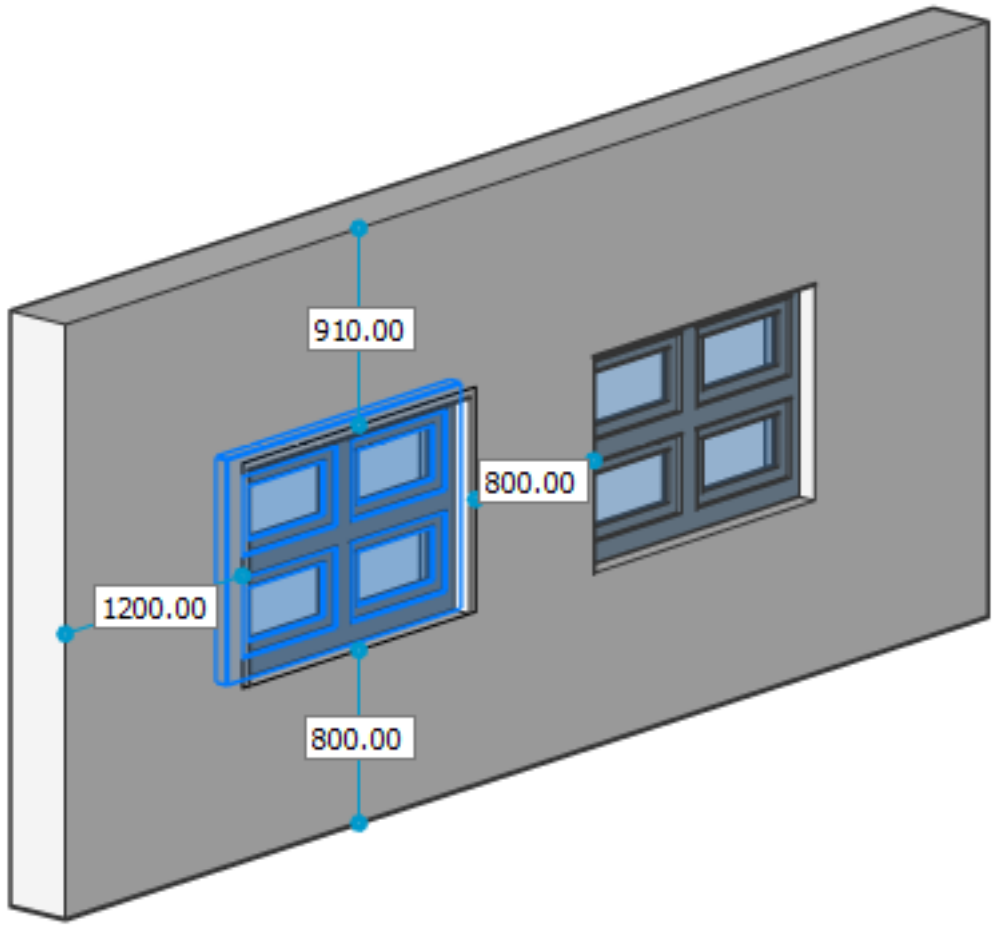
In BricsCAD, there multiple methods to move an insert in the face of a solid:

- Using Distance fields.
- Using Push / Pull
- Using the Manipulator (1.32.10)

Procedure: Using distance fields

1. Select the insert in the model. Current distances from the insert to the nearest parallel faces of the parent solid display: (2.367 on the following page)
2. Double click a distance field, then type a value and press Enter.

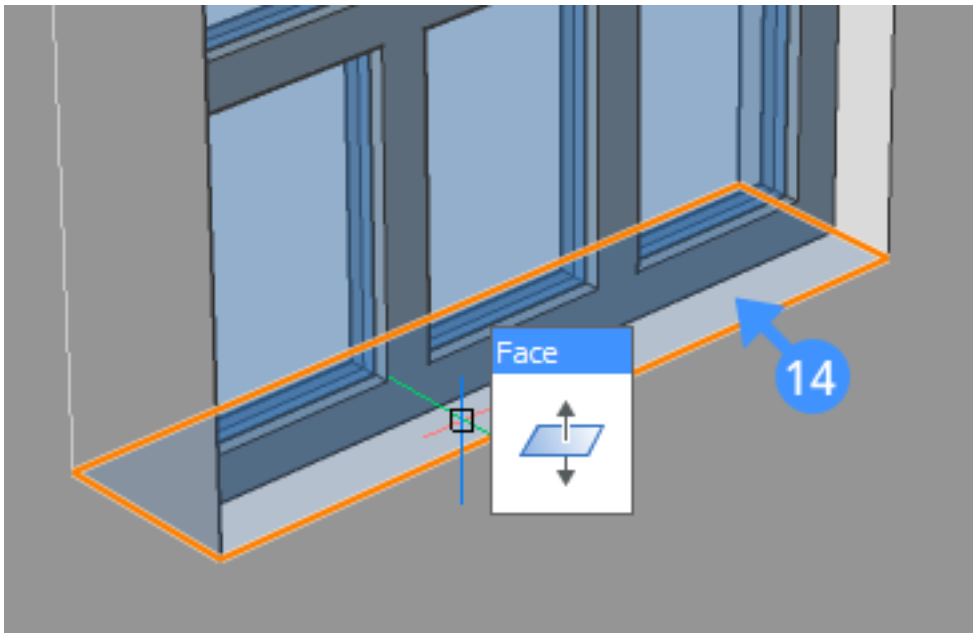
Figure 2.367



Procedure: Using Push/Pull to move an insert

1. Hover the cursor over the top or the bottom inner face of the opening (14) made by the insert to move the insert vertically. Or to move the insert horizontally, hover the cursor over the left or the right inner face of the opening (15) made by the insert. (2.368 on the next page) (2.369 on page 1909)

Figure 2.368

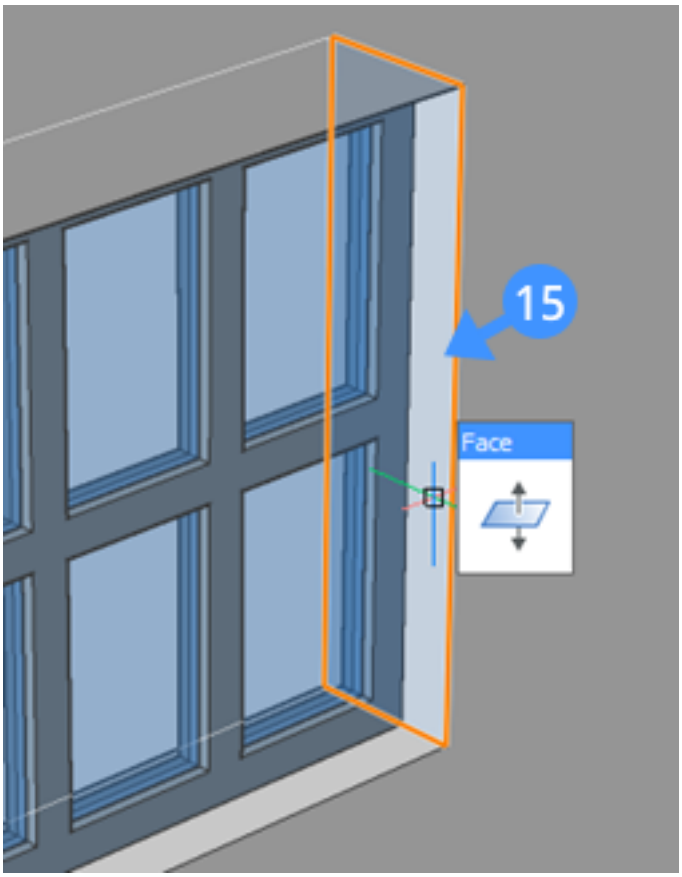


2. When the face highlights, select DmPushPull (6.12.25) from the **Model** tab of the Quad. The insert will move vertically if the top or bottom inner face is highlighted. The insert will move horizontally if the left or right inner face is highlighted.

3. Do one of the following to complete the moving insert process.

- Specify a point.
- Type a distance in the dynamic dimension field.
- Use Adaptive Grid Snap (1.21.13) of the Ruler.

Figure 2.369



Procedure: Using the Manipulator

1. Select the insert by holding the left mouse button down a bit longer.* The Manipulator displays. (2.370 on the next page)
2. Hover over the vertical or horizontal axis trigger zone of the Manipulator. The axis highlights and the rest of the Manipulator fades. (2.371 on the following page)
3. Click to start the movement operation.** The window moves dynamically. The Ruler displays. (2.372 on page 1911)
4. Do one of the following:.
   - Type a distance in the dynamic dimension field.
   - Use Adaptive Grid Snap (1.21.13) of the Ruler.

* When the value of MANIPULATOR = 2. ** Hold down the Ctrl key to create a copy of the selected insert.

