2.5.21 Using Parametrize

Command: Parametrize, (6.24.7) ParametersPanelOpen (6.24.10) **Overview:** In this lesson, you learn how to automatically parametrize pure geometric models using the Parametrize tool. **Lesson Objectives:** After completing this lesson, you will be able to:

- Use Parametrize to automatically parametrize pure geometric models.

Tutorial: How to automatically Parametrize objects Click here (2.4.17) to watch

About

Parametrizing is a process that automatically adds constraints and parameters to a set of 3D solids, without any manual work. For each unique value, a specific parameter is created. The constraints and parameters are represented by their name and expression in the Mechanical Browser. Each parameter can be animated to show what the parameters correspond to in the model. The parametrized geometry becomes controllable in terms of shape and size. When one of the parameters is changed, the geometric model will be updated automatically.

Procedure: Parametrizing a component automatically

1. Open the geometric model that represents your component. (2.407 on the following page) **Figure 1, a geometric model of the sample chair**
2. Open the Mechanical Browser clicking its icon in the Toolbar Panel. **Note:** If the Browser icon is not displayed in the Toolbar Panel, place the cursor on a toolbar, then right-click and choose Mechanical Browser (1) in the context menu. (2.408 on page 1953) If the model does not contain any parameters and constraints it will display only the 3D solids under the Bodies (2) section. If the model contains any constraint or parameter, the parameterized tool asks whether you want to reuse the existing ones (2.409 on page 1954)
3. Launch the Parametrize tool in the Constraints tab from the Quad. **Or** type PARAMETRIZE in the command line. **You are prompted: Select entities to auto constrain:**
4. Select the component geometry you want to parametrize, and press Enter. (2.410 on page 1955) **Figure 2, selected object** A set of parameters and constraints are defined automatically. These parameters and constraints are shown in the Mechanical Browser (3 and 4). (2.411 on page 1956) **Note:** Parametrize creates Distance, Radius, Rigid Sets, Fix, Coincidence, Concentric constraints (2.5.24) depending on the geometric model. **Note:** Perpendicularity and tangency can be set (if they are applicable) by changing the DmRecognize (1.26.3) system variable in the Settings dialog.
5. To check easily which parameter corresponds to what, right-click one of the parameters, and choose Animate (5) in the context menu. (2.412 on page 1957) **Note:** In the attached .dwg file after parametrizing the chair geometry, parameters and constraints will be assigned and shown in the Mechanical Browser. Each parameter corresponds to one measurement in the chair geometry. For instance, Length_X_Y controls the width and depth, Length_Z controls the overall height, p_1 controls the seat thickness p_2 controls the leg thickness ratio_1 controls the ratio between seat height and overall height.

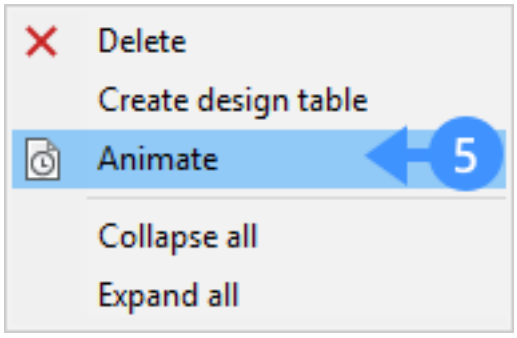
Figure 2.412



Procedure: Changing the parameters and constraints in the parameters manager

Note: After the auto parametrizing, it's possible to change what you do not find clear about the parameters and constraints using the parameters manager.

1. Select one of the faces (6) of your component. The constraint type (e.g. distance, fix) regarding the face is displayed. (2.413 on the following page)
2. Click the distance constraint (7) icon on the element. The editable dimension(s) is shown inside the box.
3. Click the editable dimension box (8). (2.414 on page 1959) A parameter manager displays (9). The parameter manager shows the expressions of the distance constraint (10) and the parameter (11) depending on the selected face. (2.415 on page 1960)
4. Change the parameter name by clicking its field (12) in the parameters manager. (2.416 on page 1961)

5. **Optional** a new parameter can be defined using the New option in the parameter manager's context menu.
6. To do so, right-click the parameters manager and select **New** (13).
7. A new parameter is added to the list (14). (2.417 on the following page) (2.418 on the next page)
8. Specify a name (15) for the newly created parameter and enter an expression using the expression field (16). (2.419 on the following page)
9. To link the newly created parameter with an existing constraint, change the expression field of the constraint with the new parameter name (17). (2.420 on the next page) **Note:** The above procedure can also be done using the Mechanical Browser (3.3.2).

2.5.22 Using BIM Quickdraw

Command: BimQuickDraw (6.7.41) **Overview:** In this lesson, you will learn how to use the QuickDraw tool to easily create and edit, rectangular and L-shaped rooms and buildings. **Lesson Objectives** After completing this lesson, you will be able to:

- Use the magnetic snapping feature.
- Define the room height, wall width, and slab thickness.
- Align the rooms with existing walls.
- Make a story
- Make a flat roof

Tutorial: How to use Quickdraw Click here (2.4.26) to watch

About

The Quickdraw tool allows you to get started with conceptual modeling easily. It also automatically adds BIM data. You can use the Quickdraw tool to create a room or a whole building. Once in use, Quickdraw will remain active until you explicitly exit the command or until another command is executed.  For more information about this command, visit the Command Reference article BimQuickDraw (6.7.41).

The magnetic snapping feature

With the magnetic snapping feature, you can easily align the QuickDraw cursor. When the command is active, move the cursor close to the object you want to align to. The QuickDraw cursor automatically snaps to the object. You have the following options: **1. Align to the origin**
(2.437 on page 1976) **2. Align to existing walls** To the wall itself (2.438 on page 1977) To the extents of the wall (2.439 on page 1978) **3. Align to lines** To grid lines (2.440 on page 1979) (2.441 on page 1980) **Note**: If you use Quickdraw to copy a story, the gridlines will only be copied if the grid is assigned to the same spatial location of the ground floor slab and walls. If this is not the case, the gridlines that lie in the boundary of the ground slab will be projected on the slab of the top floor. This is only a visual help. The gridlines on the slab of the top floor will disappear when you exit the Quickdraw command.

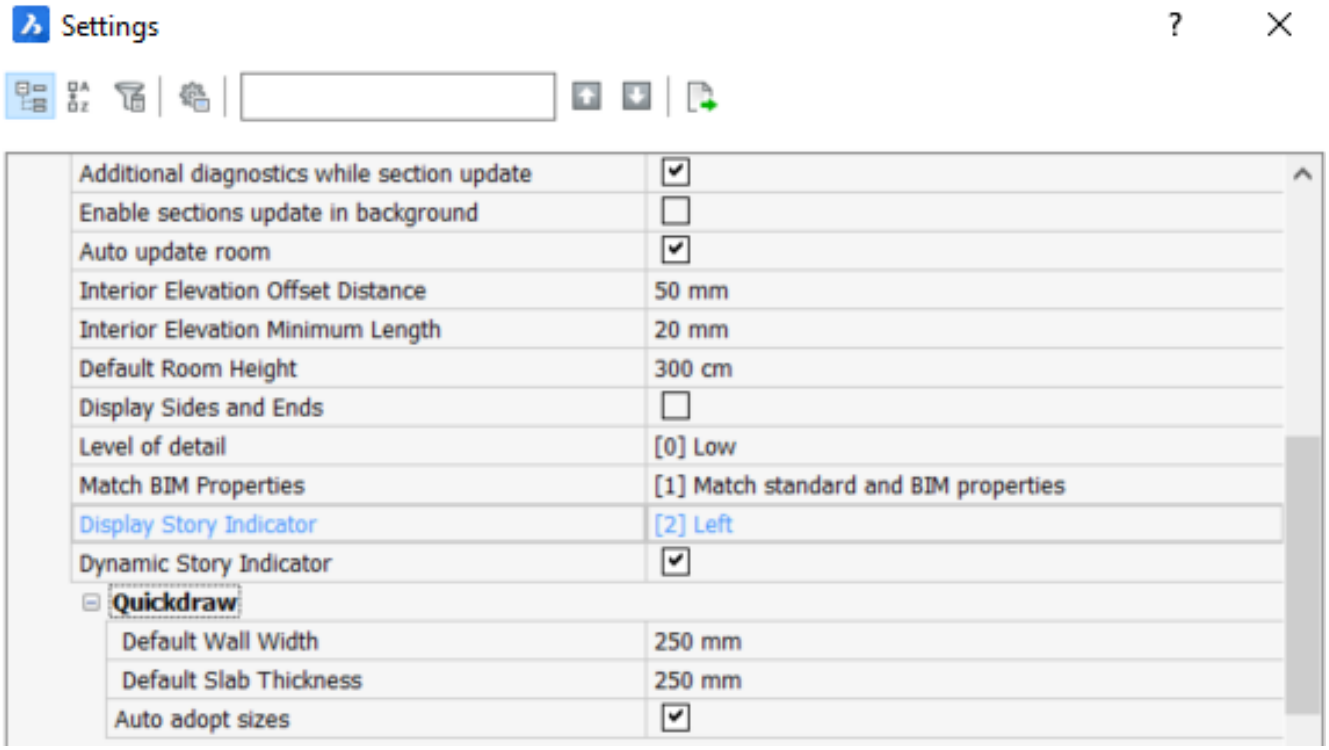
(2.442 on page 1981)(2.443 on page 1981) To X- and Y- aligned lines and line segments (2.444 on page 1982) (2.445 on page 1982) To parallel lines (2.446 on page 1983)

Setting the Quickdraw system variables

You can use the **Quickdraw Settings** to set the Quickdraw system variables:

1. When the Quad cursor is in the 'No Selection' state (nothing is highlighted or selected), select Quickdraw (6.7.41) from the Model tab, click the Quickdraw icon in the ribbon or type **BIMQuickdraw (6.7.41)** in the commandline.
2. **You are prompted:** Select first point or [quickdraw Settings]:
3. Enter **S** for the Quickdraw Settings.
4. Specify a new value to the system variables of Quickdraw to change their default values (e.g. Default Wall Width, Default Slab Thickness, and Default floor to floor distance). When the "auto adapt sizes"-option is turned on, the dimensions of the walls and slab of the new room will be the same as the walls and slab you snap to. (2.421 on the following page)

Figure 2.421



Changing system variables while running Quickdraw

It is possible to edit the dimensions of the walls you will draw while the Quickdraw command is launched. Change these settings in the Quickdraw Settings dialog box, select the settings in the prompts menu or enter the specific letters in the commandline and press Enter to change the dimensions.

- **H:** Change the dimension of the floor height.
- **W:** Change the dimension of the wall width.
- **T:** Change the dimension of the slab thickness.
- **A:** Adapt the dimensions of the room you are drawing in/against automatically.

Note: Make sure that you enable the hidden options in the prompt menu. Type **PromptMenuFlags** in the commandline, press Enter and enter option 1.

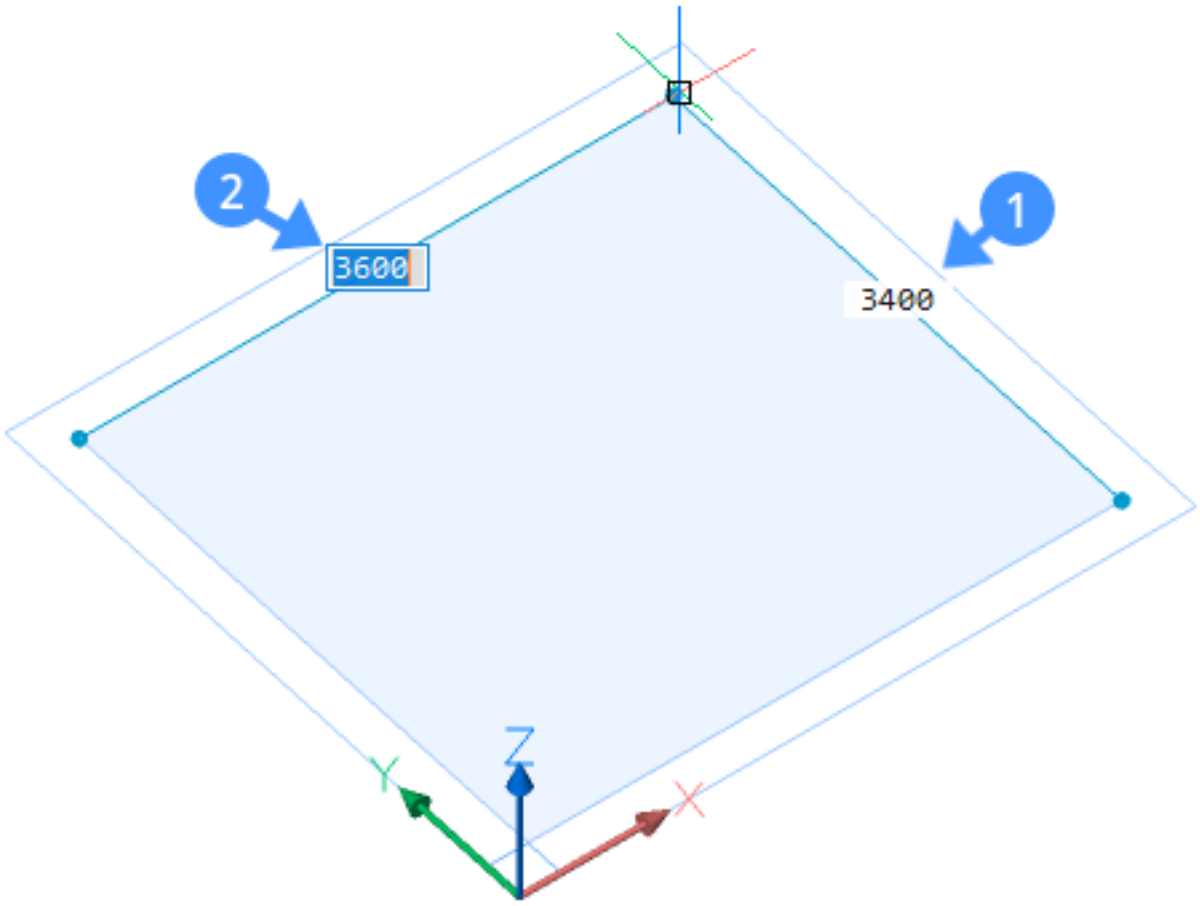
Procedure: Creating an L - shaped house

1. When the Quad cursor is in the 'No Selection' state (nothing is highlighted or selected), select Quickdraw (6.7.41) from the Model tab, click the Quickdraw icon in the ribbon or type **BimQuickdraw** in the commandline. **You are prompted:** Select the first point or [quickdraw Settings]: **Note:** Use the Quickdraw Settings to change the wall width, wall height and slab thickness of the room **before** you click and then specify the first corner of a building.

2. Select any point in the drawing area to set the first corner. **Note:** To start from the origin, use the magnetic snapping feature of Quickdraw.

4. Drag the mouse cursor to define the footprint of the building. **Note:** If the Dynamic dimension (DYN) option is on, the current values of the room width (1) and length (2) are displayed in a dynamic dimension field. (2.422 on the next page) Specify the values of the room width and length in the Dynamic dimension field. Press the Tab key to switch between width and length and press Enter **or** just click freely. Press Enter **or** Escape to leave the Quickdraw command **or** you can continue to create more rooms.

Figure 2.422



5. Place the Quickdraw cursor inside the existing building to create more rooms. When you place the Quickdraw cursor inside the existing building, the dynamic dimension fields display the distances from the Quickdraw cursor to the adjacent walls (3,4,5,6). When the "auto adapt sizes"-option is turned on, the dimensions of the walls of the new room will be the same as the wall you snap to. (2.423 on the following page) If the cursor aligns with one or two existing walls in the model, the layout of the cursor will adapt and depict the alignment. (2.424 on the next page) To actually draw new walls, choose the distances from the already existing walls to specify your first point. Move your cursor **or** type the values in the dynamic dimension fields to do this. Draw walls in the same way as explained in steps 2 and 3.
6. To remove a section of a wall from the existing room, first, align the Quickdraw cursor with an existing wall at the inner side of the building. Then click and drag the cursor outside of the existing building. The outer wall will turn red (9) to indicate the part of the wall that will be removed. **Note:** you can also align your cursor with an existing wall at the outer side of the building to remove a part of the slab. Then click and drag the cursor inside the existing building.
7. Select a second point. The wall highlighted in red will automatically be deleted and an L shaped room will be created. (2.425 on page 1967)

Figure 2.423

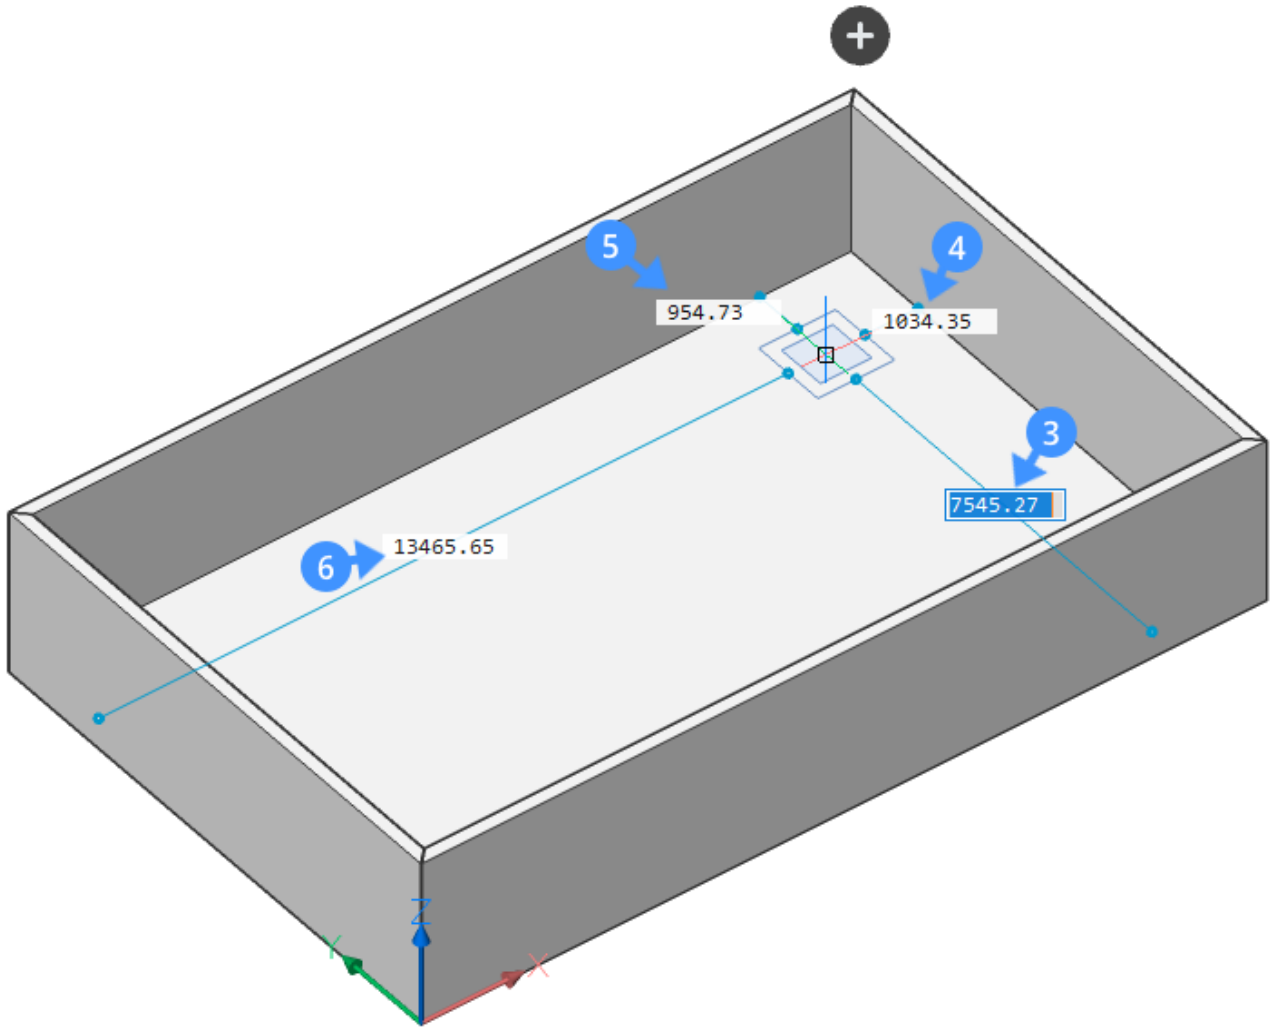


Figure 2.424

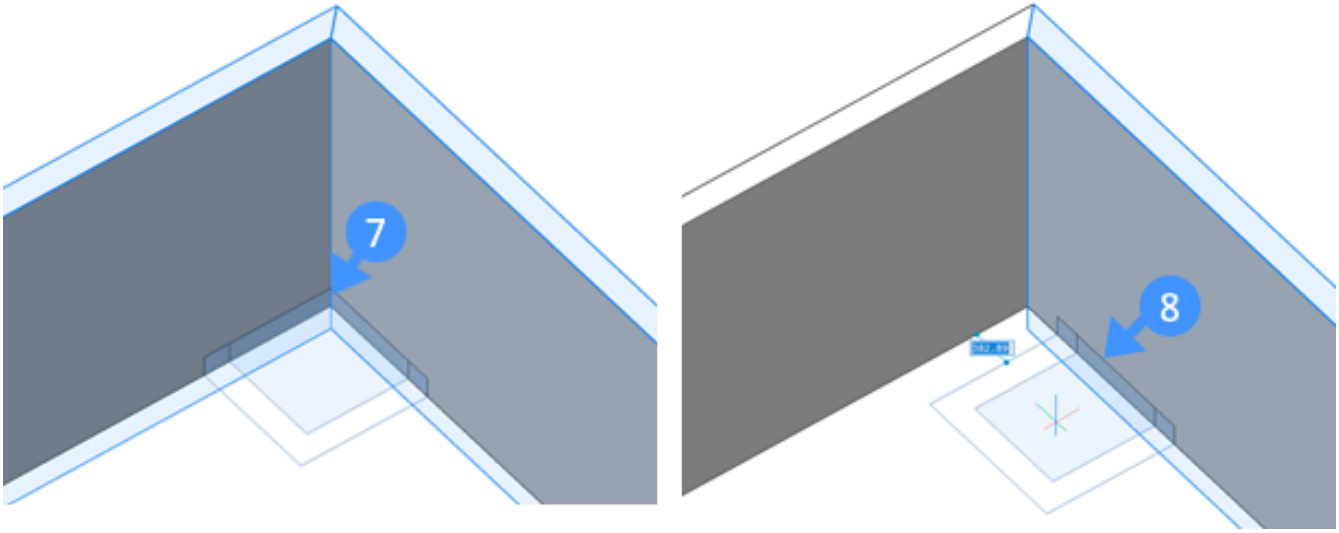

Figure 2.425

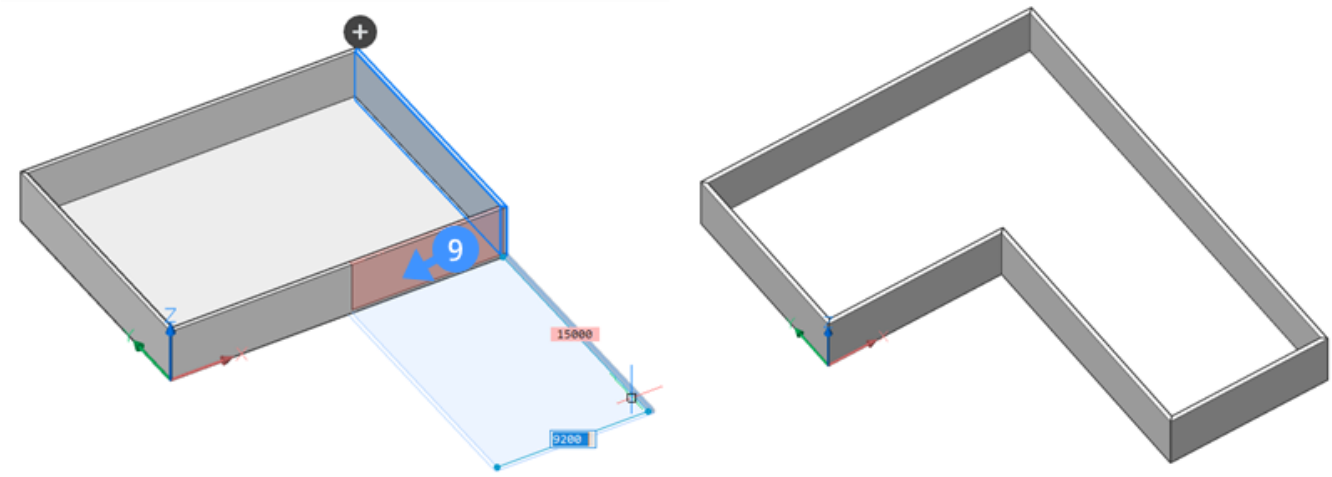

Procedure: Creating a story and a roof

Start with a similar configuration: (2.426 on the next page) Go through the following steps to create two extra stories, a floating part and a flat roof.

1. When the Quad cursor is in the 'No Selection' state (nothing is highlighted or selected), select Quickdraw (6.7.41) in the Model tab or type **BIMQuickdraw** in the commandline.
2. Click on the icon ( ) to see the options:
   - Fully copy the top floor. All features will be copied (windows, doors, interior walls, and furniture, excluding doors on the outer walls of the ground floor).
   - Copy the slab and the outer walls of the top floor.
   - Finish the building with a flat roof.
3. For the first story, choose the first option (Full copy). (2.427 on the following page) **Note:** The interior wall and interior door and the windows in the exterior wall are copied. The door in the exterior wall on the ground floor is not copied. **Note:** The furniture is not copied in this case, because it is not assigned to the ground floor (see the Properties panel). If you want to copy the furniture, use Bimify (2.9.1) to assign the furniture to a spatial location. The new furniture will be automatically assigned to the new spatial location. **Note:** Walls inherit the spatial location of the slab on which they are created.
4. Repeat step 2. Choose the second option (Copy the slab and the outer walls) to create the top story. (2.428 on page 1969)
5. To make the overhang you should remove parts of the outer walls of the second floor. First, snap the Quick-draw cursor in the corner of the two outer walls, inside the building. Then click and drag the cursor outside. The outer walls will turn red to indicate that the walls will be removed. (2.429 on page 1970) (2.430 on page 1972)

Figure 2.426

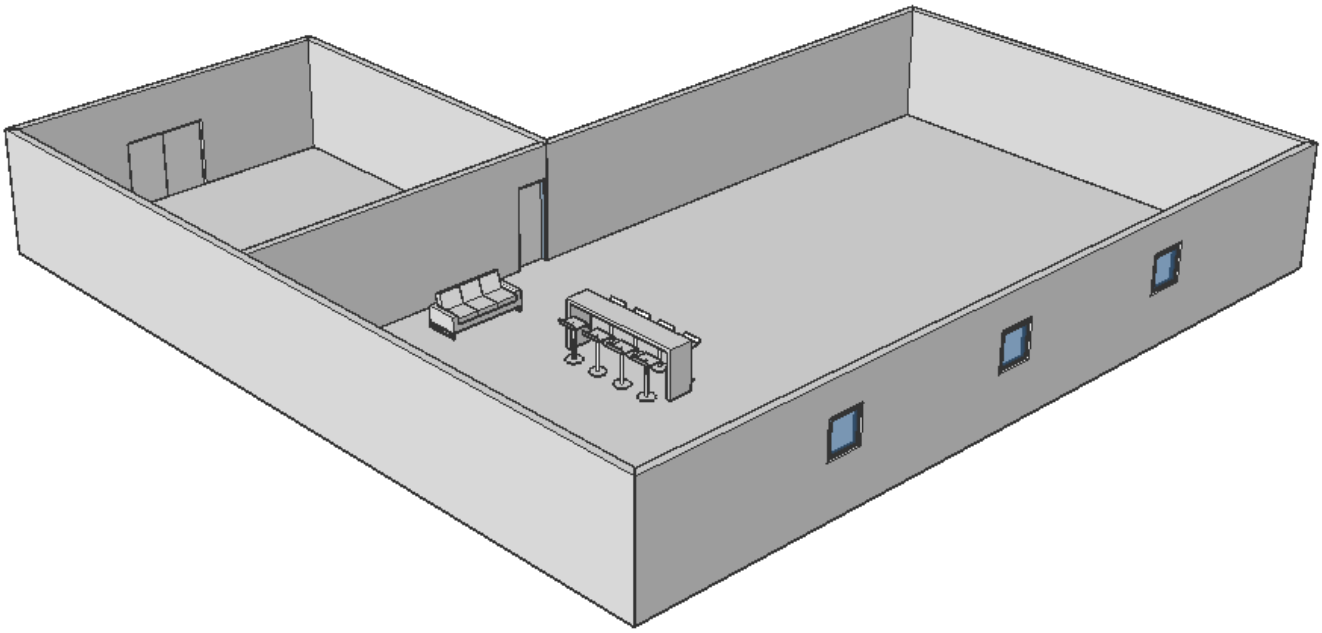

Figure 2.427

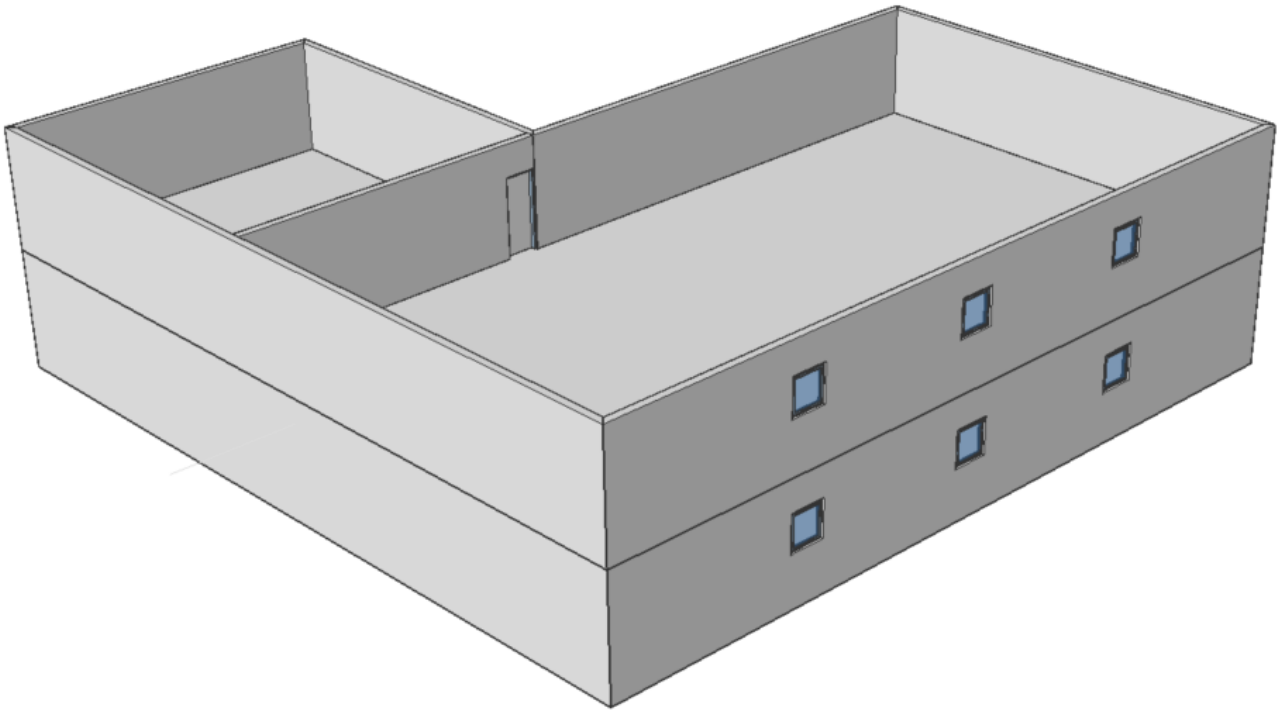

Figure 2.428

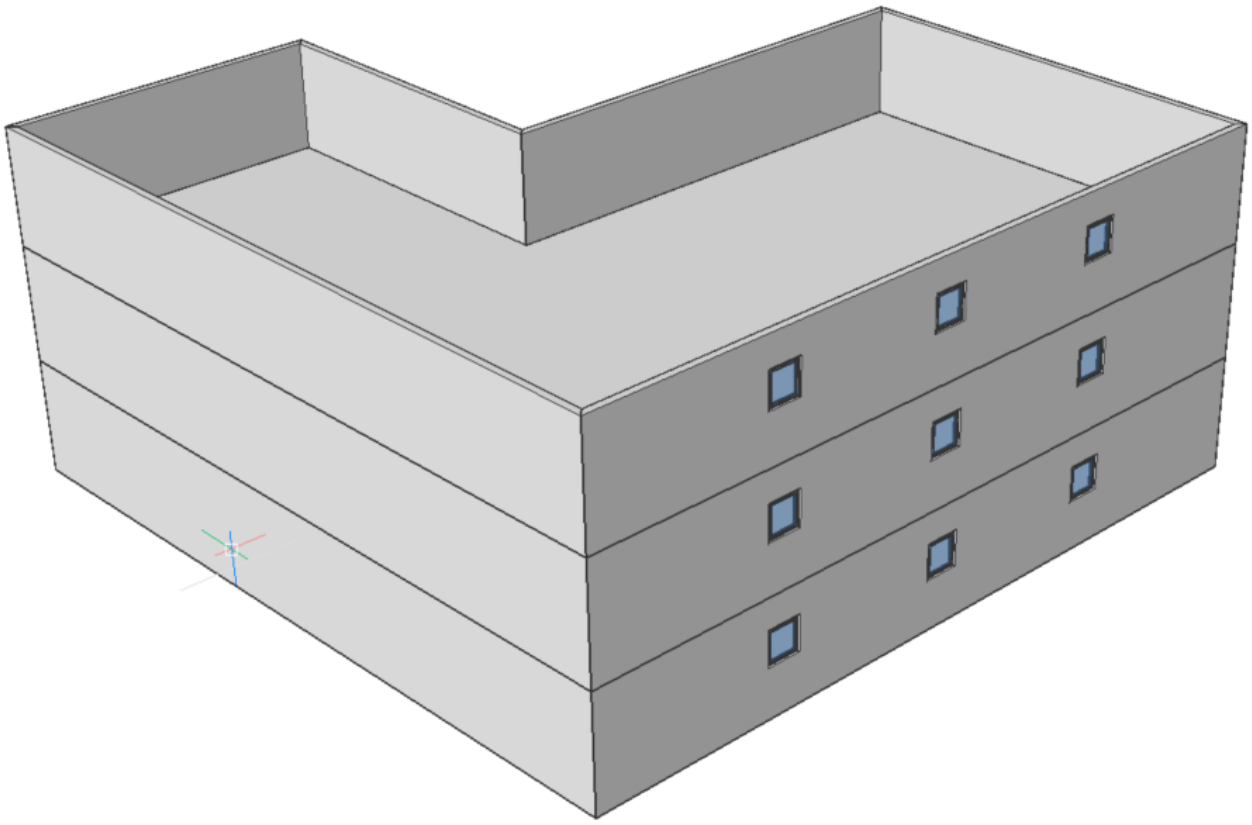

Figure 2.429

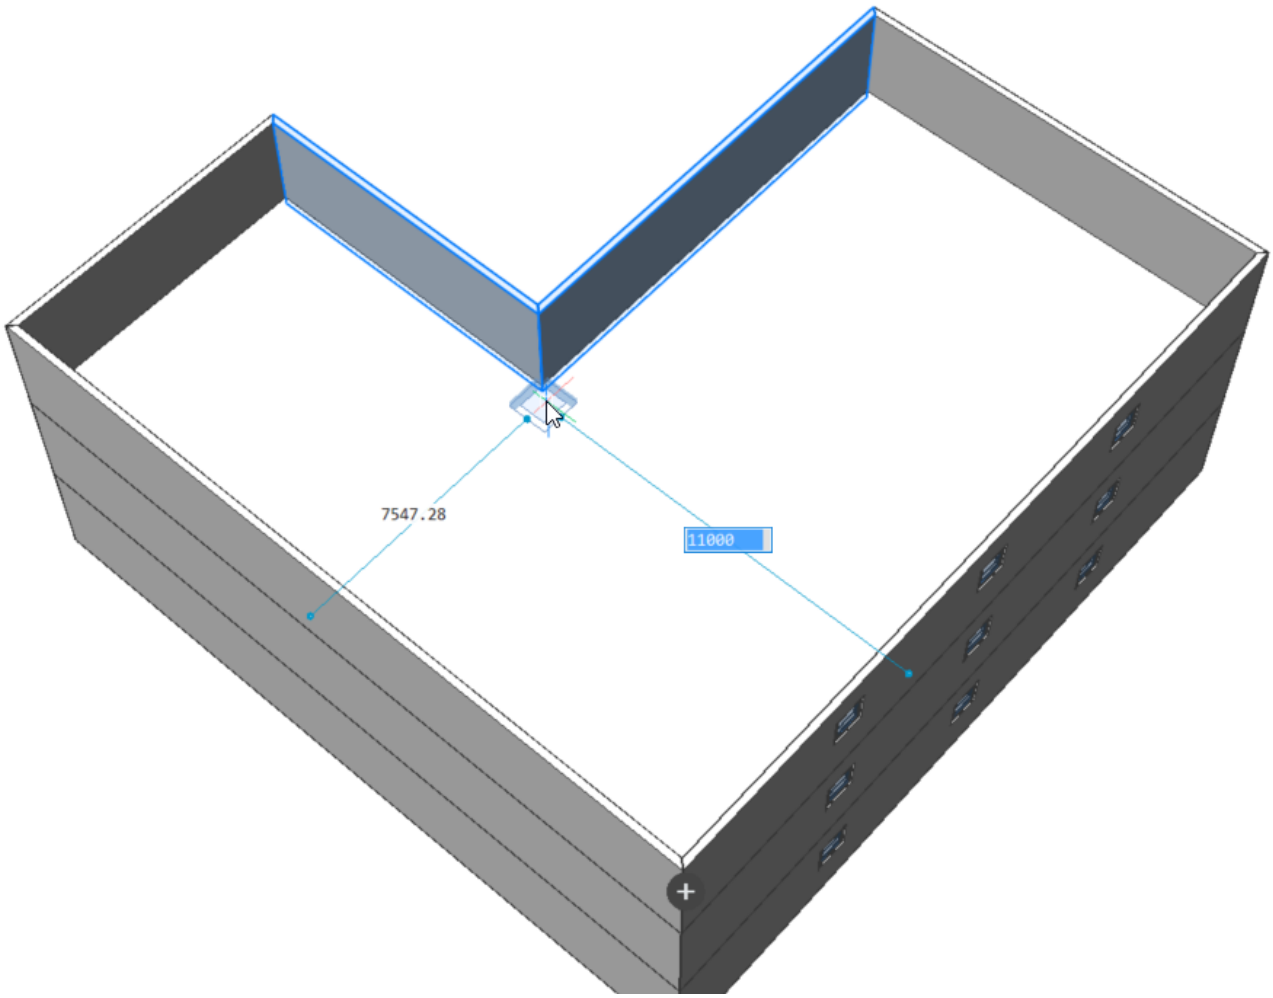

6. Use the same method as in step 2, selecting option 3 (Finish the building with a flat roof). (2.431 on page 1973)

Figure 2.430

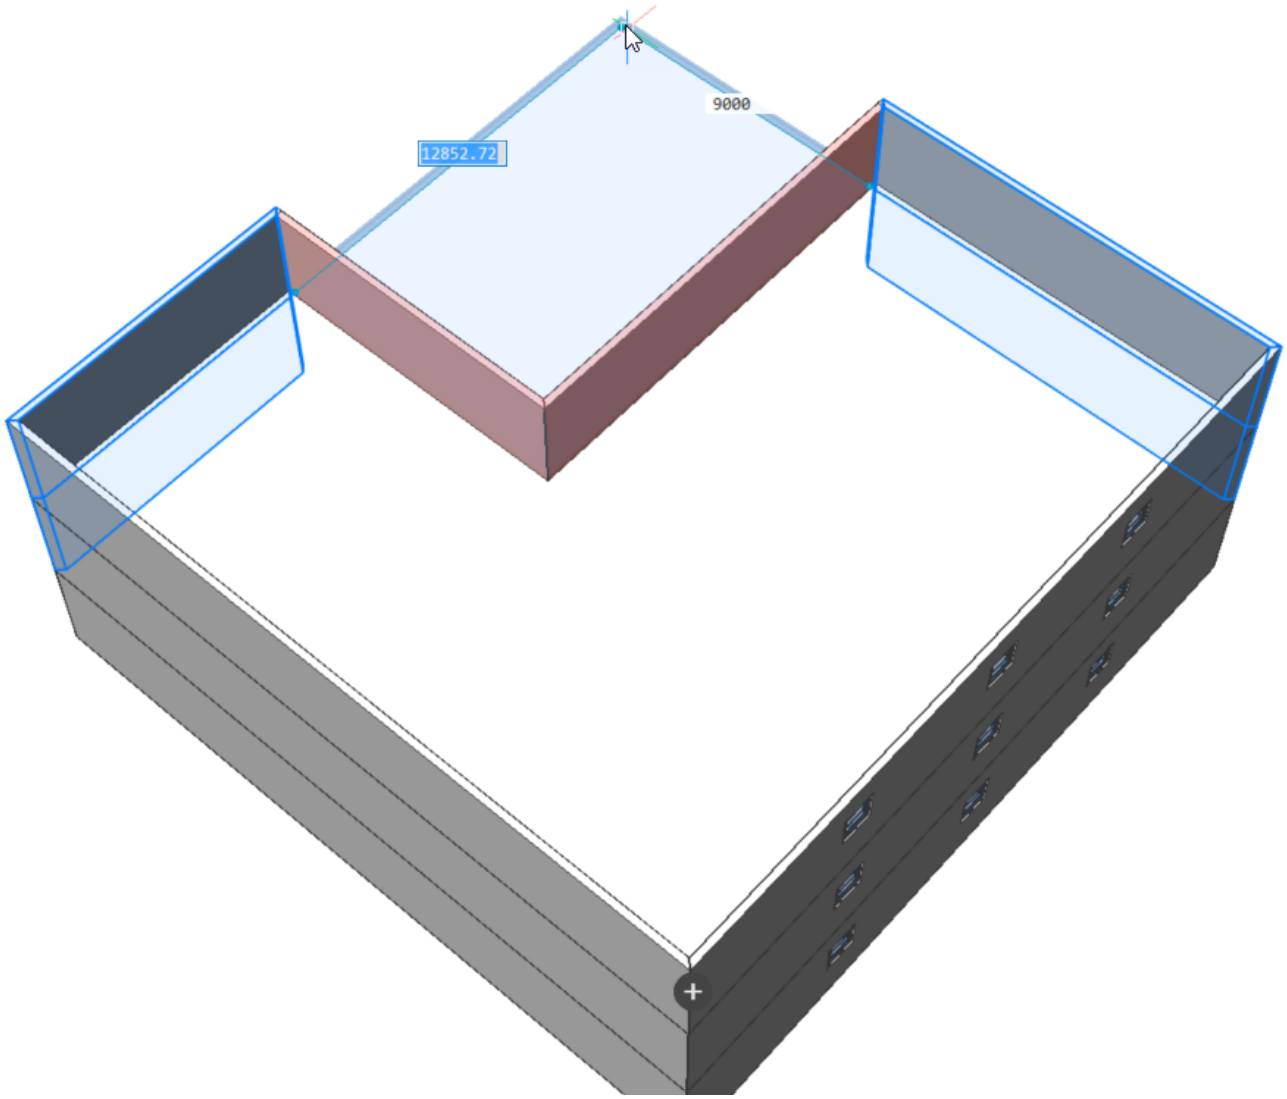

Figure 2.431

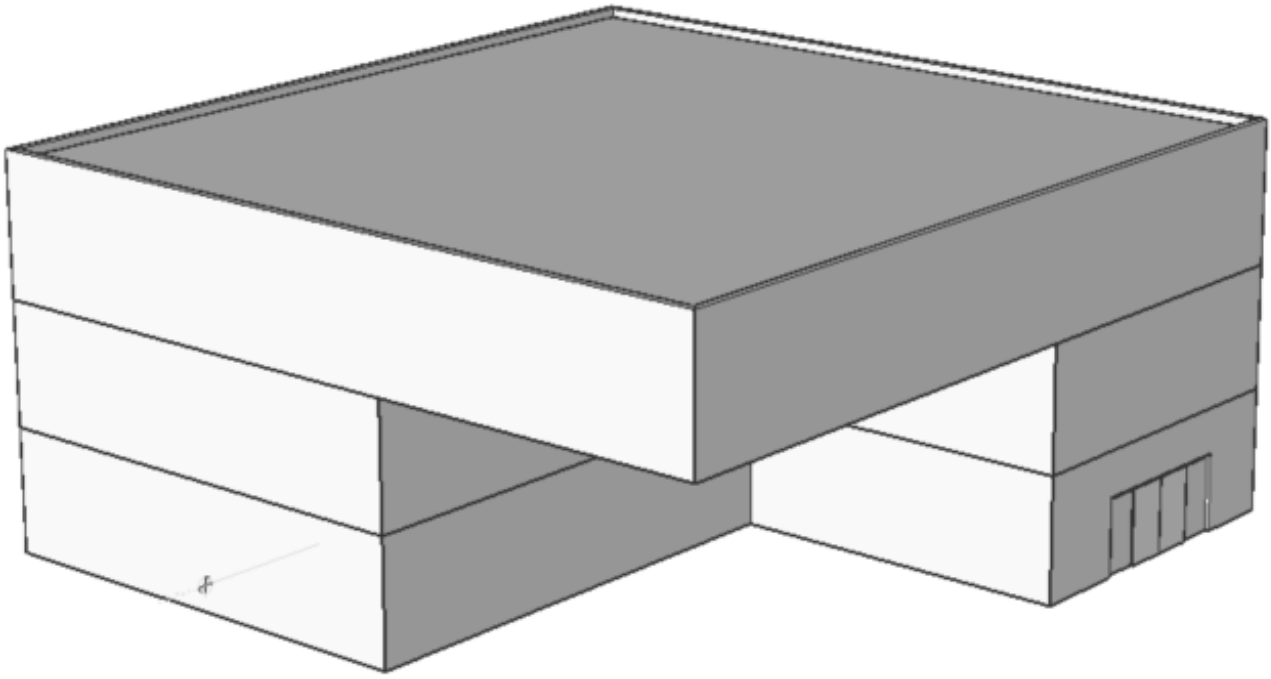

Procedure: Using Quickdraw starting from a 2D layout

1. Open a 2D floorplan of a rectangular or L-shaped building. (2.432 on the next page) **Note:** it is also possible to draw a simple 2D floor plan with the (poly)line command to start from. In this case, the default wall thickness of the BIM Quickdraw command will be used. **Note:** The Quickdraw cursor now supports snapping to (double) lines inside XREFs.