Figure 2.370

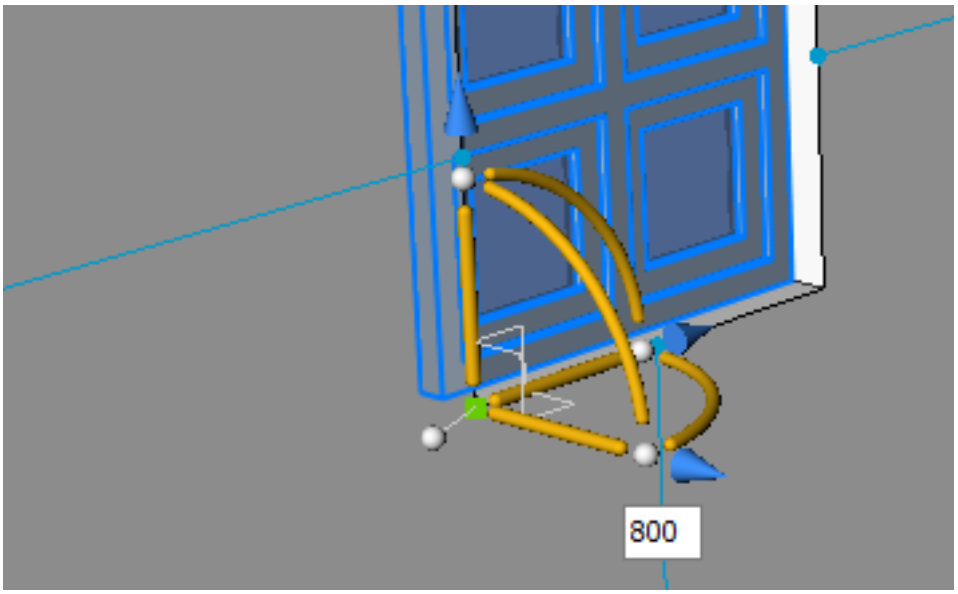


Figure 2.371

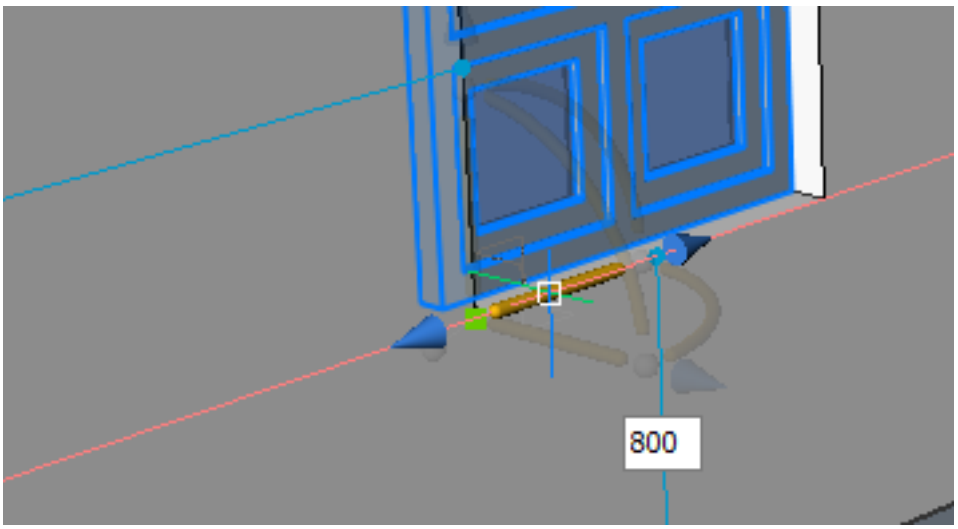

Figure 2.372

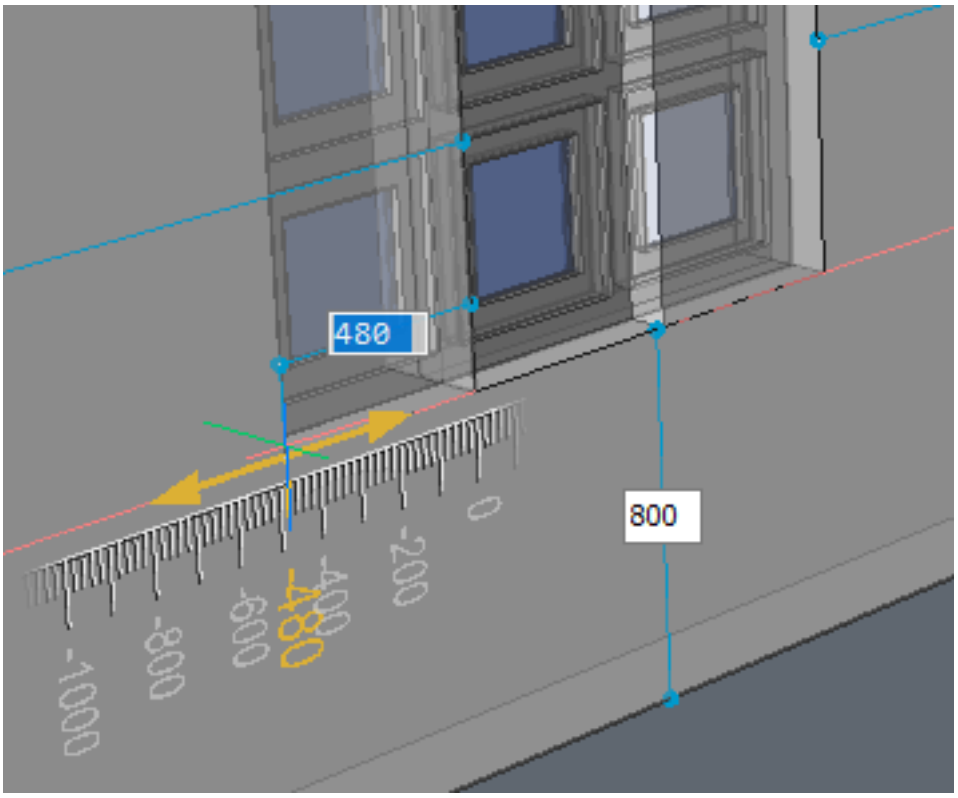

Copying Inserts

Inserting a copy of an insert

1. Hover over the insert. When the insert highlights, choose **Insert BIM Component** in the **Model** command group in the Quad. You are prompted: **Select insertion point or [Edit inserted entity/Rotate component/set Base point/Name/insertion Type/Flip/mUltiple/Change target 3d solids] <0, 0, 0>:**
2. Optionally choose the **Multiple** option to insert multiple copies.
3. Proceed with the Inserting Windows and Doors (2.5.19) procedure from step 2 on.

Copying an insert in a solid The **Copy** tool can be used to place copies of an insert in the same solid. Using the repeat option on the copy tool you can create a series of copies at the same interval. **Note:** The movement vector for the copy should be parallel to the face of the wall. If the orientation of the wall, in which the source window or door is placed, is not parallel to either the X- or Y axis of the current UCS, use the **Face** option of the **UCS** command to align the UCS.

Procedure: Copying an insert on the wall face

Note: Make sure that Dynamic UCS (DUCS) and Dynamic Dimensions (DYN) are active.

1. Select an insert using the BIM Insert tool. **You are prompted:** Select insertion point:
2. Place the insert on the wall face. The insert should align with the wall face.
3. Next, hover over the insert to create a copy of it. When the insert highlights, choose **Copy** in the Modify command group in the Quad. (2.373 on the following page) **You are prompted:** Enter base point [Displacement/mode] <Displacement>:
4. Pick a point in the drawing area. **You are prompted:** Enter second point <Use base point as displacement>.
5. Type a displacement distance from the coordinates of the base point. **Note:** Displacement specifies the distance to position the copy. You can use the dynamic dimension fields (16,17) to specify the displacement. (2.374 on the next page) **You are prompted:** Enter second point [Undo/Repeat/Exit]

Figure 2.373

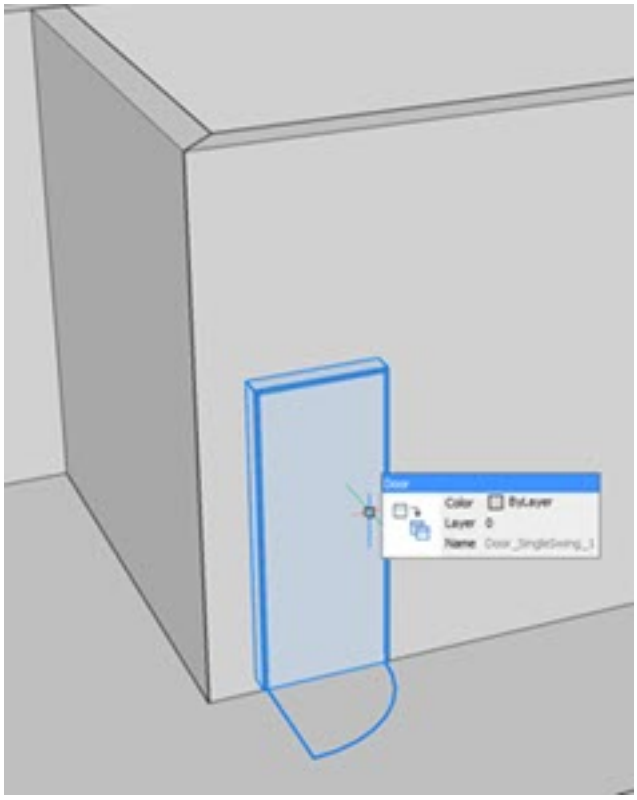

Figure 2.374

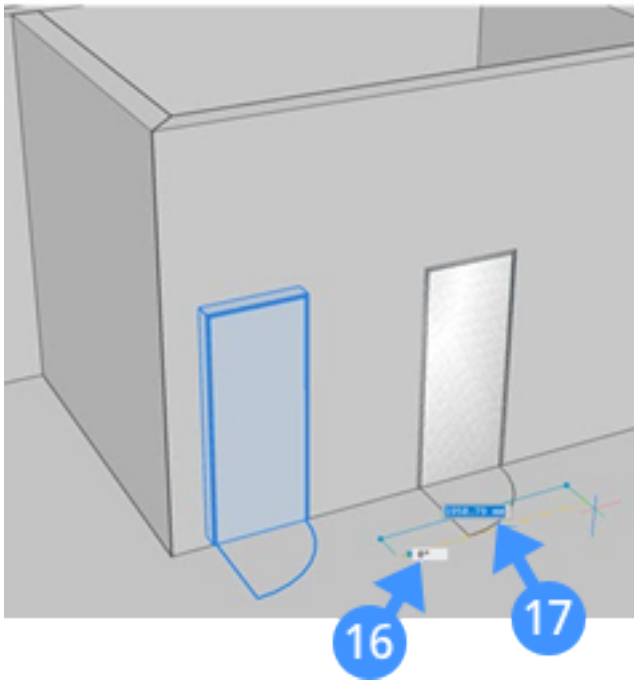


6. Optionally, use the **Repeat** option to create multiple copies of the insert keeping the displacement distance of each copy same.

7. Press Enter to accept the copying.

Replacing an insert

Use the BMREPLACE (6.8.31) command to replace an insert.

2.5.20 Structural Steel

Command: BimApplyProfile (6.7.10), BimLinearSolid (6.7.29), BimStructuralConnect (6.7.61), BimAddEccentricity (6.7.7), BimRecalculateAxis (6.7.51), Drag (6.10.38), BimStretch (6.7.48) **Overview:** In this lesson, you learn how to insert structural steel profiles into your drawing and how to connect them. **Lesson objectives** After completing this lesson, you will be able to:

- Insert profiles into your BIM model
- Apply a profile to an existing line or solid in your model
- Connect different profiles to each other
- Alter the positioning of profiles without losing their connection
- Alter the positioning of the axis of a profile

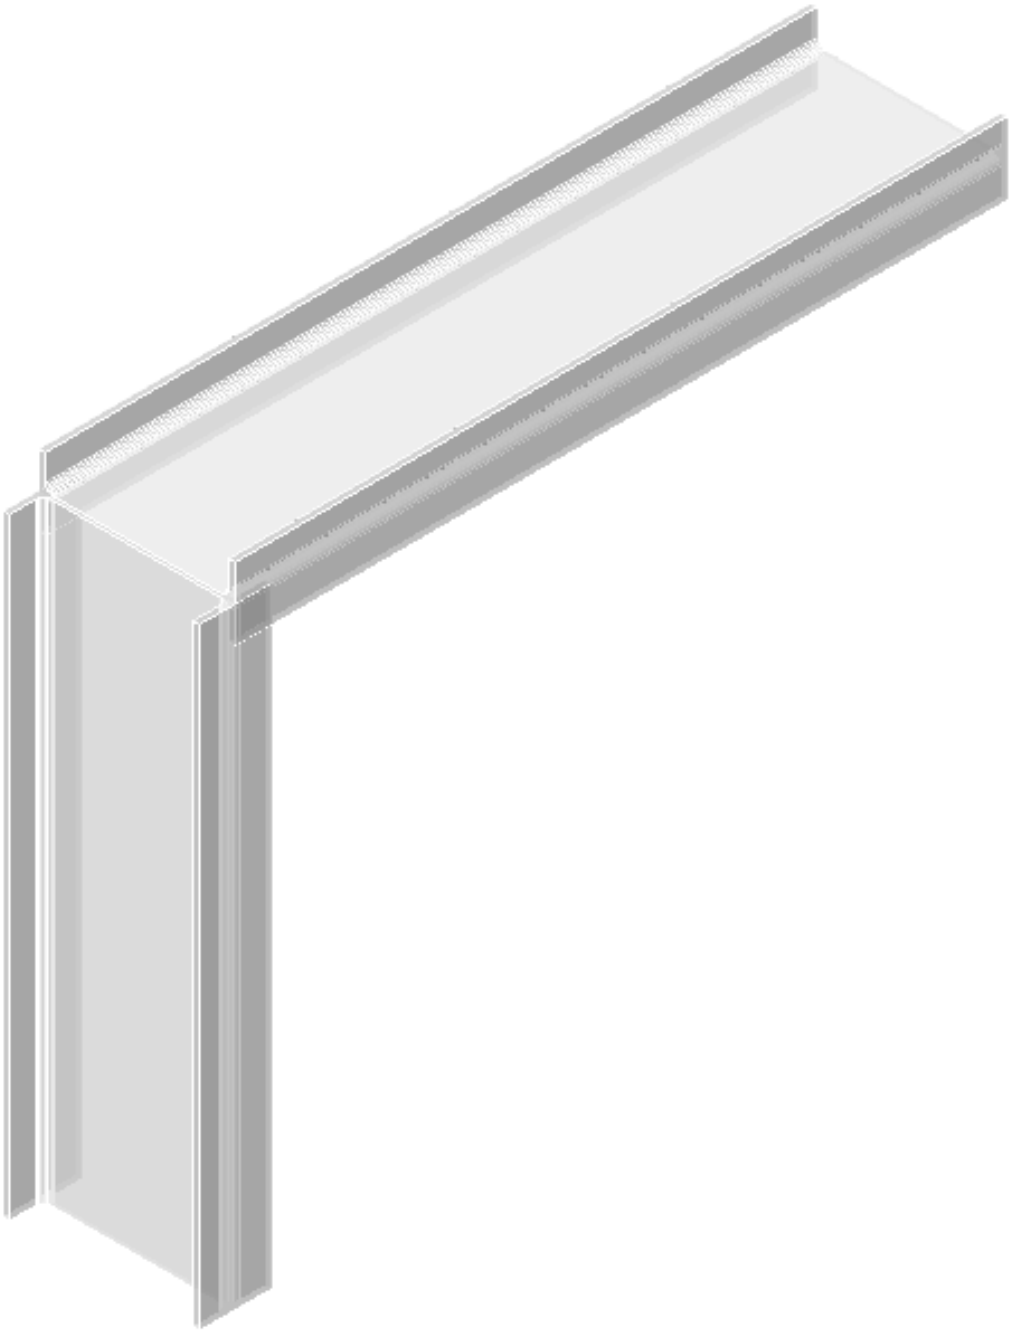
Tutorial: How to use the Structural Steel modeling tools Click here (2.4.21) to watch

How to use the BIM Profiles Panel

1. Drag and drop the desired profile from the BIM Profiles Panel (2.5.1) to the model space. **Note:** This command works in the same way as the Line (6.20.31) command.
2. To define the starting point and the following point(s) click in the model space or use the dynamic dimension fields.
3. Press Enter to end the command.

(2.375 on the following page) **Note**: BricsCAD doesn't automatically generate the connections between the different segments because the chosen profiles are structural steel.

Figure 2.375



About BimStructuralConnect

The **BimStructuralConnect** command automatically generates connections for profiles.  For more information about this command, visit the Command Reference article BimStructuralConnect (6.7.61).

Tutorial: How to connect linear solids Click here (2.4.18) to watch

Making a structural connection to linear solids

1. Select the profiles you want to connect with.
2. Launch the **BimStructuralConnect** command. by typing it in the command bar or select StructuralConnect in the Model tab in the Quad.
3. When the Hot Key Assistant is on (**HKA** on the status bar), a widget (as displayed below) appears on the screen. Tap the CTRL-key to cycle through the different options. (2.376 on the next page) (2.377 on page 1919) (2.378 on page 1920)
4. Press Enter to accept the selected option and end the command.

Figure 2.376

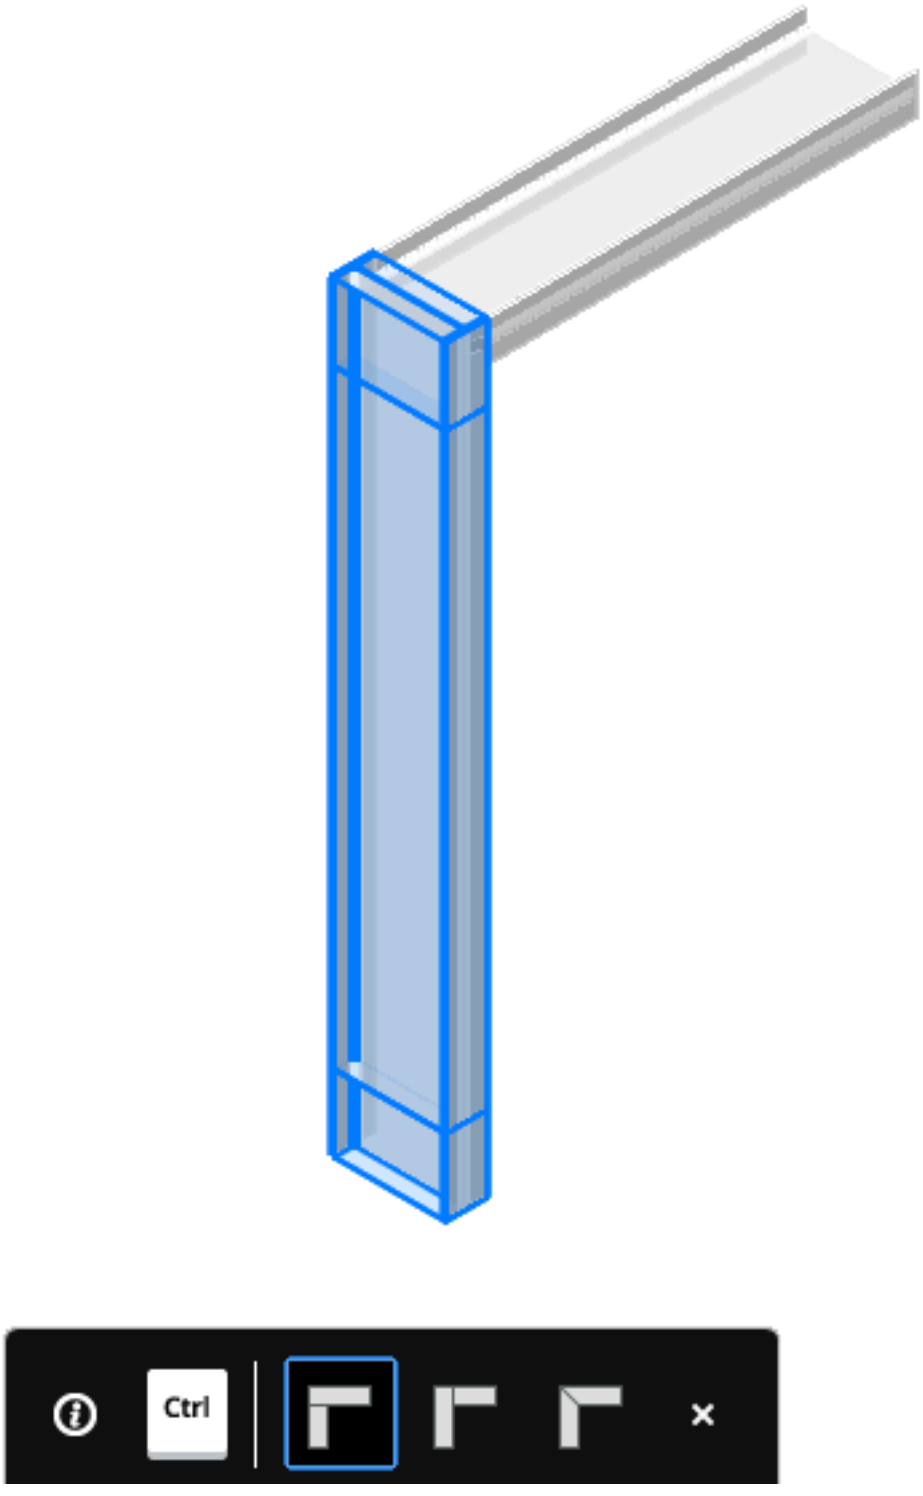


Figure 2.377

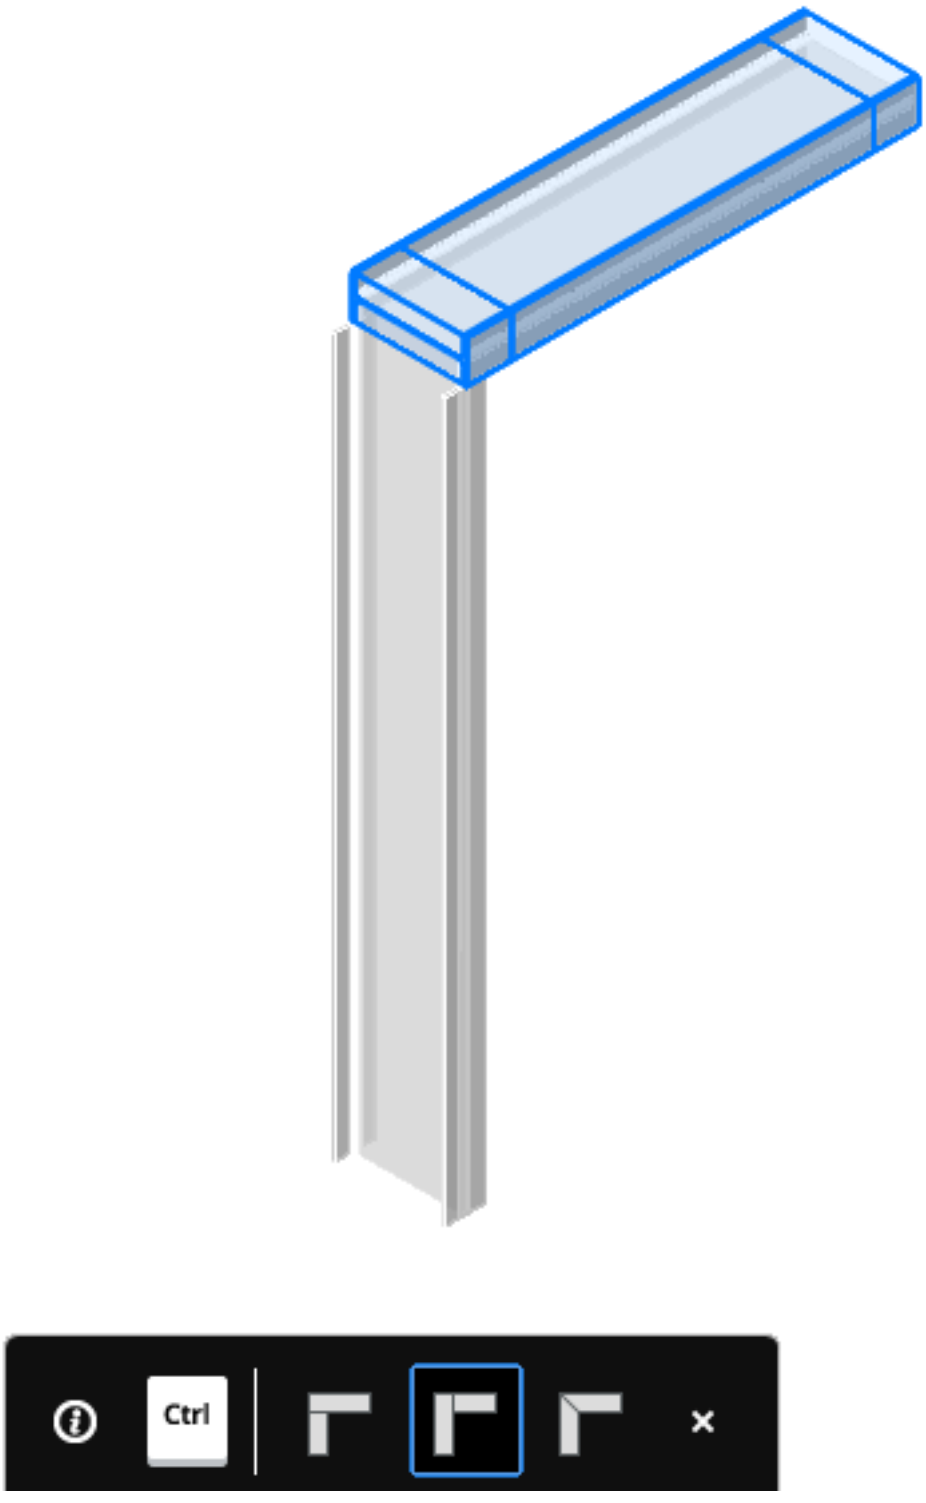

Figure 2.378

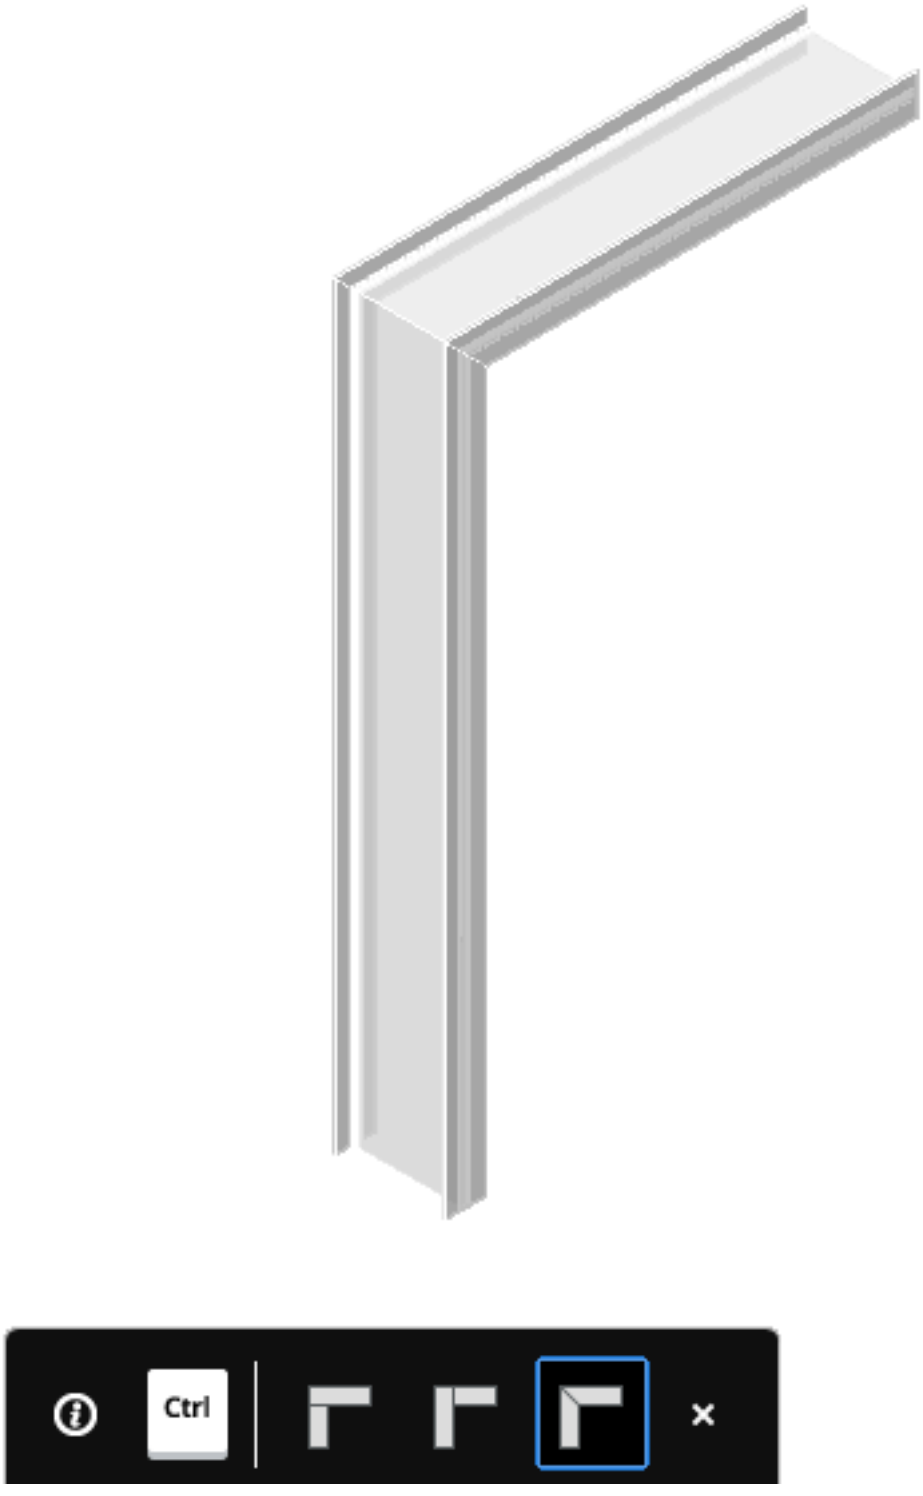

About Drag

The **Drag** command makes it possible to alter a segment of a drawn profile without losing the connection to other segments.  For more information about this command, visit the Command Reference article Drag (6.10.38).