2. When the Quad cursor is in the 'No Selection' state (nothing is highlighted or selected), select Quickdraw (6.7.41) in the Model tab, click the Quickdraw icon in the ribbon or type **BIMQuickdraw** in the commandline.

3. Hover over one of the outer walls with the cursor. (2.433 on the following page) **Note**: The thickness of the wall automatically adapts to the distance between the parallel lines of the 2D drawing. **Note**: If the lines in the (imported) 2D floorplan are not optimal (e.g. not exactly X- or Y-aligned), the QuickDraw-cursor will not snap to it (as it is perfectly X-Y-aligned). In that case, use the Optimize (6.23.15) command to make sure all 2D lines exactly X- or Y-aligned.

4. Draw the outer walls, using the magnetic snapping feature to snap to the lines of the 2D drawing. (2.434 on page 1975)

5. Hover over one of the inner walls with the cursor, using the magnetic snapping feature to snap to the lines of the 2D drawing. (2.435 on page 1975)
Note: The thickness of the wall automatically adapts to the distance between the parallel lines of the 2D drawing.

6. The 2D plan has been transformed into a 3D model. (2.436 on page 1976) **Note:** you can use the same method as in step 2 and 6 of the previous procedure to add floors or finish the building with a flat roof.

2.5.23 Stair Tool

Command: BimStair (6.7.47) **Overview:** In BricsCAD BIM, the Stair Tool creates a flight of stairs in only two clicks. The Stair Tool asks for two input clicks: one for the first step and one for the last step. **Lesson Objectives:**

- Create a fully parametric flight of stairs, with full BIM data and properties automatically assigned.
- Create single-flight straight, double-flight L-shaped, and double or triple-flight U-shaped stairs.
- Snap to walls, slabs, and gaps for easy positioning.

About

The Stair Tool is a powerful tool that allows you to add a custom flight of stairs for your project in just two clicks. You can change the default stair settings as required. The Stair tool will automatically try to fit these requirements. It is possible to create single-flight straight, double-flight L-shaped, and double or triple-flight U-shaped stairs.

 For more information about this command, visit the Command Reference article BimStair (6.7.47).

Create a straight flight of stairs

1. Select the Stair Tool from the Quad (1). (2.447 on the facing page)
2. Hover over a slab. The Stair Cursor will appear (2) and the slab on which the stair cursor hovers, is highlighted. This indicates the position of the first step. If the position of the cursor is invalid, the cursor will turn red (3). (2.448 on the next page) (2.449 on page 1986)
3. To flip the direction of the first step, click the Flip-button (4) or type **F**. To turn the direction of the first step 90°, click the Quarter-turn-button (5) or type **Q**. To cycle through the different stair variants, the CTRL-key can be used when the Hotkey Assistant is active. **Note:** the cursor will automatically flip or quarter-turn when it is positioned close to a wall or the edge of a slab. This auto-quarter-turning/flipping behavior is only active when the relevant Stair Setting is turned on. (2.450 on page 1986)
4. Once the cursor is in position, press Left-click. If the upper slab is blocking the view, the slab will become transparent. (2.451 on page 1987)
5. To create a straight flight of stairs, align the mouse perpendicular to the first step. **Note:** A live preview of the flight of stairs to be created (blue) will follow the mouse dynamically (6). The Stair Tool will automatically snap to the configurations that correspond to "ideal step length" setting, as can be seen in the animation below. When the optimal configuration is satisfied, this preview will display in a darker shade of blue. The other settings are taken into account as well of course, but not to this specific snapping feature (where the stair preview turns darker blue). (2.452 on page 1988)
6. Once you have the cursor in the correct position, left-click. A flight of stairs will be created. A hole is automatically generated in the upper slab, corresponding to the headroom setting (7). (2.453 on page 1989)

Figure 2.447

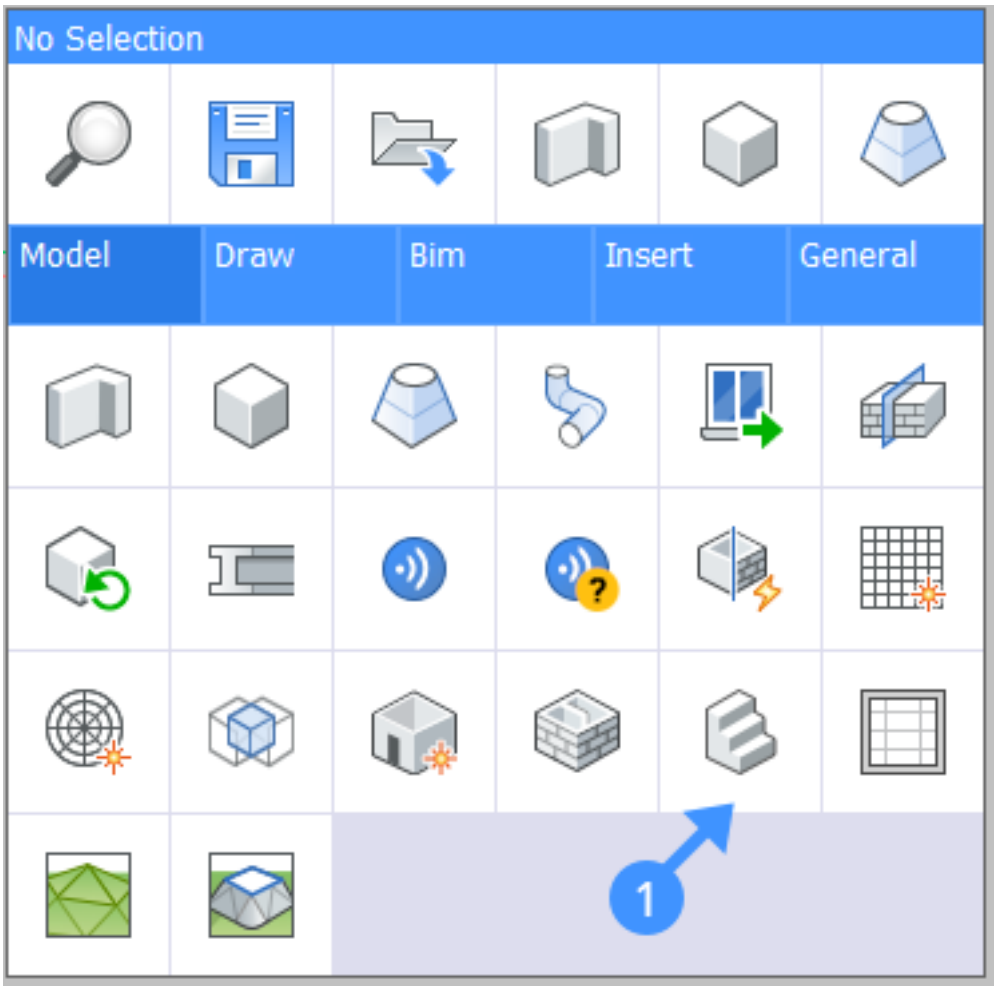

Figure 2.448

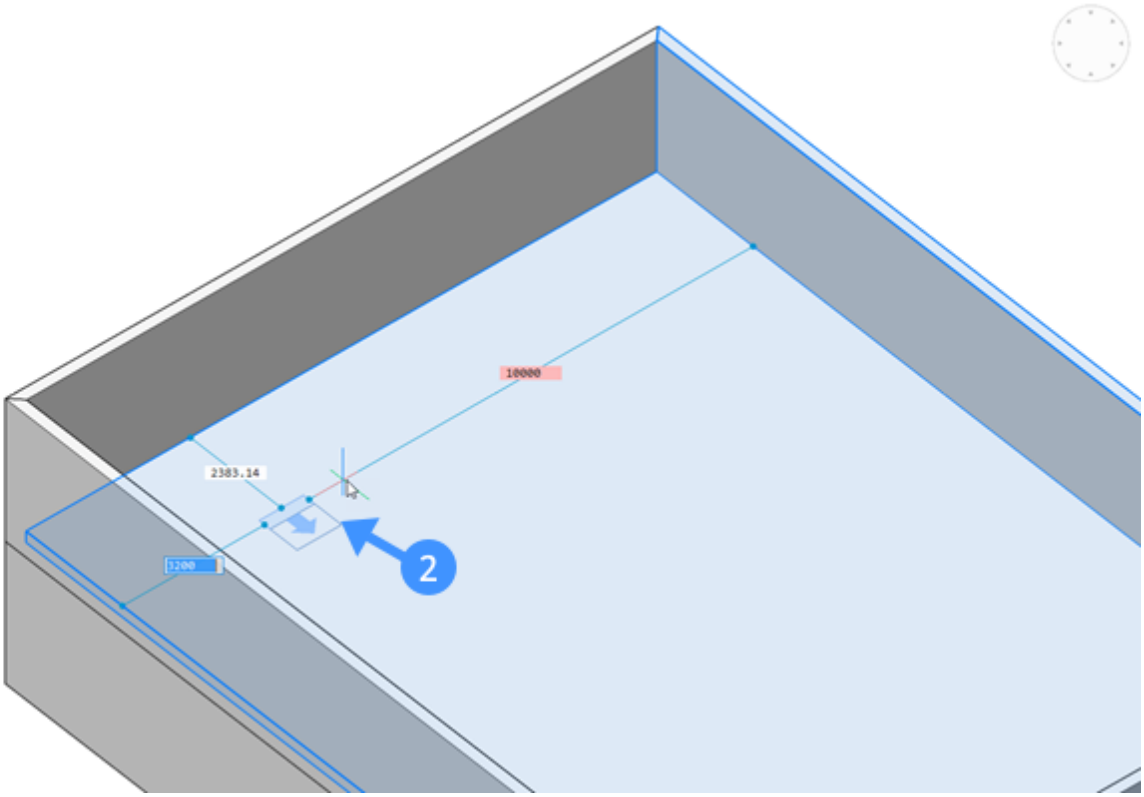

Figure 2.449

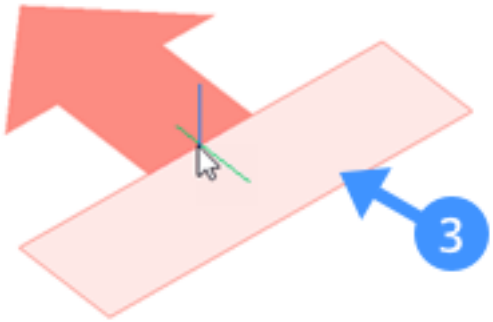

Figure 2.450

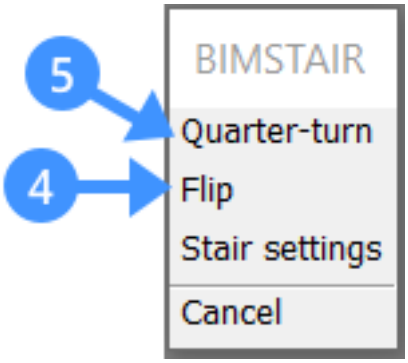

Figure 2.451

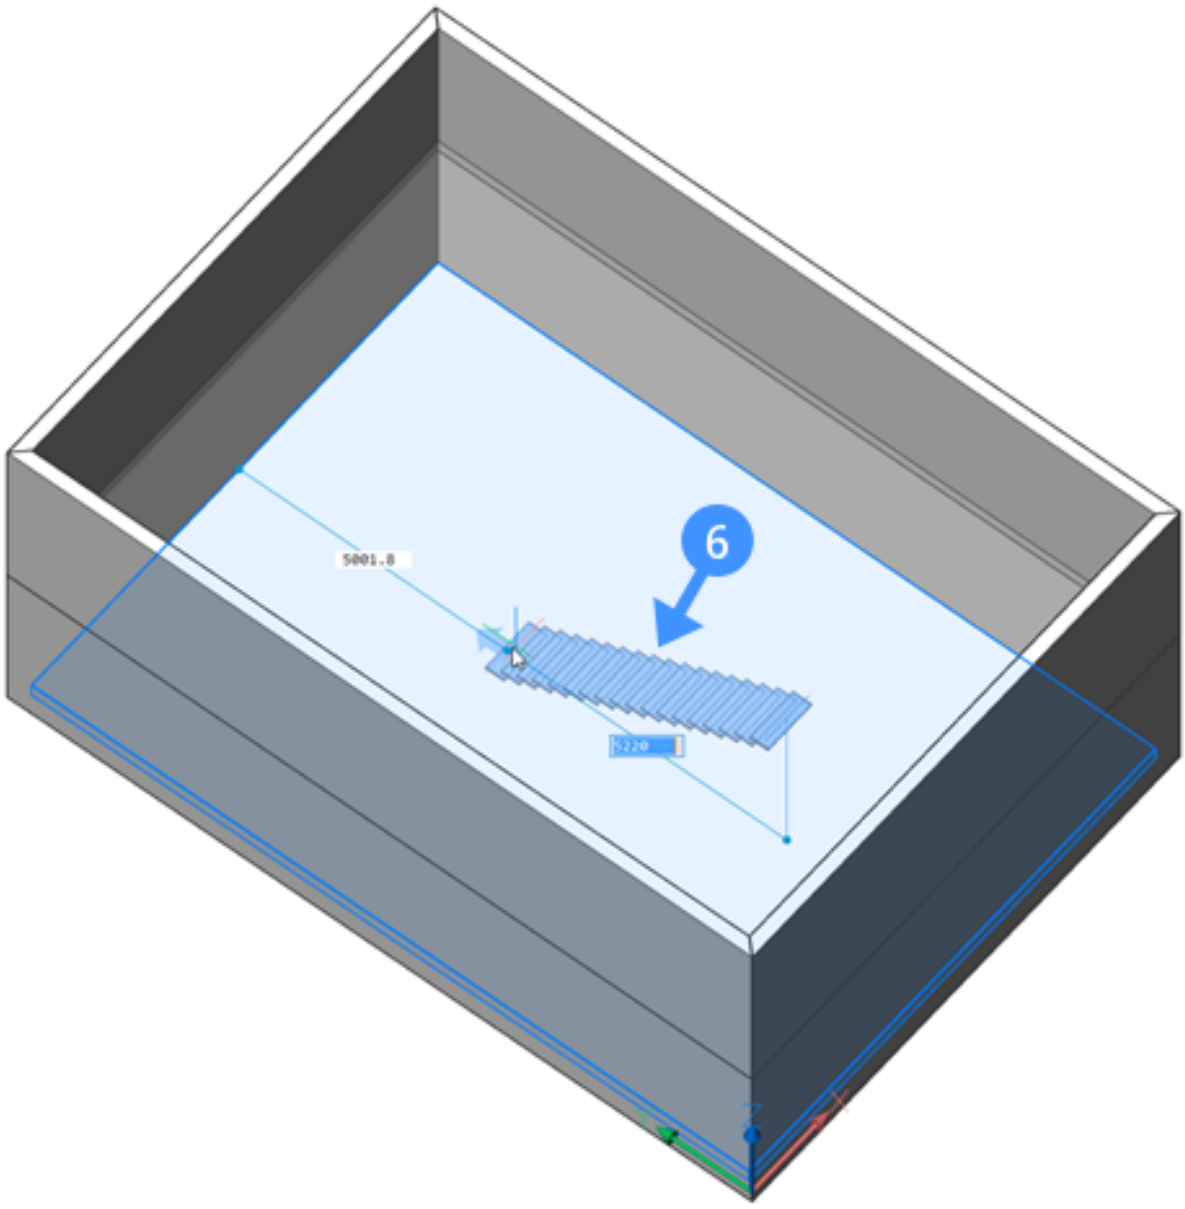

Figure 2.452

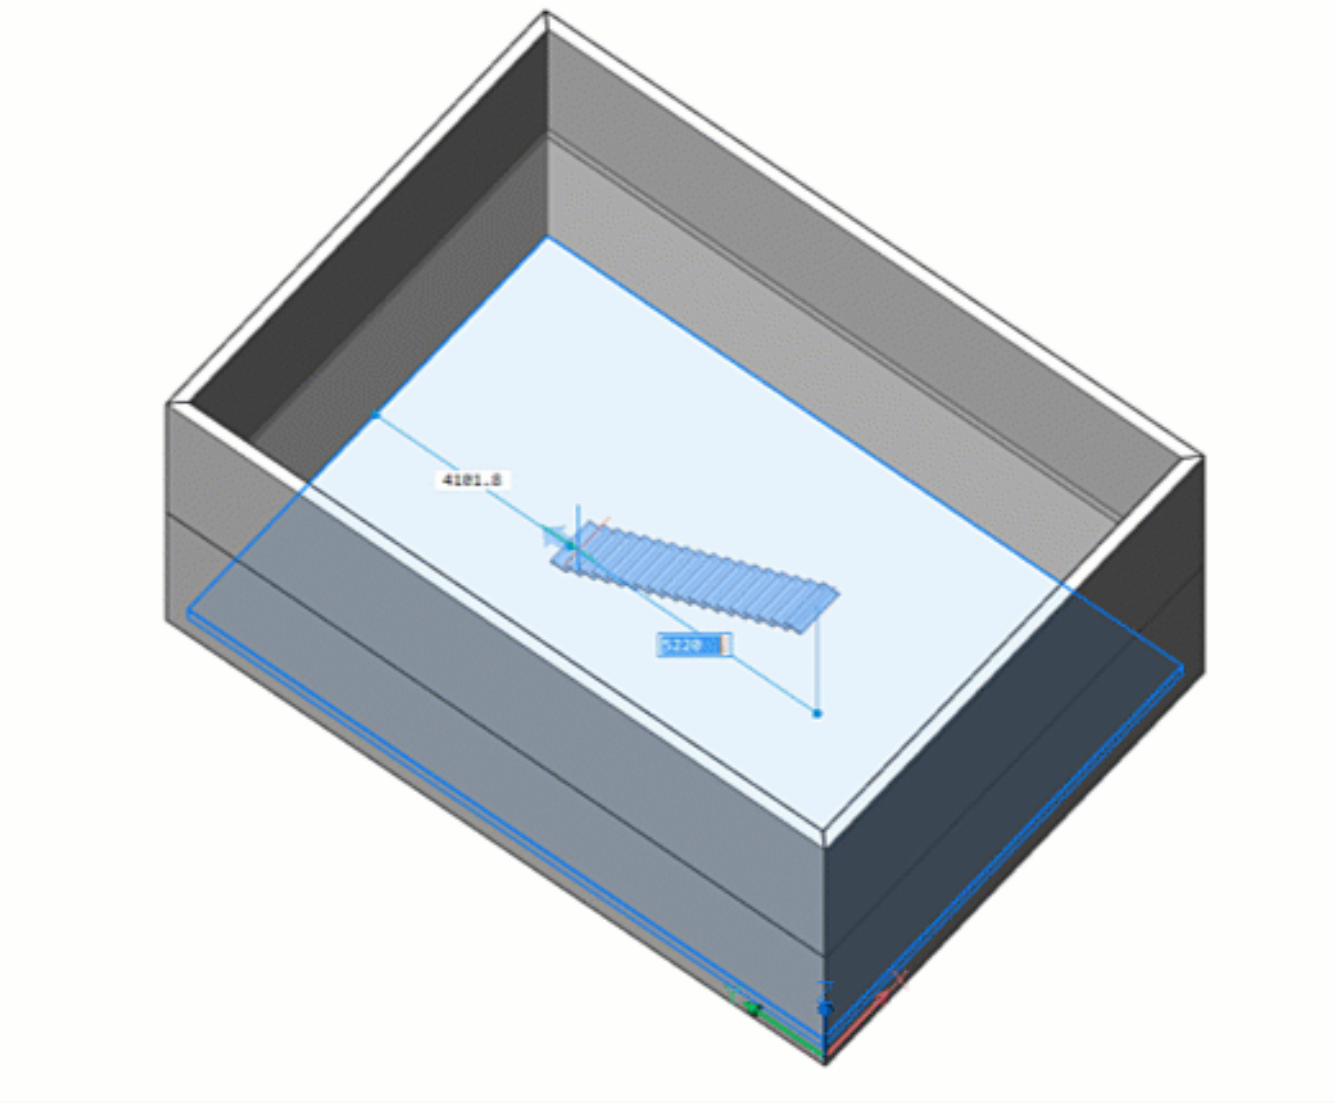

Figure 2.453

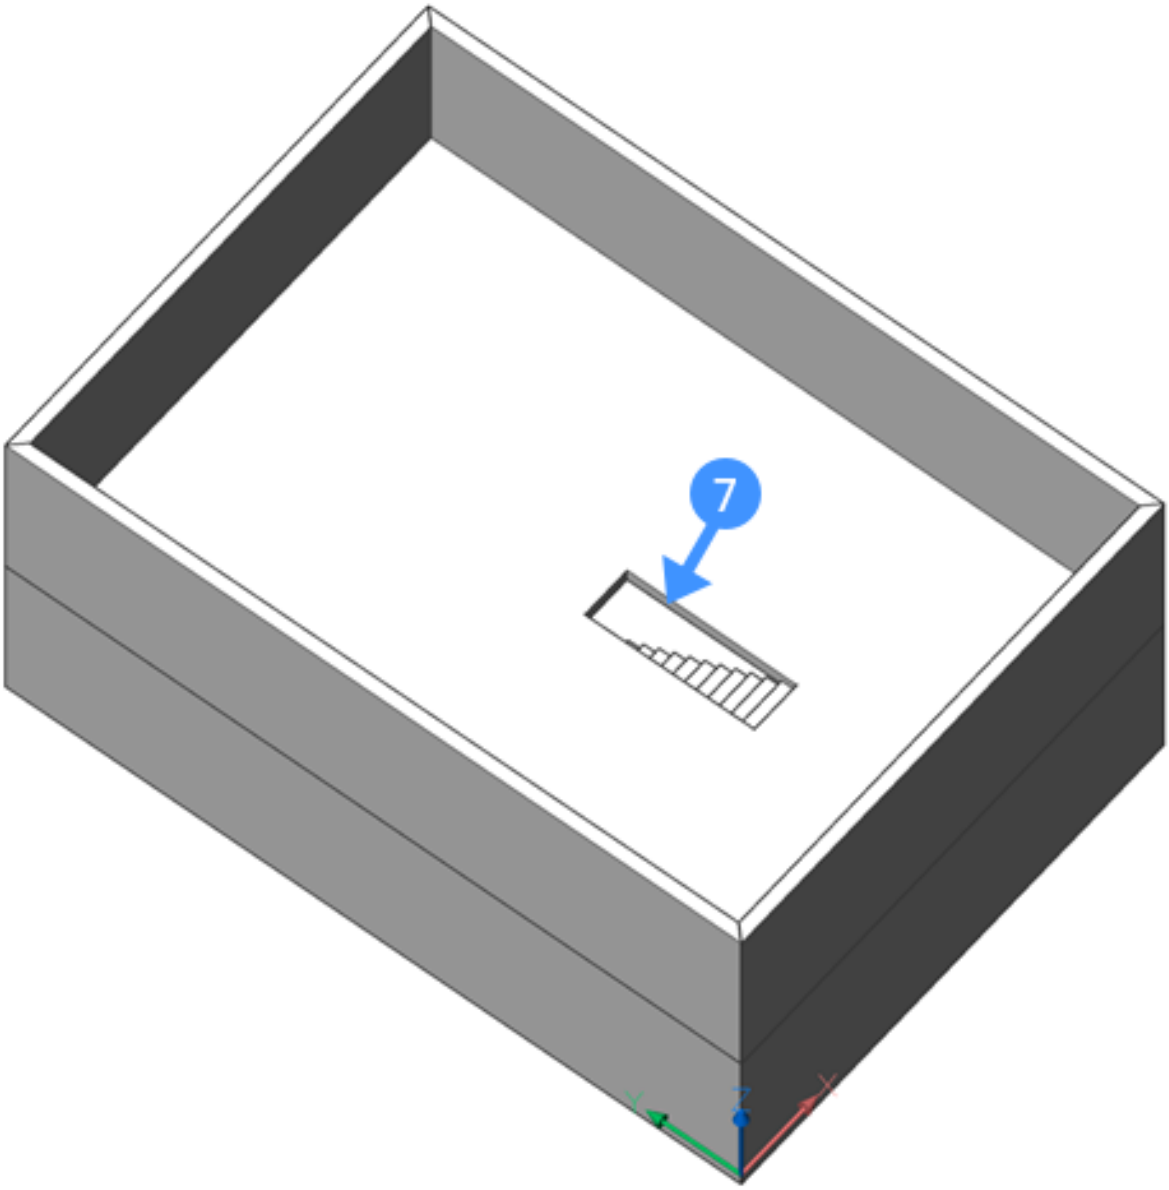

Create an L-shaped staircase

1. Select the Stair Tool from the Quad.
2. Hover over a slab. The Stair Cursor will appear. Left-click once the stair cursor is in the correct position.
3. Move the cursor away from the perpendicular to create an L-shape flight of stairs (8). (2.454 on the next page) **Note:** A live preview of the flight of stairs to be created (blue) will follow the mouse dynamically (8). The Stair Tool will automatically try to find optimal configurations of the stair that correspond with the dimensions given in the settings dialog. It will snap to the optimal configuration and display this preview in a slightly darker color.
4. When you are satisfied with the preview, left-click. A flight of stairs will be created and a hole will be automatically generated (9). This time, the hole may be L-shaped, depending on the length of the upper flight and the "Headroom" stair setting. If the headroom is so large it cannot be covered with only the topmost stair flight, it will span also a part of the second stair flight and thus be L-shaped. (2.455 on page 1992)

Figure 2.454

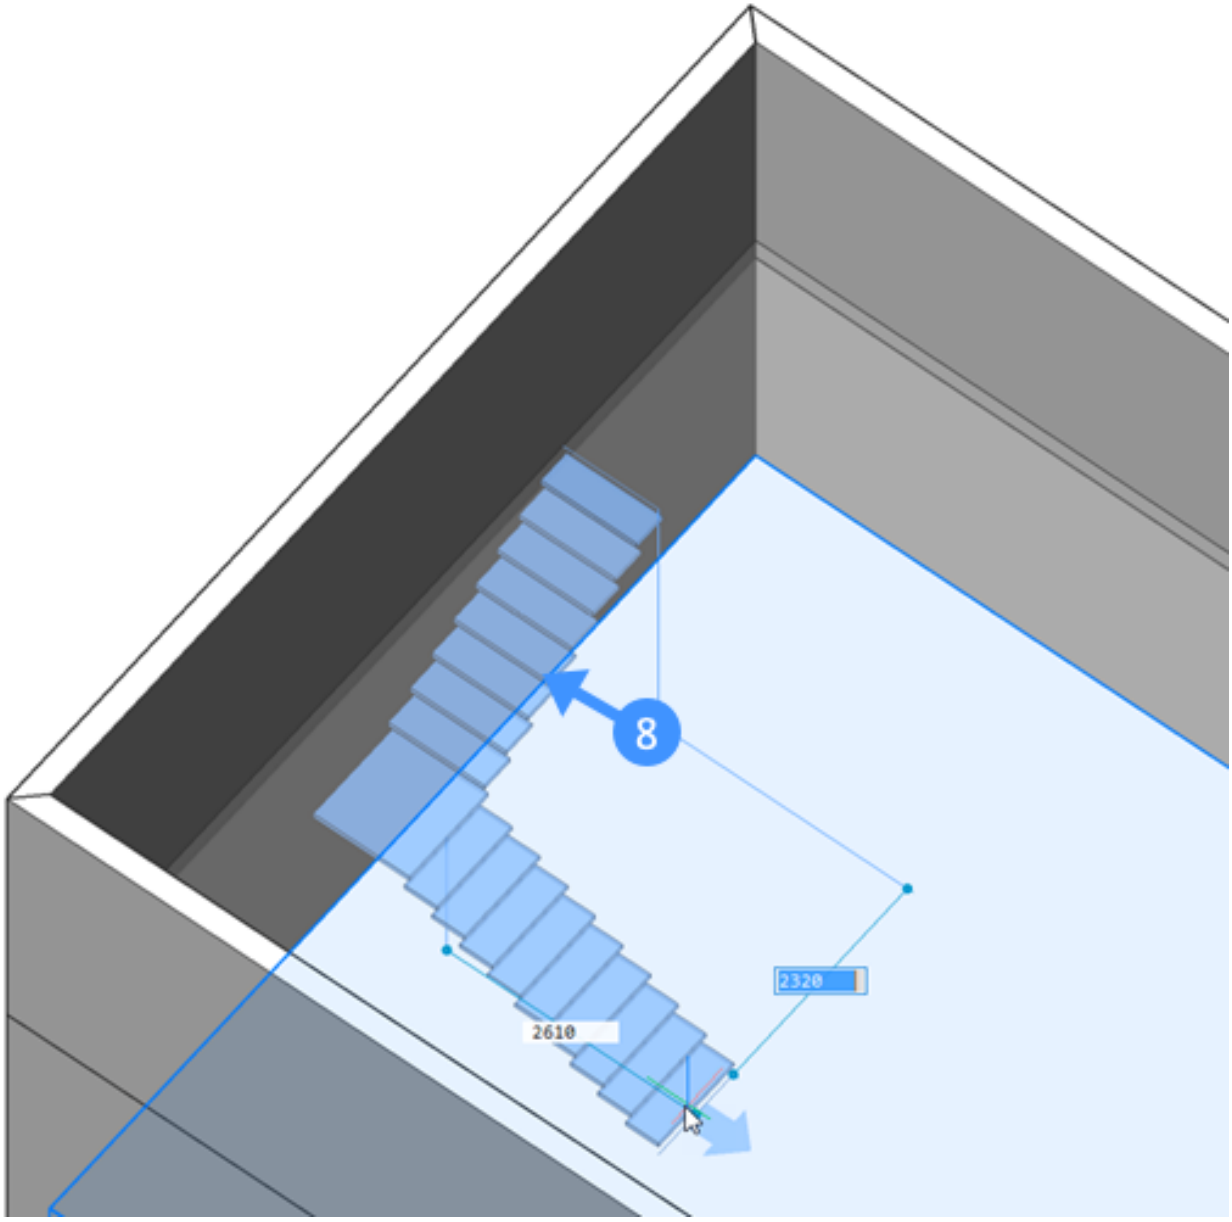

Figure 2.455

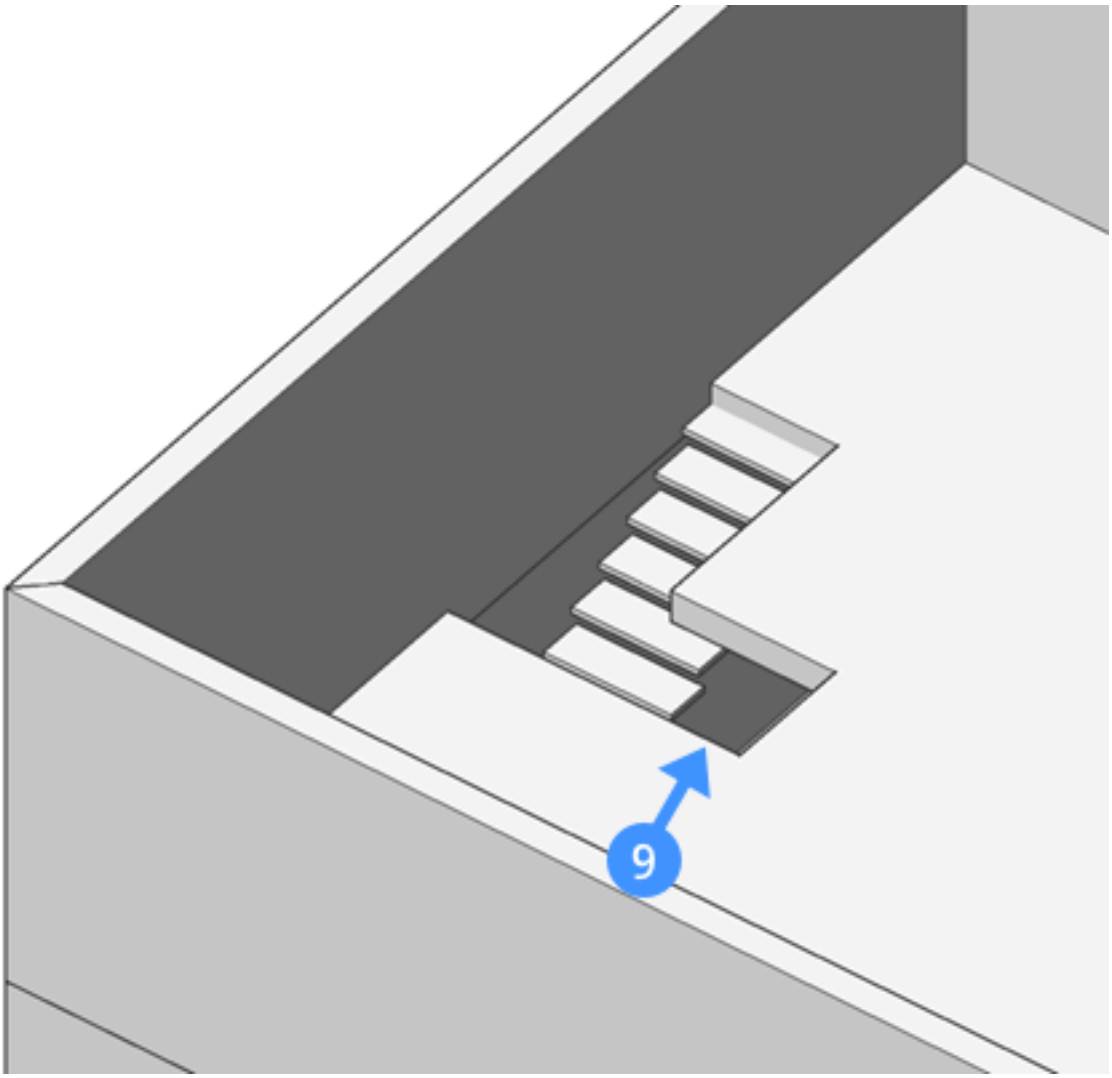

Create a U-shaped staircase

1. Select the Stair Tool from the Quad.
2. Hover over a slab. The Stair Cursor will appear. Left-click when the stair cursor is in the correct position.
3. Move the cursor away. You can type **Q** and Enter so that the direction of the second cursor is rotated 180° with respect to the first cursor.

Or use the CTRL-key when the Hot Key Assistant (HKA field in the Status bar (1.15.2)) is ON

1. Select the Stair Tool from the Quad.
2. Hover over a slab. The Stair Cursor will appear. Left-click when the stair cursor is in the correct position.
3. Move the cursor away from the perpendicular to get an L-shaped stair.
4. Press the CTRL-key for switching between an L-shaped stair and a U-shaped stair.

Or align the last step with the first fixed step. When entering a strip parallel to the first step, the last step will automatically quarter turn. (2.456 on the next page)

Note: A live preview of the flight of stairs to be created (blue) will follow the mouse dynamically (10). The Stair Tool will automatically snap to the configurations that correspond to the current settings. When the optimal configuration is satisfied, this preview will display in a darker shade of blue.

5. There are two possible types of U-shaped stairs you can switch between: - The middle section includes steps (10). - The middle section is a landing in between the two opposite stair flights (11). It is possible to switch between these two modes by typing **U** and hitting Enter. **Or** press CTRL to cycle between different stair variants.