Altering the positioning of segments **Note:** This only works if the connections were created with the BimStructuralConnect (6.7.61) command.

1. Ensure that face detection is toggled on. This can be done by typing **DisplaySidesAndEnds** and pressing 1.
2. Select a face perpendicular to the section of the profile. (2.379 on the following page)
3. Launch the **Drag** command.
4. Click the mouse to set a new position for the segment. Or use the dynamic dimension field to enter a value for the displacement. (2.380 on page 1923)

Figure 2.379

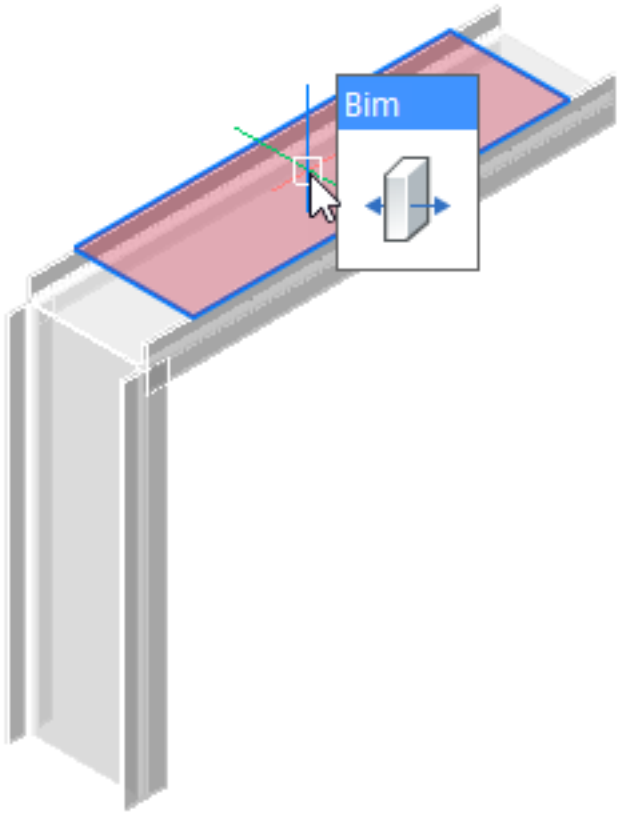

Figure 2.380

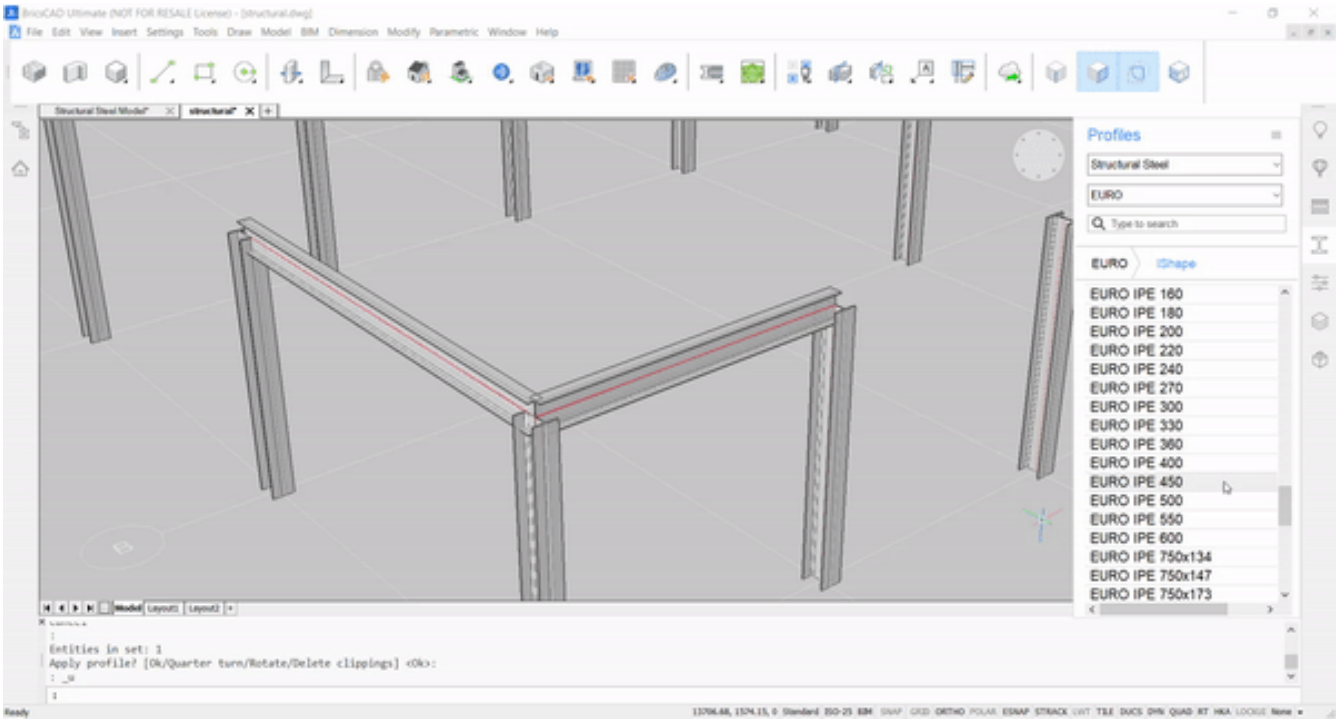

Procedure: Use modeling tools to create a structural steel model

1. Draw a BimGrid (6.7.21) as a base.
2. Launch the **BimGrid** command.
3. Click a starting point and enter values into the dynamic dimension fields.(2.381 on the following page)
4. Draw a base slab underneath the grid.
5. Create a slab using the Box (6.6.18) command.
6. Ensure that the grid is entirely on top of the slab and that the axes of your profiles are displayed. (2.382 on the next page)
7. Go to the **Settings** dialog and under the **BIM > Structural** section. Ensure that **'Display Axes'** is checked. (2.383 on page 1925)
8. Open the Profiles Panel (2.5.1) and drag a structural steel profile into your model. Start drawing at the intersection point of two grid axes and draw vertically upward. **Note:** To snap specific points, make sure you have toggled on the different types of points you want to snap in the context menu when right-clicking on **ESNAP**. (2.384 on page 1927)

9. Launch the Propagate (2.9.2) command.
10. Select the slab as base solid and press Enter.
11. Select the column as your detail element and press Enter. BricsCAD will zoom into the 3D detail. Press **C** to copy the column as a solid, not as a block. **Note:** The default setting for Propagate is to copy the object as a block.
12. Hit Enter. **Note:** BricsCAD automatically copies the beam to every grid intersection. This is because you chose the floor slab with a BimGrid as your base solid.
13. Hover over the green checkmark and click BimGrid in the dialog box. (2.385 on the facing page)
14. Click Explode (6.13.16). You can now manually toggle individual suggestions to create the pattern of your choice.
15. Press Enter to accept and end the command. (2.386 on page 1928)