(2.457 on page 1995)

Figure 2.456

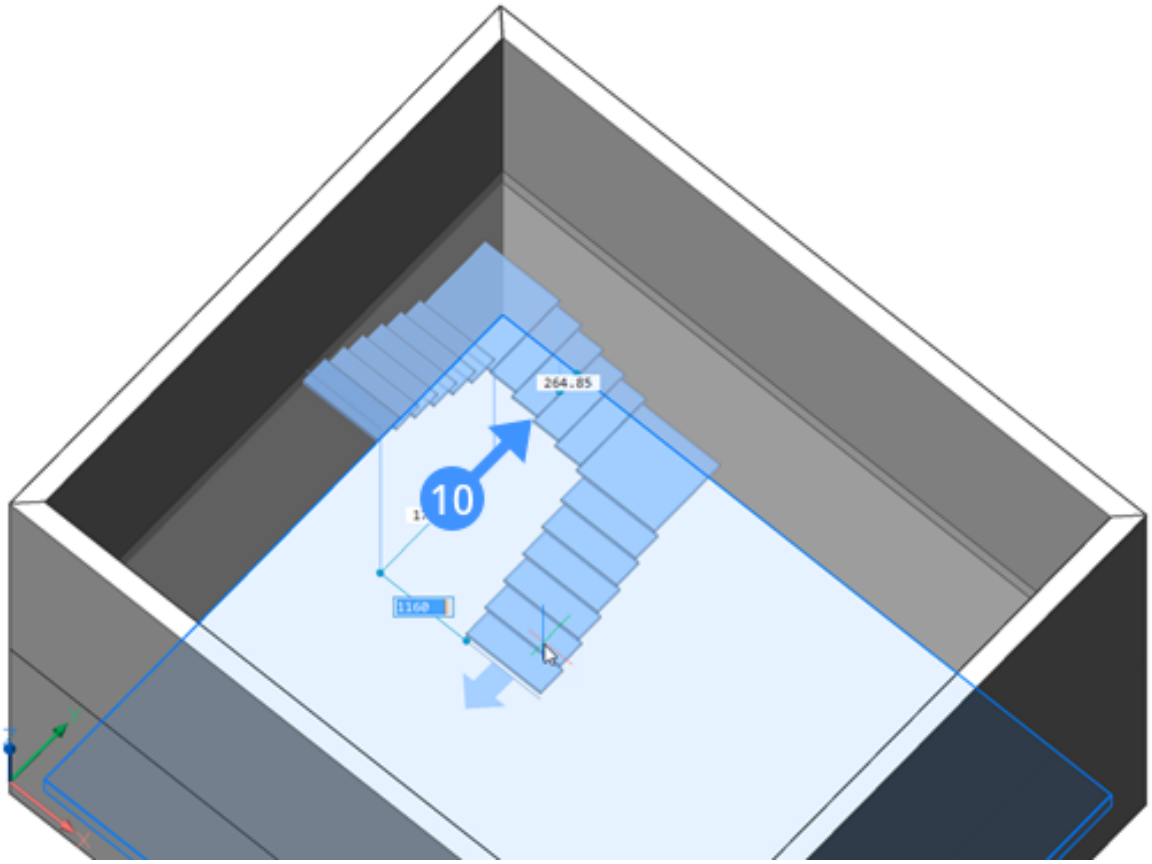

Figure 2.457

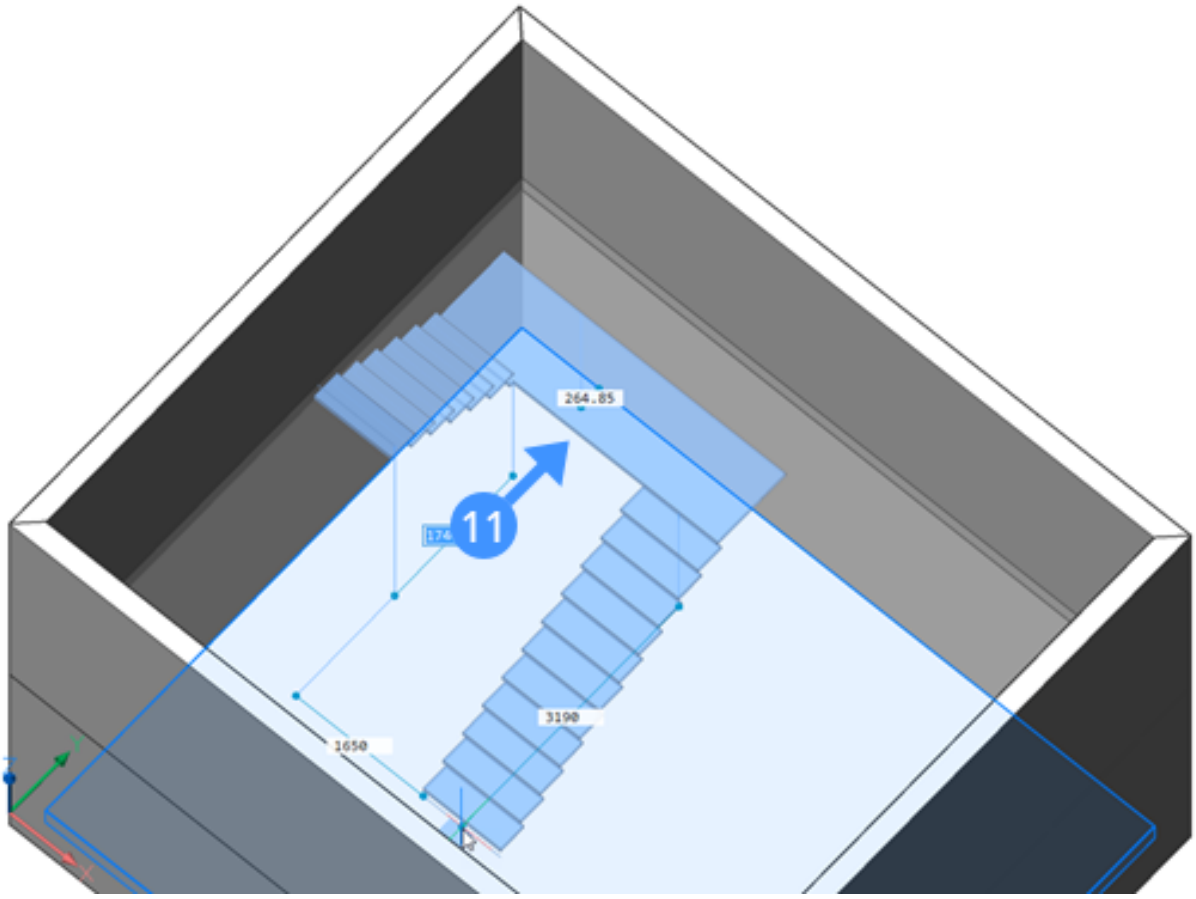

Create a flight of stairs in an existing opening

Sometimes it is necessary to create a flight of stairs starting from the edge of a slab, where an opening already exists. (2.458 on the next page) In the example above, different floors need to be connected with flights of stairs. However, an opening does not need to be created.

1. Select the Stair Tool from the Quad.
2. Hover the Stair Cursor near the edge of the slab (12). The cursor automatically snaps to the outer side of the edge. (2.459 on the facing page)
3. You can now create a flight of stairs as described above. (2.460 on page 1998)
4. You can also make a flight of stairs by starting at the lowest point. This time select a starting point on the first floor. (13) (2.461 on page 1998)
5. Now hover over the edge of the slab on the second floor. The Stair Cursor automatically snaps to the edge of this slab. Left-click to create the flight of stairs. (2.462 on page 1999)

Figure 2.458

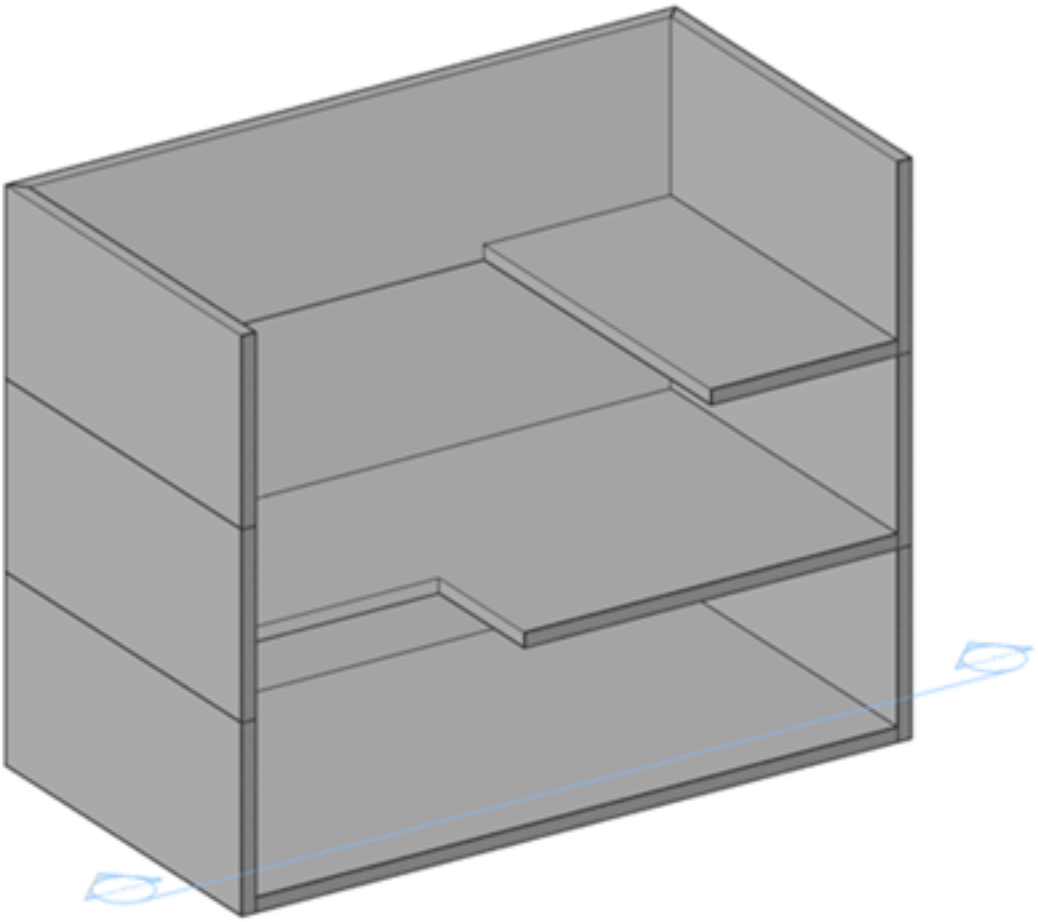

Figure 2.459

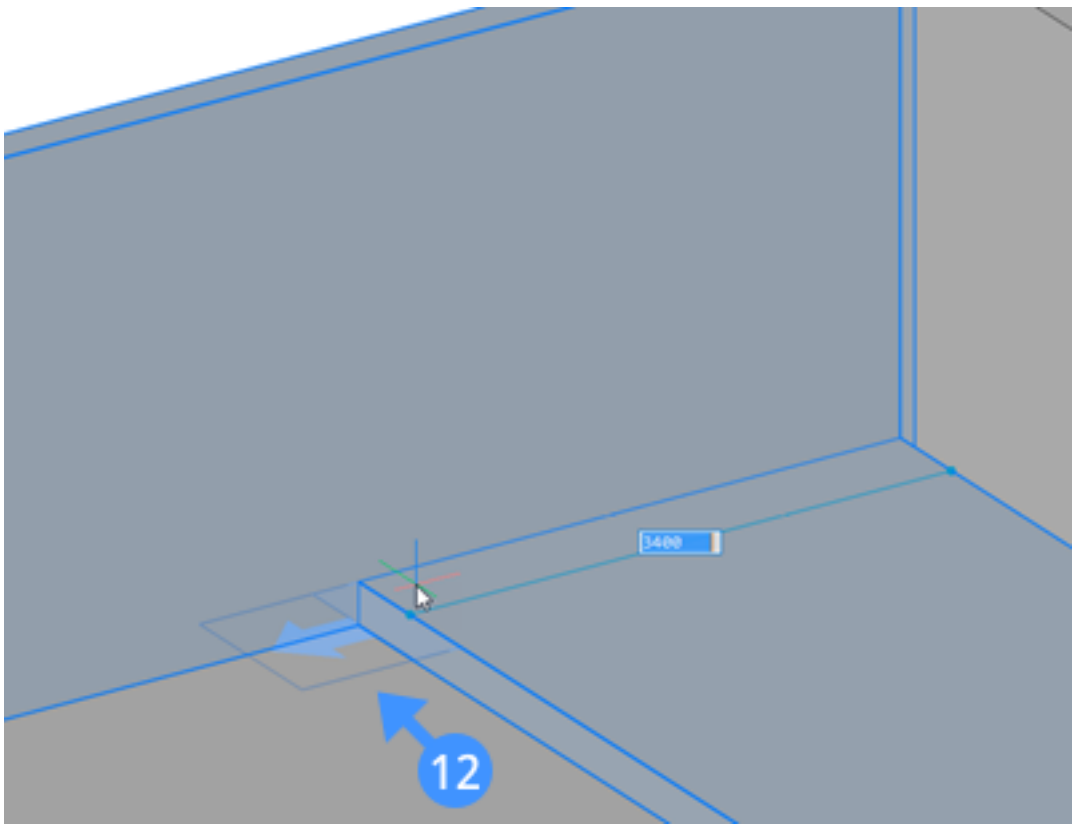

Figure 2.460

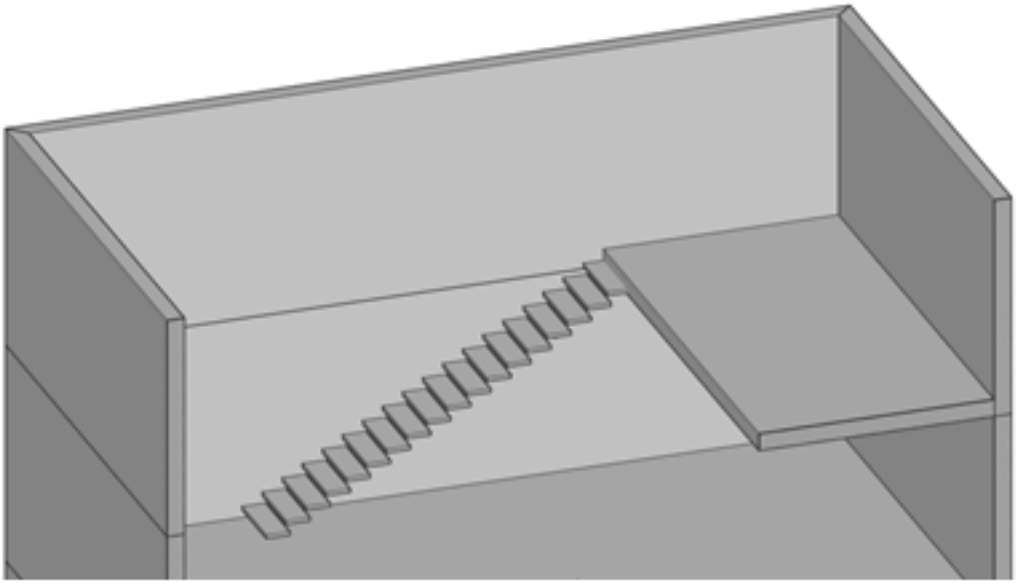

Figure 2.461

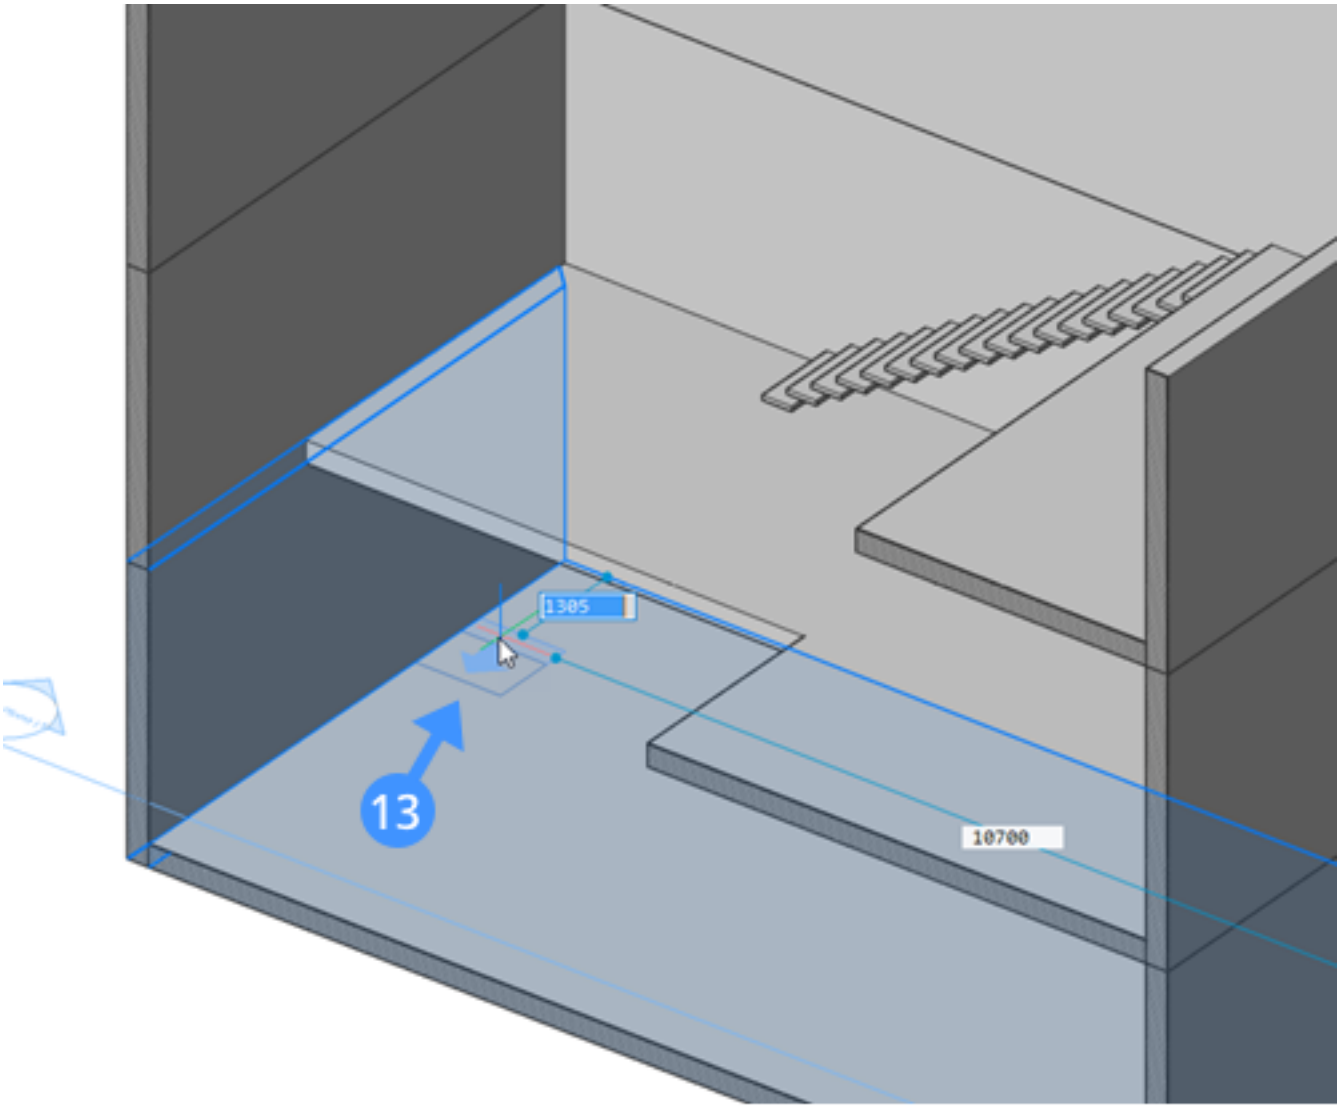

Figure 2.462

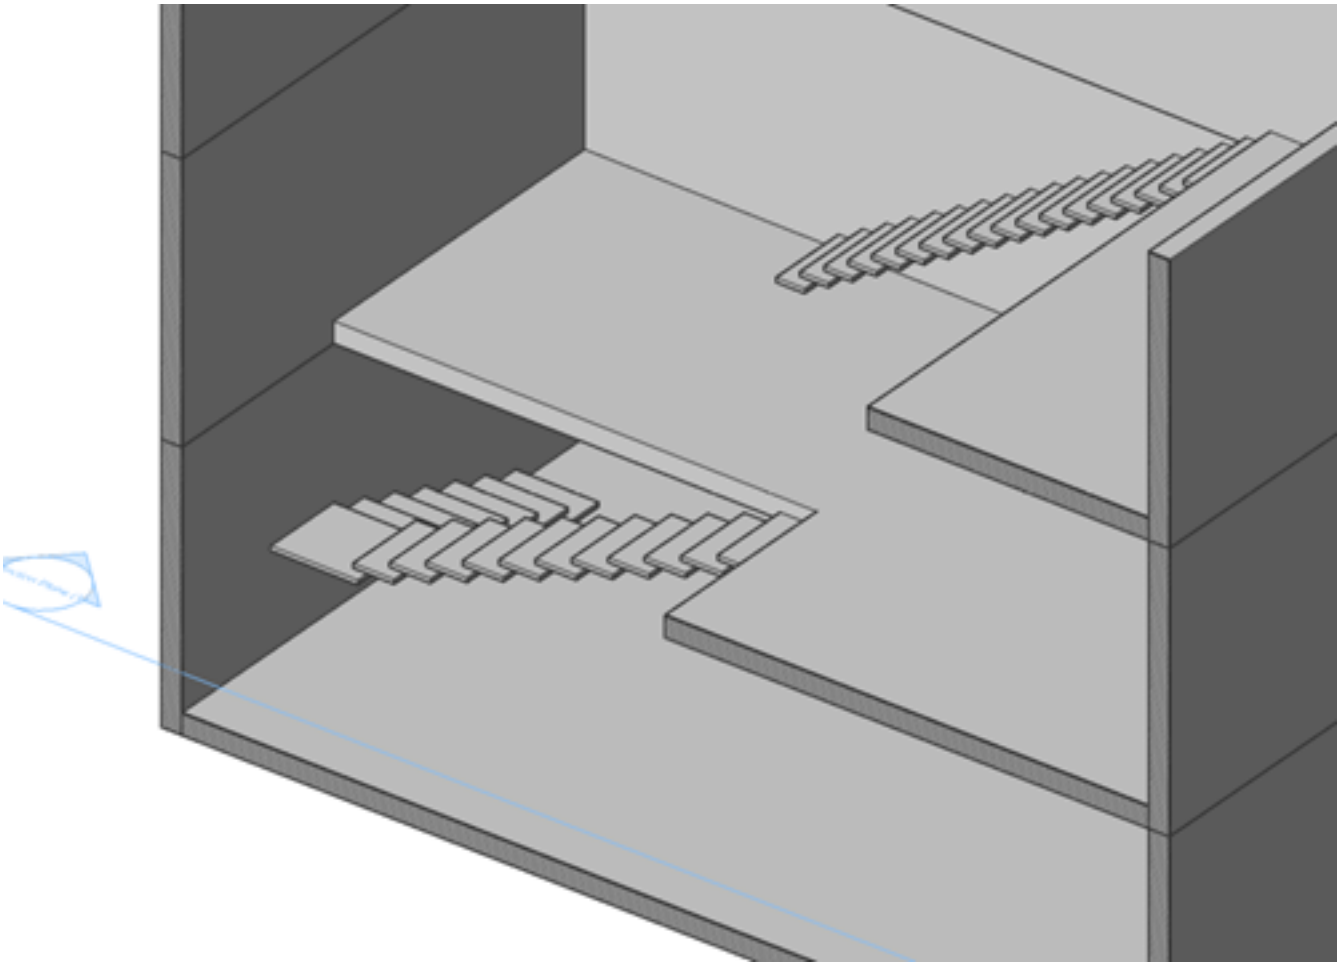


Change the Stair Tool Settings

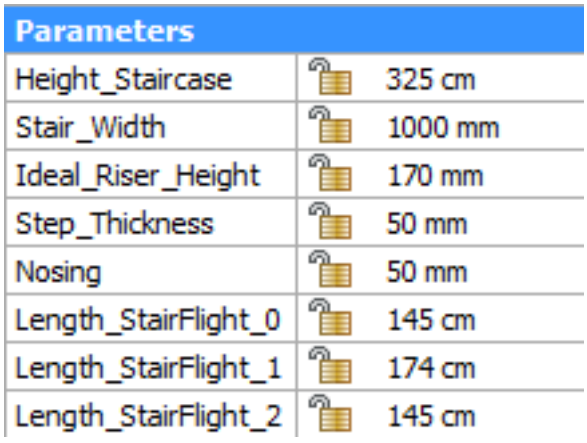
You can change the stair settings by clicking the 'Stair settings'-button in the Stair Tool menu after the Stair Tool command is launched **Or** simply open the Settings dialog and search 'Stair'.

Edit a flight of stairs

You can adjust multiple parameters of a flight of stairs created with the Stair Tool in the Properties Panel. These parameters include: (2.463)

Height_Staircase	The overall height of the flight of stairs. The height is fixed at the top and will adjust from the base.
Stair_Width	The width of the flight of stairs. When a flight of stairs is selected a green dot appears on the upper slab. This dot indicates the insertion point of the flight of stairs. When this point is in the middle of the flight of stairs, the flight of stairs will widen from the center. When it is located at the side, for example when a stair is attached to a wall, the stair will only widen the side away from the dot.
Ideal_Riser_Height	The ideal riser height. When creating a flight of stairs, the real riser height will be calculated based on the ideal riser height and the height of the steps, so that the risers are equally divided as close to the ideal riser height as possible.
Thickness_Step	The step thickness. The upper face of the steps is fixed so that the thickness increases downwards.
Nosing	The horizontal distance of overlap between subsequent treads.
Length_StairFlight_0	The length of the first flight of stairs. Decreasing this value will shorten the length. The length of the treads and the number of treads for each flight will be updated according to the total length of all the flights of stairs.
Length_StairFlight_1	The length of an optional, second flight of stairs. Decreasing this value will shorten the length. The length of the treads and the number of treads for each flight will be updated according to the total length of all the flights of stairs. This option is only available for L-stairs and U-stairs.
Length_StairFlight_2	The length of an optional third flight of stairs. Decreasing this value will shorten the length. The length of the treads and the number of treads for each flight will be updated according to the total length of all the flights of stairs. This option is only available for U-stairs.
Landing_Extension_Up	The length of the landing going down the first flight of stairs. The first flight is fixed so the second flight adjusts to the given parameter value.

Figure 2.463



Landing_Extension_Down	The length of the landing going down the second flight of stairs. The first flight is fixed so the second flight adjusts to the given value.

(2.464 on the next page) **Setting: Landing Extension Up.** (2.465 on the following page) **Setting: Landing Extension Down.** You can re-position a flight of stairs created with the Stair Tool using the Move command. For complex edits to a flight of stairs created with the Stair Tool, use the BEdit command to edit the block definition. When in the BEdit-mode navigate to the Mechanical Browser and here you can see and edit all the constraints that apply to a flight of stairs.

Figure 2.464

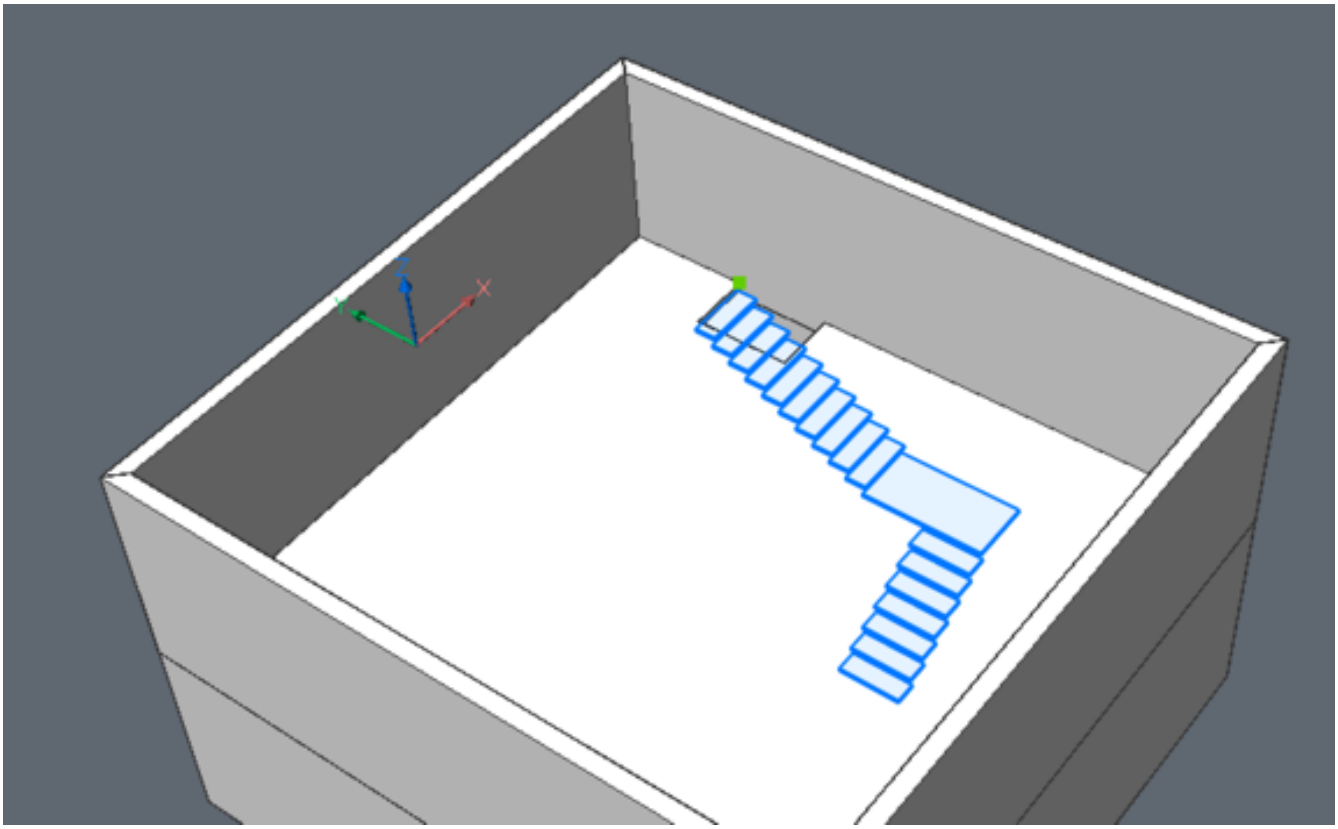


Figure 2.465

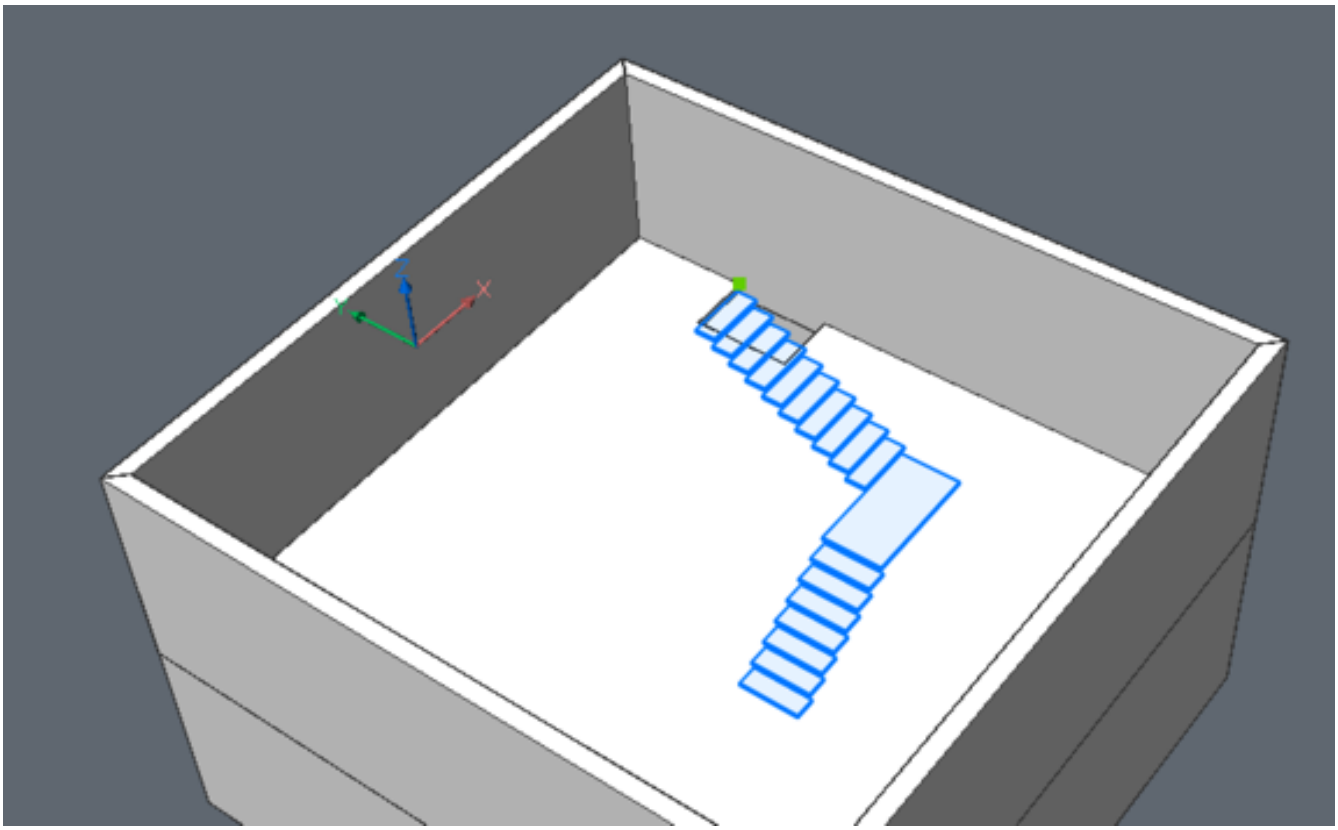


2.5.24 Working with Parameters and Constraints

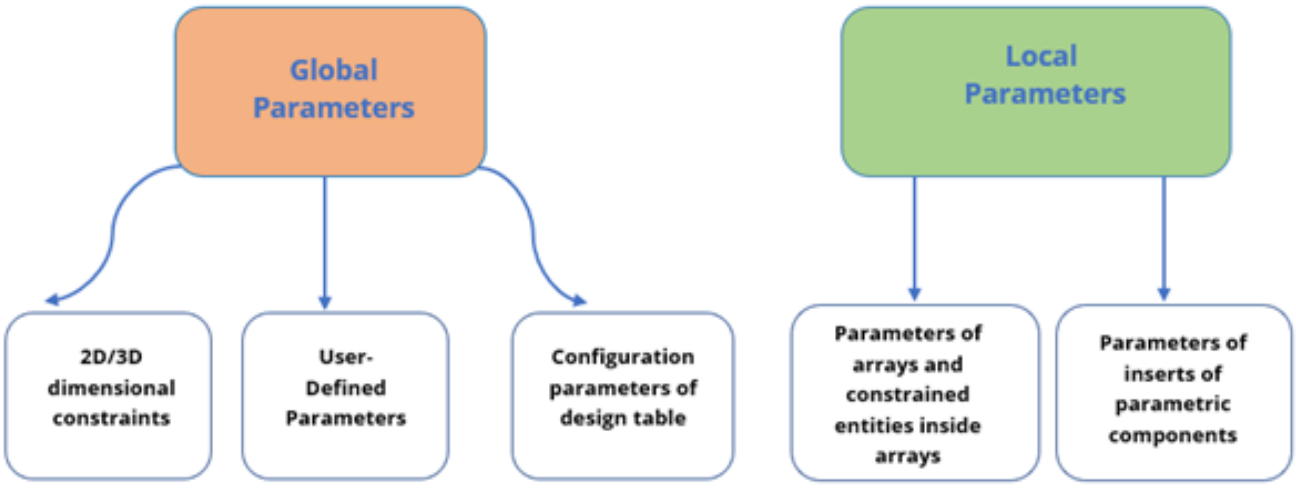
Overview: In this lesson, you learn how to parametrize your BricsCAD BIM entities. **Lesson Objectives** After completing this lesson, you will be able to:

- Understand the difference between global and local parameters.
- Identify the geometric and dimensional constraints.
- Set an expression to a parameter.
- Parametrize your custom component.
- Control your 3D geometry with parameters.

Parametric Modeling

In BricsCAD, parametric modeling is done through the use of geometrical and dimensional constraints. A rich toolset controls the 2D and 3D geometric model with a set of parameters. Each parameter will be displayed with a value in the Mechanical Browser. The value from the different parameters can be linked together via expressions. When one of the parameter values is changed, the geometric model is updated automatically. The toolset allows BricsCAD users to add parametric behavior to any geometry and easily explore design intent. **Note:** In BricsCAD, there are no parent-child dependencies between geometric elements. For instance, if you change a sketch used to create an extruded 3D solid, the solid is not changed accordingly. Any kind of dependencies can be created using the parameters and expressions. There are two types of parameters: Local parameters are attached to a particular entity. Global parameters are not attached to a particular entity. (2.466)

Figure 2.466



Working with constraints

If you create some components (e.g. windows, doors,...) in your BIM model, you can parametrize them by applying 3D constraints. Defining constraints allows you to control the shape and size of the elements. Together with constraints, parameters determine the positions of entities through an expression. There are two types of 3D constraints in BricsCAD: one specifies the size of the entities, the other locate their positions.

Geometrical constraints

Geometric constraints allow you to control the position of 3D entities with respect to each other.
Toolbar: **Parametric > 3D constraints** Quad: **Constraints** The following table shows the 3D geometrical constraints.

Fix		Keeps solids, edges or faces of solids in-place in the drawing.
Coincident		Applies a coincident constraint between two edges, two faces or an edge and a face of two different solids.
Concentric		Keeps two cylindrical, spherical or conical surfaces centered.
Parallel		Keeps the two faces of a solid or of different solids parallel.
Perpendicular		Keeps the two faces of a solid or of different solids perpendicular.
Tangent		Keeps a face and a curved surface of different solids tangent.
Rigid set		Makes a set of entities or sub-entities a rigid body.

Dimensional constraints

Dimensional constraints allow you to control the sizes of 3D entities in drawings, and the distances between them. (2.467) Toolbar: **Parametric > 3D constraints** Quad: **Constraints** Ribbon: **Parametric Tab > 3D constraints** The following table shows the dimensional constraints.

Distance		Creates a distance between two sub-entities.
Radius		Creates a radius to cylindrical surfaces or circular edges.
Angle		Creates an angle between two faces of a solid or of different solids.

Figure 2.467

Setting an expression to a parameter

In BricsCAD, you can set an expression to any parameter, be it global or local. As an example, you can create a simple expression that only contains a number or a name of a global parameter and apply it to the related geometry in the drawing. You can also use more complex formulas that include the use of standard operators and functions.

NOTES

- Local parameters cannot be referenced by names in expressions.
- The constants **Pi=3.14...** and **e=2.72...** can be used in expressions. The constants names are not allowed to be used as parameter name and name of 3D constraint.

The following table shows the operators that can be used in expressions.

Addition (+)	Produces the sum of numeric values.
Subtraction or Negative (-)	Subtracts the two numeric values.
Multiplication (*)	Multiplies the numeric values.
Division (/)	Divides two numeric values.
Exponentiation (^)	Calculates the exponential value of the given numbers.
Modulo or Remainder operator (%)	Gives the remainder after the division of one numeric value to another e.g. The expression "5 % 2" would evaluate to 1, because 5 divided by 2 leaves a quotient of 2 and a remainder of 1.

The following table shows the functions and the syntax which can be used in expressions.

Cosine	cos(expression)
Sine	sin(expression)
Tangent	tan(expression)
Arc cosine	acos(expression)
Arc sine	asin(expression)
Cosine	cos(expression)
Arc tangent	atan(expression)
Hyperbolic cosine	cosh(expression)
Hyperbolic sine	sinh(expression)
Hyperbolic tangent	tanh(expression)
Arc hyperbolic cosine	acosh(expression)
Arc hyperbolic sine	asinh(expression)
Arc hyperbolic tangent	atanh(expression)
Square root	sqrt(expression)
Signum function (-1,0,1)	sign(expression)
Round to nearest integer	round(expression)
Truncate decimal	trunc(expression)
Round down	floor(expression)
Round up	ceil(expression)
Absolute value	abs(expression)
Largest element in array	max(expression1;expression2) *
Smallest element in array	min(expression1;expression2) *
Degrees to radians	d2r(expression)
Radians to degrees	r2d(expression)
Logarithm, base e	ln(expression)
Logarithm, base	10 log(expression)
Exponent, base e	exp(expression)
Exponent, base 10	exp10(expression)
Power function	pow

Random decimal, 0-1	Random(expression1;expression2) *

*Use the list separator character as defined on your system: , (comma) or ; (semicolon).

Parametric Blocks

Parametric Blocks refer to blocks that have parameters that determine the size and shape of the 3D geometry. Once the parametric block is created, it can be inserted as a block reference in the drawing. The parameters of your block can be changed after you insert it in your model. Thus, no need to modify the parametric block file individually. The parametric blocks also enable you to use the same block in different sizes and in different shapes in your model.

Procedure: Parametrizing a custom component

The window that was created in the previous lesson is used to demonstrate how the parametric design works. This window consists of three solids: subtractor, fixed frame, and glass pane.

Step 1: Before starting to add constraints:

1. Open the Mechanical Browser with the **MechanicalBrowserOpen (6.8.32)** command, to control and manage the values of 3D constraints and parameters. **Note:** The Mechanical Browser allows to navigate through all the constraints and parameters in the drawing and to edit dimensional constraints.