Figure 2.384

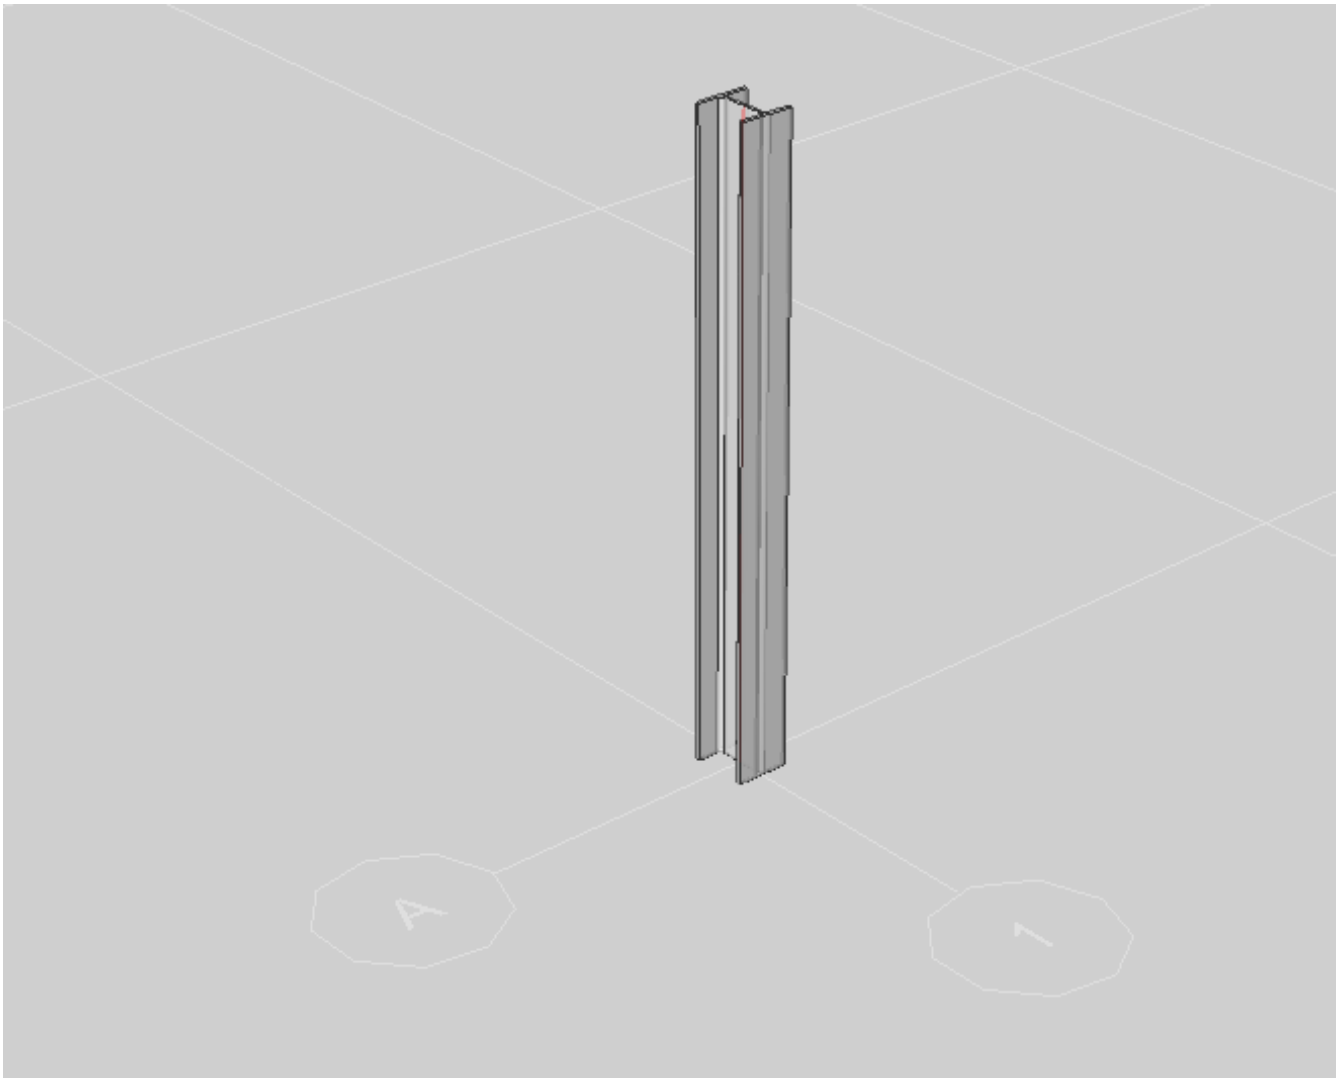

Figure 2.385

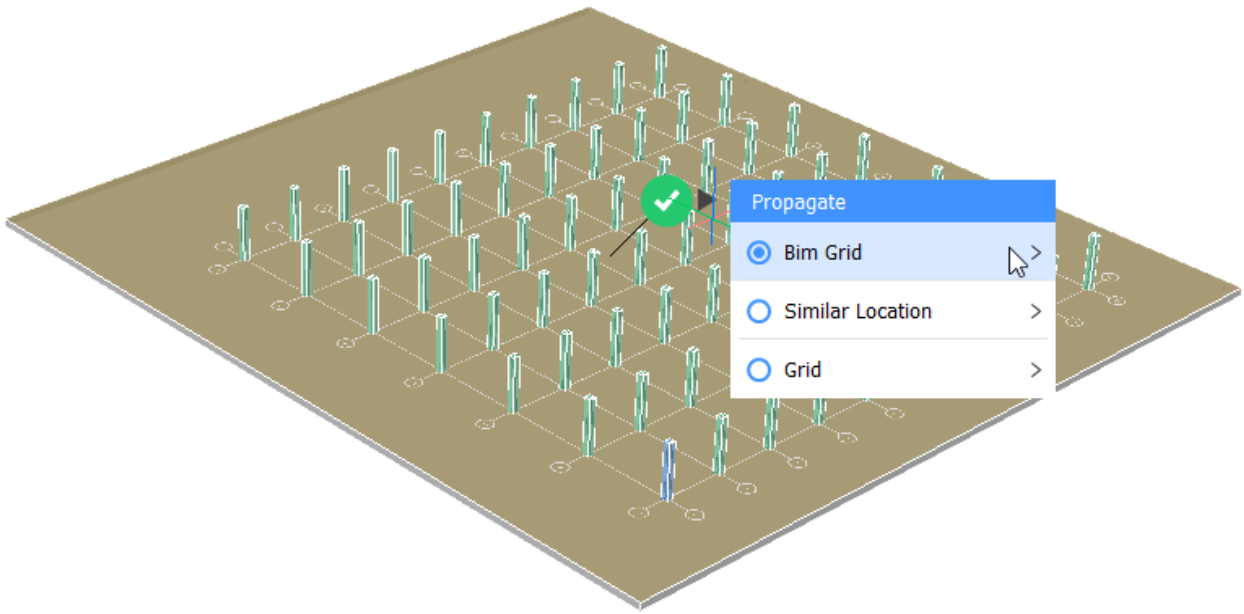

Figure 2.386

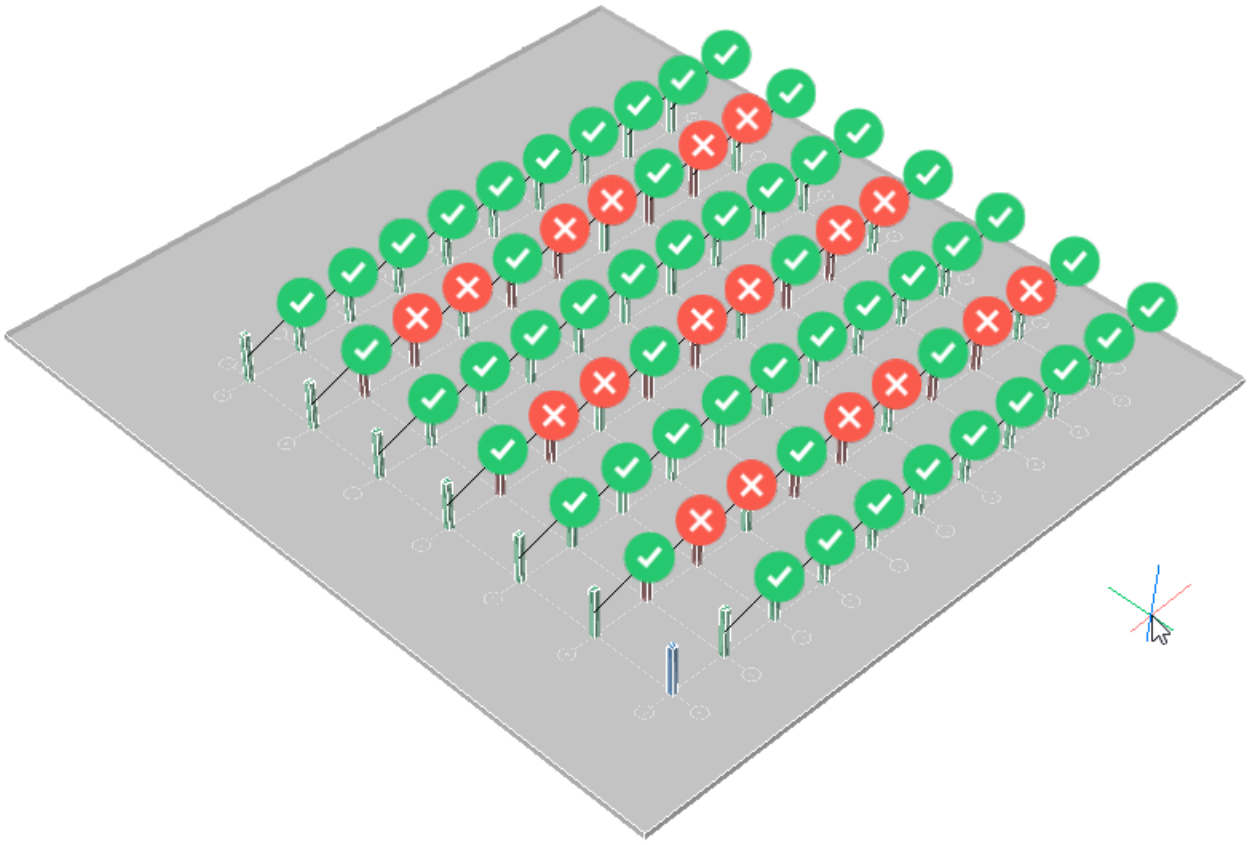

Create beams between the columns.

1. Open the Profiles Panel (2.5.1) and drag a structural steel profile into your model. To set the start and endpoints, click the top of the column and then the next. Do this in both directions. **Note**: if you want to turn your profiles to make the flanges are facing upwards, press **Q** (from Quarter turn). The profile will turn 90 degrees around its axis. (2.387 on the facing page)
2. Drag and drop a beam profile from the Profiles Panel onto this beam. Give the second beam a large profile, as it has a longer span. (2.388 on page 1930)
3. Select a beam and launch the BimAddEccentricity (6.7.7) command to alter the relative position of the axes of the beams. (2.389 on page 1931)
4. Click the down arrow. The beam moves down in relation to its axis.
5. Press Enter to end the command.
6. Repeat steps 3-5 for the other beam.
7. Select the column and the two beams then launch the BimStructuralConnect (6.7.61) command to make a simple connection. Press Enter to accept the default option. (2.390 on page 1932)
8. Repeat step 7 for the other 2 junctions.
9. Select the two columns connected to the beam in the Y-direction and launch the Propagate (2.9.2) command.
10. Select the beam in the Y-direction as the detail solid.
11. Press **C** to copy it as a solid, not as a block.
12. Press Enter.
13. Choose which suggestions to accept. Hit Enter to accept and finish the command. **Note:** Suggestions are made at the bottom of every column because the situation is symmetrical. You can toggle the suggestions off.

Figure 2.387

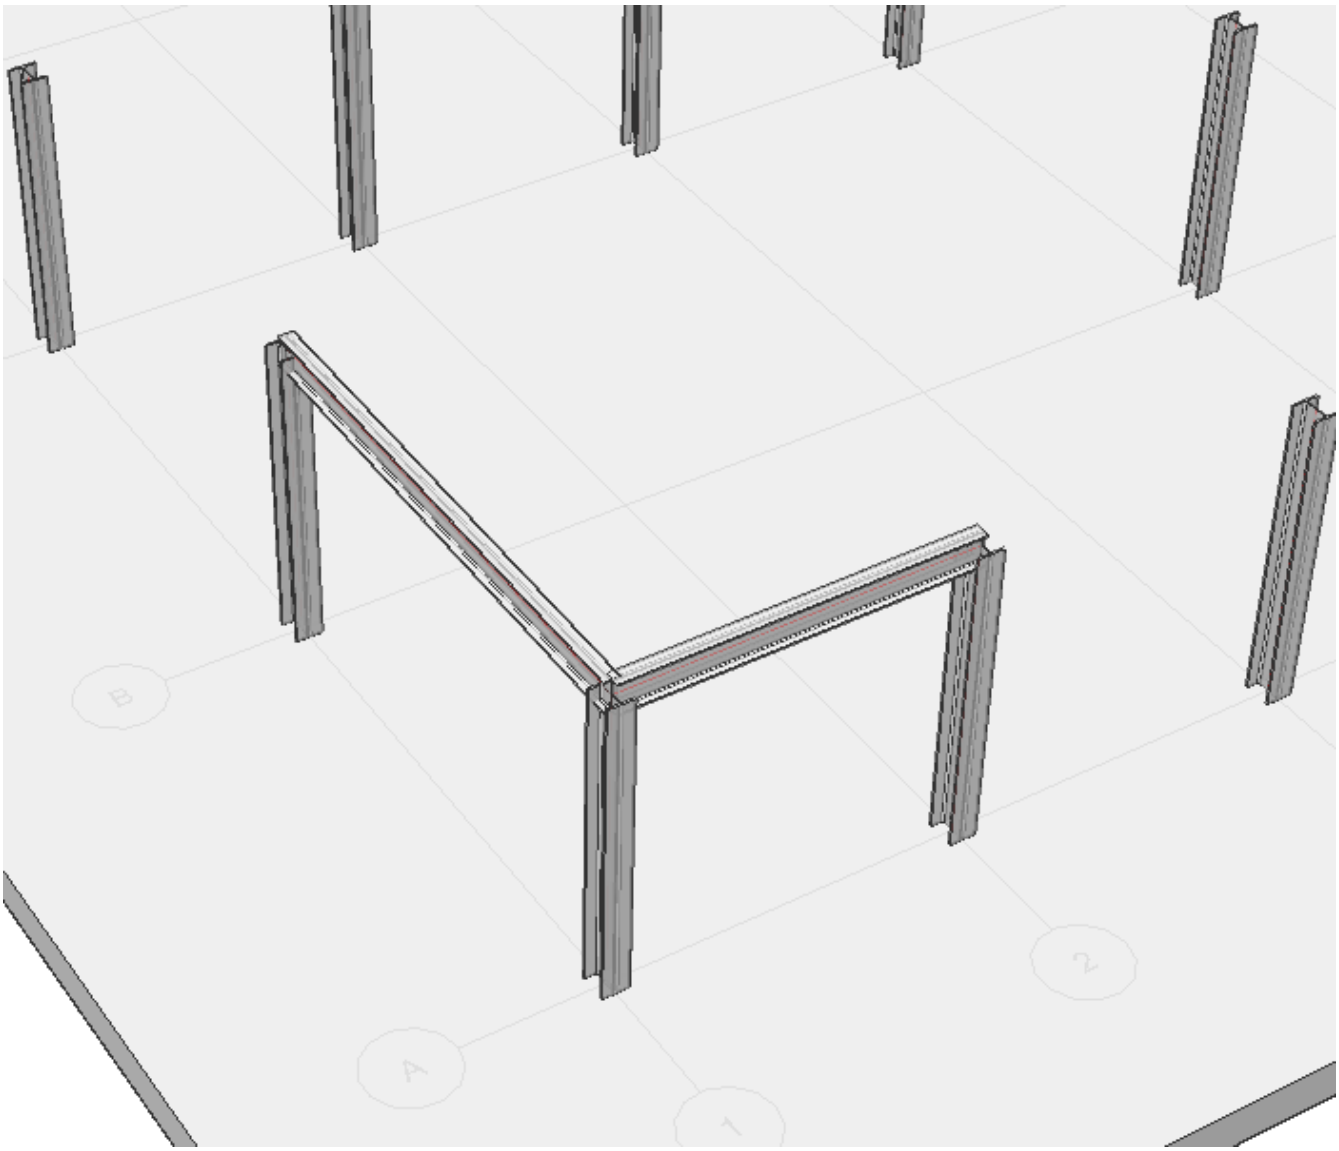

Figure 2.388

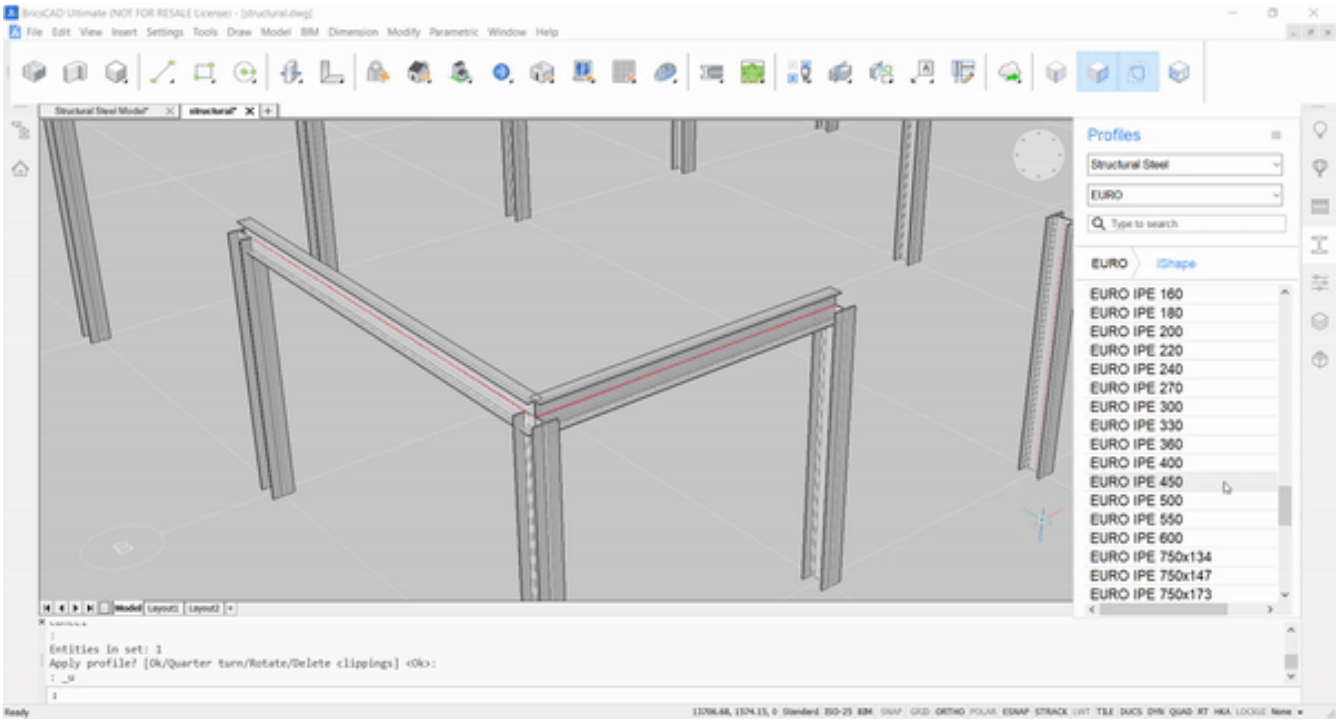

14. Repeat steps 9 - 13 to create beams on the X-direction. **Note:** You can use box selections to select all the lower beams at once.