2. Make sure that the **Enable selection of 3D solid faces** () is toggled on in the **Selection Modes** To easily follow the steps, make sure **Boundary Detection** is toggled off.

Step 2: Applying fix constraints Command: DmFix3d (6.12.15)

1. Turn on the BIM_Subtract layer.

2. Select the entities (1) you want to add a fixation to. (Optional) Press the TAB key to select obscured geometry.

3. Choose Add Fixation (2) in the 3D constraints command group in the Quad. (2.468 on the next page) The fixation appears in Mechanical Browser as ' Fix_1'. (2.469 on the facing page)

Figure 2.468

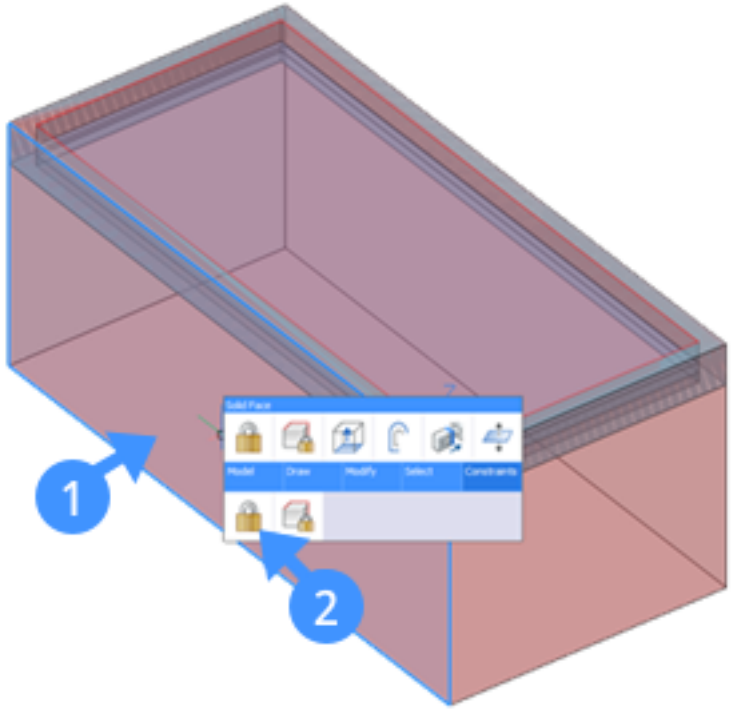


Figure 2.469

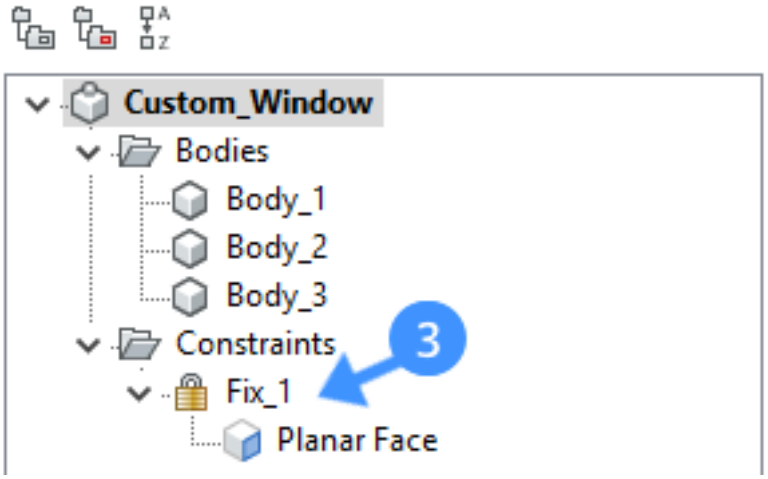

Step 3: Applying rigid constraints Command: DmRigidSet3d (6.12.23)

1. Select the entities to apply the Rigid Set constraints. The entities remain in the same position with respect to each other when they are in a Rigid Set. To select more than one sub-entity of the same type at a time, take the following steps:

   - Use Look From Widget (4), by default it is at the top right of your screen, to change the view from 3D to TOP.
   - Select the entities using the selection box (5). While drawing a selection box, press CTRL key to change the type of sub-entity selection. Every time you press CTRL key the type of the sub-entity selection will change. The type of the sub-entity can be seen under your mouse cursor, for instance, faces (6) or edges (7).

   Note: By default, the selection boxes see and select solids. (2.470 on the next page) (2.471 on page 2010) (2.472 on page 2011)

2. Choose Add Rigid Set () in the 3D constraints command group in the Quad.

3. Repeat the same process for the other sides: top, bottom, and right side.

Figure 2.470

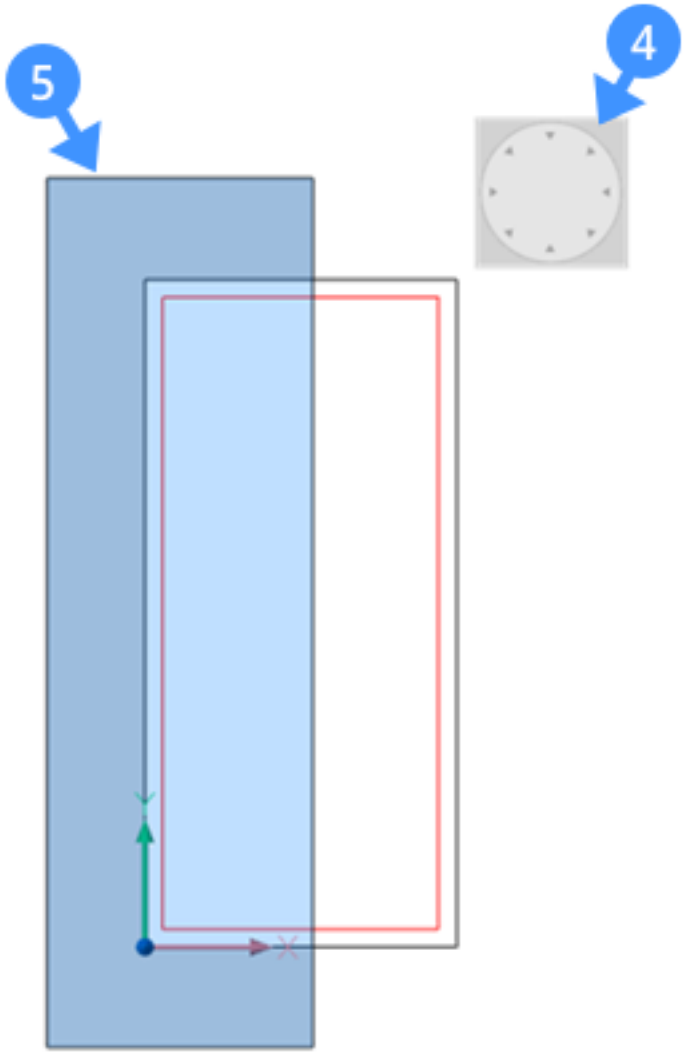

Figure 2.471

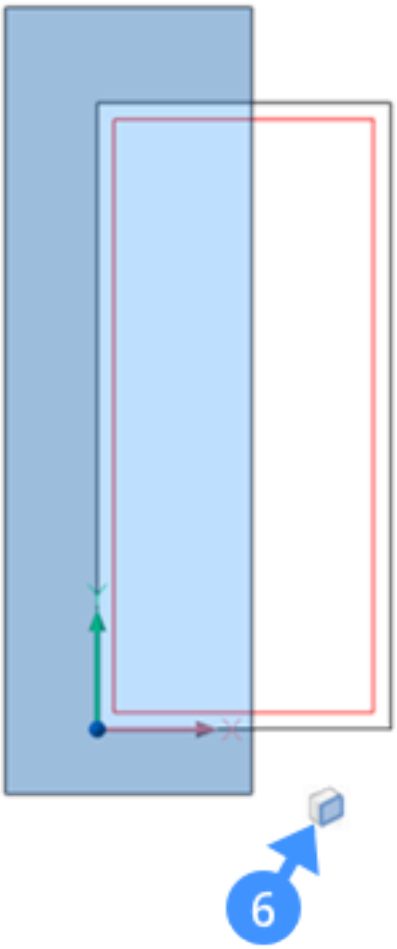

Figure 2.472

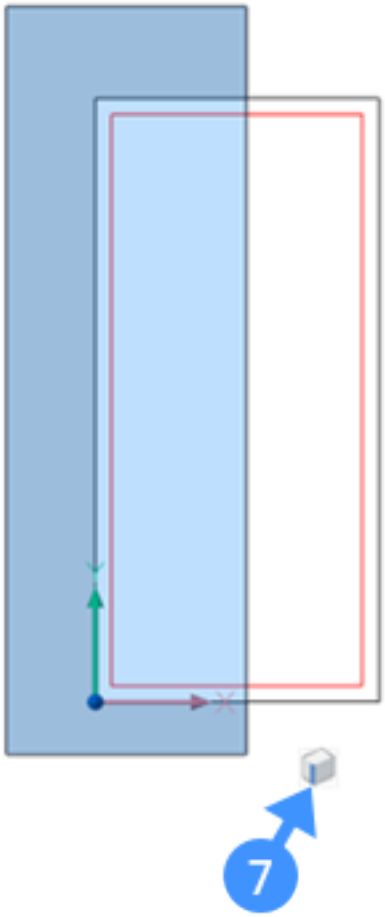

Step 4: Applying distance constraints Command: DmDistance3d (6.12.10) Dimensions of the window and the thickness of the glass pane.

1. Turn off the BIM_Subtract layer.
2. Select the first face. The face highlights.
3. Hover over the second face. Hit the TAB key to highlight an obscured face.
4. When the second face highlights, choose **Add Distance** (8) in the 3D Constraints command group in the Quad. (2.473 on the following page) **You are prompted:** Specify distance value or [Geometry-driven] <xxx.xx>:
5. Do one of the following:
   - Press Enter key or right-click to accept the current value. The current value displays in the dynamic dimension field (9) when the Dynamic Dimensions (DYN) is active. (2.474 on the next page)
   - Type a value in the command line.
6. The distance value between the two surfaces appears in the Mechanical Browser. **Note:** To remove any constraint in your model, select the constraint in the Mechanical Browser, e.g. fix, rigid set..., and press the Delete key or right-click and select the Delete option.

Figure 2.473

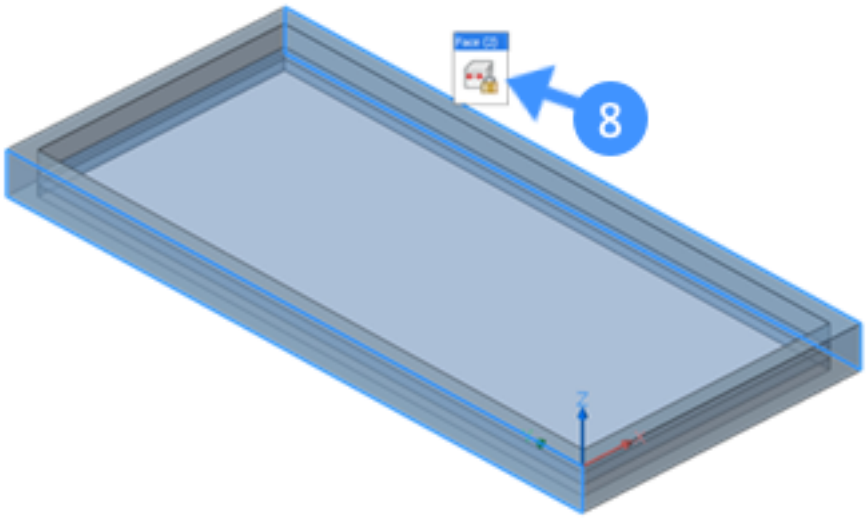

Figure 2.474

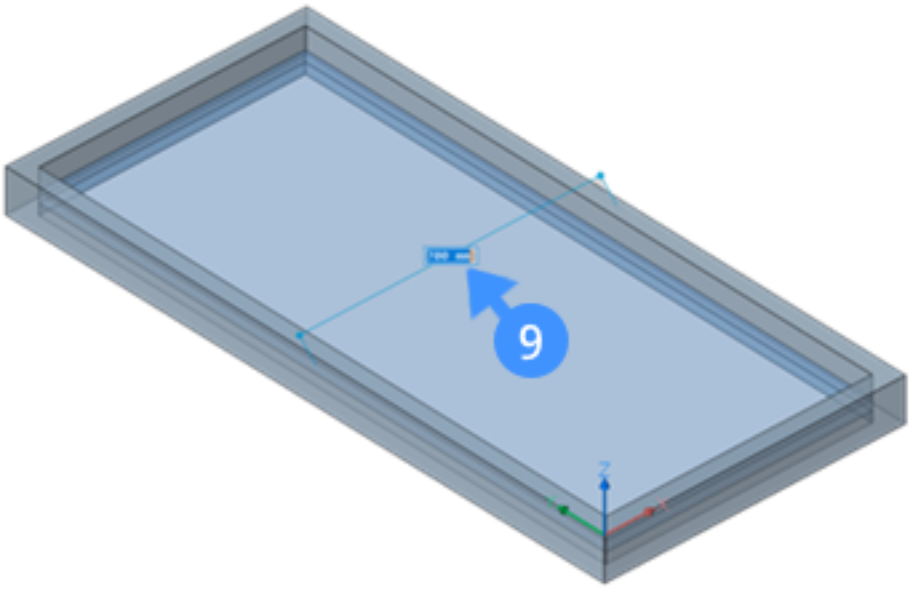

Step 5: Applying parameters We will create a parameter that controls the width of the window.

1. Right-click the file name (10) in the Mechanical Browser.
2. Select **Add New Parameter** (11)in the context menu. The parameter settings grid is created and the parameter is added in Mechanical Browser as 'v1 = 1' (12). (2.475)
3. Select the parameter, then edit its properties in the settings grid. The following illustration shows the properties of a Width parameter of the custom window. The table below demonstrates each property. (2.476 on the next page)

Name	Type a parameter name.
Expression	Type a value or formula.
Value	Shows the current value of the parameter.
Geometry-driven	If yes, makes the parameter geometry-driven (1.27.3).
Description	Define an optional description of the parameter.
Exposed	Controls whether the parameter is available in the properties panel when the component is inserted into a model.
Units	Specifies whether the parameter is linear, areal or volumetric.

4. To link the parameter you just created with the dimensional constraint, select the distance constraint in the Mechanical Browser and use the parameters to formulate an expression in the Expression field in the settings grid of the constraint. (2.477 on the following page)
5. **(Optional)** change the expression value of the parameter and press Enter. The assigned distance constraint is changed accordingly.

*In your drawing, you can design as many constraints as possible. Note that the software will keep you away from applying more constraints than are necessary.

Figure 2.475

This tutorial shows how the Properties Panel is structured and which properties it shows. Back to Tutorial Overview

2.7 Building Data

2.7.1 Analytical Model

Command: BimAnalyticalModel (6.7.6) **Overview:** In this lesson, you will learn how to generate, edit and export an analytical model from a fully classified BIM model. **Lesson Objectives** After completing this lesson, you will be able to:

- Generate an analytical model from a fully classified BIM-model with different deviation settings
- Remove connection nodes
- Add or remove restrictions
- Edit the nodes or axes of an analytical model
- Export the analytical model to an IFC file or a CIS/2 file

About BIMAnalyticalmodel

An **Analytical Model** is in essence a simplified wireframe model that only contains the load-carrying building elements. The linear building elements like columns, beams and members are represented by lines. The planar building elements like walls and slabs are not yet supported in the analytical model. In BricsCAD, the BIMAnalyticalModel (6.7.6) command allows you to generate an analytical model from a full 3D model of a structure. The command starts with an automatically generated proposal but allows you to further adapt the model to your desire. The automatic proposal will try to minimize rigid links (eccentricities) as much as possible by shifting, extending and even rotating some axis lines. The number of such changes can be controlled by the deviation settings. You can modify the generated proposal afterward by using the options when you select an element (nodes or axes). To propagate the effect of a local change further you can use recalculate. This will launch a global solution that again tries to minimize rigid links but will respect the changes you made. After editing the model you can export it to an IFC file (2.11.3) and a CIS/2 file. This analytical model can then be used for further structural analysis after import in a dedicated analysis software package. It's important to emphasize that the input model has to be fully classified since the BIMAnalyticalModel (6.7.6) command assumes that all the load-carrying elements are indicated in the building element properties. In the procedures, the analytical model is explained with an example model. You can find this model in the appendix.

Procedure: Creating an analytical model with strict deviation settings

1. First, you have to classify your BIM model. This is necessary for using the BIMAnalytical model command. Use the **Bimify (2.9.1)** command on your model or classify elements manually. **You are prompted: run Bimify on entire model or [Advance] <model>**

2. Press Enter if you want to classify everything in your model or type **A** if you want a selection of elements. (2.478 on the next page)

3. Launch the **BIMAnalyticalModel** command in the commandline.

4. A pop-up window opens. (2.479 on the facing page) This window allows you to set the level of freedom used when generating an analytical model. When hovering over one of the options, a tooltip shows you what type of restrictions are imposed for that option. In this case, choose the **Restricted parallel deviation** with a maximal deviation in profile directions of **0 mm**. No axis is allowed to deviate from its central position in the profile.

5. An interactive preview of the analytical model is constructed based on the chosen global deviation setting. (2.480 on page 2028) Also, the visual settings window appears. In this window, you can check and uncheck different features of axes and nodes in order to highlight (in yellow) the axes and nodes which correspond to those features. This allows you to explore the current properties of the axis and nodes of the analytical model. Based on what you find you can determine if any adjustments need to be made. You can also change the size of the disks representing the nodes. This is useful in combination with the node highlighting, which can be used for example to find nearly coinciding nodes. (2.481 on page 2028)

6. Select the checkbox **Nearly coinciding with another node** in the visual settings window. You will see that the center axes at these nodes do not align perfectly. As a result, small rigid links (eccentricities) had to be introduced. This is because of the previous setting in step 4. These small rigid links are displayed in purple. (2.482 on page 2029) To avoid this, restart the command with a slightly more flexible setting. In the **Allowed deviations from center** window, choose again for restricted parallel deviation but this time with a maximal deviation in profile directions of **30 mm**. (2.483 on page 2030)

Figure 2.478

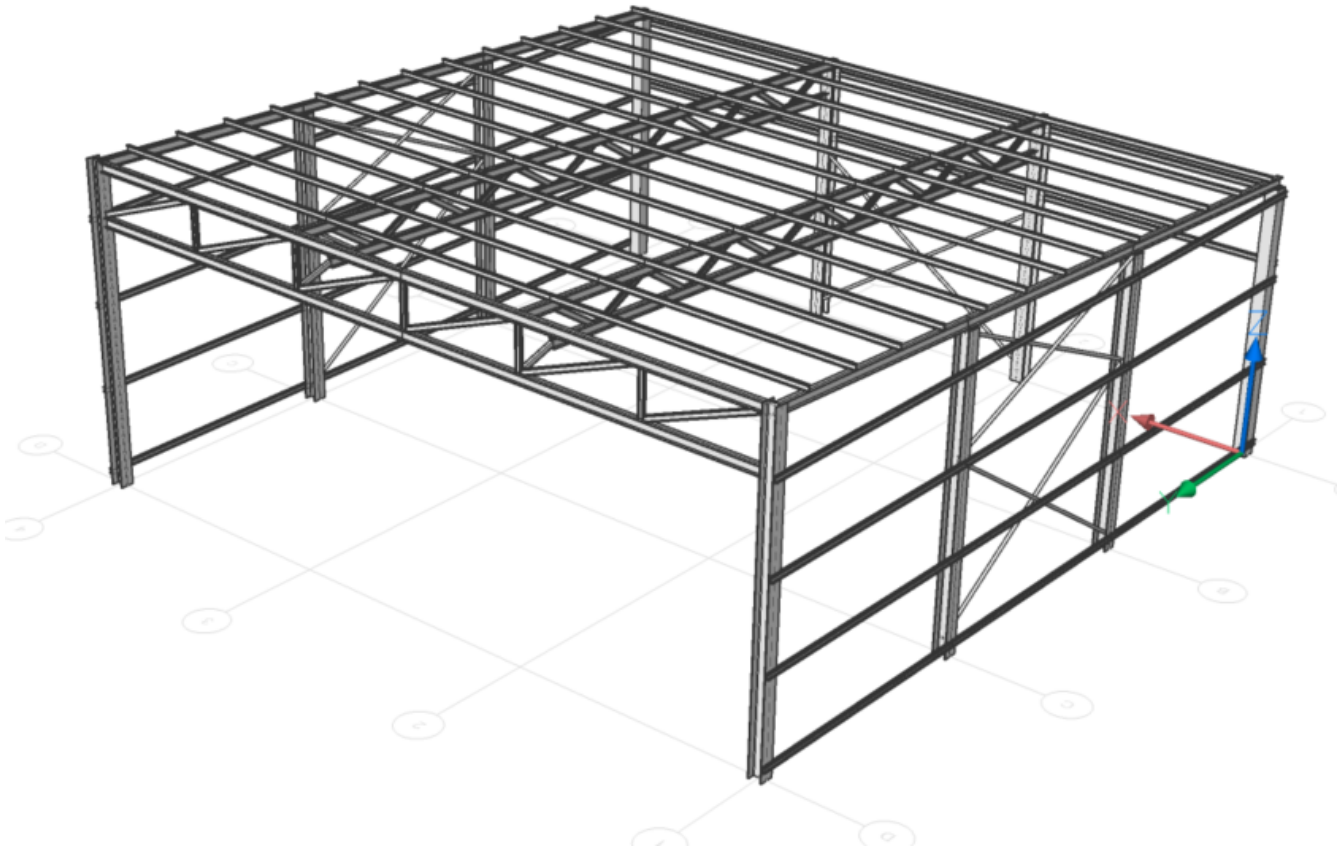

Figure 2.479

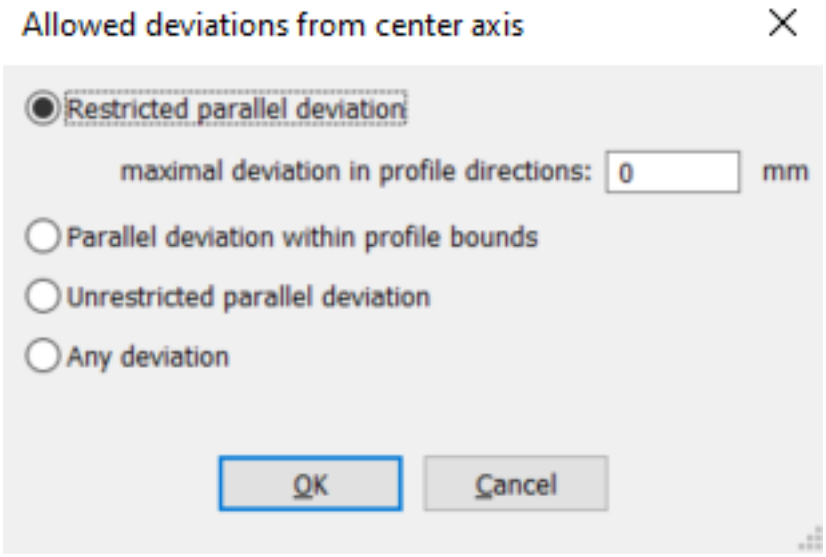

Figure 2.480

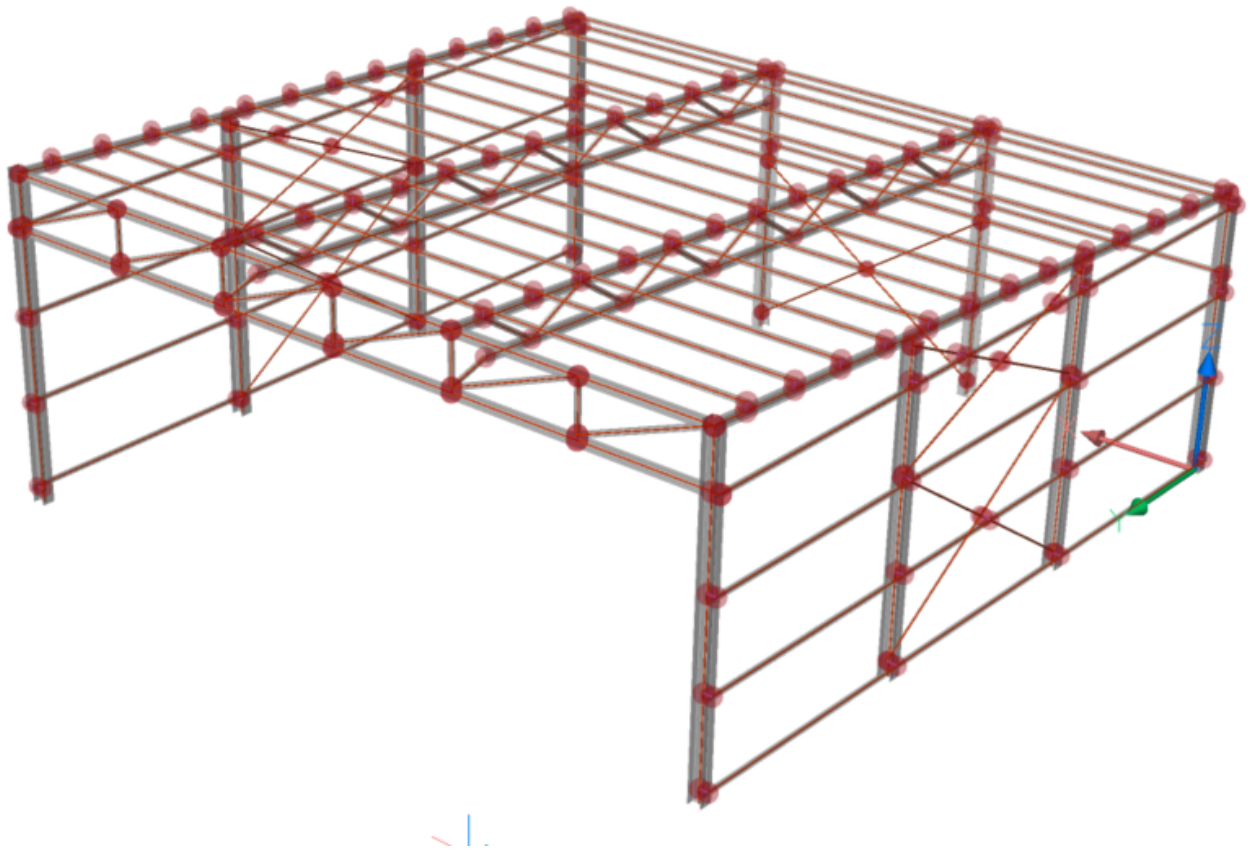

Figure 2.481

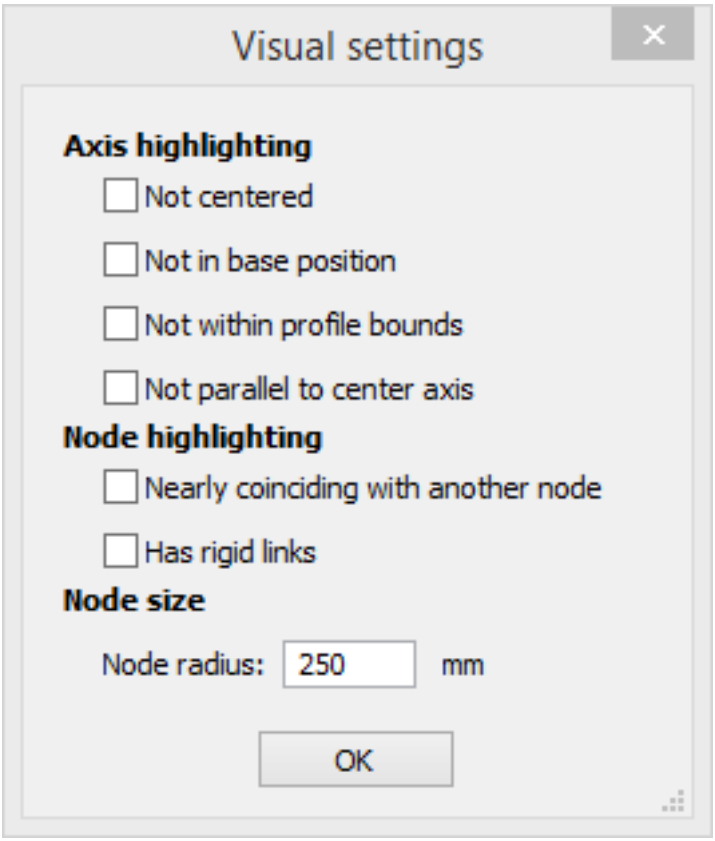

Figure 2.482

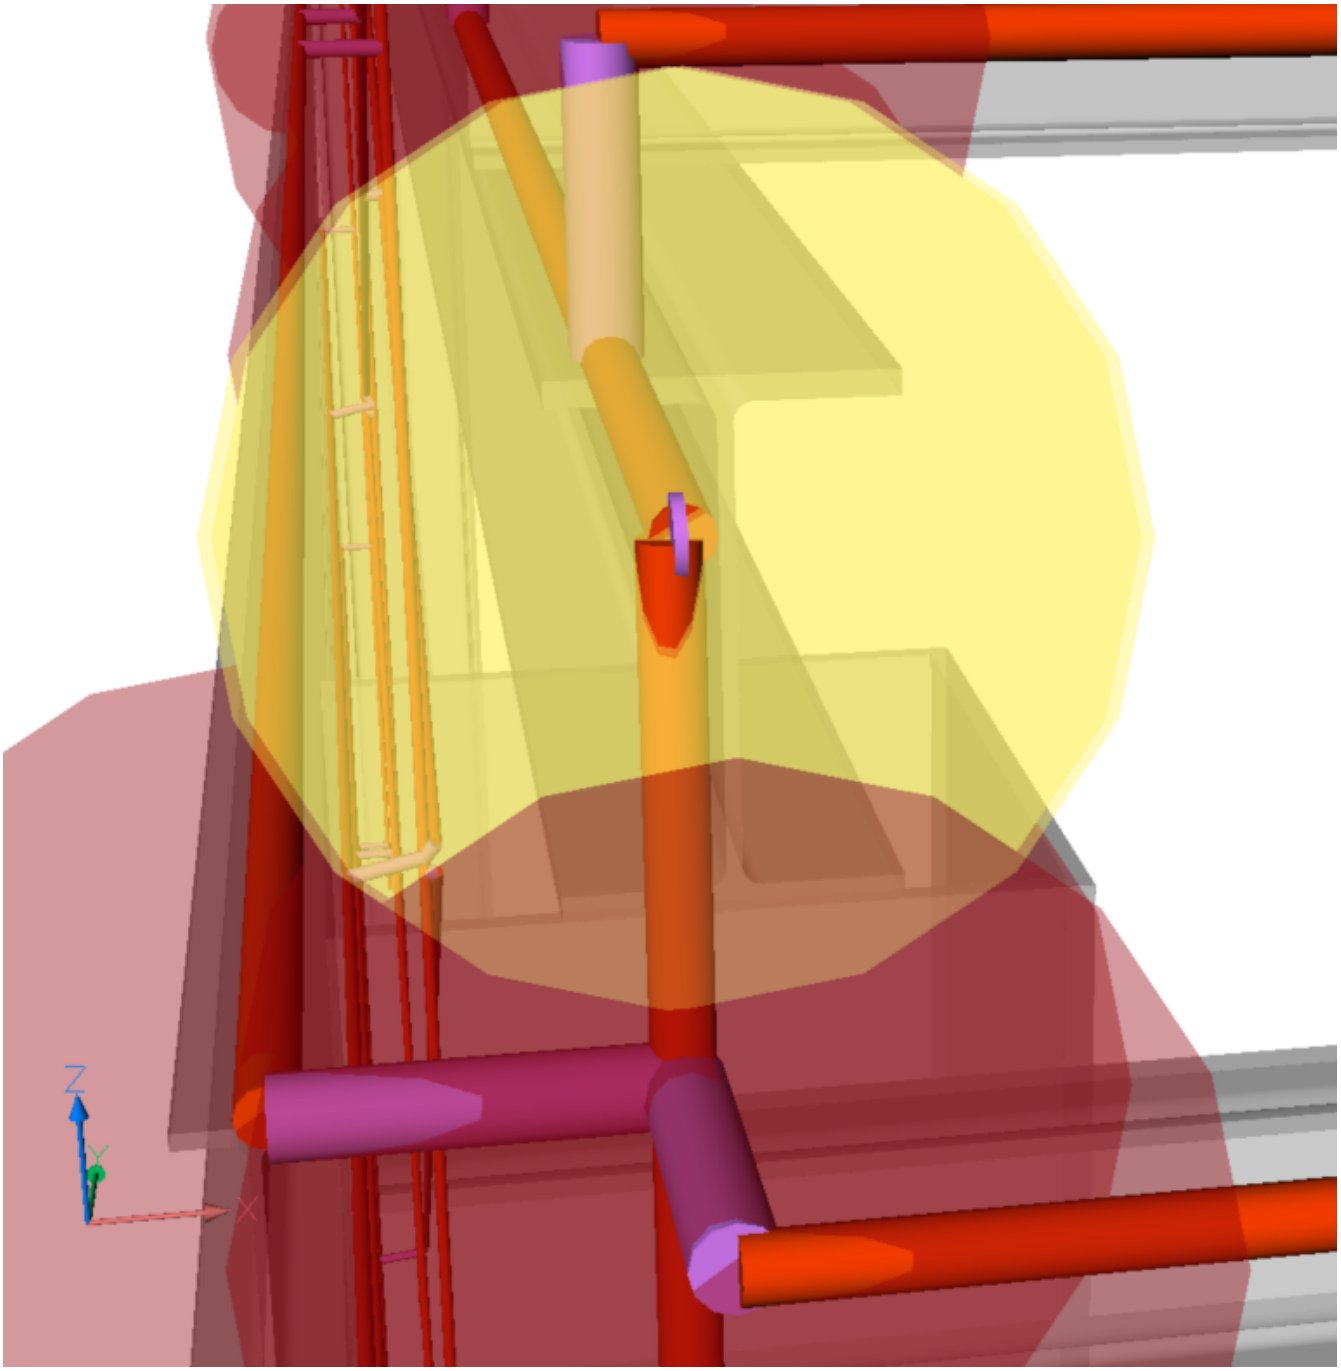

Figure 2.483

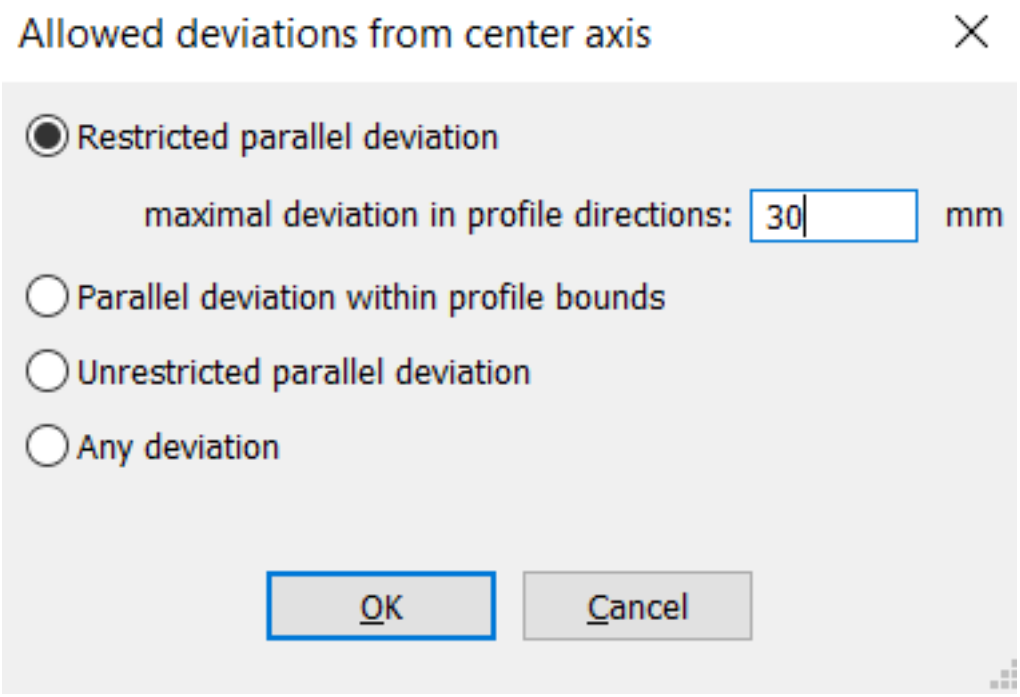

7. For the detection of nodes in the preview of the analytical model, the proximity of structural elements is used. Because of this, it is possible that there arise nodes in the model where tie rods cross. You can easily remove these nodes by clicking on the node and select **remove**. **Note**: you can select several nodes at once using box selection. (2.484 on the next page)

8. If you take a look a the remaining coinciding nodes, you see that the tie rods are not aligned perfectly with the center lines of the columns and small rigid links are formed. You can remove these rigid links by relaxing the position of the axes of the tie rods to a non-parallel position. You can do this by clicking on the tie rod, click **relax restriction** and click **non-parallel**. The extra freedom will be used to remove the rigid links by moving the axes of the tie rods a bit. (2.485 on page 2032)

9. The only coinciding nodes that are left are at the front truss of the hangar structure. If you take a look at the side of the front truss, you see that a tilted member is connected to the horizontal beam rather than the column. You can disconnect the tilted member by clicking on it and choose **disconnect from node**. (2.486 on page 2033)
   You are prompted: Select node disconnect from axes [Ok] Select the node you want to disconnect from. Type **O** to choose Ok. (2.487 on page 2035)

Figure 2.484

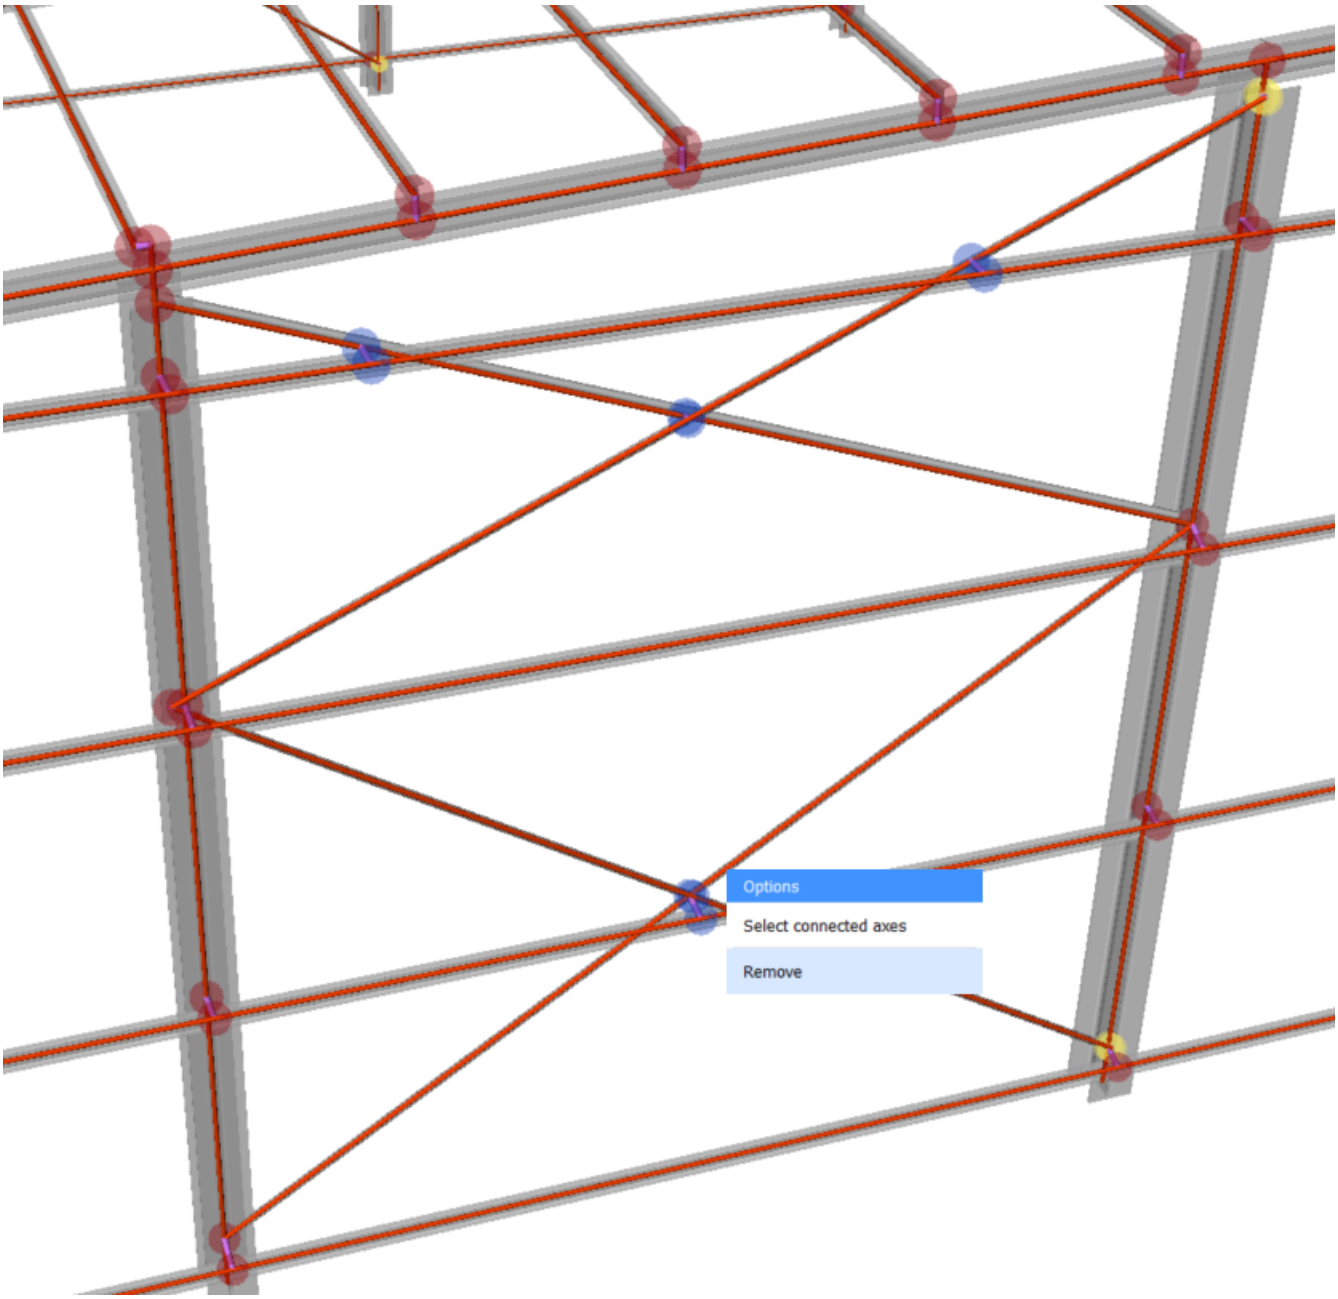

Figure 2.485

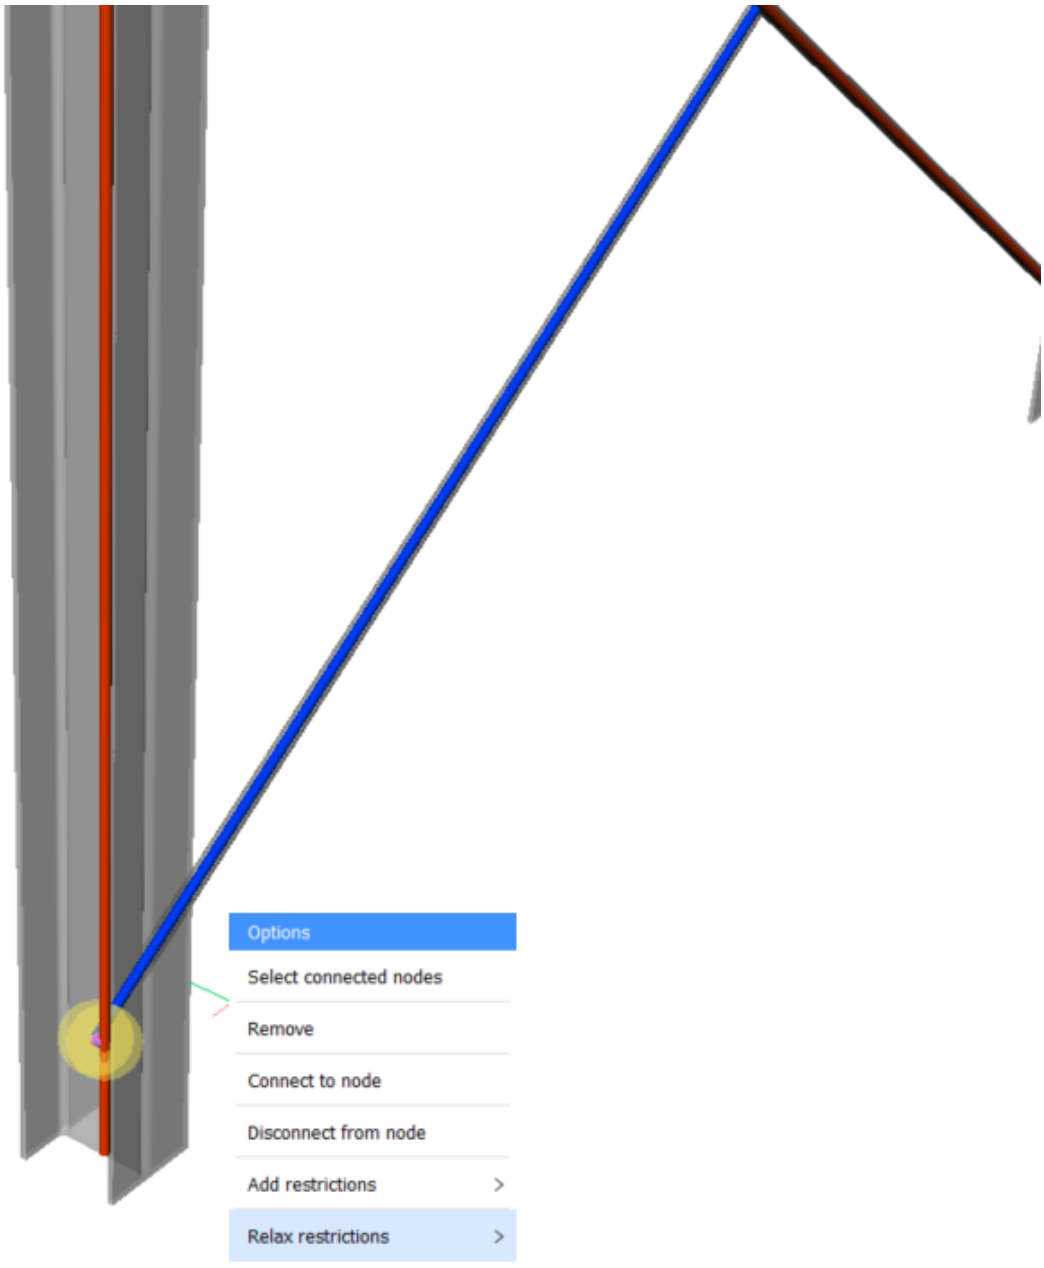
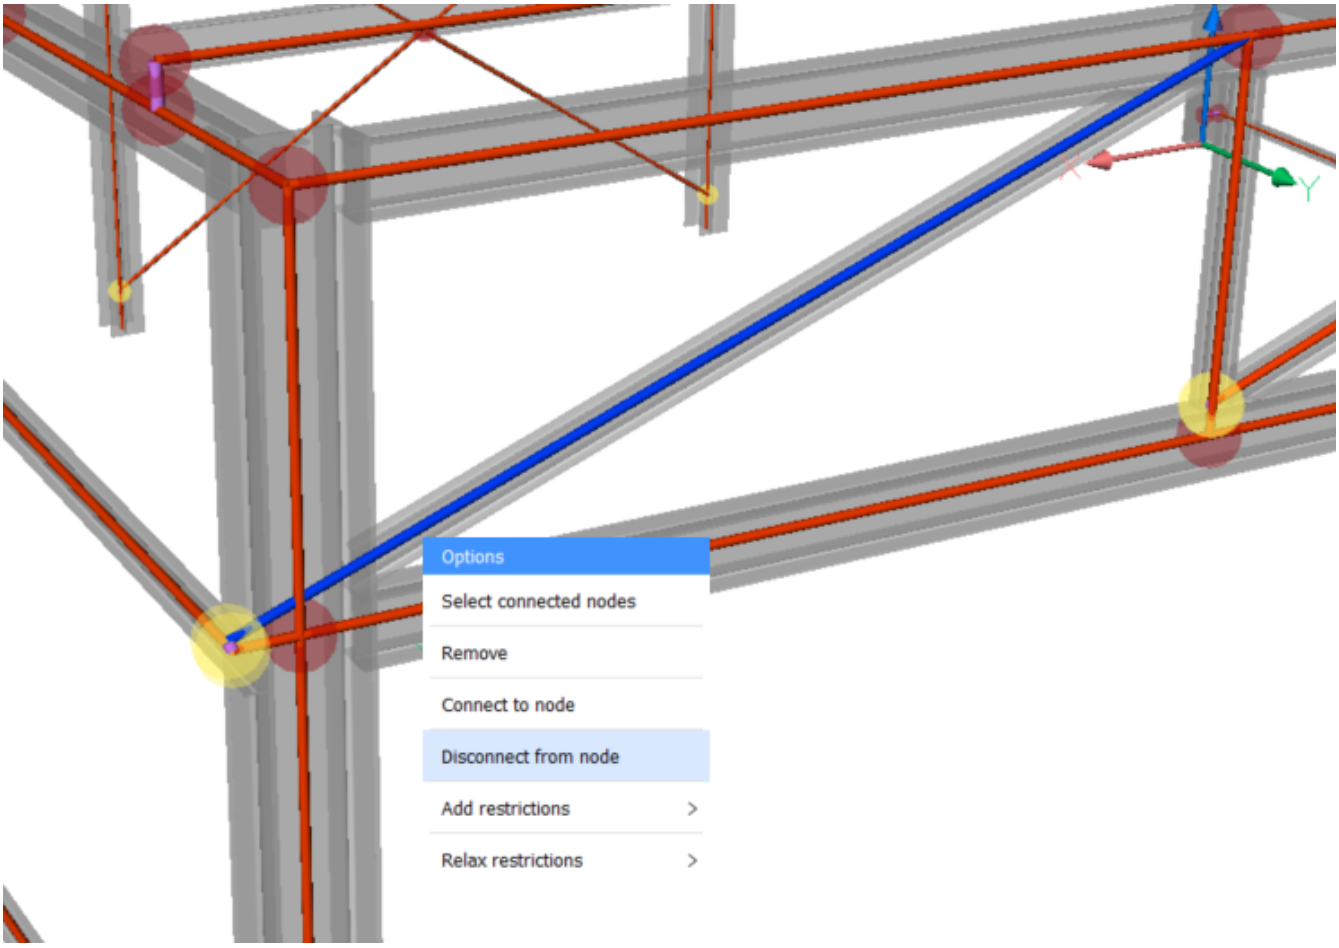


Options
Select connected nodes
Remove
Connect to node
Disconnect from node
Add restrictions
Relax restrictions

Figure 2.486



Options
Select connected nodes
Remove
Connect to node
Disconnect from node
Add restrictions
Relax restrictions

Now select the two axes that you want to connect and click **Connect axes**. (2.488 on page 2036)
With the global deviation setting, you chose this can only be done by introducing a small rigid link again. You can remove this by merging the two nodes. Select both nodes and click **Merge**. (2.489 on page 2037)

10. You see that the side member also is attached to the front beam instead of the column. Repeat step 9 for the side member. (2.490 on page 2038)

11. You can remove the last coinciding nodes in the front truss by merging the nodes. This will shift the axes of the tilted members and introduces rigid links on the other end. **Note**: If you take a look at **the axis not parallel to center axis** by using the visual setting window, you will see that the tilted member in the front truss has been allowed to be non-parallel to the center axis. So you could also remove the small rigid links by relaxing the tilted member to a non-parallel position like as we did for the tie rods. (2.491 on page 2038)

Figure 2.487

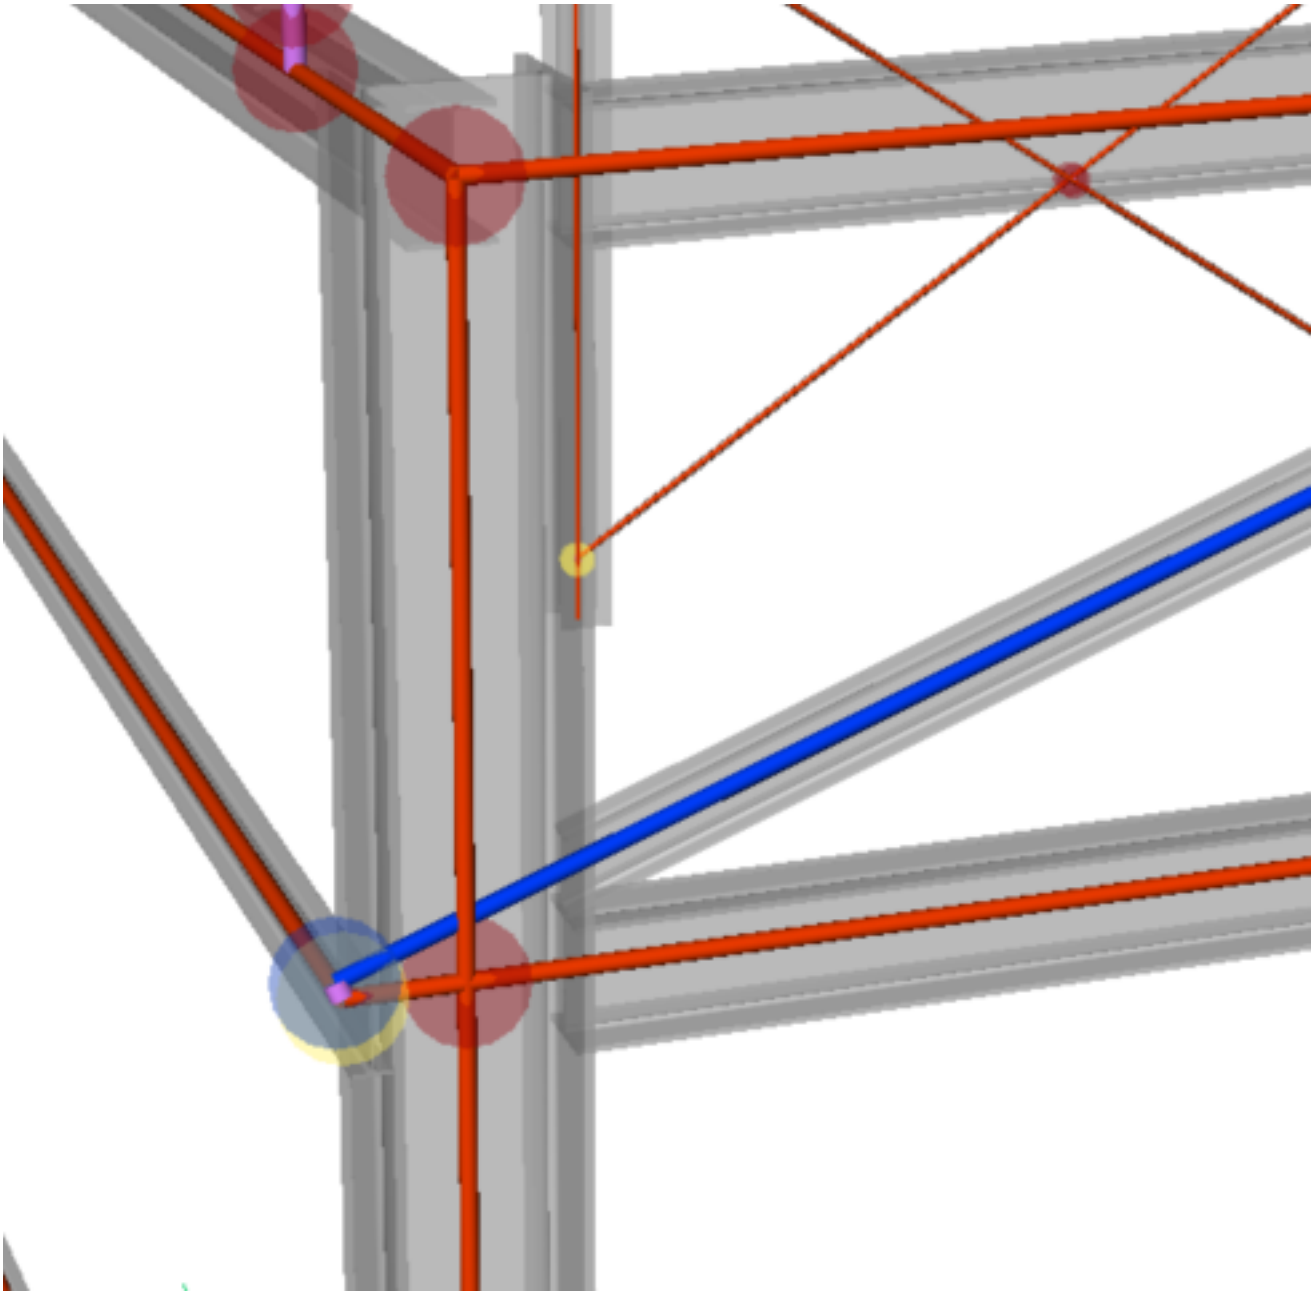


Figure 2.488

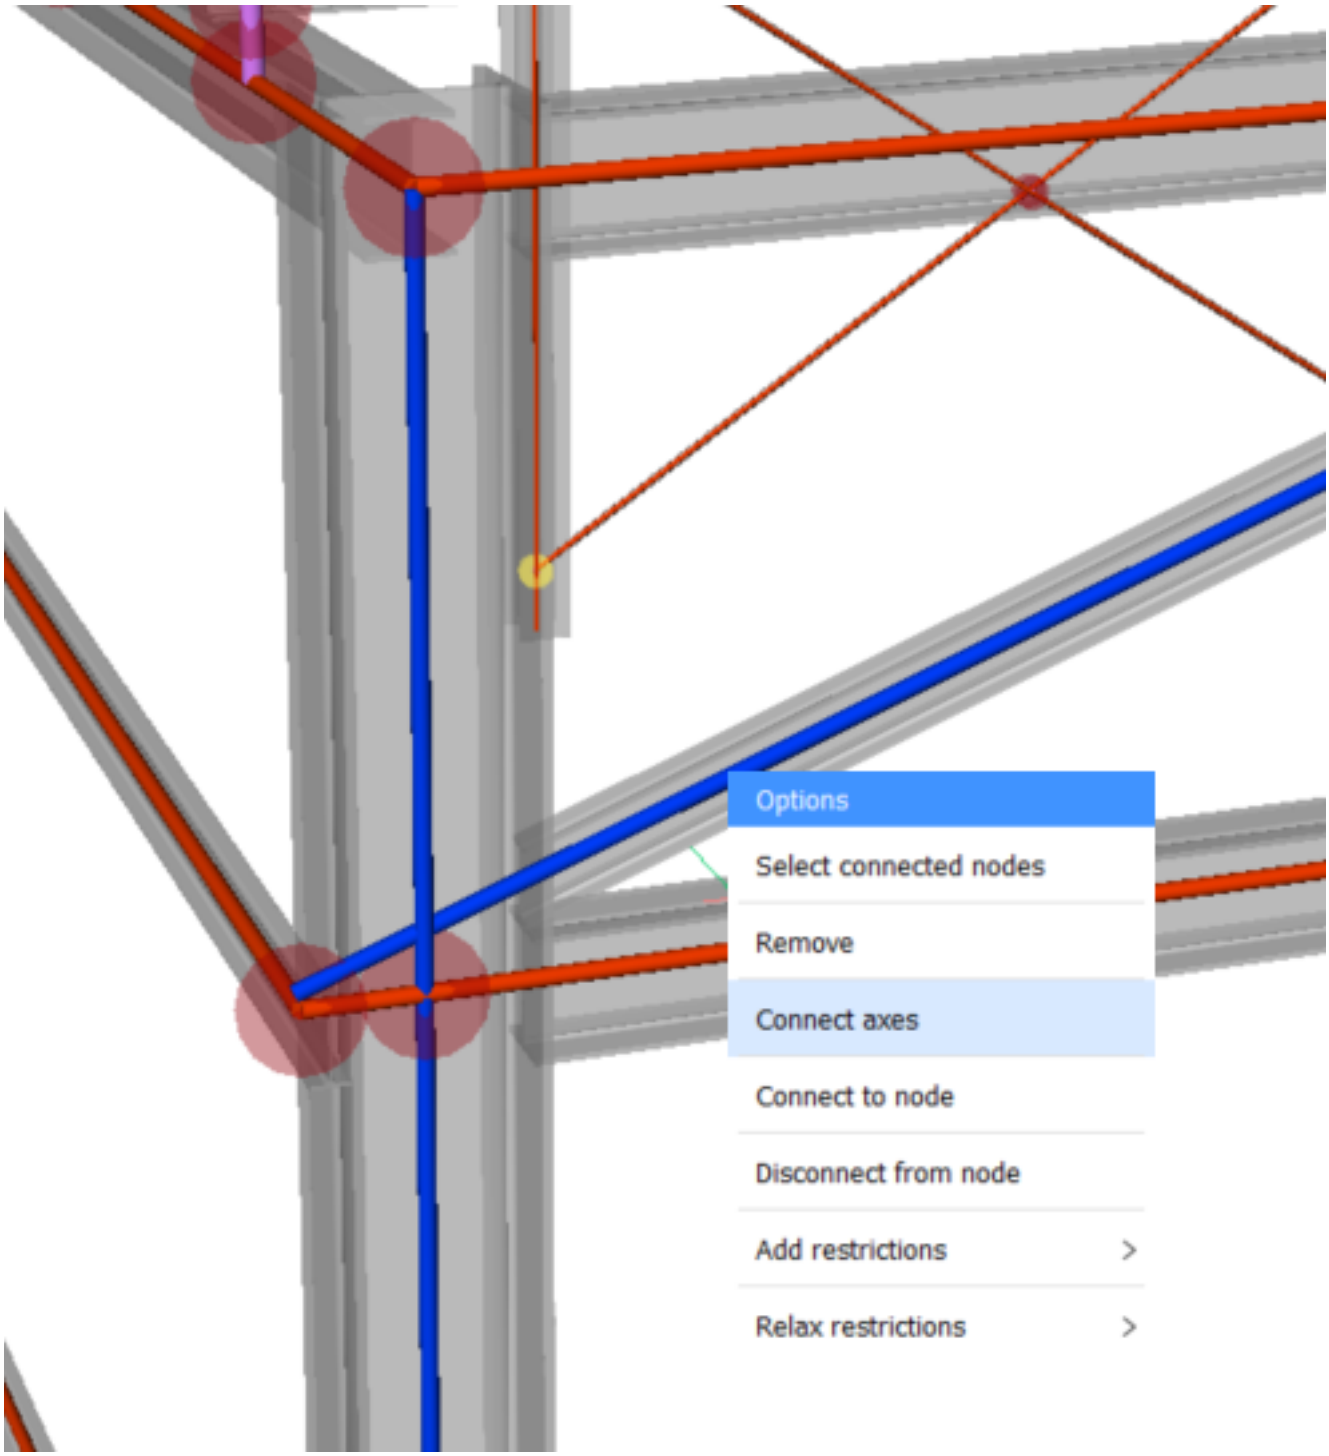

Options
Select connected nodes
Remove
Connect axes
Connect to node
Disconnect from node
Add restrictions
Relax restrictions

Figure 2.489

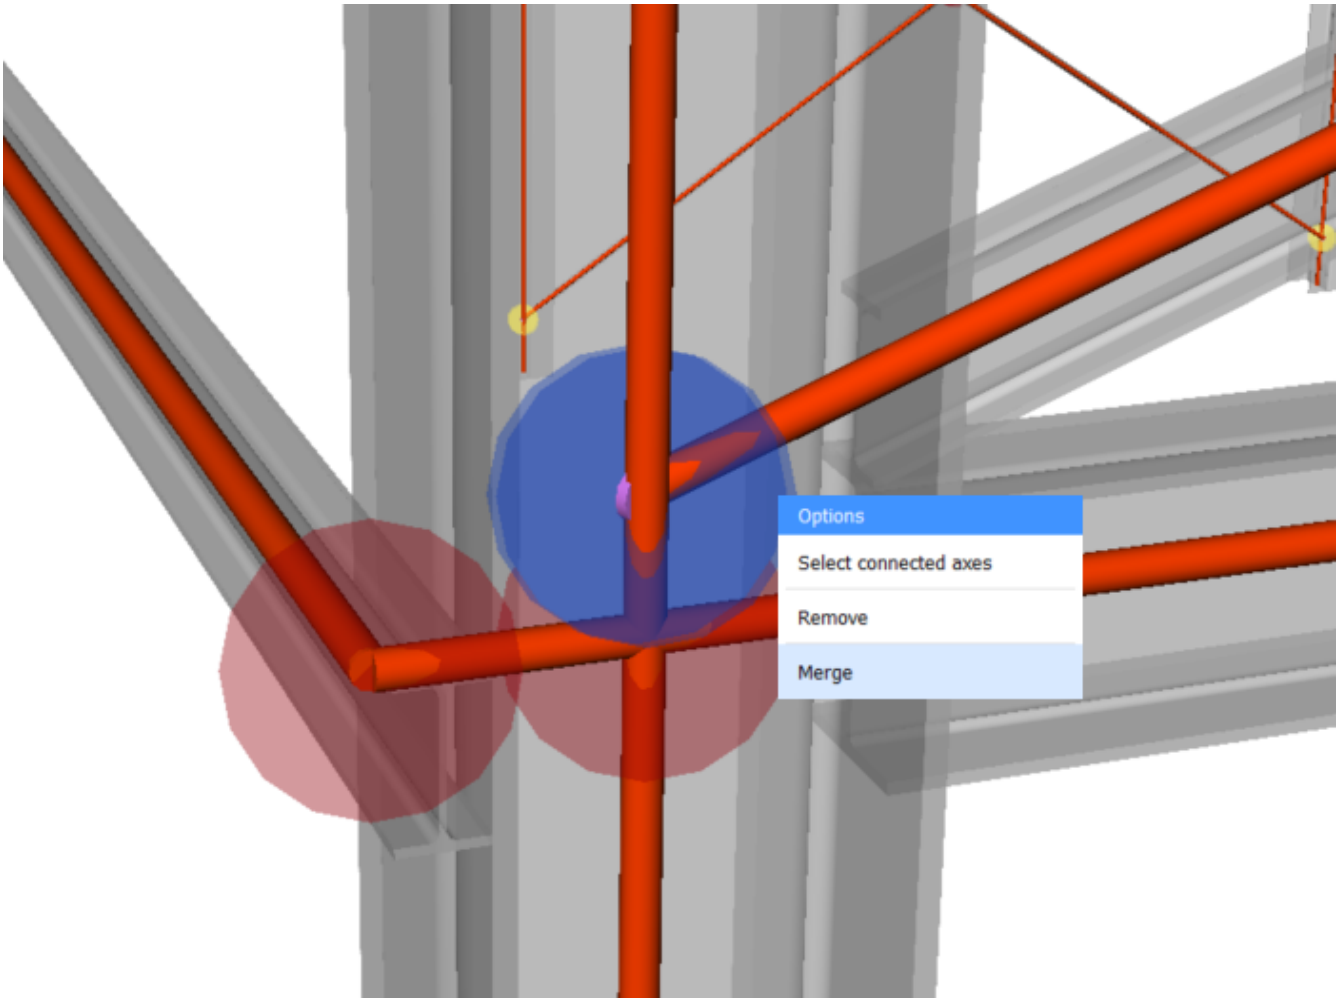

Figure 2.490

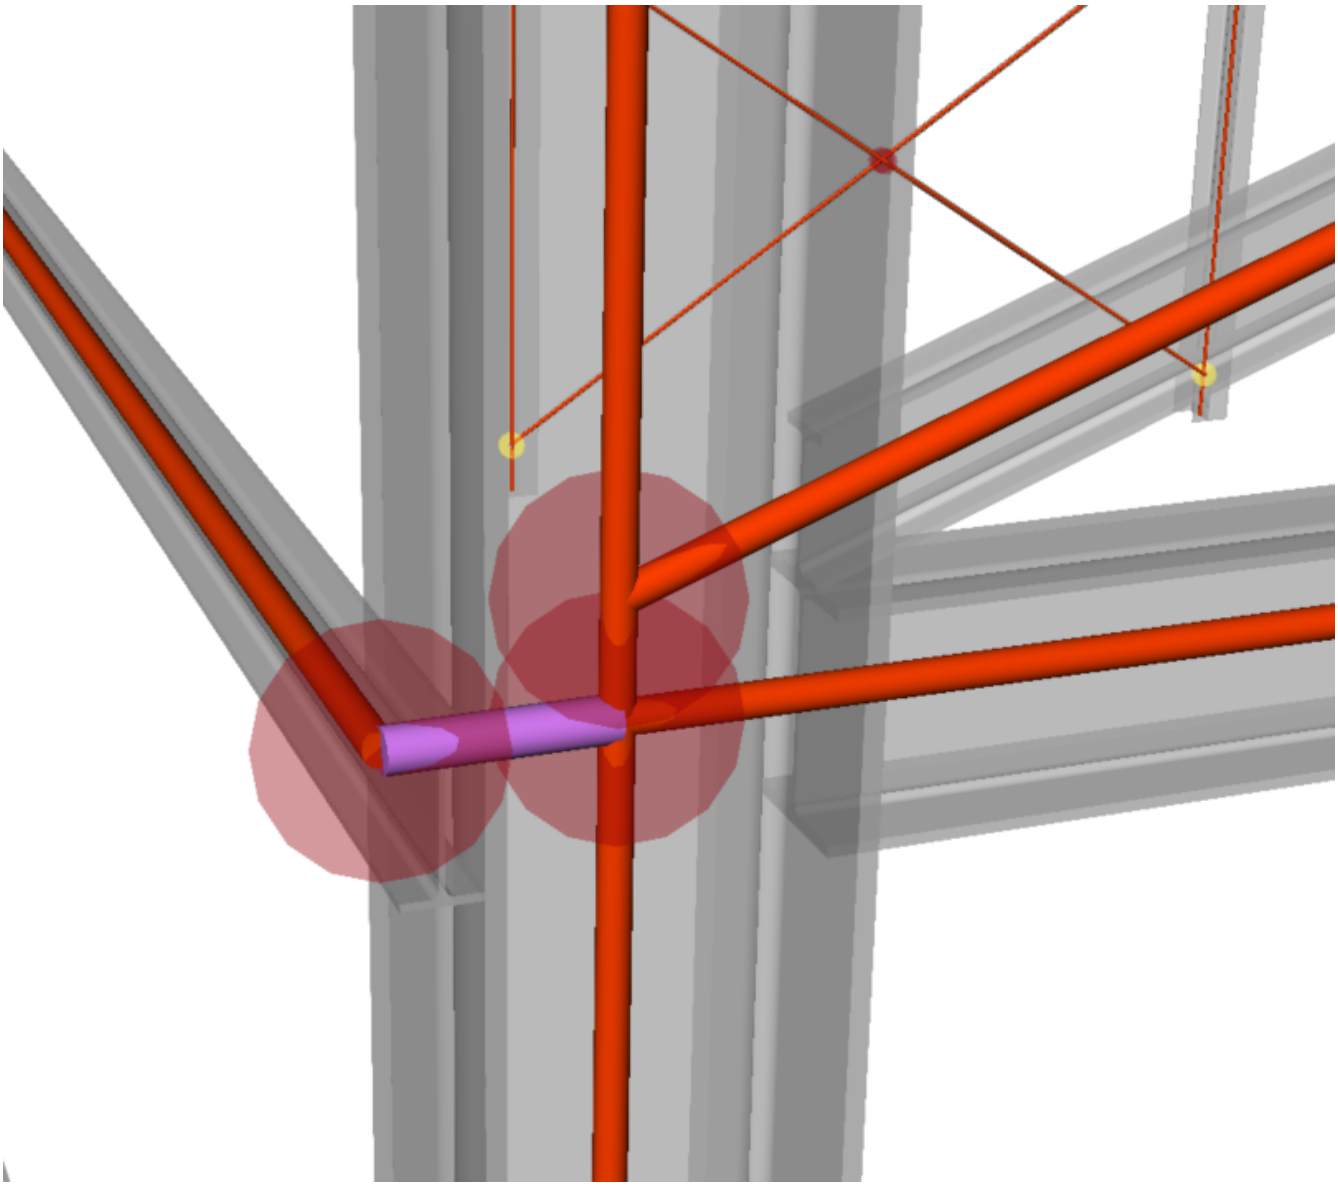

Figure 2.491

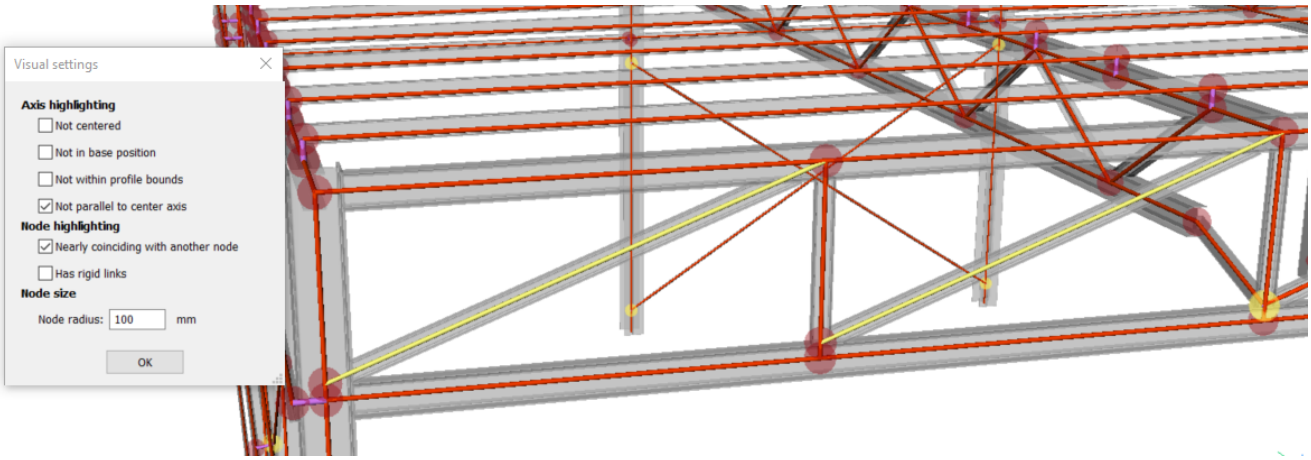

Procedure: Creating an analytical model with the least restrictive deviation settings

1. Repeat the steps from the previous procedure until step 4.
2. Choose **Any deviation** in the **Allowed deviations from center axis**. This allows all kinds of freedom to avoid any rigid links. In the preview of the analytical model, you will see that some axes have been tilted. For example, the small members in the trusses are not centered and the column axis is moved towards the profile bounds to find connections with smaller side members there. (2.492 on the next page)
3. Remove the unwanted tie rod nodes as in step 7 of the procedure with a strict deviation setting.
4. In the interactive preview of the analytical model, the column axes were moved towards the profile bounds. In this step, you will center the axis of the columns. You can do this by clicking on the axis of the column, click **Add restriction** and click **To center**. This introduces rigid links very locally. (2.493 on page 2041) (2.494 on page 2042)
5. In the visual settings window, select the checkbox **has rigid links**. Type **R** in to choose **Recalculate**. (2.495 on page 2043)
   Recalculate will propagate the effect of a local change. It will launch a global solution that again tries to minimize rigid links, but will respect the modifications already imposed. In this case, the rigid links will be removed and the hole side of the structure shifts inward to the center plane of the columns. The axes of the smaller side members are hereby moved outside their profile bounds to avoid rigid links. You can repeat this for the other side.
6. In the visual settings window, select the checkbox **Not centered**. You will see that one of the columns is still not centered because the connection at its top includes not only the larger beams but also one of the smaller ones. You change this by imposing a center restriction on this column as well. (2.496 on page 2044)

Procedure: Exporting an analytical model

1. Before starting the command, open the **Settings** dialog.
2. In the Settings dialog, click the option **Structural Analysis Model** and choose the export format of the analytical model. You can choose between **IFC** and **CIS/2**. (2.497 on the following page)
3. Launch the **BIMAnalyticalModel** command. Change the analytical model to your desire.
4. When you have finished the model, type **E** to choose Export and exit.
5. The document window appears where you can name and save the file in the desired folder.

Note: There are some remarks about the exported result.

- The **node concept** used by BimAnalyticalModel does not completely coincide with CIS/2 and IFC node concept: In the BimAnalyticalModel, only connections between linear elements are modeled with a node. For example, columns will not have a floor node if there is no connection to another element there. During export, missing end nodes are added to be compatible with CIS/2 and IFC export. In the BimAnalyticalModel, a node always lies exactly on every connected axis. Eccentricities are modeled with explicit visual rigid links (purple bars in preview). During export, each cluster of BricsCAD nodes that are interconnected with rigid links is translated into a single connection node with eccentricities in CIS/2 and IFC.
- The **axis concept** used by BimAnalyticalModel does not always coincide with the CIS/2 and IFC axis concept: In the BimAnalyticalModel, there will be one single axis for each physical element. An axis can be attached to more or less than two nodes. During export, an axis that has multiple nodes along its length gets split up into several analysis members, each with one end and one start node, for the CIS/2 and IFC export.
- The concept of **Base Position** in BricsCAD is similar to **cardinal points**. Base positions in BricsCAD form a subset of the cardinal points specified in the CIS/2 standard. For now, only cardinal positions 1 to 9 are supported.
- In the analysis model, as calculated by BricsCAD, an axis can shift away from the center of the physical entity, essentially to any point within certain bounds. This means that the final position of the analysis axis does not necessarily coincide with a cardinal point or base position of the profile. During export, the section profile is linked to the analysis axis using the closest base position of the profile to the final analysis axis, using the cardinal point concept in CIS/2 and IFC. This means that if you visualize the structure in a CIS/2 or IFC viewer that shows physical members as extrusions of the profile section along the analysis axes, you will see that the structure shown there can slightly deviate from the original structure as modeled or imported into BRICSCAD. The structure as described by the **exported analysis model** is therefore an **approximation of the actual structure**.

2.7.2 AutoComplete BIM Data

Commands: BimAutoMatch (6.7.11) **Overview:** In this lesson, you learn how to automatically copy BIM data in drawings. **Lesson Objectives:** After completing this lesson, you will be able to:

- Automatically autocomplete BIM data in a drawing
- Automatically copy BIM data between two drawings

About AutoComplete BIM Data

Instead of assigning compositions to every element manually, BimAutoMatch detects the difference between interior and exterior walls and their respective composition and automatically assigns it to other walls. It can also make distinctions between different floors, different sides of the building, walls with a balcony, etc...  For more information about this command, visit the Command Reference article BimAutoMatch (6.7.11).

Note	Before you use BimAutoMatch make sure that you have Bimified ( ) everything. AutoMatch works best with a fully Bimified model.

AutoComplete BIM Data in one file

1. Do one of the following:

   - Select **Automatch** from the **Classify** tab in the Ribbon.
   - Select **Model | Automatch** in the Quad.
   - Type **BIMAUTOMATCH** and press Enter.

   You are prompted: Compositions/BIM Properties/Window Parameters/Stair Parameters: (6.313 on page 3633)

2. Select one of the following:

   - **Compositions:** Copy compositions.
   - **BIM Properties:** Copy BIM Properties.
   - **Window Parameters:** Copy window parameters.
   - **Stair Parameters:** Copy Stair Parameters.

3. Under 'Select Source', choose **Autocomplete**

4. If the file contains multiple buildings, BimAutoMatch asks you to define the source building. **You are prompted:** (2.502 on page 2051) Select the building from the menu.

Figure 2.498

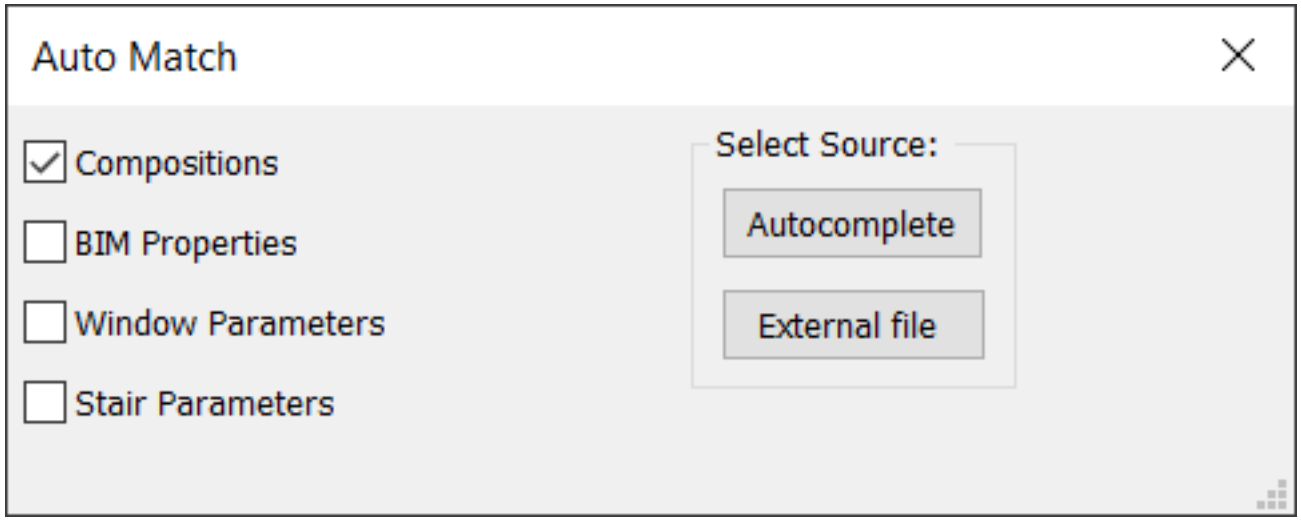

Figure 2.499

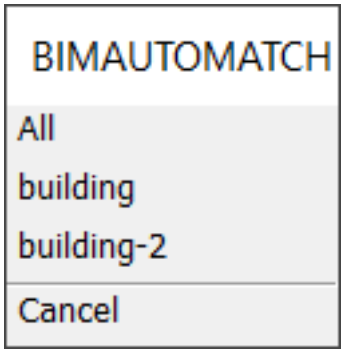

5. If BimAutoMatch finds a logical distinguishing feature between objects it will automatically use this. When it can not, BimAutoMatch asks you to define the source composition or window. **You are prompted:** (2.500 on the next page)

AutoComplete BIM Data with an external file

1. Do one of the following:

   - Select **Automatch** from the **Classify** tab in the Ribbon.
   - Select **Model | Automatch** in the Quad.
   - Type **BIMAUTOMATCH** and press Enter.