Figure 2.389

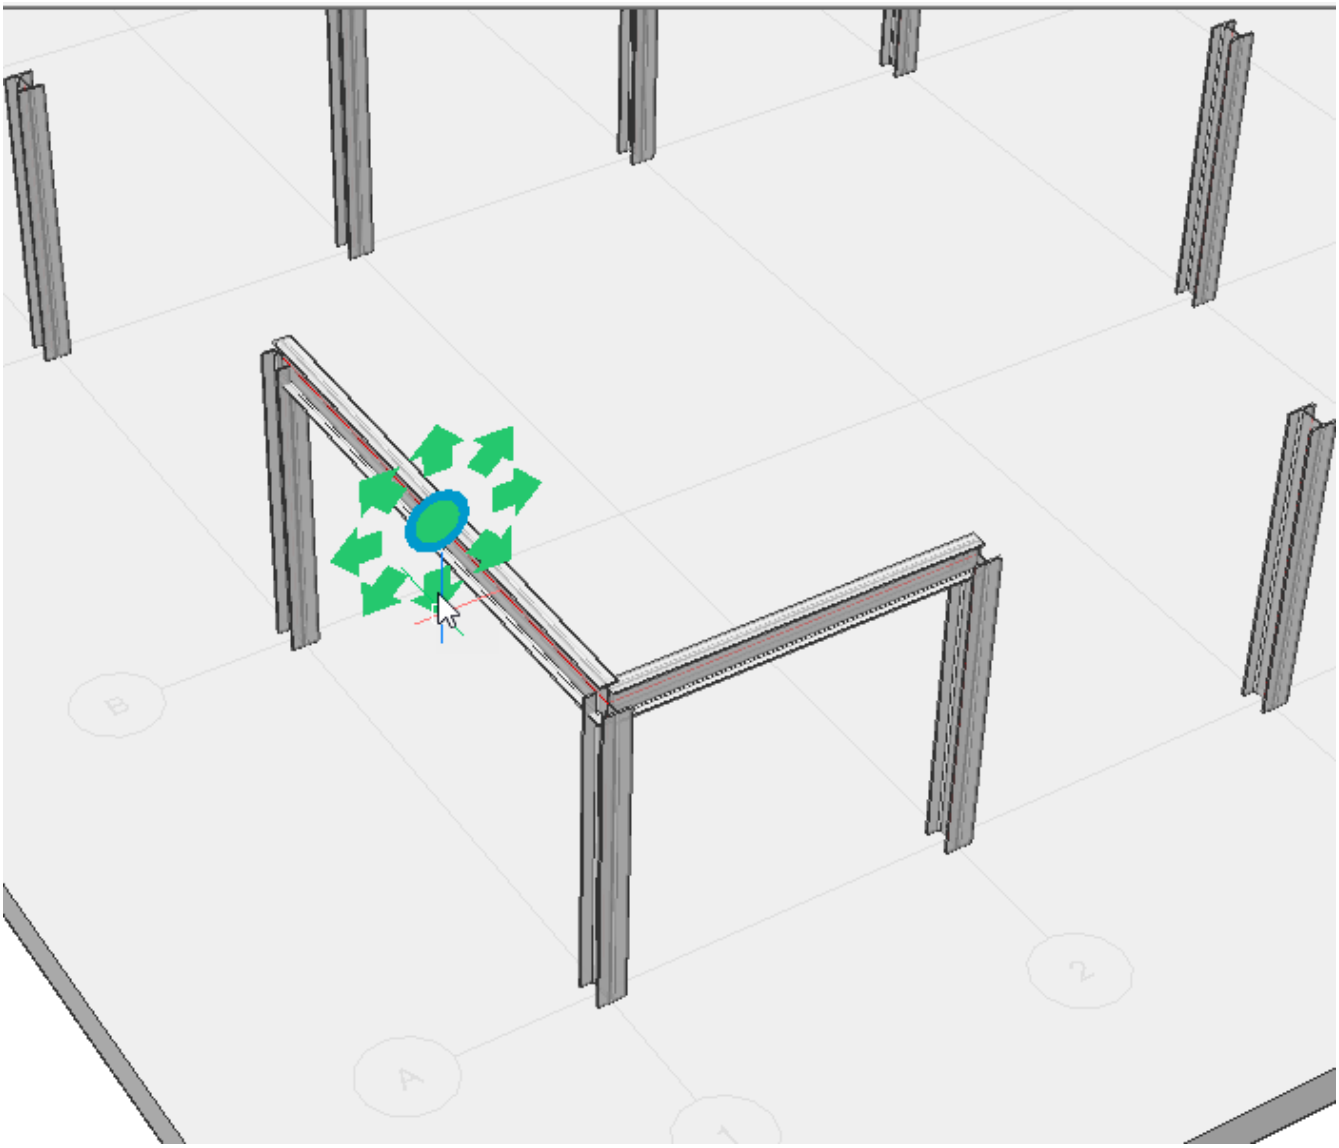

Figure 2.390

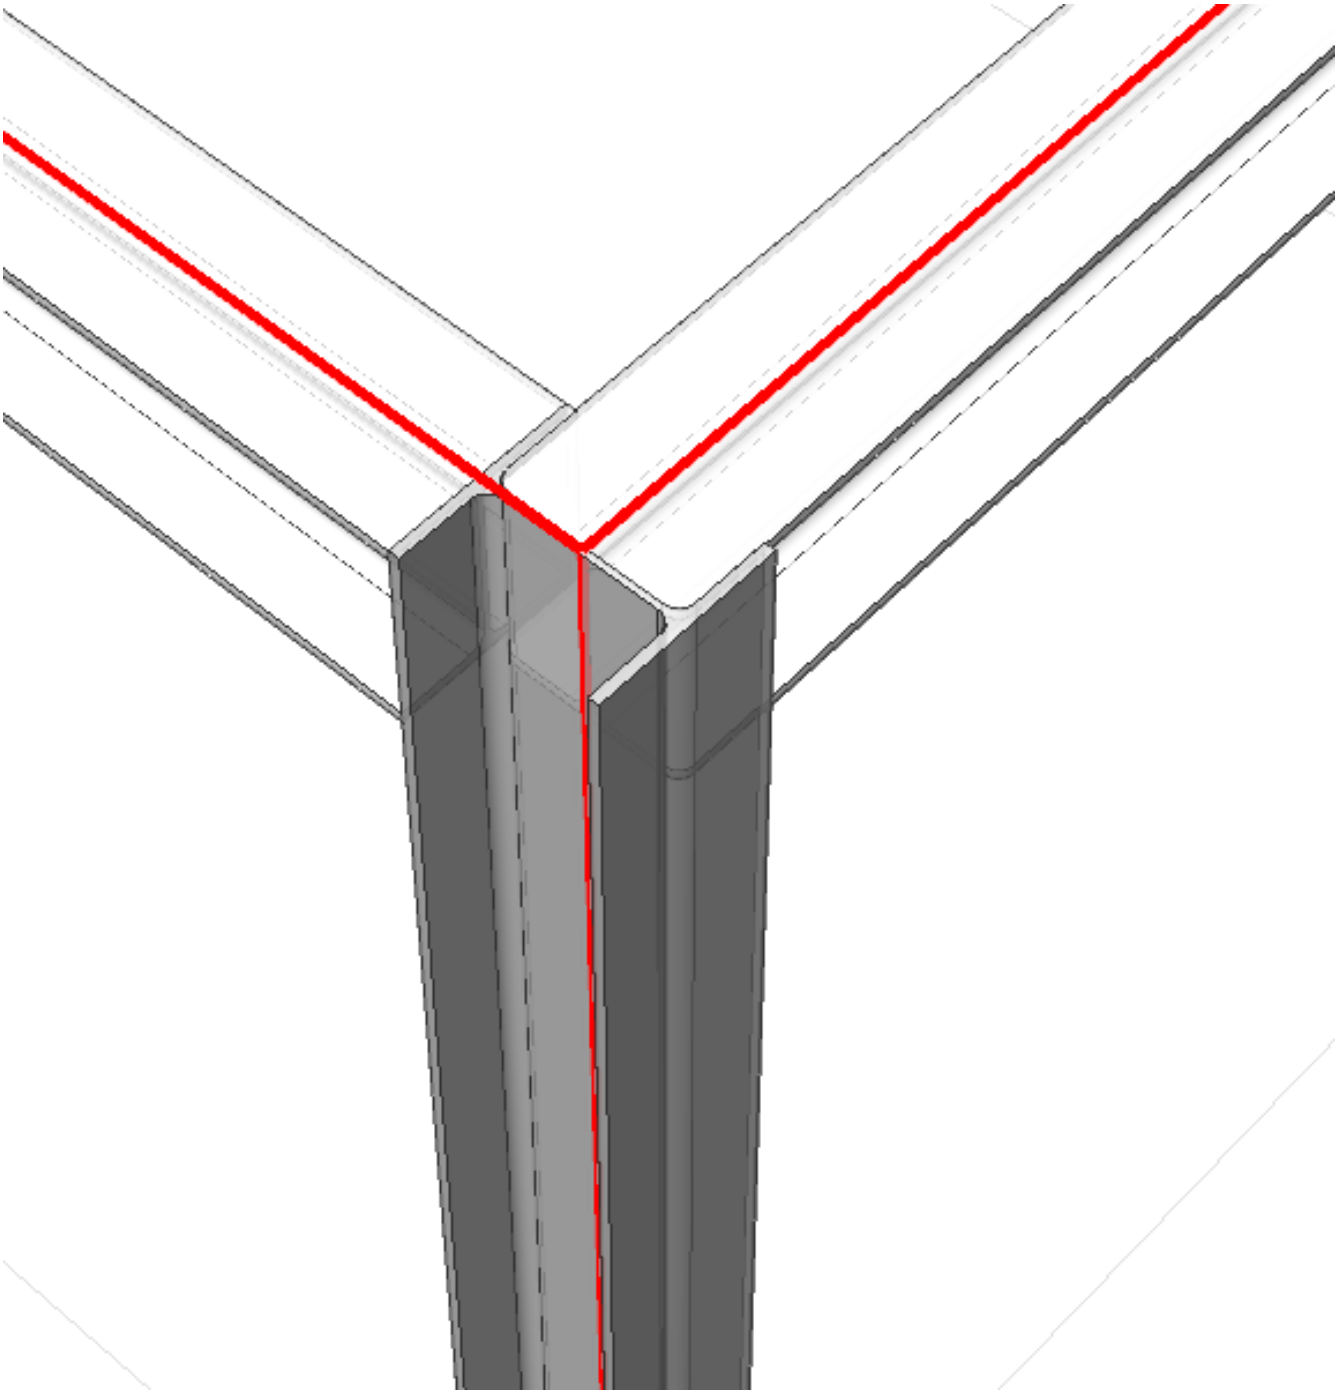

Move a Beam

1. Ensure that face detection is toggled on. This can be done by typing **DisplaySidesAndEnds** in the commandline and pressing 1.
2. Highlight the side face of the desired column and launch the Drag (6.10.38) command. (2.391 on the following page)
3. Move the column to the desired position. (2.392 on page 1935) **Note:** The connections with the adjoining beams are maintained.