   You are prompted: Compositions/BIM Properties/Window Parameters/Stair Parameters: (6.313 on page 3633)

2. Select one of the following:

   - **Compositions:** Copy compositions.
   - **BIM Properties:** Copy BIM Properties
   - **Window Parameters:** Copy parameters of windows.
   - **Stair Properties:** Copy properties of stairs.

3. Under 'Select Source', choose **External file**
4. Select source file and click **Open**.
5. If the file contains multiple buildings, BimAutoMatch (6.7.11) asks you to define the source building. **You are prompted:** (2.502 on the next page)
6. Select the building from the menu.

Figure 2.501

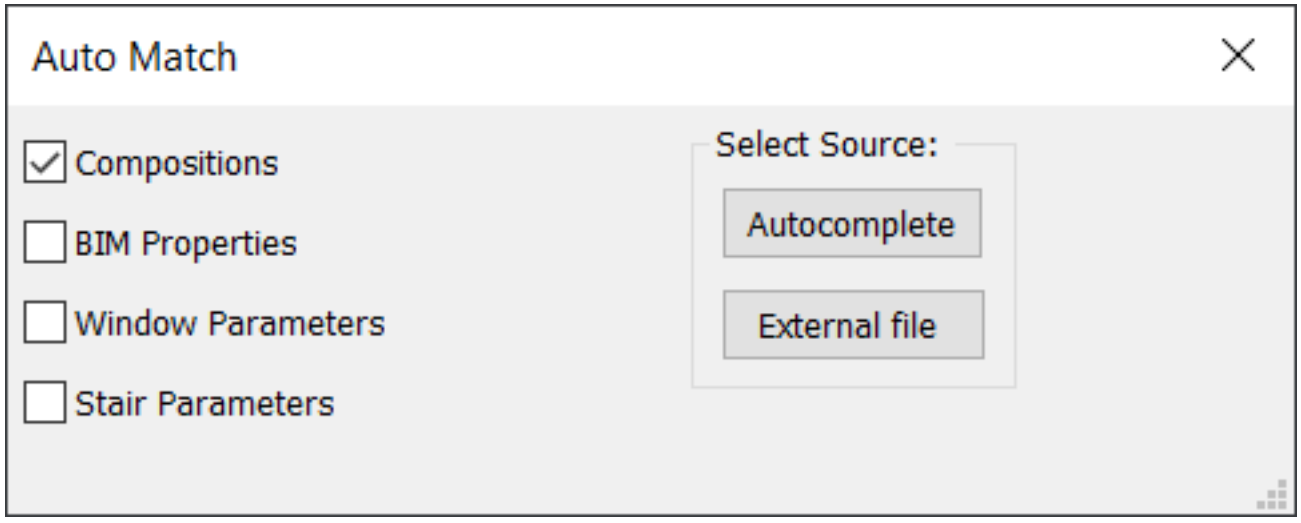

Figure 2.502

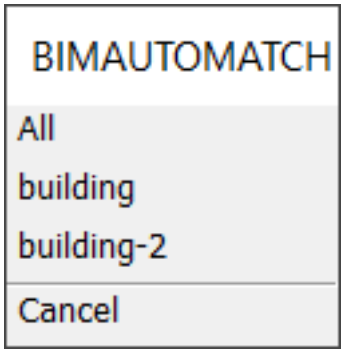

Procedure: using autocomplete in one file

1. Open up a file to start from. Here we use a basic rectangular building that looks like this: (2.503) **Note:** No BIM data or compositions should be added yet.
2. Add the compositions that you want. Don't do this for all your elements, but only for one element of each type. In our example we give a composition to 1 outer wall, 1 inner wall, 1 floor slab and the roof: (6.314 on page 3637) **Note:** It could be that you have different types of outer walls, for example the wall facing north that needs more insulation. In this case, you give one of these northern walls a different composition.
3. In this example, we also want to adjust the parameters of our windows. Select only 1 of the windows and change the parameter you want in the properties panel.

(2.511 on page 2055)	The window before changes
(2.512 on page 2056)	Changing the Frame Depth in the property panel of the window.
(2.513 on page 2056)	The window after the changes

4. Select **Automatch** from the **Classify** tab in the Ribbon **or** select **Model | Automatch** in the Quad **or** type **BIMAUTOMATCH** and press Enter. The following box appears: (2.508 on page 2054) We want the compositions and the window parameters that we chose to be completed in our entire drawing, so we check the boxes from **Compositions** and **Window Parameters**.
5. Select 'Autocomplete'. The compositions and window parameters within your file are automatically copied. The drawing looks like this: (6.315 on page 3637) By using BimAutoMatch, we very quickly have all our compositions and window parameters as we want them, without having to worry about forgetting anything. **Note:** You can see that different types of outer walls are no problem. All the walls facing north have been given the correct adjusted composition.

Figure 2.503

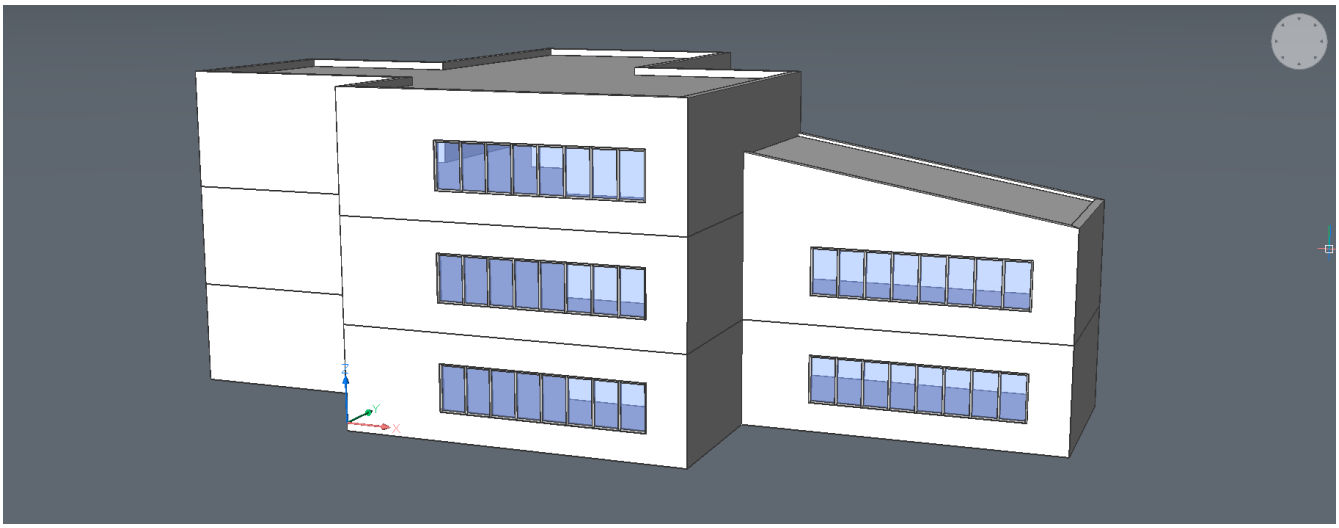

Figure 2.504

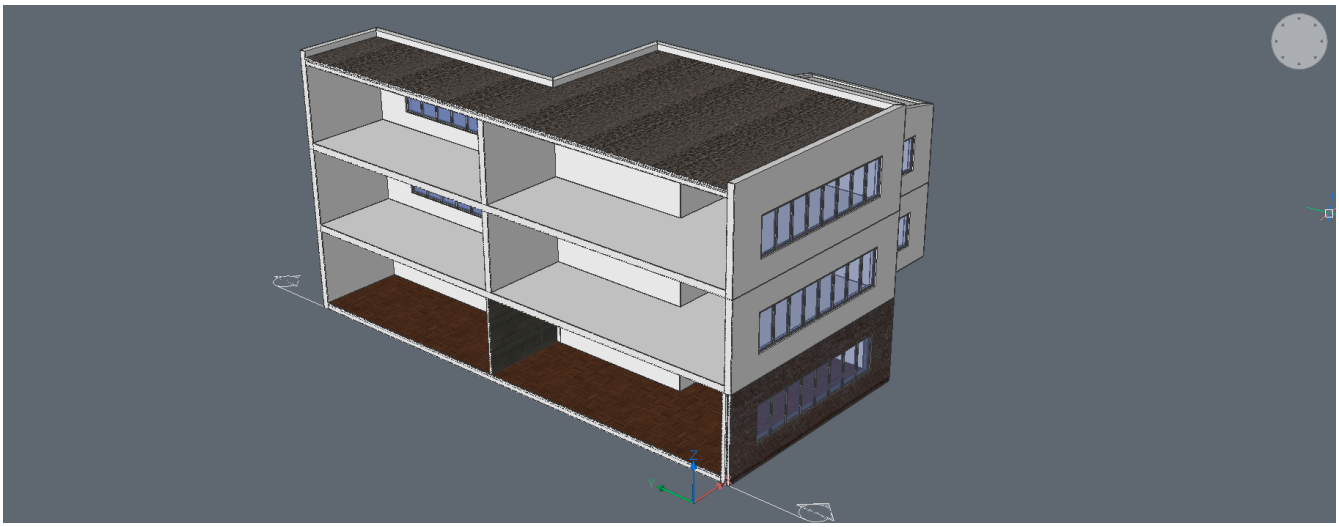

Figure 2.505

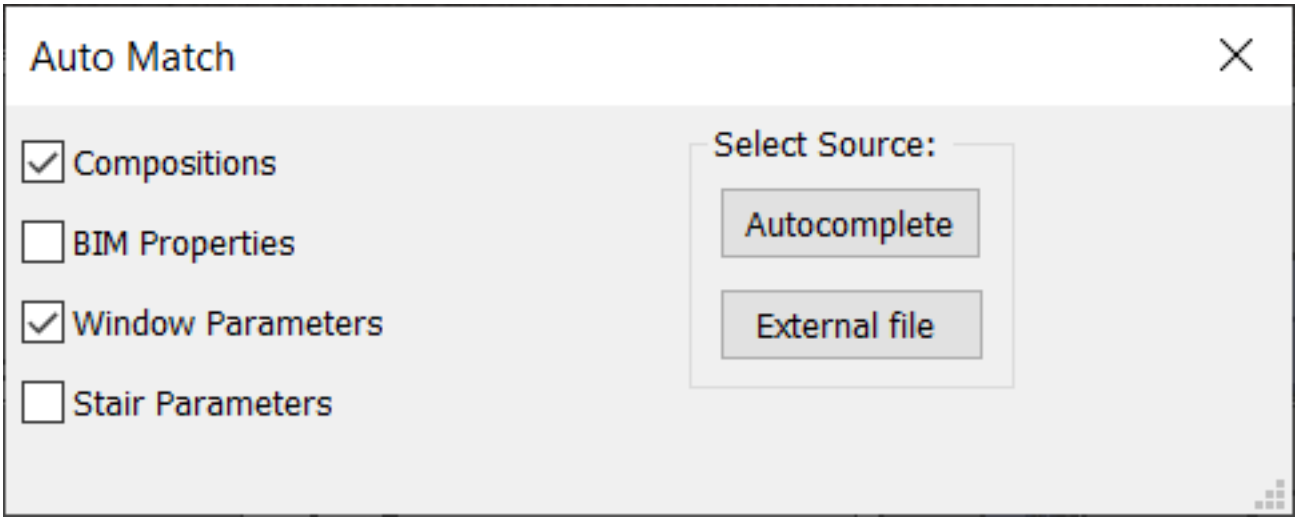

Figure 2.506

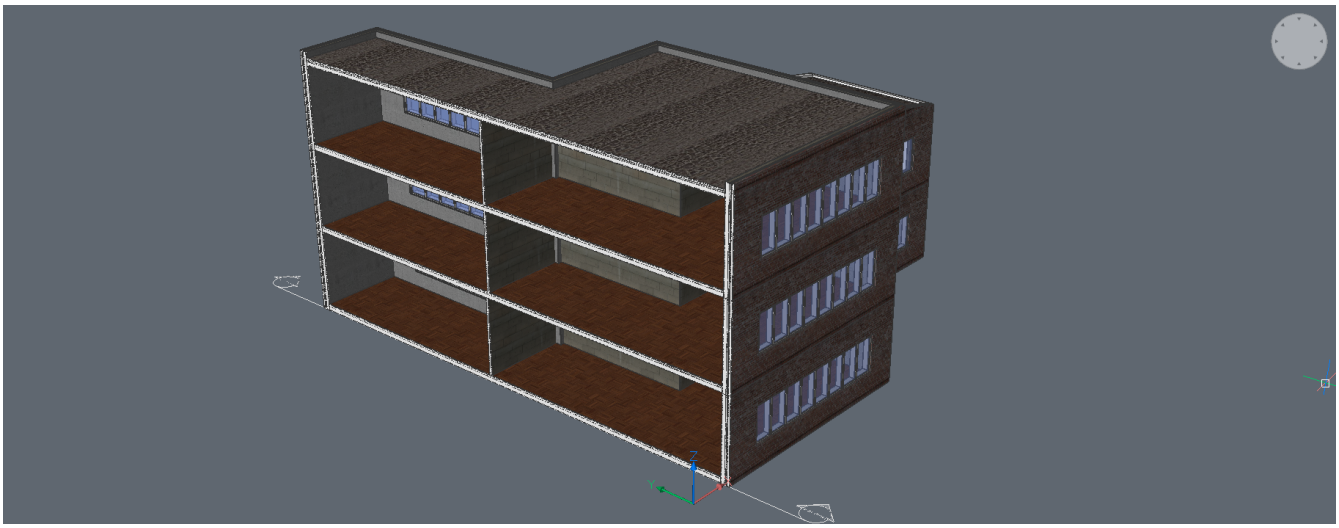

Procedure: using autocomplete with an external file

1. Open up a project that is similar in style to another project that you already finished. In this case, we take another rectangular building, similar to the one we looked at before: (2.507)
2. Select **Automatch** from the **Classify** tab in the Ribbon **or** select **Model | Automatch** in the Quad **or** type **BIMAUTOMATCH** and press Enter. The following window appears: (2.508 on the following page) We want the compositions and the window parameters that we chose to be completed in our entire drawing, so we check the boxes from **Compositions** and **Window Parameters**.
3. Select 'External file'.
4. Select the file that we made in the previous procedure. The compositions and window parameters from the external file will be copied to your new file. The drawing looks like this: (2.509 on the next page) (2.510 on page 2055) **Note:** It can be handy to make a library of building styles with their typical compositions, in order to use BimAutoMatch with external files in a very efficient way.

2.7.3 BIM Classify

Command: BimClassify (6.7.12) **Overview:** In this lesson, you learn how to classify an entity according to the corresponding building element type. **Lesson Objectives** After completing this lesson, you will be able to:

- Classify the entities by the appropriate building elements.
- Use the classification categories.
- Convert an entity to a block and classify the block reference as a BIM element.
- Automatically classify a set of entities.

Tutorial: How to classify BIM elements Click here (2.6.3) to watch

About

If you have a conceptual model without any classification you can turn these elements into classified BIM elements using BIM Classify.  For more information about this command, visit the Command Reference article BimClassify (6.7.12).

Classifying entities

1. Select an entity in the drawing to classify.
2. Choose a classification type (1) in the BIM command group in the Quad. (2.514 on the next page) The BIM data is assigned to the selected entity.
3. **(Optional)** Choose the classify manually option from the Quad to access the BIM Element classification types. This displays the Classify as BIM Element dialog box (2): (2.515 on page 2059) **Note:** The classification types are grouped into the following categories:

   - Building Core Elements
   - Building Architecture Elements
   - Building Service Elements
   - Building Structure Elements

   Do one of the following:

   - Enter a specific name of the BIM Element type in the **Search** field (3) to filter the available element types
   - Select a Building Element type from the list
   - (Optional) Check the **Convert to block option** (4) and enter a name in the **Block name field** (5)

   This option will convert the selected entity to a block and classify the block reference to the defined Building Element type.

   - Click the OK button (6) to accept it.
4. **(Optional)** Use the Auto () option from the Quad to classify the selected entities automatically. This automatic classification is done based on the geometrical features of the object. Always check whether it was correctly classified.
5. To remove the assigned BIM data from the entity, select the entity in the drawing and choose the Unclassify () option from the Quad. The BIM data is removed from the selected entity.

2.7.4 BIM Compositions

Commands: BLCompositions (6.7.57), BimClassify (6.7.12), BLMaterials (6.7.58), BimAttachComposition (6.7.8)
Overview: In this lesson, you will learn how to make and edit compositions. **Lesson Objectives** After completing this lesson, you will be able to:

- Use the BIM Compositions panel
- Use the Compositions editor to create, edit or delete compositions in a project
- Use the physical materials library to create single-ply compositions
- Display composition plies
- Remove a composition from a solid

Tutorial: How to add and create Compositions Click here (2.6.1) to watch

About

BIM compositions:

- Are stored in the library database.
- Are either multiply or single-ply. Ply materials are managed in the **Physical Materials (6.7.58)** editor ().
- Can be assigned to any solid in a BIM model.
- Are listed in the **BIM Compositions** panel ()
- Are managed in the **Compositions (6.7.57)** editor ().

For more information about Attaching Compositions, see the procedure article Attaching Compositions (2.7.5).

Using the BIM Compositions (1.15.7) panel

(2.520 on the next page)

(1) Menu	(2.527 on page 2072)
(2) Composition types list	(2.528 on page 2073)
(3) Search field	Filters the list of the compositions. Only compositions that contain the current search term are displayed.
(4) Available compositions	All compositions of the selected type in both the Library and the Project database display, unless the **Show only compositions in project...** menu option is selected.

Using the BIM Composition Editor

The BIM Composition editor is a dialog box that contains options to create, modify and delete compositions. Using the composition editor you can also sort the compositions by category and view the properties of the composition. The BLCompositions (6.7.57) command opens the BIM Compositions Editor: (2.521 on the following page)

(5) Composition category selection	Filters by category: Wall, Slab, Roof, or Generic.
(6) New composition	Creates a new composition.
(7) In project	Displays the compositions of the selected category (wall, slab...) in the Project database.
(8) In library	Displays the compositions of the selected category (wall, slab...) in the Library database.
(9) Preview pane	Displays the currently selected composition.
(10) Name field	Displays the selected composition name. You can change the default name.
(11) Category drop-down box	Displays a category for the new composition.
(12) Structure grid	Displays the material and thickness of the composition plies. The ply on top (exterior) is applied to the reference of the solid.
(13) Add ply	 Opens the physical materials editor which allows you to choose a material from the library or project database. Here you can also create a new material.  Inserts a copy of the selected ply.
(14) Properties grid	Shows the properties of the selected composition.
(15) Custom properties	Opens the custom properties dialog.

Creating a new composition

You can create a new composition in either the **Project** or the **Library** database.

1. To open the BIM composition editor. Do one of the following:
   - Select the **Open the compositions dialog...** in the menu on the Compositions panel.
   - Type BLCompositions (6.7.57) in the command line.

Click the **New** icon () on the left of the compositions toolbar. A new (empty) composition is added to the selected database. To add and edit plies, go to Edit a composition.

Editing a composition

Step 1: Changing name and type

1. Select the new composition.
2. Type a new name in the **Name** field for the composition.
3. Use the **Type** drop-down box to specify the composition type: **Wall**, **Slab**, **Roof** or **Generic**. Composition categories are used to filter the list of the compositions and the Compositions dialog.

Step 2: Changing the plies

Adding, editing and deleting plies

1. Click the **Add Ply** button () on the right of the compositions editor. The **Physical Materials** dialog displays: (2.522 on the next page)
2. Select a material either in the Project **or** the Library database and double-click **or** press the **OK** button to assign the material to ply in the composition.
3. Double-click on the **Pattern** or **Name** of the ply to edit the material. See the Physical Materials (2.7.17) article for more information.
4. To choose another material, pick a material in the Library **or** Project list and press **OK**.
5. To delete a ply, select the ply and click on the **Delete** tool button.
6. **(Optional)** Right-click the material and choose **Make composition** (16) in the context menu to create a single-ply composition.

Modifying the thickness and changing the ply order

1. Click the **Thickness** field (17) to modify the thickness of a ply in the **Structure** grid. You can only modify the ply thickness if the **Allow Custom Thickness** property of the material is set to **Yes.** (2.523 on the following page)
2. Enter a value in the field (18) and press Enter to accept it. The overall thickness of the composition is updated accordingly.
3. The plies of a composition are ordered from Exterior (top) to Interior (bottom). Drag the ply number (21) on the desired position to change the ply order.

Note: when a composition has been modified, the solids that have this composition attached are updated automatically. Use the BimUpdateThickness (6.7.62) command apply the changes in the model.

Figure 2.522

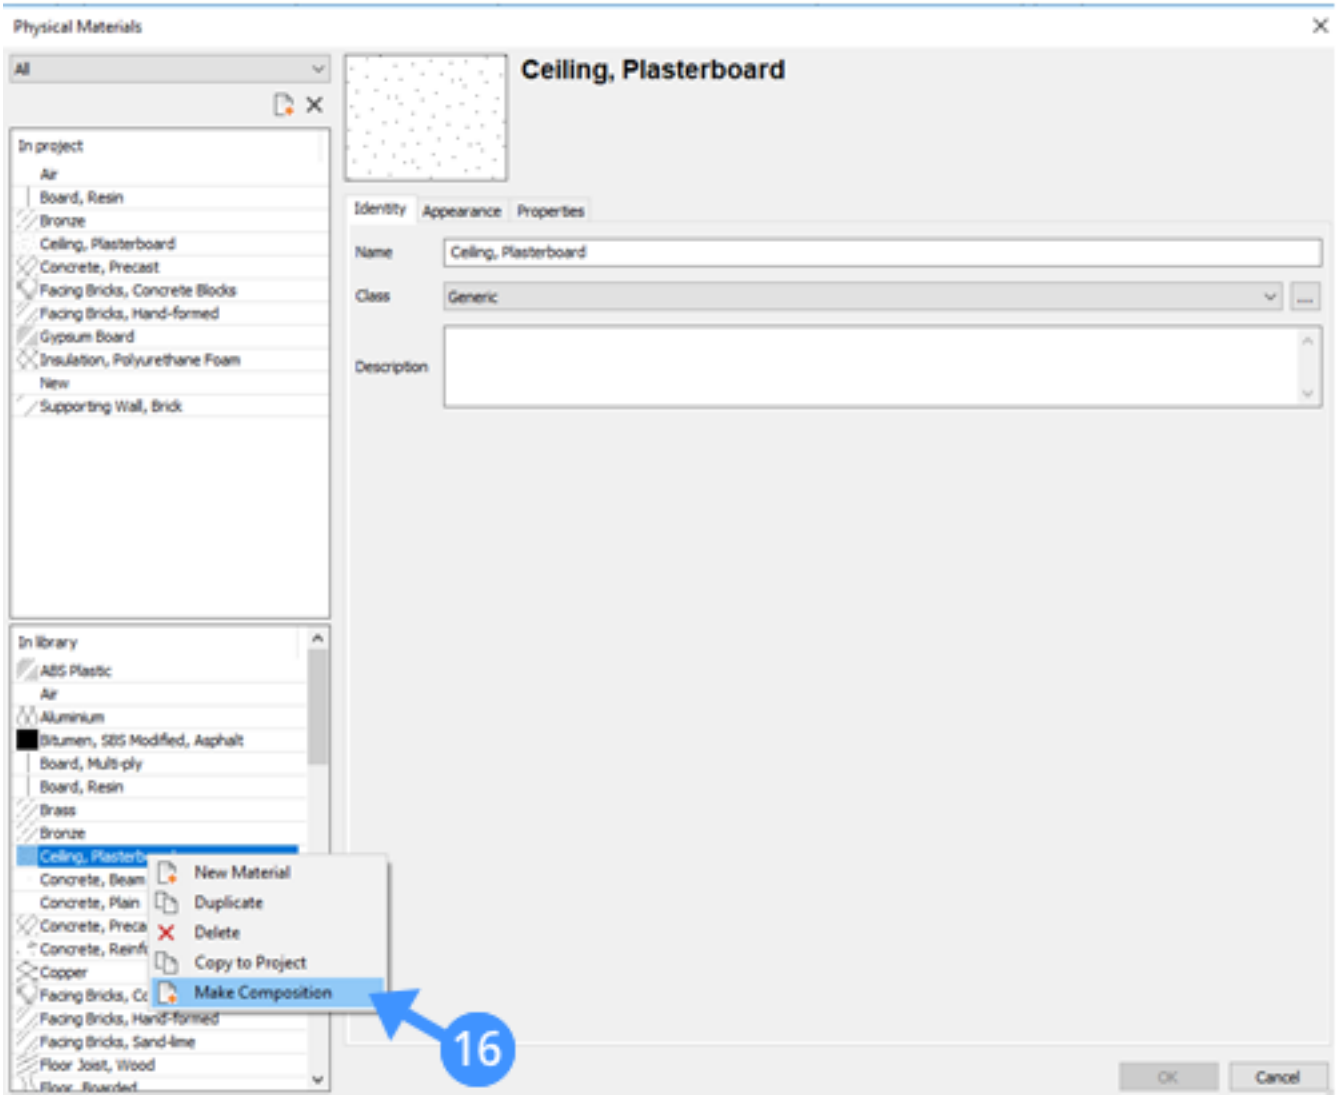

Figure 2.523

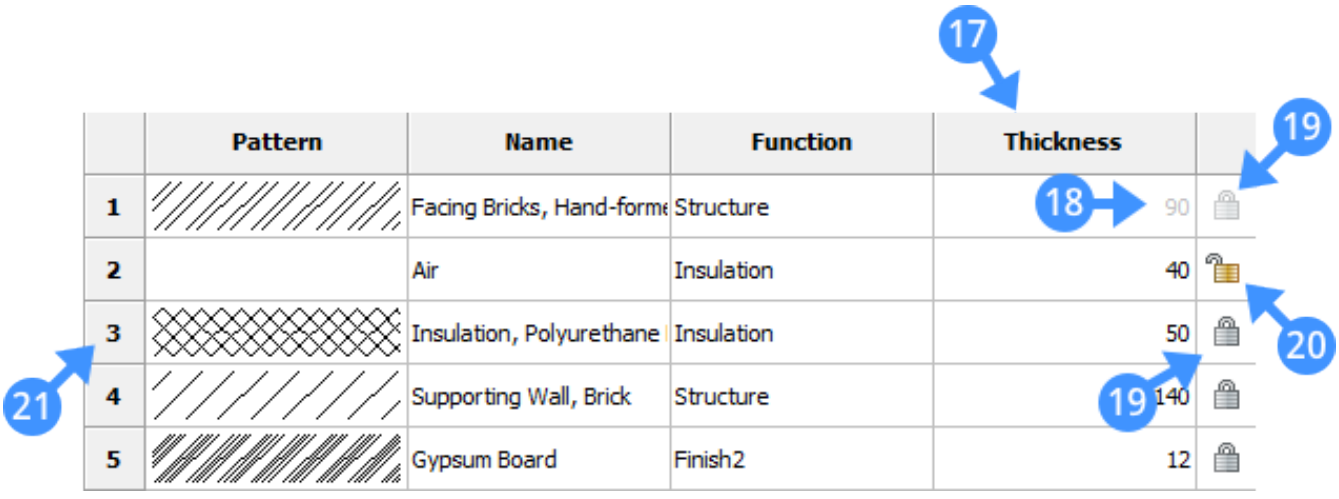

Figure 2.524

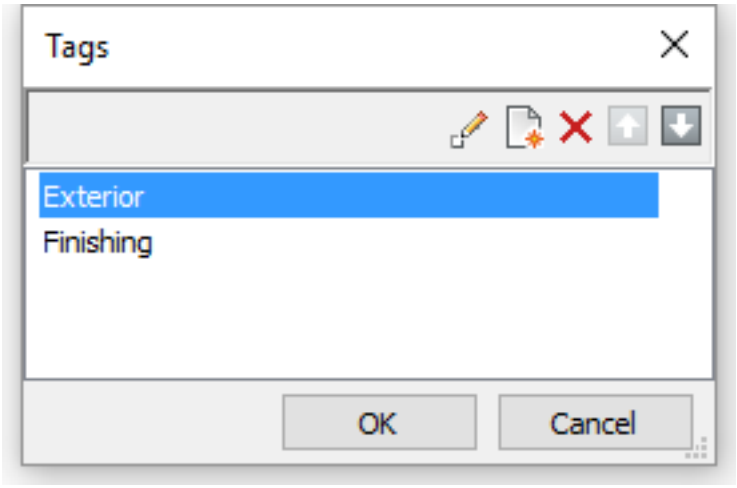

Locking/unlocking the composition thickness The overall thickness of a composition is equal to the sum of the thicknesses of the composing plies. The thickness of a ply can be either locked or unlocked (see image above).

- Locked thickness (19): the thickness of the ply is fixed.
- Unlocked thickness (20): the thickness of the ply is variable.

Note: only one ply in a composition can have an unlocked thickness. As a result, the total thickness of a composition can be:

- **Fixed:** all plies have locked thicknesses.
- **Minimal:** the composition contains at least two plies and one ply has an unlocked thickness. The minimum thickness is equal to the sum of the thicknesses of the locked plies.
- **Free:** a single ply composition has an unlocked thickness.

The thickness of a ply can only be unlocked if the **Allow Custom Thickness** property of the material is set to **Yes**.

Adding Tags

1. Select the **Tags** field.
2. Type the tags, separated by commas. Tags are case sensitive.
3. Click the **Browse** button ( ) next to the tags field in the composition dialog box to open the **Tags** dialog. (2.599 on page 2171)
4. Click the **New Item** button ( ) to add a new tag at the bottom of the list.
5. Select a tag in the list and click a tool button:
   - : edit the selected tag
   - : delete the tag
   - : move the tag up
   - : move the tag down
6. Click the **OK** button to save the changes.

Step 3: Creating new materials You can create new materials from scratch or copy them from an existing material. See Physical Materials (2.7.17) for more details.

Displaying Compositions

Whether the various plies of a composition show in the 3D model is controlled through the LevelOfDetail (1.17.10) user preference. The RenderCompositionMaterial user preference controlls whether the ply material is rendered or not. Click the icons in the **Home/View** panel in the ribbon or the **BIM** toolbar to toggle the status of the composition display:

- Level of Detail: 
- Render Composition Material:  When LevelOfDetail=0, the major faces of a solid are rendered using the material of the outside plies. The minor faces (for example top, bottom, start and end face of a wall) are rendered using the material of the exterior ply.
-

Copying compositions

You can use the following procedure in both the BIM Compositions panel (1.15.7) and the Compositions editor:

1. Select the composition(s) in the source database. Press and hold the Ctrl key to select multiple compositions.
2. Do one of the following:
   - Drag the selection to the other database.
   - Right-click and choose **Copy to Library** or **Copy to Project** in the context menu. (2.525 on the facing page)

If the value of the **CopyOverwrite** user preference is 0 (zero), a dialog box displays if the composition already exists in the target library. You can choose to overwrite, duplicate or skip existing compositions. **(Optional)** Check the **Apply to all compositions** in this operation option. (2.526 on the next page)

Figure 2.525

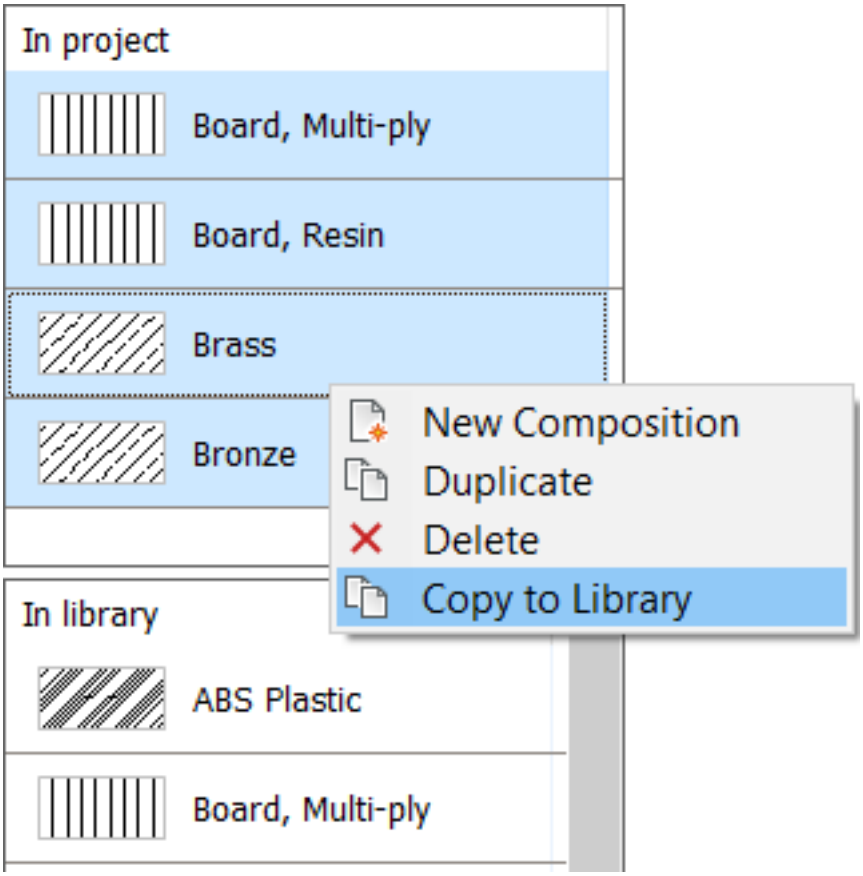

Figure 2.526

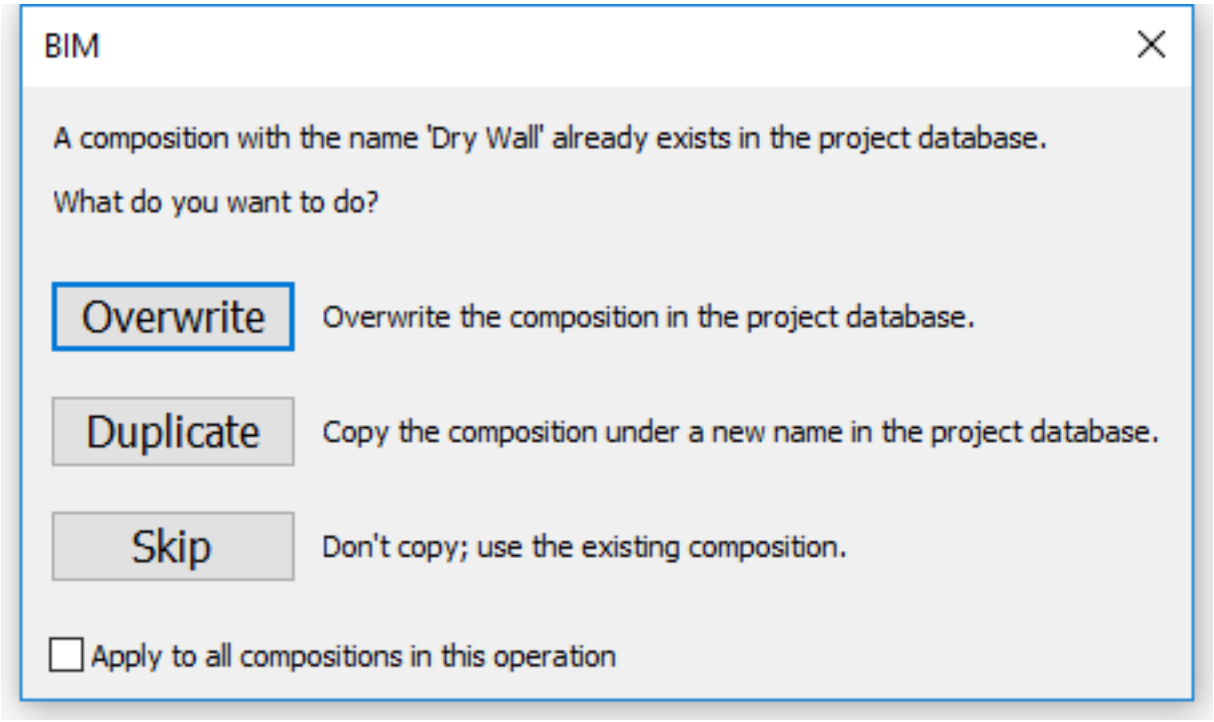

Deleting compositions

1. Select the compositions in the **In Project** or **In Library** list on the BIM Compositions panel (1.15.7) or the Compositions editor.
2. Do one of the following:
   - Right-click and choose **Delete** in the context menu.
   - Click the **Delete** button (Compositions editor only).

Note: Compositions that are used in the project cannot be deleted from the project database.

Figure 2.527

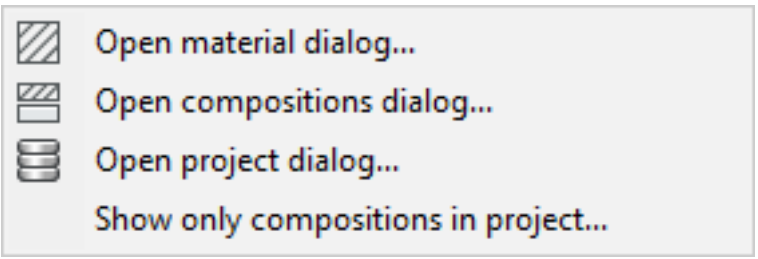

Figure 2.528

2.7.5 Attaching Compositions

Commands: BimAttachComposition (6.7.8), BLCompositions (6.7.57) **Overview:** In this lesson, you will learn how to attach compositions to solids. **Lesson Objectives** After completing this lesson, you will be able to:

- Attach compositions to solids
- Flip and redefine the composition
- Align the solids by reference face or center

About BIM Attach Composition

The **BimAttachComposition** command allows you to easily apply a composition to a selection of solids. The assigned composition can be flipped or redefined to a different reference face. Optionally, you can align solids based on a reference face or the center of a composition.  See BimAttachComposition (6.7.8) for more information about attaching a composition. See BIM Compositions (2.7.4) for more information about managing compositions.

Attaching a composition

To attach a composition, you can:

- Use the BimAttachComposition command.
- Drag a composition from the BIM Compositions (1.15.7) panel on the solid(s).

Using the BimAttachComposition command

1. Launch the BimAttachComposition (6.7.8) command. **You are prompted:** Enter the composition name or [Dialog/Entity] <Dialog>.
2. Do one of the following:
   - Type a composition name in the command bar and press Enter. **Note**: composition names are case sensitive.
   - Press Enter to display the Compositions dialog and click on a **Composition** in the **In Project** or **In Library** list to open the menu of the composition. If you want to select the composition without opening the menu, double-click it.
3. Choose a Composition **Type** from the dropdown menu and press **Select** to accept. (2.529)
4. Select entities to attach the composition to and press Enter.
5. Choose the reference face. If you hover over the widget, a submenu displays showing different options. For more information about how to redefine the reference face, see BimAttachComposition (6.7.8). (2.530 on the next page)
6. Press Enter to accept the reference face. BricsCAD responds: The composition has been assigned to <xxx> element(s).

Note: Using Bimify (6.7.23) building elements are automatically classified. This makes it easy to select the right entities.

Figure 2.529

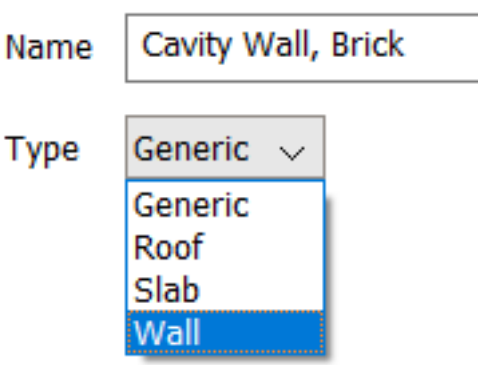

Figure 2.530

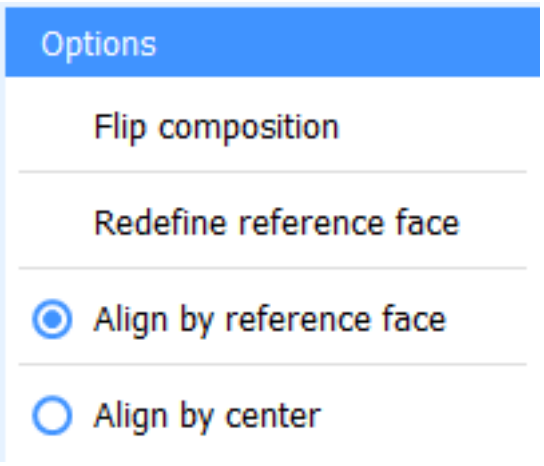

Dragging a composition on a solid

1. Select the composition in the BIM Compositions panel ( ). See Dockable panels. (1.15.7)
2. Hold down the left mouse button and drag the composition on the solid. The solid face under the cursor highlights, indicating that this face is the reference face to attach the composition.
3. Release the left mouse button to attach the composition.
4. A widget appears that allows you to choose the reference face. The reference face is fixed, while the opposite face moves if the thickness of the composition does not fit the current thickness of the solid. (2.531 on the following page) For more information about how to redefine the reference face, see BimAttachComposition (6.7.8).
5. A darker volume indicates the volume and position of the solid after attaching the composition. (2.532 on the next page)
6. Press Enter to accept the current reference face and attach the composition.

Note: when a single ply composition with a variable thickness is selected, it is not needed to select a reference face. The composition is attached to the selected solid.

Figure 2.531

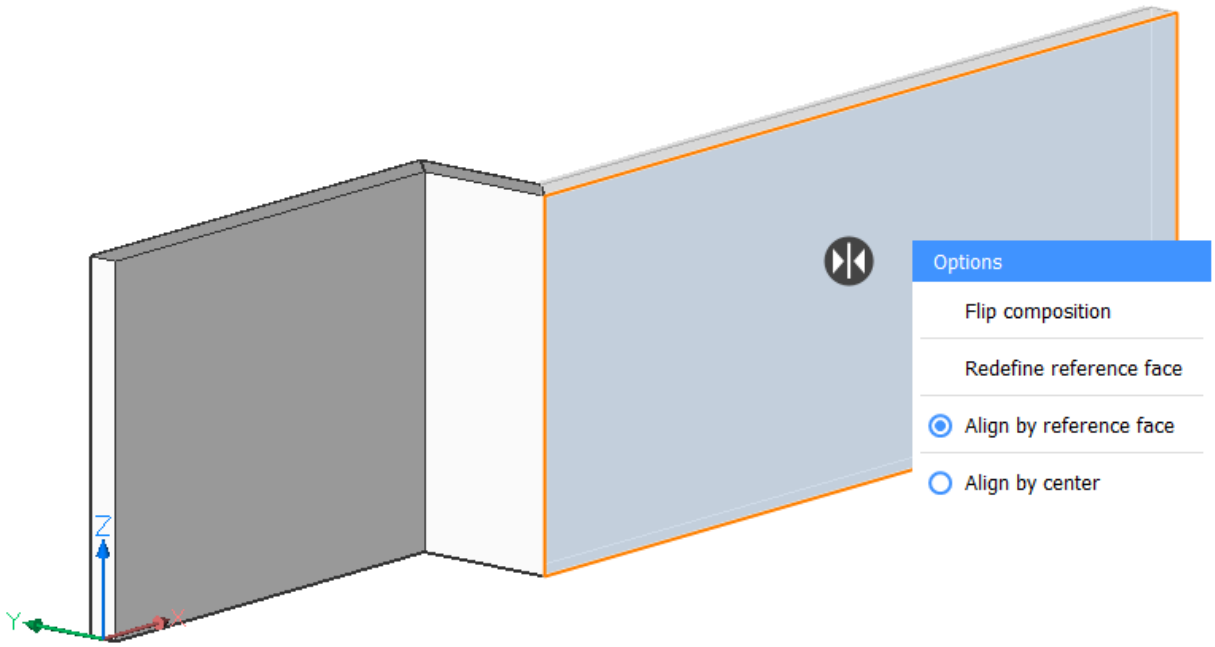

Figure 2.532

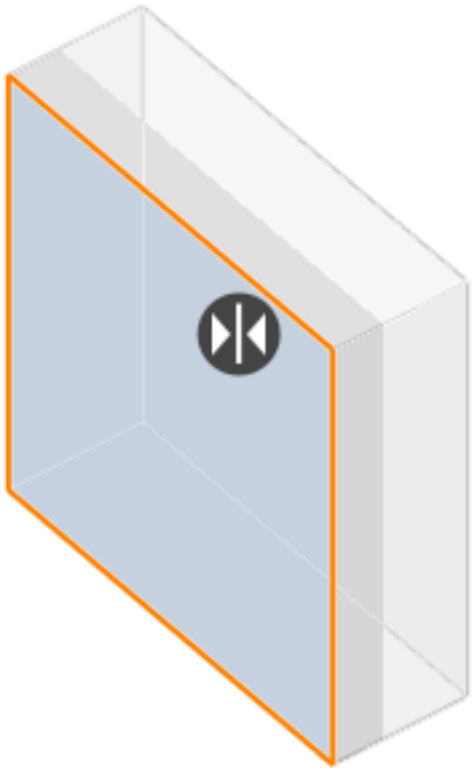


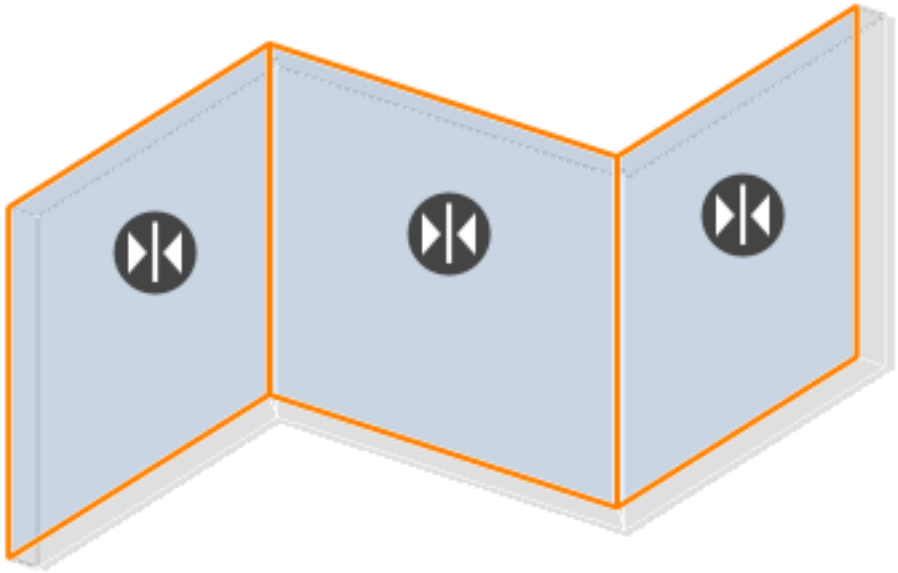
Dragging a composition on a selection of solids

1. Select the solids you want to apply the composition to.
2. Select the composition in the BIM Compositions panel (6.7.8).
3. Hold down the left mouse button and drag the composition on any of the selected solids.
4. Release the left mouse button to attach the composition. A widget appears which allows you to choose the reference face for every segment separately.(2.534 on page 2079) For more information about how to redefine the reference face, see BimAttachComposition (6.7.8).
5. Press Enter to accept the current reference face and attach the composition.

Notes:

- BIM compositions (6.7.57) are copied to the Project database upon attachment.
- Attaching a **Wall** composition to a solid, automatically classifies the solid as a wall.
- Attaching a **Slab** or **Roof** composition to a solid, automatically classifies the solid as a slab.

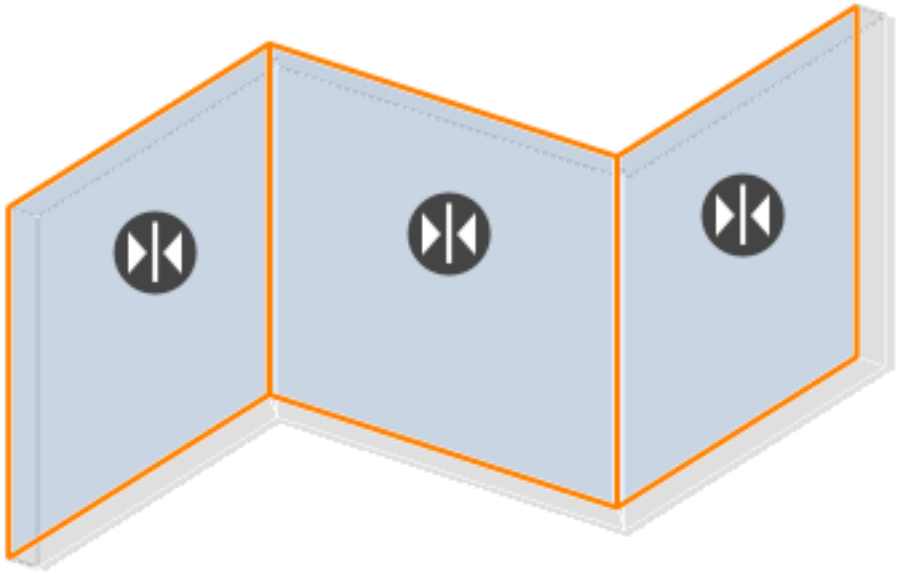
Figure 2.533



Copy compositions from other solids

1. Launch the BimAttachComposition (6.7.8) command.
2. Select the **Entity** option. Prompts you: **Select other entity to get composition:**
3. Select the solid to copy the composition from.
4. Select the solids(s) to attach the copied composition to.
5. A widget appears which allows you to choose the reference face for every segment separately.(2.534 on the next page) For more information about how to redefine the reference face, see BimAttachComposition (6.7.8).
6. Press Enter to accept the current reference face and attach the composition.

Figure 2.534



Removing compositions from solids

The **Unclassify** option of the BimClassify (6.7.12) command removes a composition from a solid.

1. Select the solid(s).
2. Choose **Unclassify** from the **BIM** command group in the Quad.

2.7.6 BIM Data Structure

Commands: BIMSpatialLocations (6.7.63), BIMAttachComposition (6.7.8), BLCompositions (6.7.57), BIMProfiles (6.7.26), BLMaterials (6.7.58), BIMproperties (6.7.38), BIMProjectInfo (6.7.32)

Project database and Library database

A BIM Project consists of dwg entities, classified as Building Elements, to which Compositions can be attached. All Compositions being used in a project, are stored in the Project database. The Project database can be stored inside a dwg file, or in a separate file with extension **.bsyslib:**

- When the Project database is embedded in a dwg file, that dwg file contains the complete BIM Project.
- When the Project database is stored as an external file, the BIM Project can consist of multiple dwg files, all using the same Project database.

To reuse compositions and building materials across multiple BIM Projects, a Library database can be specified, in addition to the Project database. The Library database is a **.bsyslib** file, usually stored in a location which is common to several projects. When Compositions and Building Materials from the Library database are used in a BIM Project, they are automatically imported in the Project database. To maintain and extend BIM databases, users can drag Building Materials and Compositions from one database to the other, provided that they have write access to the destination database.

Note	Sample databases are installed in the **Support** subfolder the Roamable root (1.17.2) folder. When a BricsCAD update is installed, the BricsCAD User File Manager (1.17.2) will prompt you whether to overwrite the sample databases or not. Therefore it is recommended to rename your library databases and/or save them at a different location. The location of the library databases is defined in the **Library DB** tab of the BIM Project Info (2.7.7) dialog.

Materials and Compositions

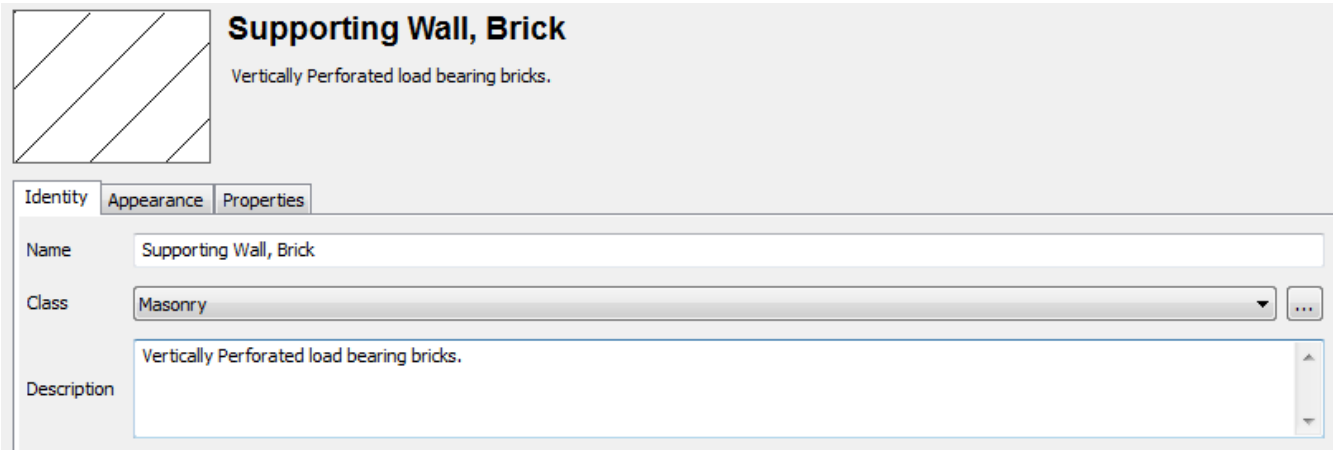
A BIM database consists of Building Materials (2.7.17) and Compositions (**??**). A Building Material contains information about one specific material: its appearance, cost, manufacturer, etc. A Composition contains information about the structure of a building element, by defining Composition layers. Each Composition layer refers to a Building Material and has a certain thickness.

Flexibility The same flexibility you have in modeling is available in attaching building information. Although Compositions are grouped into **Wall**, **Slab**, **Roof** and **Generic** Compositions, any type of Composition can be attached to any dwg entity. When attached to a 3D Solid, with specific geometrical properties, the thickness of the Composition is used to define the thickness of walls and slabs, and the cross section will show the wall or slab structure by applying the hatch patterns from the various layers on the section geometry. When a 3D Solid is assigned a Composition with a fixed thickness or a minimal thickness, and this thickness can not be applied to the geometry, the section appears in red to indicate the incompatibility between the selected Composition and the geometry of the solid.

BIM Compositions panel All BIM database features are accessible from the dockable BIM Libraries (**??**) panel.

Materials A Material definition describes the appearance and properties of a Building Material. (2.535 on the facing page)

Figure 2.535



Composition layers A **Composition** describes the structure of a building element by an ordered set of composition layers. Each composition layer has the following fields:

- Pattern and Material Name: The Building Material for this layer.
- Function: One of (None, Structure, Substrate, Insulation, Finish1, Finish2, Membrane). Currently, this field serves for information purposes only.
- Thickness: Defines the thickness of the layer.

2.7.7 BIM Project Info

Command: BimProjectInfo (6.7.32) **Overview:** In this lesson, you learn how to use the Project Info dialog box to set up your project and library database of your BIM models. **Lesson Objectives** After completing this lesson, you will be able to:

- Specify your project and library databases.
- Understand the difference between embedded and external databases.
- Use the BIM database file to set the library database.
- Filter the attached tags of the building materials and compositions on the database.

About

The BIM Project Info allows you to control the location, properties, and content of the Project and Library databases. When you launch the BIMPROJECTINFO command in BricsCAD, the BIM project info displays in a dialog box that includes certain components and tabs. Project and library databases of BIM models can be changed using this dialog box.  For more information about this command, visit the Command Reference article BimProjectInfo (6.7.32).

Procedure: Setting the project database

1. Open the BIM Project Info dialog box by typing BimProjectInfo in the command line. The following illustration shows the dialog box when the Project DB tab is current. (2.536 on the next page)

Project database (1)	Shows the BIM project info.
Project database drop-down list (2)	Choose between Embedded or External.
Embedded (3)	Saves the project library in the drawing file.
External (4)	Saves the project library in a BIM database file (.bsyslib).
Properties (5)	Shows the properties of the BIM project e.g. region, language, and units.
Statistics (6)	Shows the location, properties, and the content of the current project library of the BIM model.
Custom properties (7)	Adds custom properties to materials and compositions.
Import (8)	Imports the selected .xml and .csv library files.
Export (9)	Saves .xml library files in the defined location.

2. To change the project database from Embedded to External or vice versa, select the desired option in the Project Database drop-down list. **Note:** The external database keeps the database independent from the current drawing. This is especially useful if you want to share the library between multiple drawings.
   - When switching from Embedded to External a File dialog displays. Do one of the following:
     - Type a name in the File Name field to export the content of the project library to a new .bsyslib file, then click the Open button.
     - Select an existing .bsyslib file, then click the Open button. The current content of the project library is merged with the selected .bsyslib file.
   - When switching from External to Embedded the content of the external library is copied to the embedded project library.
3. To specify the Project Database properties, such as Region and Language, fill out the Region field and choose one of the language options in the drop-down list.
4. Optionally, use the custom properties button to add material and composition custom properties in the Project Database.
5. Press OK button to accept it.

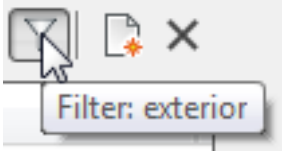
The project filter

To each Building Material (2.7.17) or Composition (6.7.57), any number of tags can be attached. Any string can be entered as a tag. Each of the tags can be used as a filter on the database. There is a button at the top of each list ( ), to switch the filter on or off. If the filter is on, only Compositions and Building Materials that match at least one of the filter tags will be listed. The **Filter** button ( ) has three states:

- If the project filter is empty, the button is not active (**BIM Compositions** panel) or is not available (**Materials** and **Compositions**editors).
- The project filter is defined, but not active. 
- The project filter is defined and active. (2.539) A tooltip shows the current project filter.

Figure 2.539



To set the project filter

1. Select the **Filter** tab page on the **BIM Project Info** dialog box.
2. Check the tags you want to use in the filter. (2.540 on the next page)

2.7.8 BIM Ply Editing

Commands: LevelOfDetail (2.3.6), RenderCompositionMaterial (2.3.6), DmPush/Pull (2.5.11) **Overview:** In this lesson, you will learn how to edit composition plies in your BIM model. **Lesson Objectives** After completing this lesson, you will be able to:

- Use the **LevelOfDetail** setting to display composition plies.
- Use the **RenderCompositionMaterial** setting to display render materials.
- Manipulate the composition plies.

Tutorial: How to extend a Ply Click here (2.6.6) to watch

About

The BIM Ply Editing function allows you to manipulate all the composition plies in your model. In BricsCAD, each drawing has settings stored inside to control the composition plies, called LOD (Level Of Detail), and the render materials, called RenderCompositionMaterial. These two settings can be turned on/off separately.

Composition plies and render materials

Composition plies display only when **LevelOfDetail = 2 (high)**. Building elements do not need to be selected, they will be automatically adjusted. When **LevelOfDetail = 0 (low)** the material definition of the solid is used. To toggle the value of the **Level of Detail** user preference, click the icon in the ribbon under the Home tab or in the quad under the BIM tab:  For more information about this setting visit the article LevelOfDetail. (2.3.6) Render materials display only when **RenderCompositionMaterial = 1 (on)**. The render material of each ply is defined in the 3D Render Material (2.7.17) setting of the material definition. To toggle the value of the **RenderCompositionMaterial** user preference, click the icon in the ribbon under the Home tab or in the quad under the BIM tab:  For more information about this command, visit the article RenderCompositionMaterial (2.3.6). (2.541 on the facing page) **RenderCompositionMaterial = 0 (off)** (2.542 on the next page) **RenderCompositionMaterial = 1 (on) Note:** Only when Visual Styles (6.31.15) have their **Face Settings / Material Display settings** set to **Materials and Textures** (e.g. **BIM**, **Modeling,** and **Realistic**), a visual representation of materials is displayed. Composition plies are displayed in the model as well as render materials. **Note:** If the render materials of the selected composition are not downloaded or the composition is incorrect, the entity will be displayed in red. There are different combinations possible with LOD and RenderCompositionMaterials turned on or off.

- **LOD =0, RenderCompositionMaterials = 0** The material definition of the solid is used and no materials are displayed. (2.543 on page 2092)
- **LOD =2, RenderCompositionMaterials = 0** The solid is subdivided into plies, no materials are displayed. When face detection is turned on, you can select the faces of different plies to push/pull for example. (2.544 on page 2093)
- **LOD =0, RenderCompositionMaterials = 1** The material definition of a solid is used. The materials of the exterior and interior face are displayed and the material of the exterior layer will be wrapped around the object.
  (2.545 on page 2094)
- **LOD =2, RenderCompositionMaterials = 1** The solid is subdivided into plies. Each ply will be displayed with its own material. When face detection is turned on, you can select the faces of different plies to push/pull for example.
  (2.546 on page 2095)

Figure 2.541

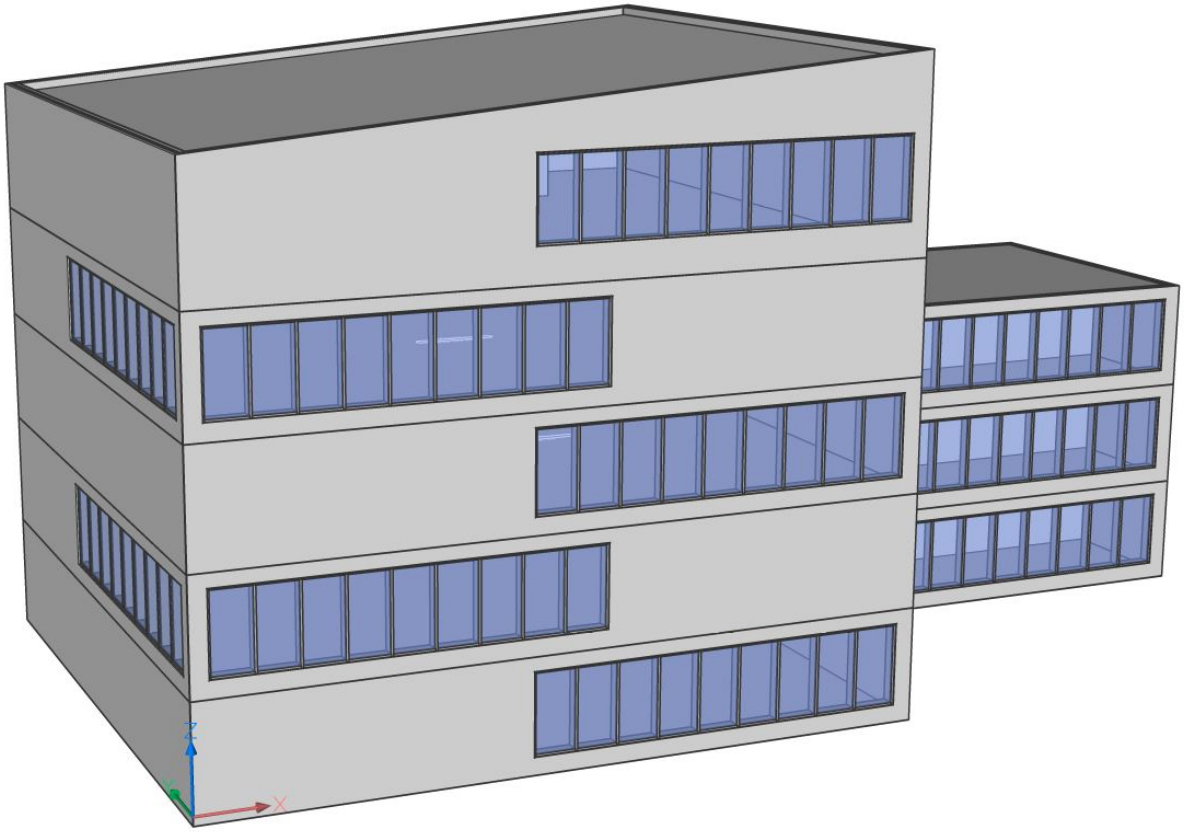

Figure 2.542

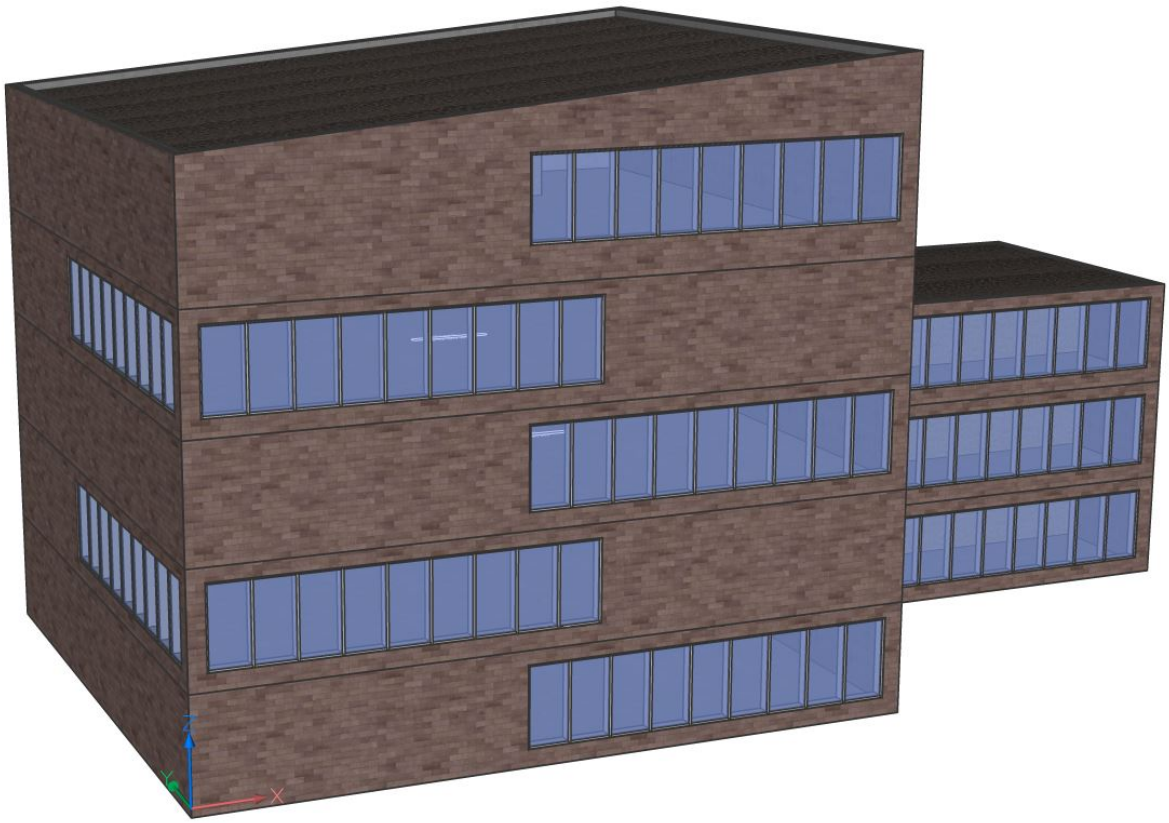

Figure 2.543

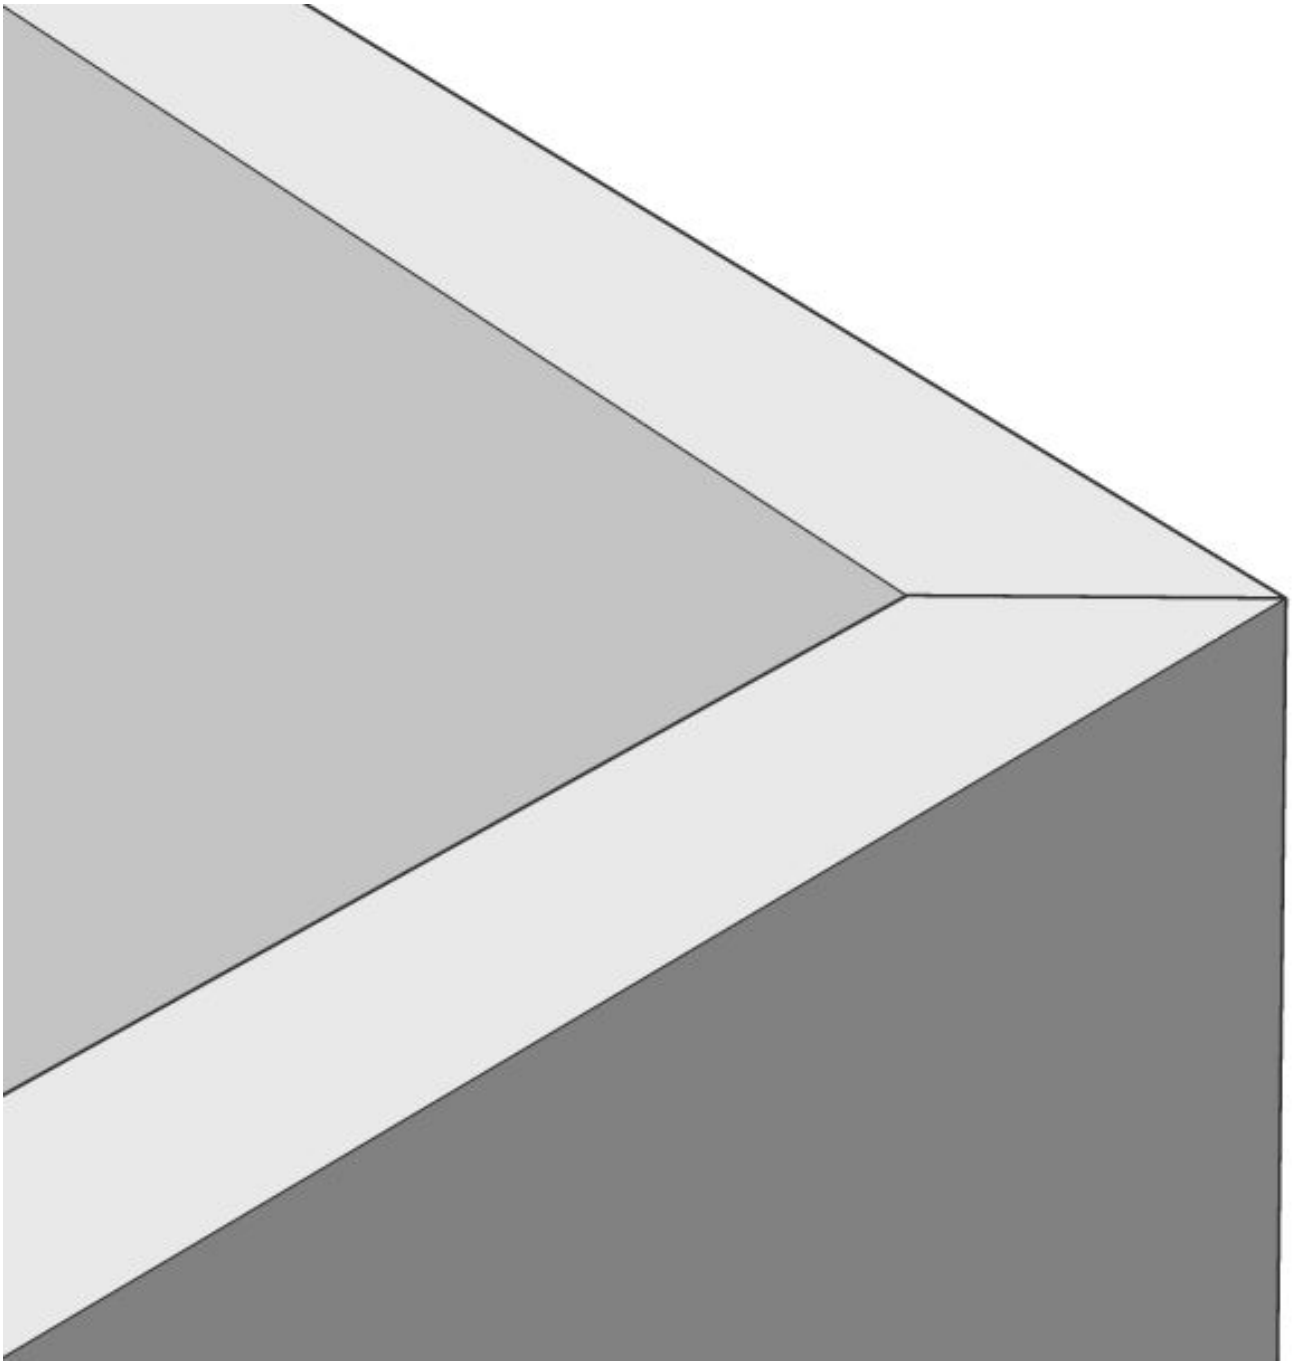

Figure 2.544

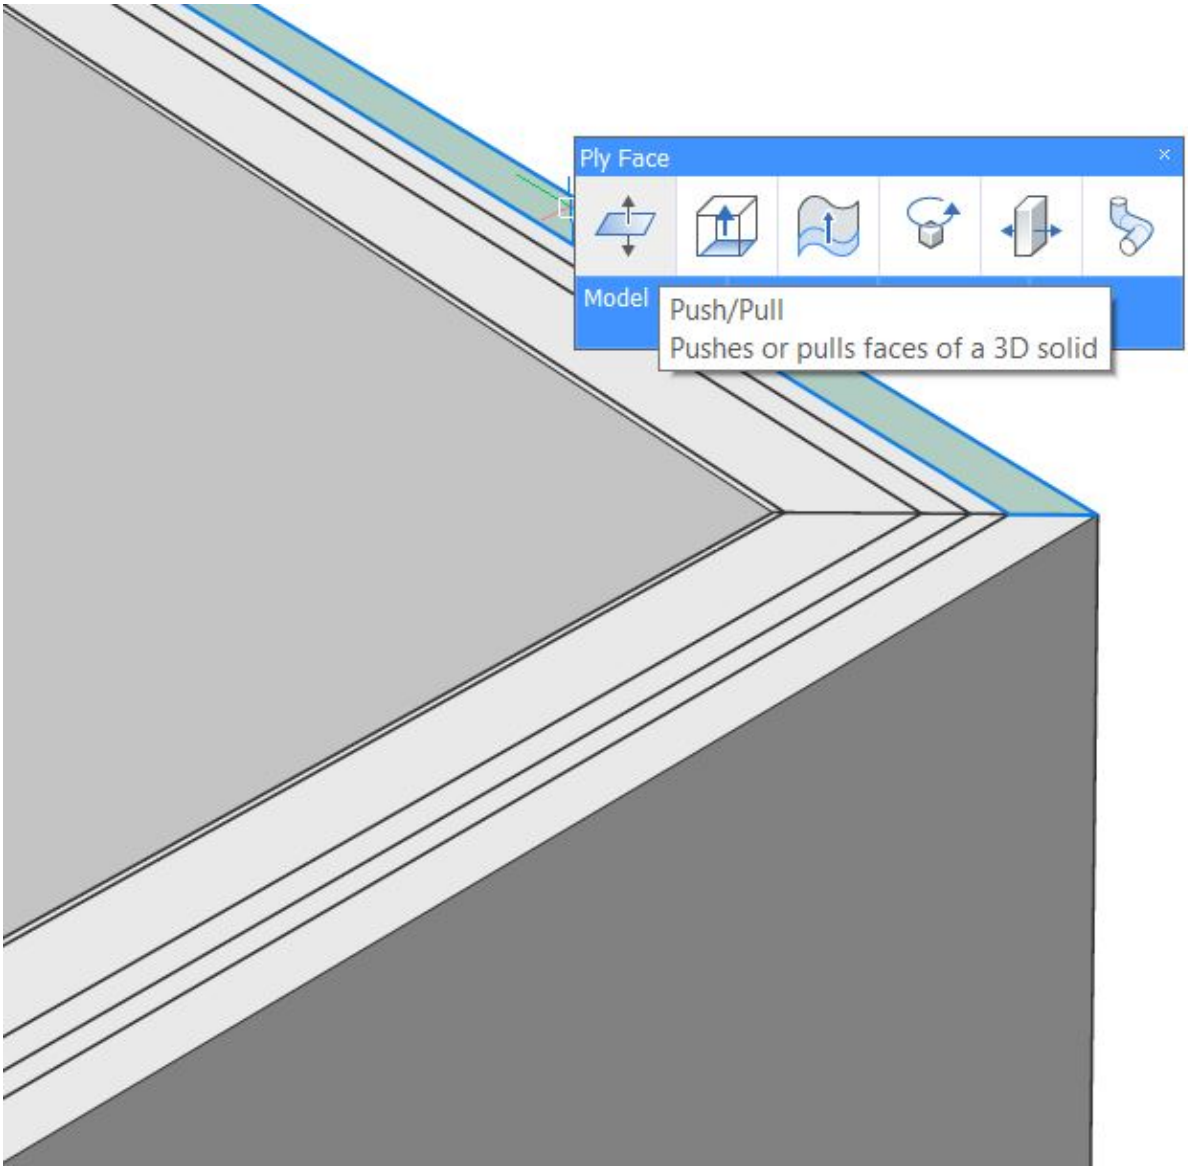

Figure 2.545

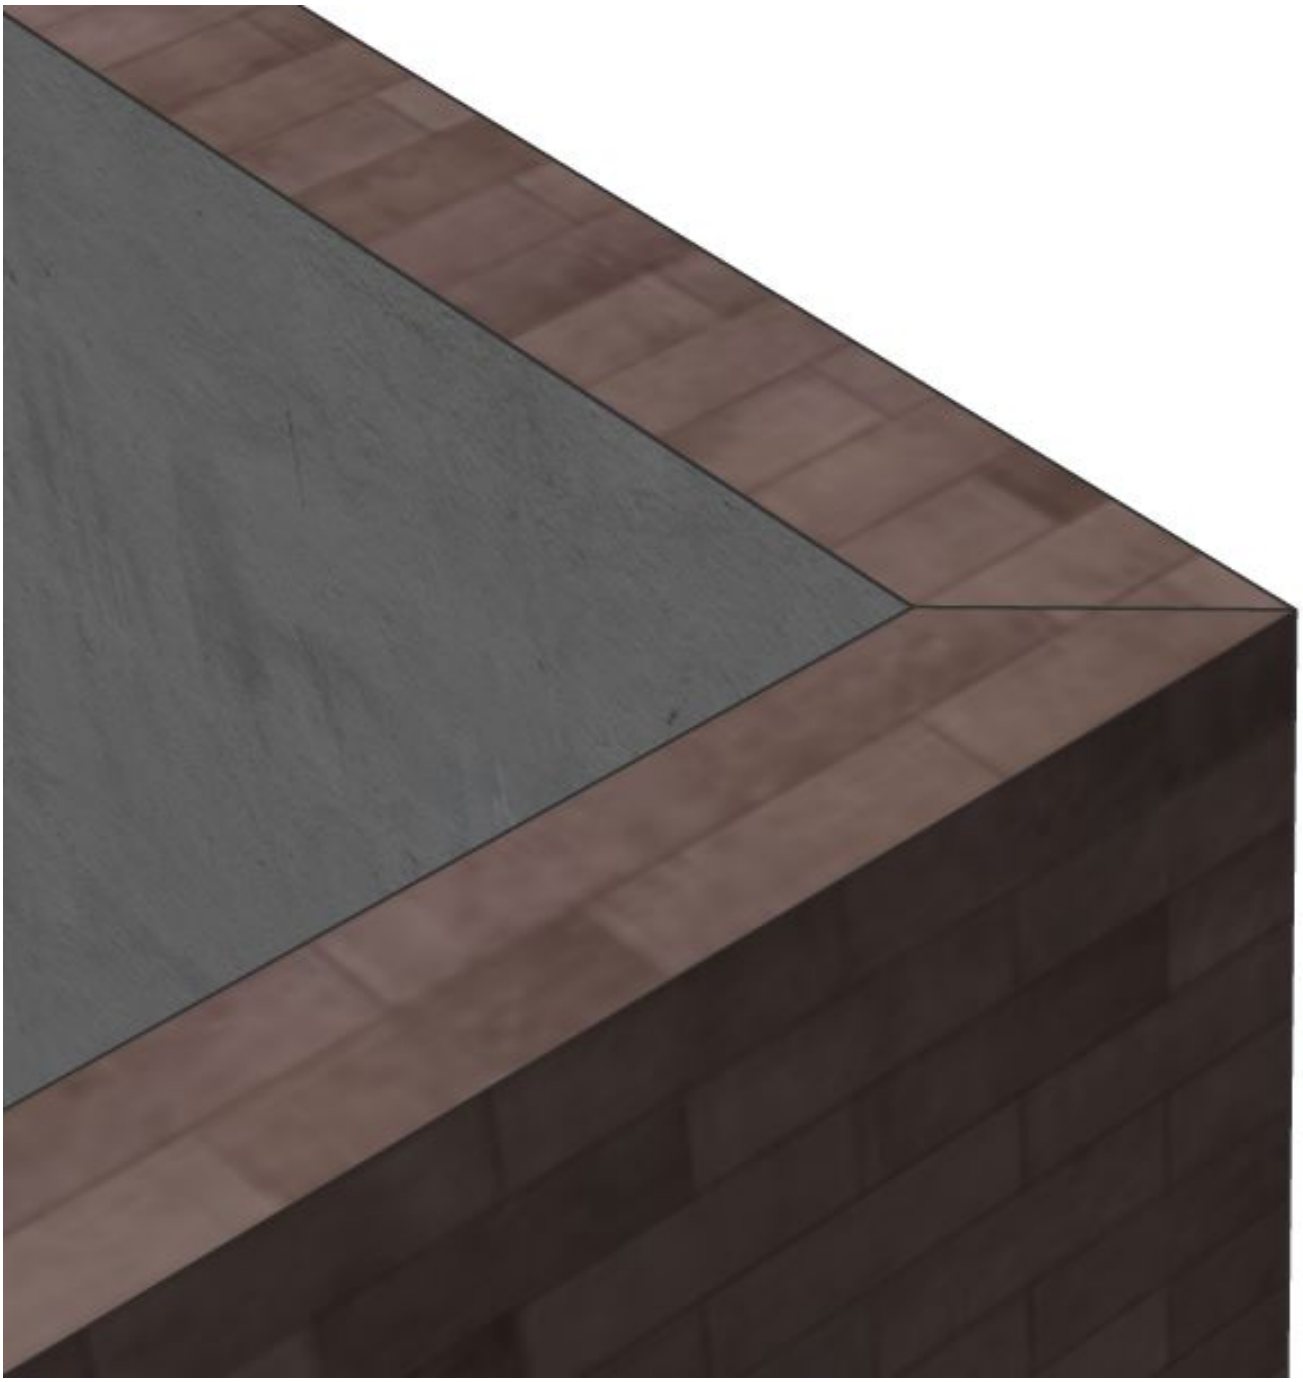

Figure 2.546

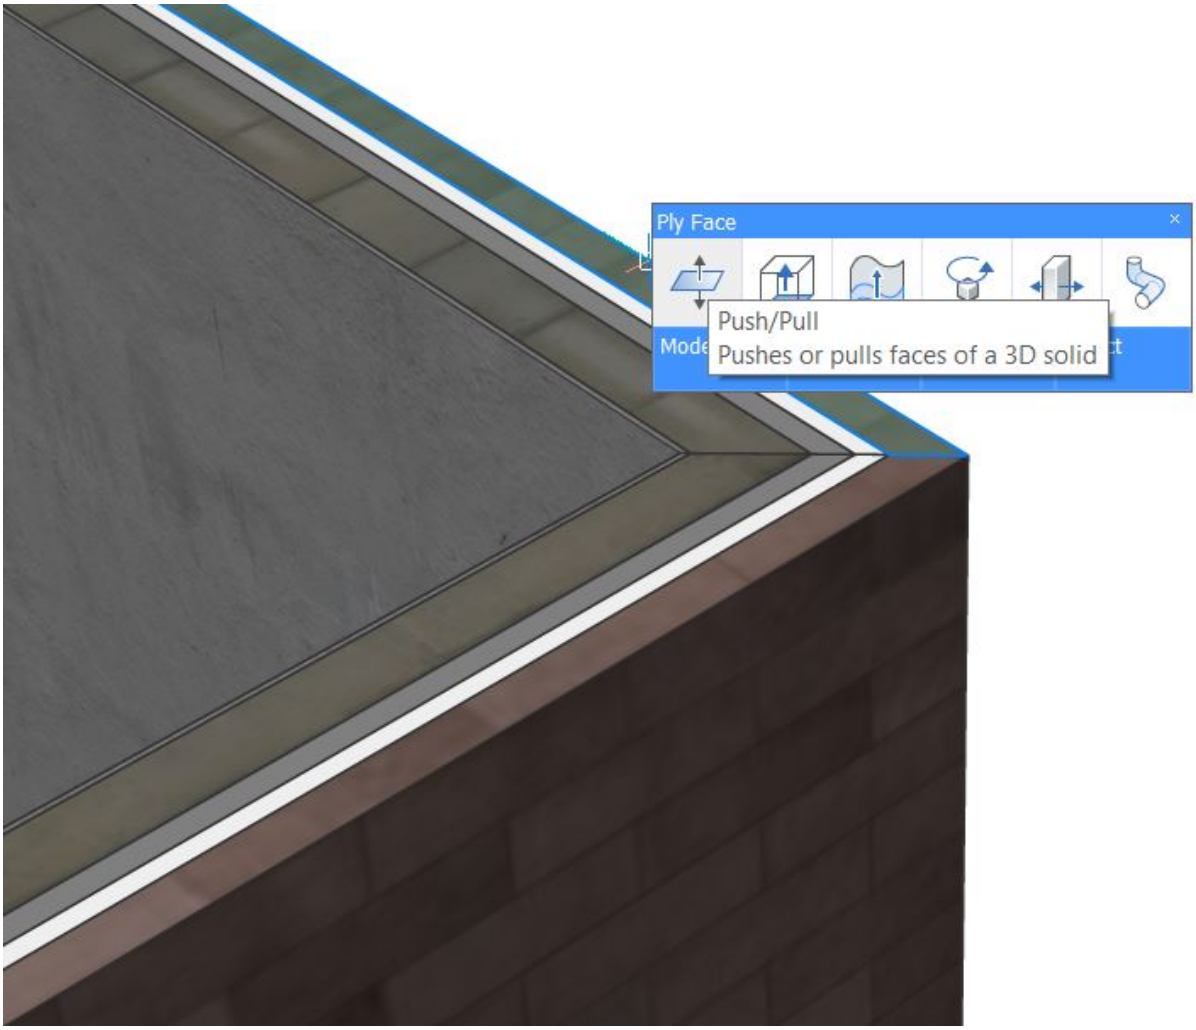

Manipulating the composition plies

1. Make sure the value of **Level of Detail = 2 (High)**.
2. Place your cursor near the composition ply you want to edit and press the Tab key until the ply face (1) highlights. (2.547 on the facing page) **Note:** The highlighted ply face is displayed in the detected boundary color (default = 95).
   Face detection must be enabled to do this.
3. Select **Push/Pull (6.12.25)** from the Quad and drag the ply to a new position (2). (2.548 on the next page) **Note:** Make sure **DmPushPullSubtract = 1**. This ensures that plies being push/pulled are subtracted from any of the other 3D solids they intersect. **Note:** Make sure ESNAP is turned on to snap to the edge of a ply.