Figure 2.391

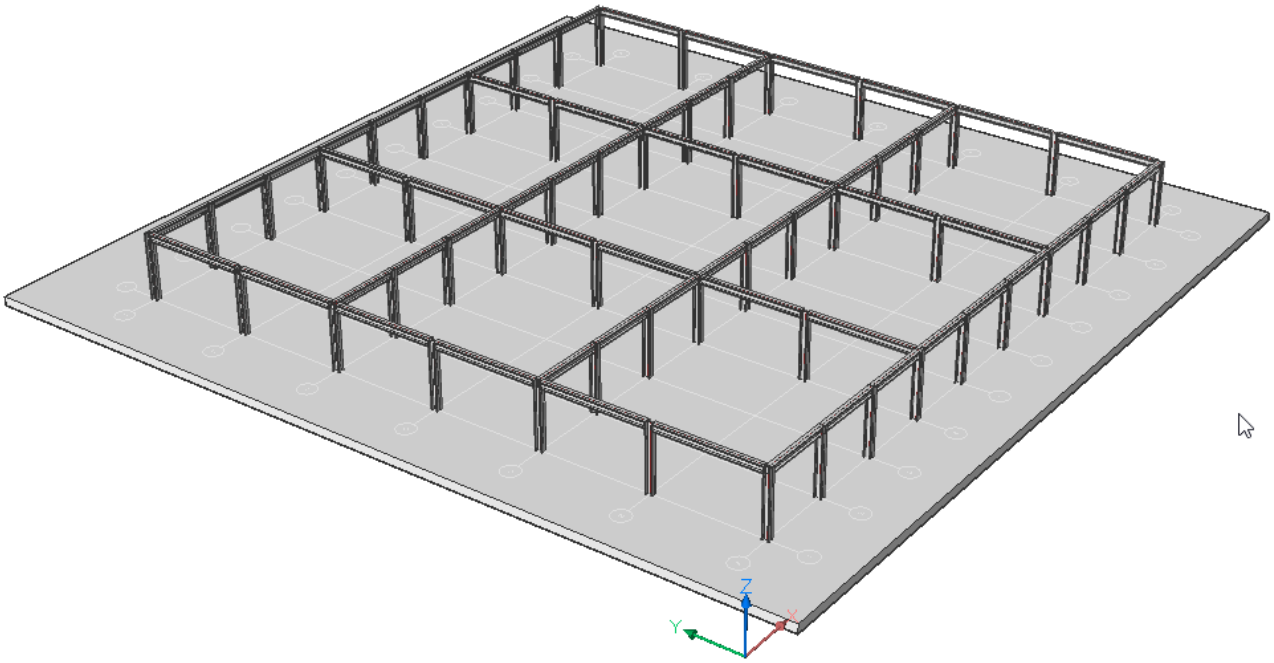

Figure 2.392

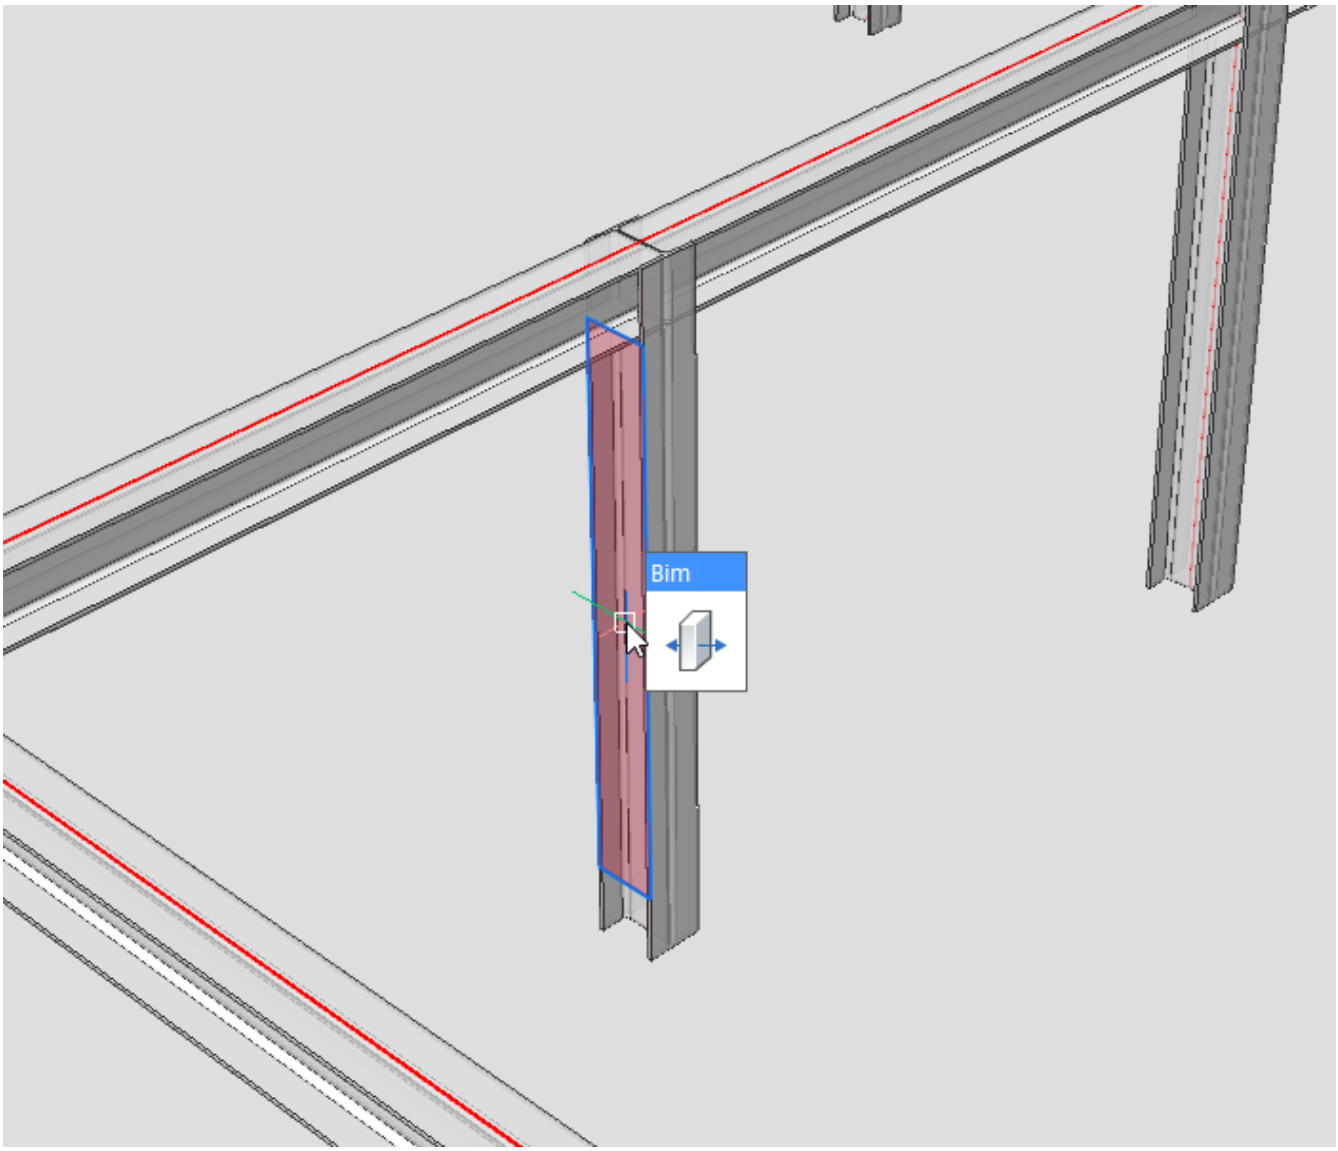
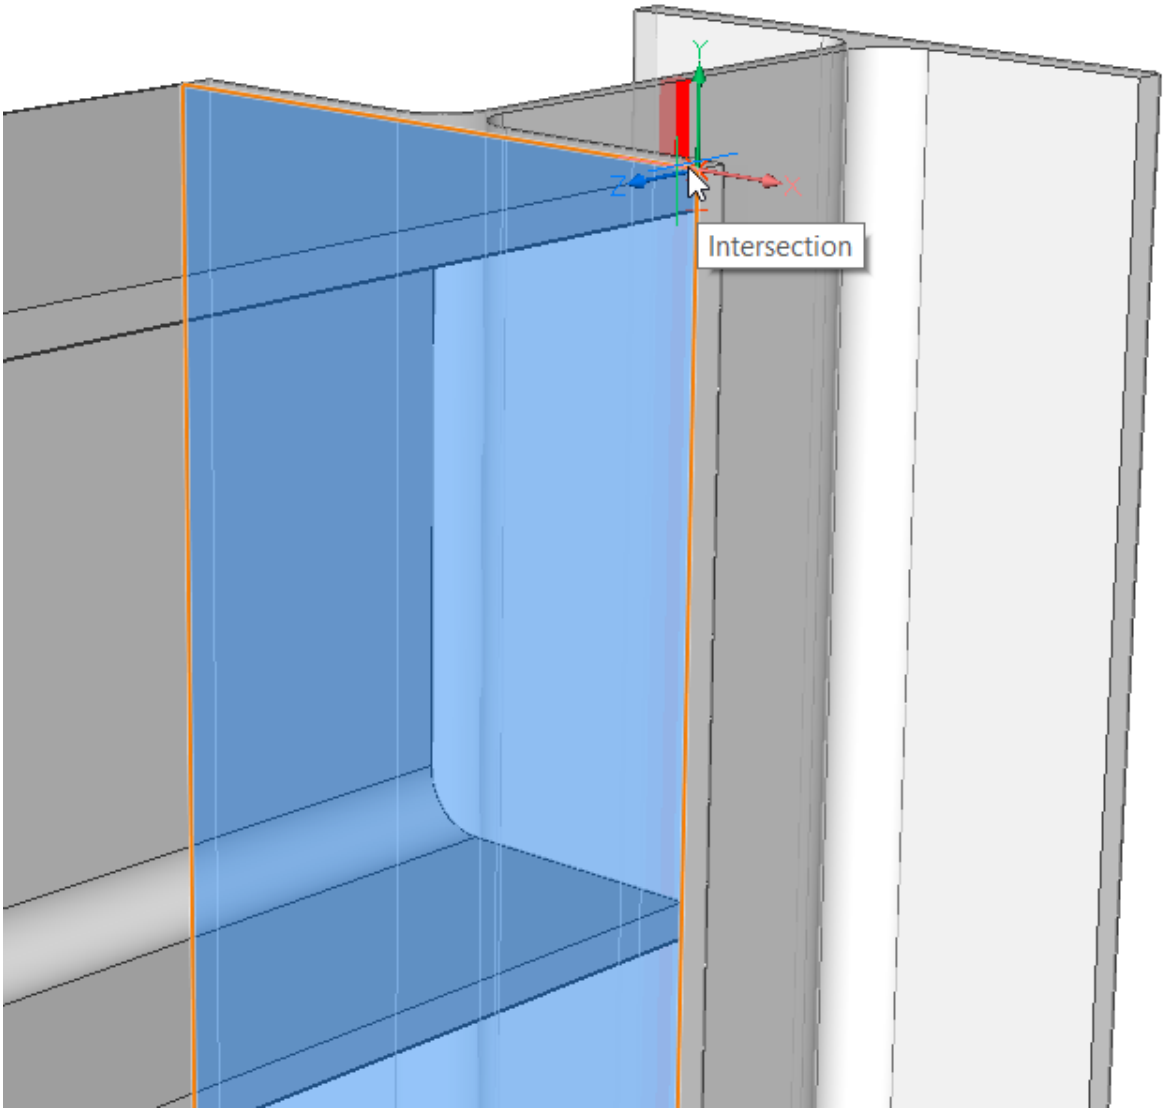


Procedure: Use the modeling tools to create a more detailed connection

1. Make sure face detection is toggled off. This can be done by typing **DisplaySidesAndEnds** and pressing 0.
2. Launch the **Box** command and hover over the side face of the column.
3. Press Shift once so that the face is highlighted in blue. (2.393 on the facing page)
4. Now draw a plate on the flange of the column. (2.394 on page 1939)

Figure 2.393



5. Select the beam and launch the Subtract (6.27.58) command.
6. Select the endplate and press Enter. (2.395 on page 1940)
7. Select the face and launch the Bimify (2.9.1) command from the Quad. **Note:** You can also Classify the plate manually by Quadselecting **Classify Manually** in the Bim tab.
8. Open the **Library Panel** and drag a bolt onto the plate. **Note:** You can position it precisely by entering values in the dynamic dimension fields.(2.396 on page 1941)
9. Select the plate and launch the **Propagate** command.
10. Select the bolt as the detail and press Enter.
11. Press Enter again and click on the blue question mark. It will turn into a green checkmark.
12. Hover over the checkmark and select Grid. (2.397 on page 1942)
13. Add one row.
14. Press Enter to end the command. (2.398 on page 1943) The detailed connection has now been created. (2.399 on page 1944)

Procedure: Using BimStretch to modify structural steel

1. Open a **New drawing**.
2. Open the Profiles Panel (2.5.1) by clicking on it on the right-hand side of your screen. **Note:** If the Profiles Panel icon isn't visible yet, right-click on the ribbon and check Profiles in the context menu under
3. Drag the profile you want to draw a structure with within the model space.
4. Draw a column with a height of **3000 mm**. Don't exit the command and draw a connecting beam with a length of **5000 mm** horizontally. Now, add another column at the end of the beam. The height of this column is also 3000 mm. **Note**: Make sure you turned the profiles in the right way. (2.400 on the next page)
5. Select the 3 beams and select Connect Structural in the ribbon or select the command from the Quad. You will be able to choose which connection you prefer. Choose the L-connection option and press enter. Your entities are now connected. (2.401 on the following page)
6. In the ribbon, make sure you enable the '**Display sides and ends'** and **'Prioritize selection of Faces'** You can find them in the Structural/MEP tab.
7. Check if the profiles are correctly classified as Beam and Columns.
8. Launch the Multislice (6.27.40) command and slice the beam in the middle**. You will be prompted: Slice along axis?** Press Enter to accept the default option (Yes).
9. Select the midpoint of the beam and press Enter. Your beam is now sliced into two beams. (2.402 on page 1947)
10. Select the 2 ends of the beams in the middle of the structure. They will be highlighted in yellow. (2.403 on page 1947)
11. Quad select the BimStretch (6.7.48) command in the model tab. (2.404 on page 1948)

Figure 2.400

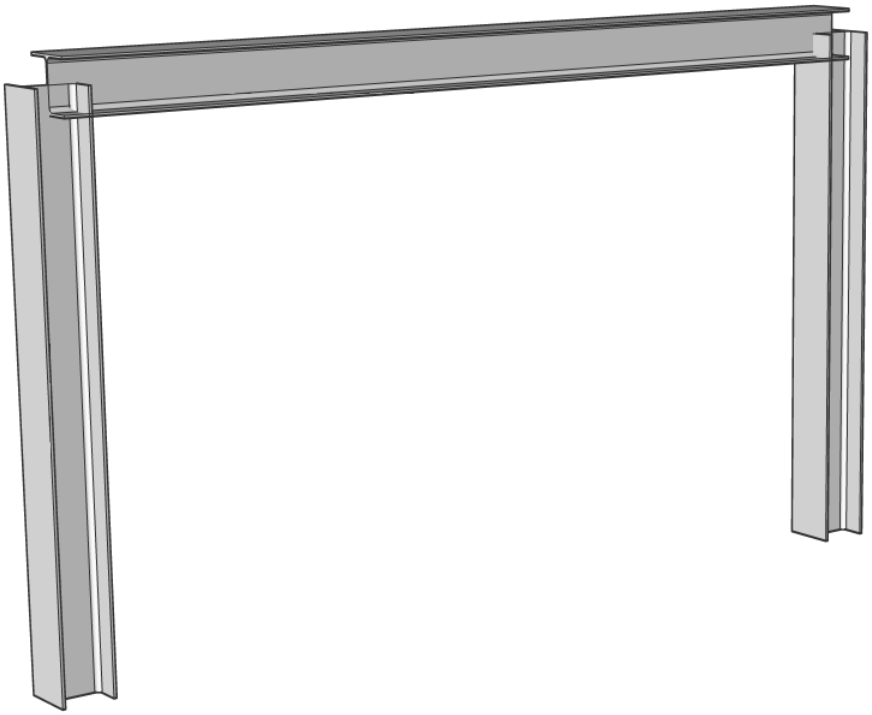

Figure 2.401

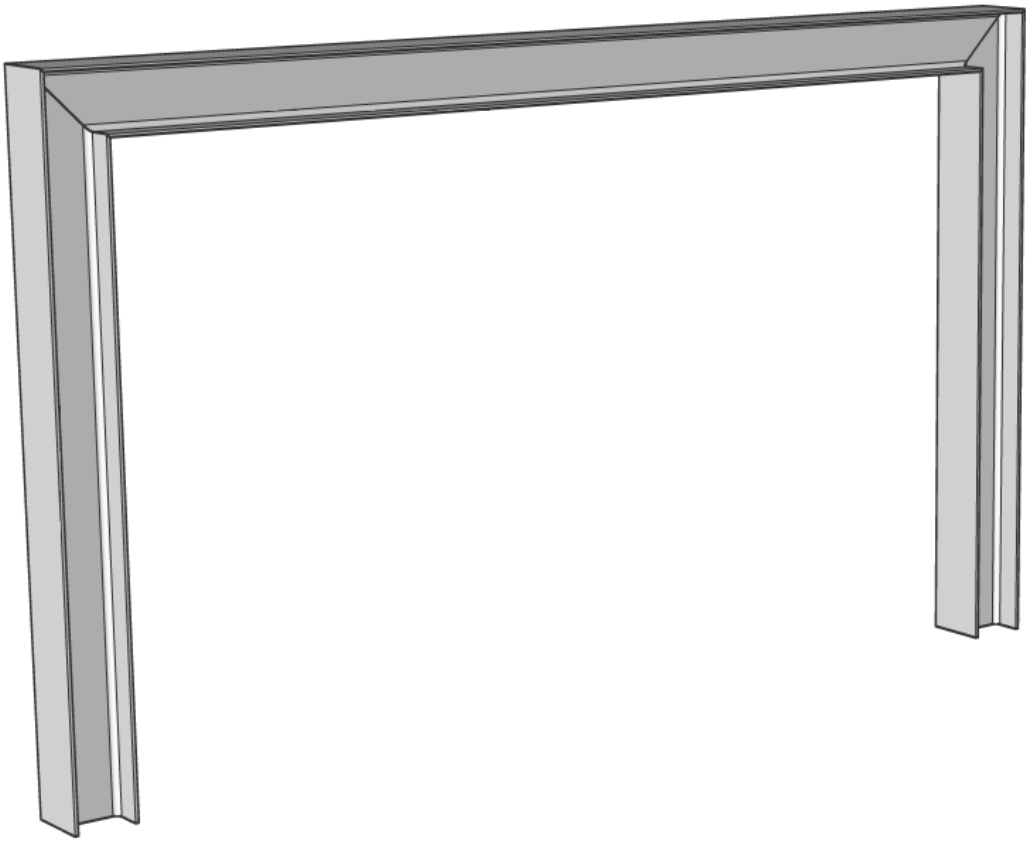

Figure 2.402

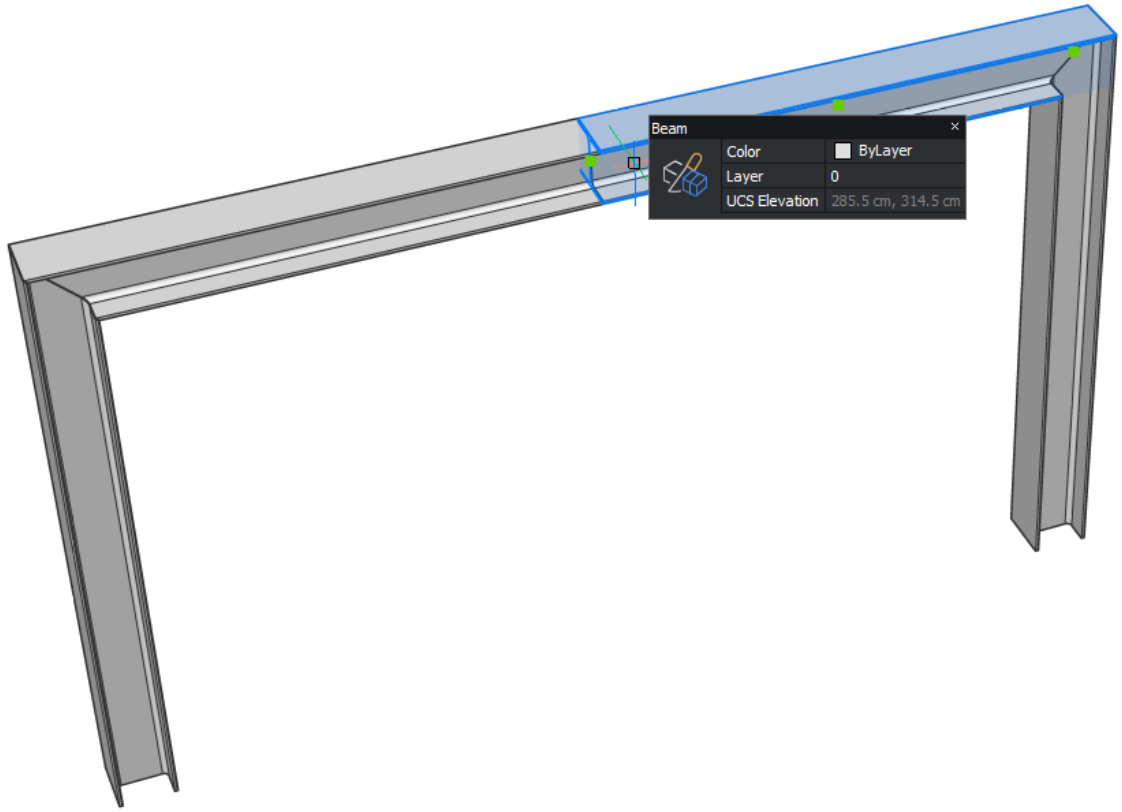

Figure 2.403

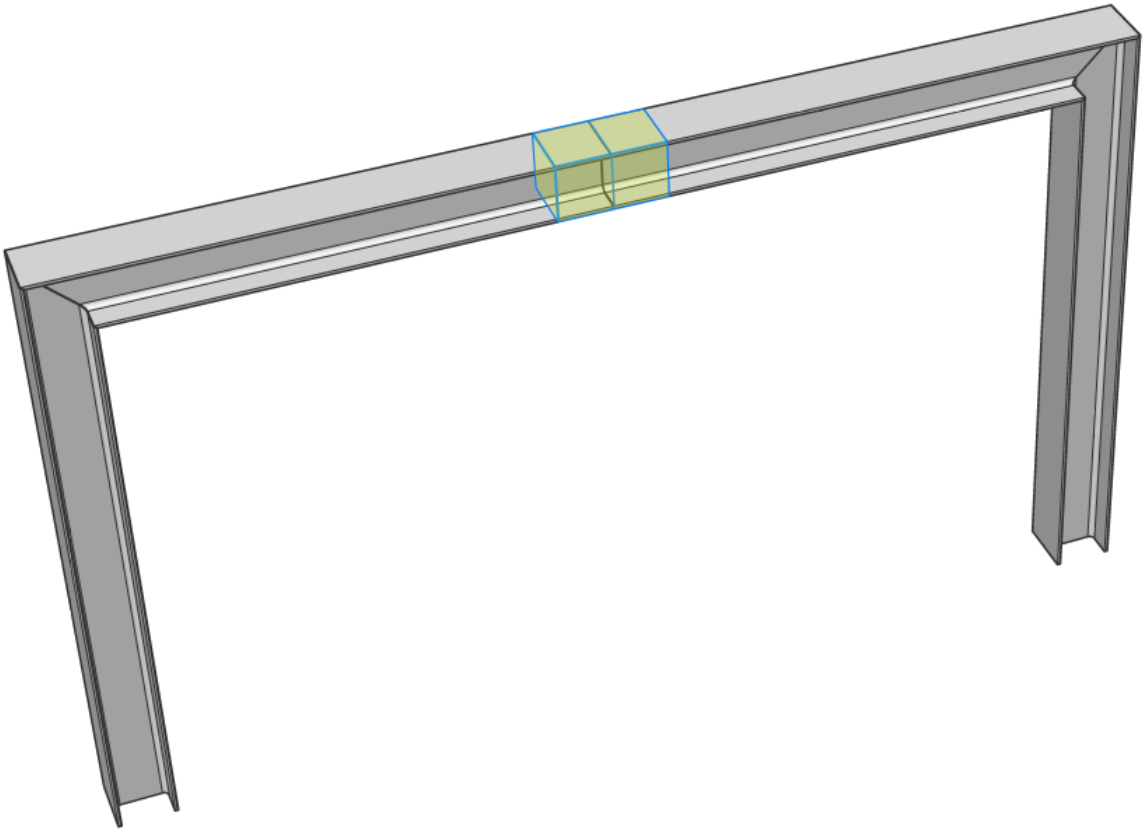

12. Hover orthogonally upwards, enter a height of **2000 mm** and press **Enter** to accept.
13. The result should look like this. (2.405 on the facing page) As you can see, the connections between the profiles are automatically adapted to the new angle between the entities. **Note:** If you would only have selected one of the two side-ends in the middle of the beam, the connections on the side that was not selected won't be included in the stretch and will look like this: (2.406 on page 1950)

Figure 2.404

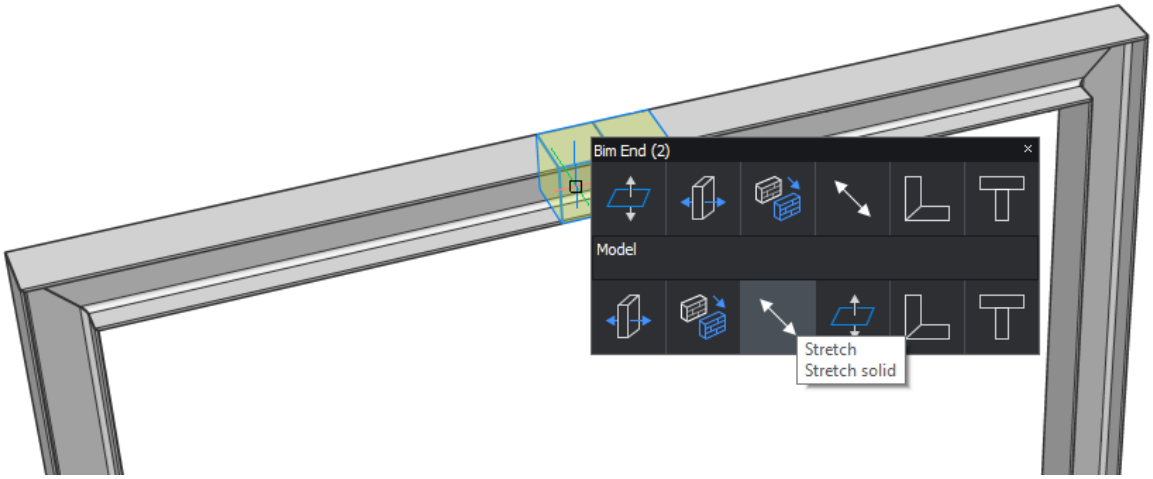

Figure 2.405