Figure 2.547

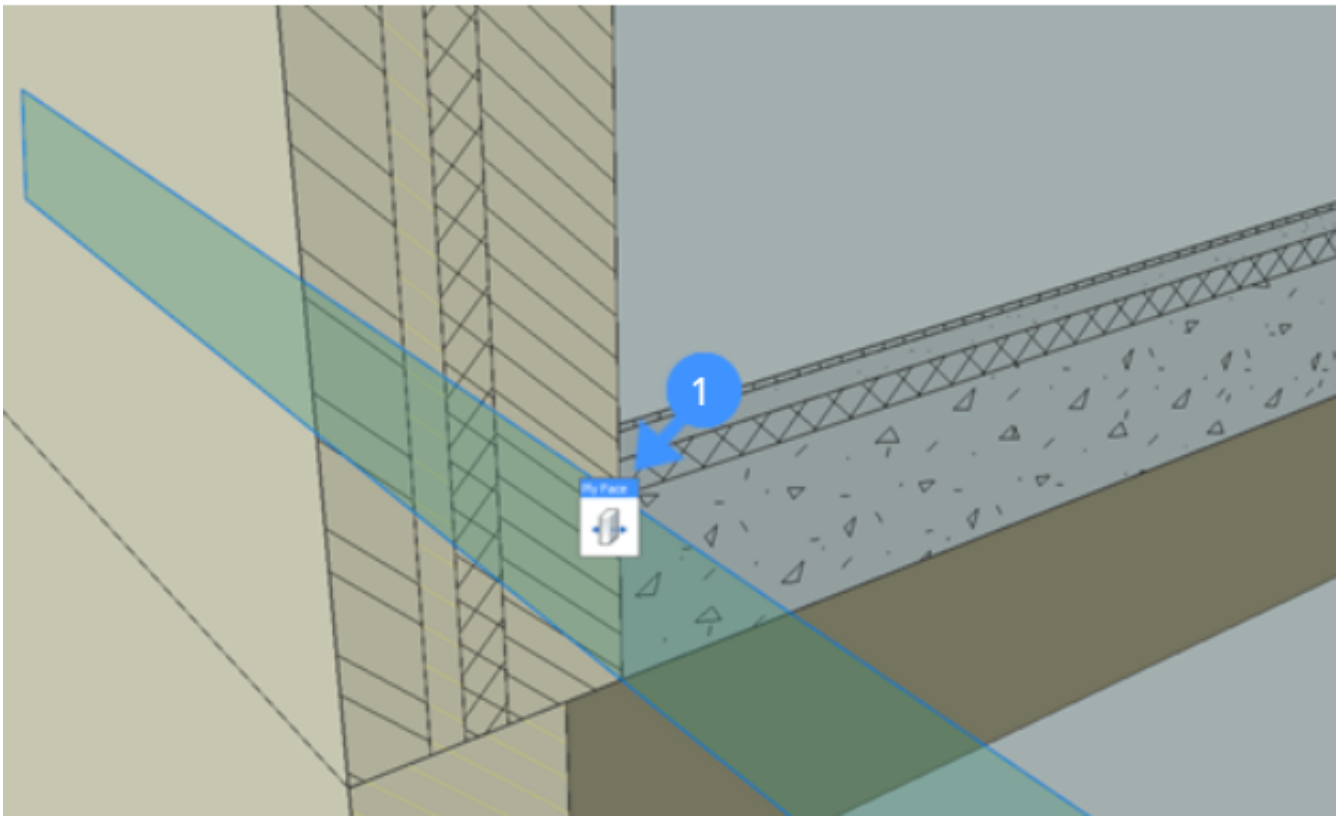

Figure 2.548

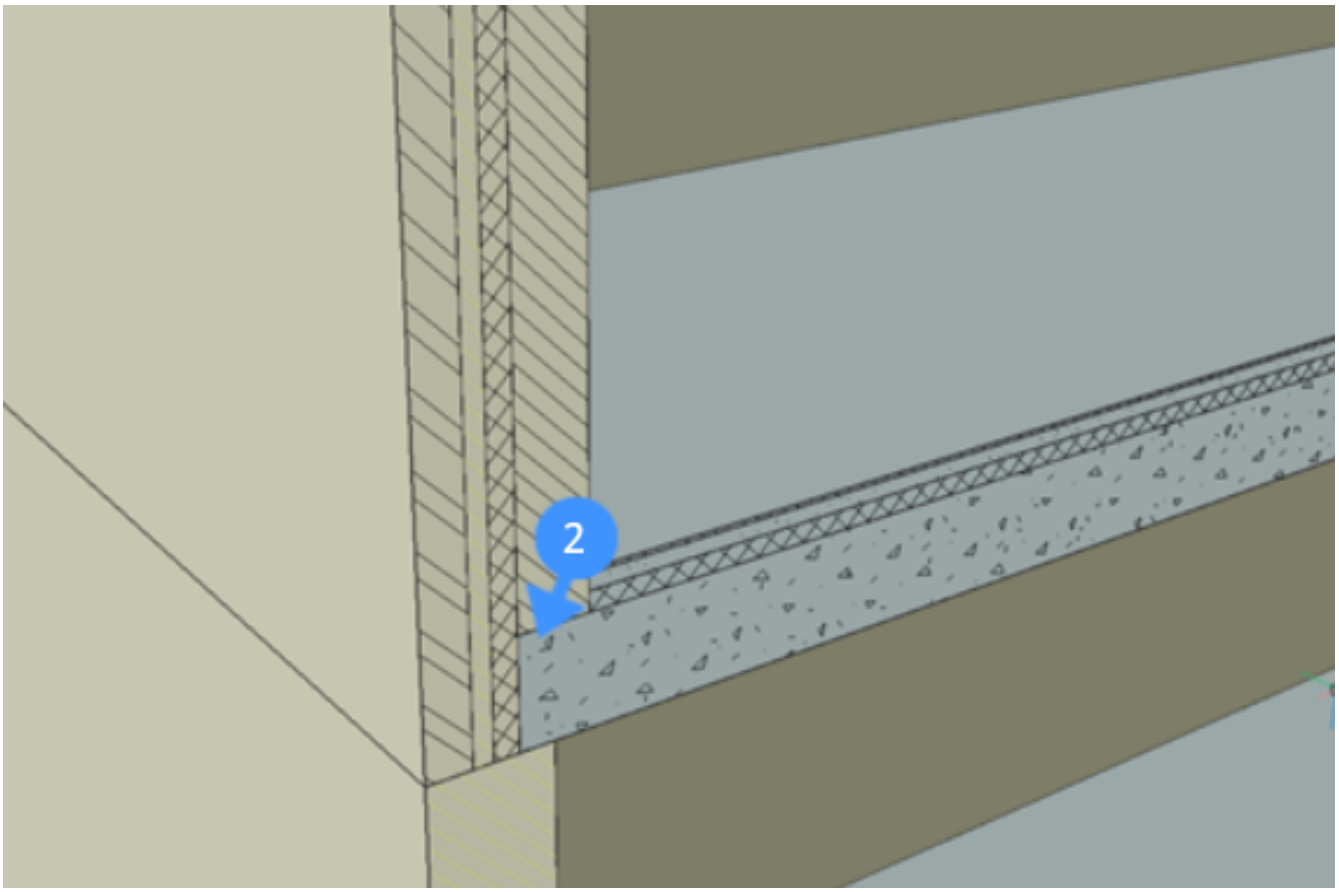

Procedure: Creating a rooftop detail

It is also possible to create more complex details with extra solids added apart from the existing compositions. As an example, a rooftop detail will be created, starting from a rooftop edge.

1. Start with this roof-wall connection (2.549 on the facing page)
2. Click the **Face detection** icon in the ribbon to enable face detection (2.3.5).
3. Turn on LOD to be able to select ply faces. Click the icon in the ribbon **or** type **LevelOfDetail** in the commandline, type **2** and press Enter.
4. Hover over the edge of the concrete ply of the floor slab and press Tab to select the face of the ply.
5. Choose **Push/Pull (6.12.25)** in the model tab of the Quad. (2.550 on page 2101)

Figure 2.549

6. Push/Pull the face to the next ply of the wall. (2.551 on page 2102)
7. To create a wall cap, select the top surface of the wall by pressing Tab and extrude the surface up for 50mm. The created cap isn't classified yet. (2.552 on page 2103)
8. Delete the part where the insulating building block will come. Hover over the surface of the supporting wall and the gypsum board and press tab to select the surface. Then **Extrude (6.13.25)** till the ply of the wall cap. (2.553 on page 2104) (2.554 on page 2105)
9. **Extrude** the same surface again, now a new solid will be created. (2.555 on page 2106)

2.7.9 Using Python Scripts (beta)

Command: BimPython (6.7.39) **Overview:** In this lesson, you will learn how to set up and execute a Python script in BricsCAD BIM. **Note:** This is a **beta** feature. Whilst beta features are new and exciting, there could still be bugs and/or rough edges left to iron out. Therefore, please be aware of the risk when trying out them as things might not go as expected. **Lesson objectives:**

- Activating the virtual Python environment in BricsCAD.
- Understanding and referencing the BIMPython module in a specimen script.
- Executing the Python script in BricsCAD.

About BIMPython

The new BimPython (6.7.39) command enables you to query and manage data from a model within BricsCAD BIM, with a suitable .py Python script. The Python scripts can be as simple as obtaining quantities and associated properties of objects and BIM entities, or as elaborate as implementing a series of calculations based on the model parameters available. BricsCAD does not ship with a Python Shell, so the scripts would need to be prepared in a text or code editor application. The Python Programming Language, together with its standard libraries, is embedded within BricsCAD BIM so there is no need for you to install them separately unless you have custom packages and libraries which you wish to use in your scripts. Before using BIMPython, you need to first turn on the virtual Python environment within BricsCAD.

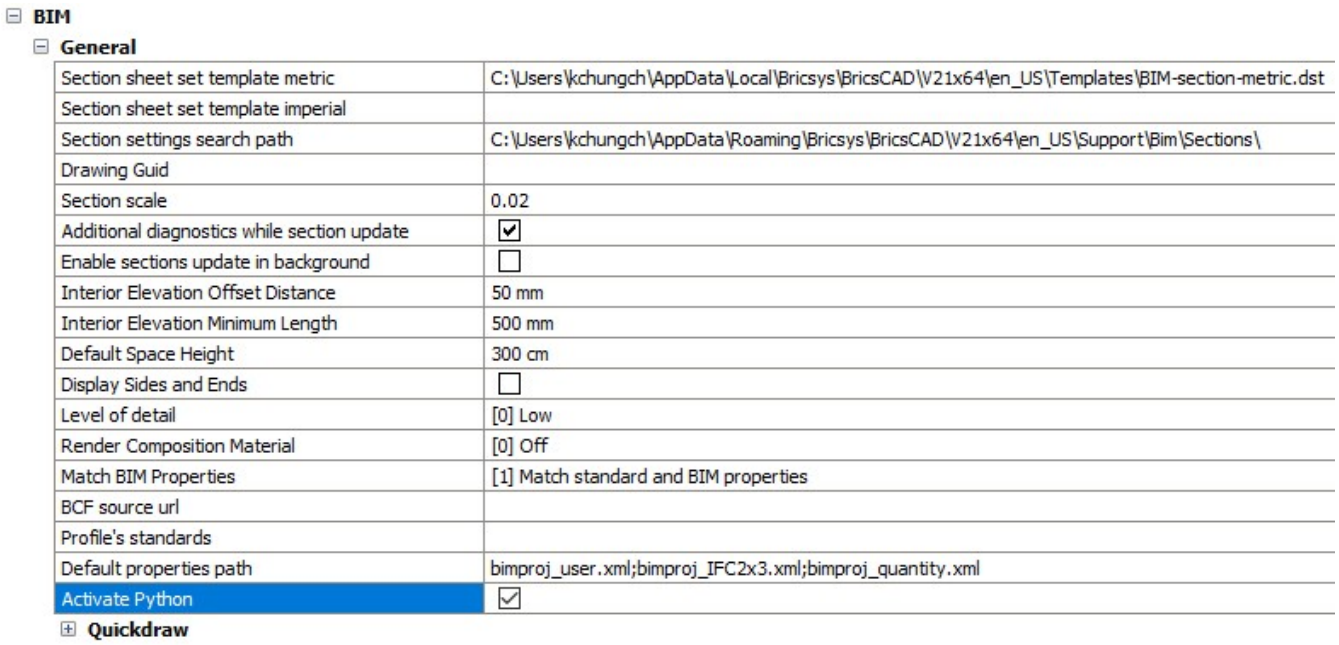
Procedure: Activating the Python environment in BricsCAD

1. Open a new or a BricsCAD file where you would like to run a Python script.
2. Type **BimActivatePython** in the command-line and press Enter.
3. **You will be prompted:** New current value for BIMACTIVATEPYTHON [1 for ON/0 for OFf] <1 for ON>:
4. By default, the value should display **<1 for ON>**. That means the Python environment is already activated. However, If the value shows **<0 for OFf>**, type **1** in the command-line and press Enter to confirm.

Or

1. Open a new or a BricsCAD file where you would like to run a Python script.
2. Access the Settings (6.27.25)  dialog box.
3. Tick the box where it says "**Activate Python**" under the **General** subcategory within **BIM**. (2.556 on the next page)
4. Close the dialog box to confirm your updated settings.

Figure 2.556



Procedure: Setting up a Python Script with the BimPython module

1. Before gaining access to the API, import or 'call' any desired modules you wish to have in the script. If they are not part of the Python Standard library, make sure they have been installed separately beforehand. For example, you can "import" a standard module, for eg. math and "import as" an external one, for example Pyplot, which is a collection of functions in the Matplotlib package:

   ```
   import math  import matplotlib.pyplot as plt
   ```

2. With your desired libraries "called" in, the next step is to gain access to the API in order to query the elements within the BricsCAD model. This is the range of bim objects and serves as an entry point to the model. Import the briqpy.bim_model:

   ```
   from briqpy import bim_model
   ```

3. Now, you can query the model with these example statements.

   ```
   # Display info about the lengths of walls in the model lengths = [wall.prop('Length') for wall in b

   # Create a selection and print the objects bim_model.filter(Type='Wall', IsExternal=True).select()
   ```

   The mappers of the briqpy.ObjectRange are chainable. This is an example to get the parts of the roof that are close to a wall:

   ```
   # Get all parts of roof within 40cm range of all walls roof_parts = bim_model.filter(Type='Roof').p
   ```

   whereas this is an example of a function statement to filter:

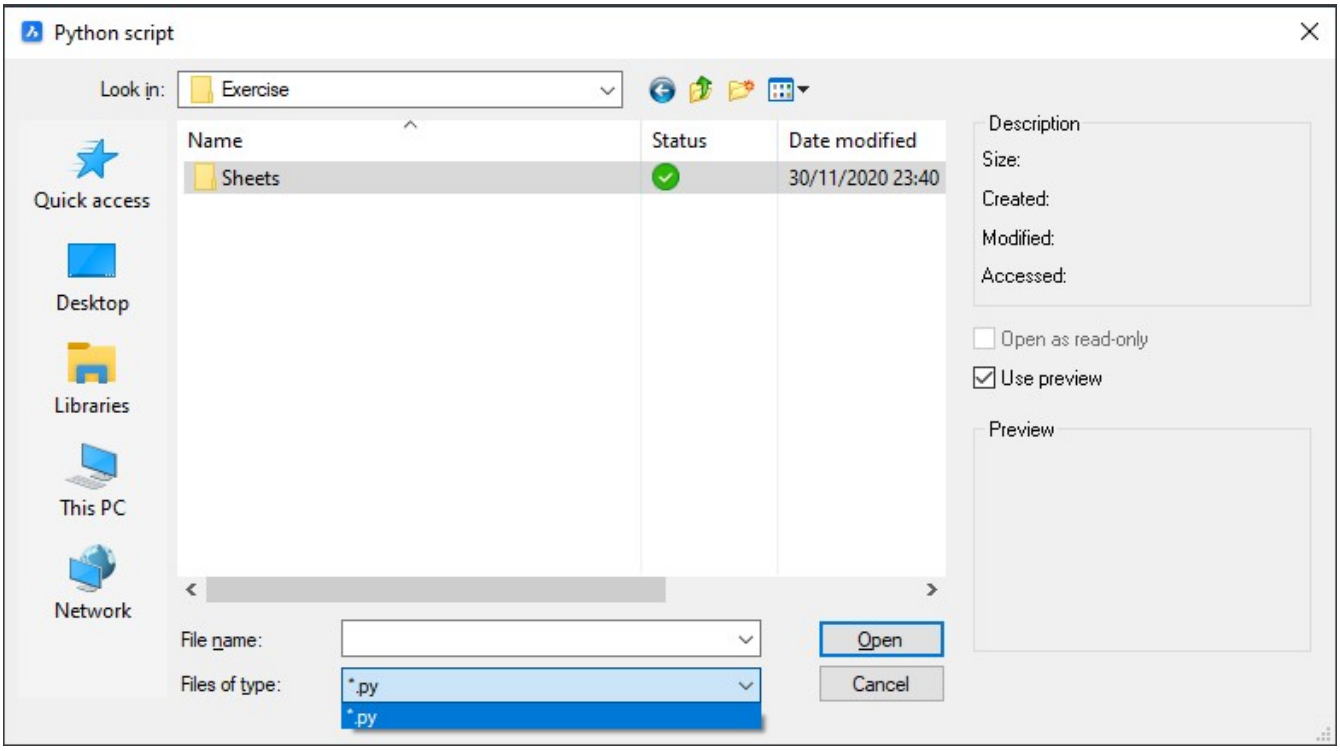
   ```
   # Filter roof parts longer than 50 project units def is_long(obj):  return obj.prop('Length') > 50
   ```

   You can also export and show data in various formats:

   ```
   # create a dictionary list wall_info = [    {   'Handle': wall.prop('Handle'),        'Length': wal
   ```

For more information on the BricsCAD API and its various classes, please visit the API chapter below.

Figure 2.557



Procedure: Executing the Python script

1. Open a new or a BricsCAD file where you would like to run a Python script.
2. Type **BimPython** in the command-line and press Enter.
3. A dialog box is displayed where you can only select a Python script file (*.py). Select it and click **Open** to execute the file. (2.557)
4. Unless you have specified the data to be exported or displayed in an external program outside BricsCAD, BricsCAD reports the output in the command-line panel.

API Dictionary

Classes and syntaxes

class briqpy.Object - defines BricsCAD BIM Objects

`prop(prop_name)`

- Returns the property value of the Object with the given name.

`distance_to( other_obj, units='mm', distance_mode='exact' )`

- Calculate the distance between two Objects.
- Options for argument **units**: any units value form insunits ('Centimeters', 'Feet', 'Parsecs' etc.) and these abbreviations: 'mm', 'cm, 'm', 'km', 'ft'.
- Options for argument **distance_mode**: 'bbox_center', 'bbox', exact'.

`parts()`

- Return the ObjectRange containing the sub-elements of this object.

`parent()`

- The opposite of **parts**(), returns the parent object of this sub-element.

`within_distance( distance, unit='mm', distance_mode='exact', search_range=bim_model )`

- Return the ObjectRange of objects that are within the distance of argument **distance**.
- Options for argument **units**: see distance_to.

- Options for argument **distance_mode**: see distance_to.

`select()`

- Add Object to selection.

`deselect()`

- Remove Object from selection.

`__eq__() and __hash__()`

- Makes Object interoperable with e.g. python set or dictionary

class briqpy.ObjectRange - defines collection of BricsCAD BIM Objects

`filter( function )`

- Filtering this range with a function parameter.

`filter( **conditions )`

- Filtering this range with conditions given as keyword arguments.

`parts()`

- Return the ObjectRange of all the parts of all the elements in this range.

`parents()`

- Return the ObjectRange of all parent objects of elements in this range.

`within_distance( distance, unit='mm', distance_mode='exact', search_range=bim_model )`

- Returns the ObjectRange of objects that are within distance to any object in this range.

`select()`

- Add Objects to selection.

`deselect()`

- Remove Objects from selection.

`__len__ ()`

- Return the number of Objects in this range.

2.7.10 Classification Codes

Overview: In BricsCAD, you can organize your BIM models with standard classification codes that are used in the construction industry. These codes can classify elements according to national or company standards.

- A set of pre-installed classification systems is available to attach to the BIM.
- Multiple classification systems can be used in the same BIM.

Tutorial: How to use Classification Codes Click here (2.6.7) to watch

About

Assigning classification codes organizes the BIM and increases the level of detail. For instance, they allow to organize library materials and project reports, estimate project costs and define product specifications. Currently, GUBIMClassCA, GUBIMClassES, Master Format, NLSfb, OmniClass, UniClass2015, Uniformat, and VMSW are available classification systems in BricsCAD.  For more information about this command, visit the Command Reference article BimProperties (6.7.38).

Assigning classification codes to the BIM

1. Open the BIM Properties dialog box from the Quad (**BIM:** Model tab). **Note**: Quad should be in 'No Selection' state. A dialog box displays: (2.558 on the next page)

2. Click the Import (1) button at the bottom-left corner of the dialog box. A file dialog displays: (2.559 on page 2113)

3. Choose the classification system on the list (2), and click Open (3) to import it into the BIM. **Note:** If the file dialog does not show the Classification folder, you should manually enter this path in the address bar: C:\Users\<User>AppData\Roaming\Bricsys\BricsCAD V19x64\en_US\Sup Support\Bim\Classification. **Available classification systems:**

GUBIMClassCA	Classification system for the BIM Users group of Catalonia.
GUBIMClassES	Unified classification system of building elements designed for the AEC industry in Spain.
Master Format	Standards for commercial and institutional building projects in the US and Canada.
NLSfb	Standards for the AEC industry in the Netherlands.
OmniClass	Classification system for the construction industry.
UniClass2015	Standards for all sectors of the UK construction industry.
Uniformat	Standards for classifying building specifications, cost estimating, and cost analysis in the US and Canada.
VMSW	Standards for the AEC industry in Belgium.

4. The classification system is added to the namespace (4), the selected classification system is added as a property set (5), and the classification code (6) is attached to this property set. By default, the classification system is applied to all sorts of building elements (7). **Optional:** Deselect the categories of building elements to which the classification system is applied. To do so, check the box next to the category name (8) (all elements in this category will be excluded), or expand the list and check the box next to the element type only. Click the OK button (9) to finalize the procedure. **Or** import another classification system following the previous steps. (2.560 on page 2114)

5. Select the element to which you want to assign a classification code, and open the properties panel. The classification system (10) and code (11) should be available in the properties panel. (2.561 on page 2115)

2.7.11 Custom Properties

Command: BimProperties (6.7.38) **Overview:** In this lesson, you learn how to organize properties in property sets and assign them to the building elements. **Lesson Objectives** After completing this lesson, you will be able to:

- Create, edit, and delete properties and property sets.
- Assign the customized property sets to the desired building elements.
- Specify values for the custom properties.

Tutorial: How to create and edit Custom Properties Click here (2.6.4) to watch

About

BricsCAD provides a way to assign your own properties to desired building elements in a single command. This is called assigning custom properties. The approach is first to create a custom property set, then assigning it to the building elements to which the property set is to be applied. The method is carried out by the BIMPROPERTIES command, which allows you to create, edit, and delete the custom property set in a dialog box. This dialog box also allows you to add properties to the currently selected property set. Important to note is that these custom properties are also included in IFC export. For more information about this command, visit the Command Reference article BimProperties (6.7.38). To learn more about creating user-defined quantity definitions, visit the Procedure article for Customizing BIM Quantities (2.7.13).

Using the BIM properties dialog box

1. Open the BIM Properties dialog box by typing BimProperties in the command line. The dialog box displays for specifying and editing properties of BIM projects. The following illustration shows the dialog box. (2.564 on the next page)

(1) Namespace	Groups property sets in namespaces.
(2) IFC 2X3 namespace	Shows the IFC2x3 properties.
(3) Quantity namespace	Shows some hardcoded quantities (**Note:** these have been deprecated and replaced by the Quantities in the IFC2x3 namespace).
(4) User namespace	Shows the custom properties.
(5) Add property set button	Creates a new property set.
(6) Add property button	Creates a new property definition.
(7) Add value button	Creates a new value definition.
(8) Remove button	Removes the selected property set, property definition or value definition.

2. To create a custom property set, select the **User** option in the namespace drop-list, then click the **Add Property Set.** A new property set is added to the User space. To edit the property set do the following:

   - Type a name in the Id (9) field.
   - Type a name in the Label (10) field.

   The Label name appears in the properties tree. If the Label name is not defined, the Id name displays. The Id must be unique. Optionally, you can choose to have the custom property be only applied to specific instances (11), and choose the visibility (12).

   - Select the building element categories (13) the property set applies to.

   When you expand one of the categories, a different type of building elements (14) displays, check the box next to its name to associate with the property set. The following illustration shows the BIM properties dialog box after inserting a new property set. (2.565 on page 2119)

5. To add a property to the currently selected property set, first, select a property set, then click the **Add Property** button to add a new property. To edit the property do the following:

   - Type a name in the **Id** (15)

- Type a name in the **Label** (16)
- Optionally, type a description in the **Description** (17)
- Select the property type. The options are **Boolean, Integer, Real,** and **String** (18)
- Optionally, define enumerated values

The following illustration shows the BIM properties dialog box after inserting a new property. (2.566)

6. To remove the property set/property, select a property set/property in the tree, then click the **Delete** button to remove.

7. Press **OK** button to accept it. Now if you select a building element, which is associated with the property set, you will see its newly assigned properties (20) are placed in a new category (21) in the properties panel. To assign a value to your custom property, select it in the properties panel, then type a new value in its field (22). The following illustration shows the custom properties in the properties panel. (2.567 on the facing page)

Figure 2.567

2.7.12 Load Bearing Direction for slabs

Command: BIMSetLoadBearingDirection (6.7.50) **Overview:** In this lesson, you will learn to specify the load-bearing direction(s) of a slab in your BIM model. **Lesson Objectives** After completing this lesson, you will be able to:

- Define if a slab in your model has 0, 1 or 2 load bearing directions.
- Change the load-bearing direction of a slab.
- Adding a load-bearing arrow in a 2D drawing using BIMTAG (6.7.59).

About BIMSetLoadBearingDirection

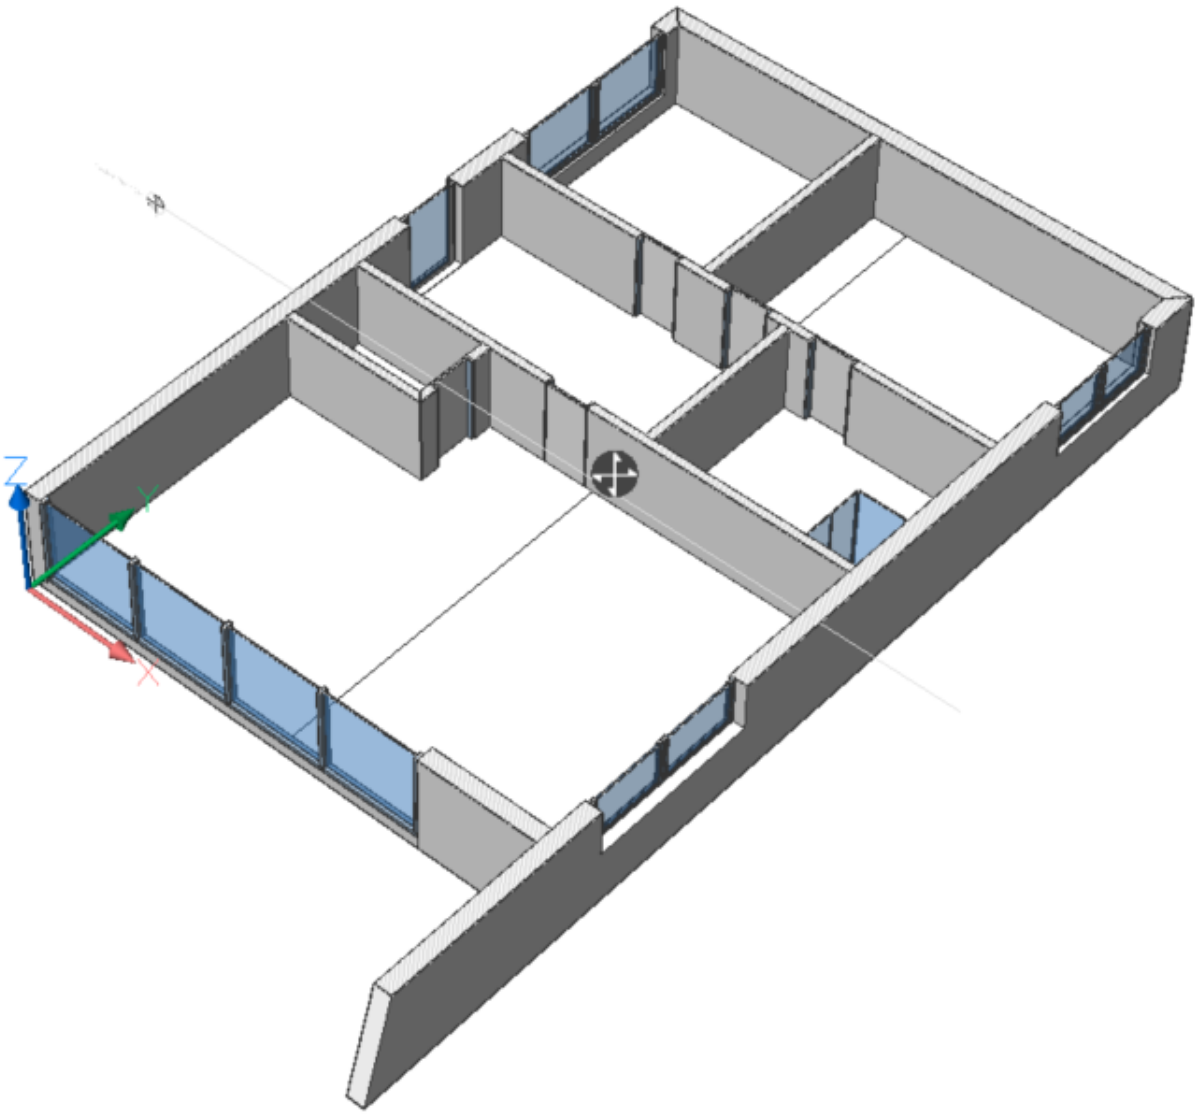
In BricsCAD BIM, the BIMSetLoadBearingDirection (6.7.50) command allows you to define 0, 1, or 2 load-bearing directions for a slab. After defining the load-bearing direction in the 3D model, you can indicate the load-bearing direction in the floorplan using the **Manual** option of the BIMTAG (6.7.59) command.

Specifying load the bearing direction(s)

Only solids which are classified as a BIM Slab can be processed by the BIMSetLoadBearingDirection command. Use the BIMIFY (6.7.23) or BIMCLASSIFY (6.7.12) command to classify a solid as a BIM slab.

1. Launch the **BimSetLoadBearingDirection** command. **You are prompted: Select a slab**
2. Click the slab. It may help to set the Clip Display property of a plan section to select the slab. A widget displays at the center of the slab. . (2.568 on the next page)
4. Repeatedly click the widget. Press Enter or right-click to confirm the loadbearing direction(s).

Figure 2.568



Adding a load bearing symbol in plan section

1. When you insert the loadbearing tag in a plan section, you need to select a line, which is generated by the slab. Since slabs usually overlap with walls, you need to set the **Hidden Lines/Show** property of the BIM Section entity to **Yes**. (2.569) Next, execute the BIMSECTIONUPDATE (6.7.43) command of the plan section.
2. Open the Plan section. (2.570 on the next page)
3. Launch the BIMTAG (6.7.59) command. Choose the **Manual** option.
4. Choose the **Change Tag Type** option.
5. Choose the **Load-Bearing Direction** tag type.
6. Click on a point on the edge of the slab. The tag displays, attached to the cursor.
7. Click to place the tag. (2.571 on the facing page)

Figure 2.569

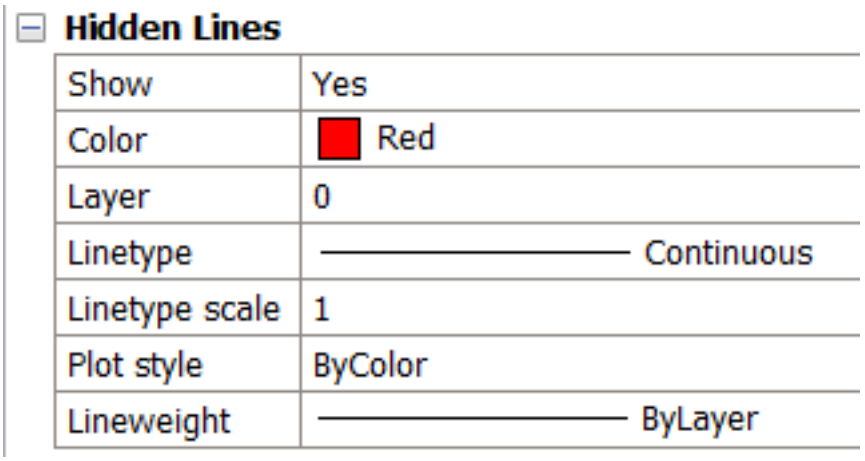


Figure 2.570

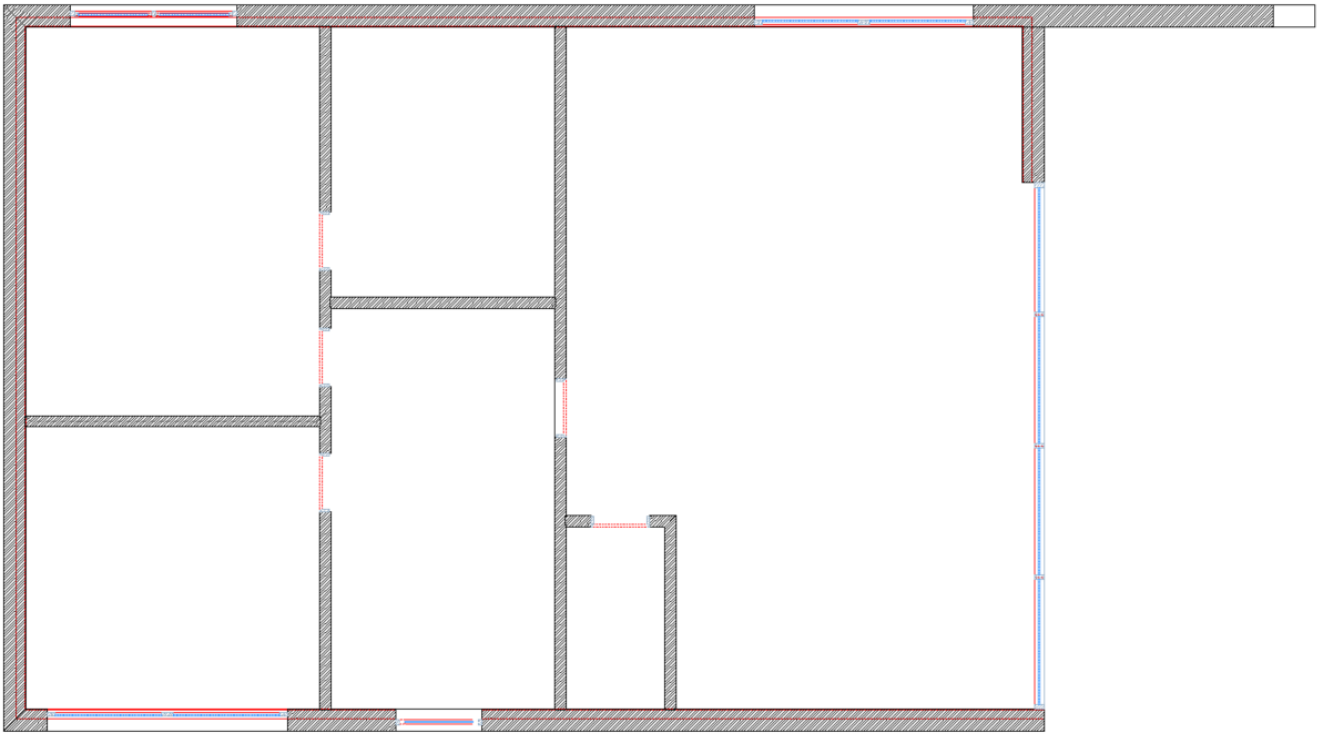

Figure 2.571

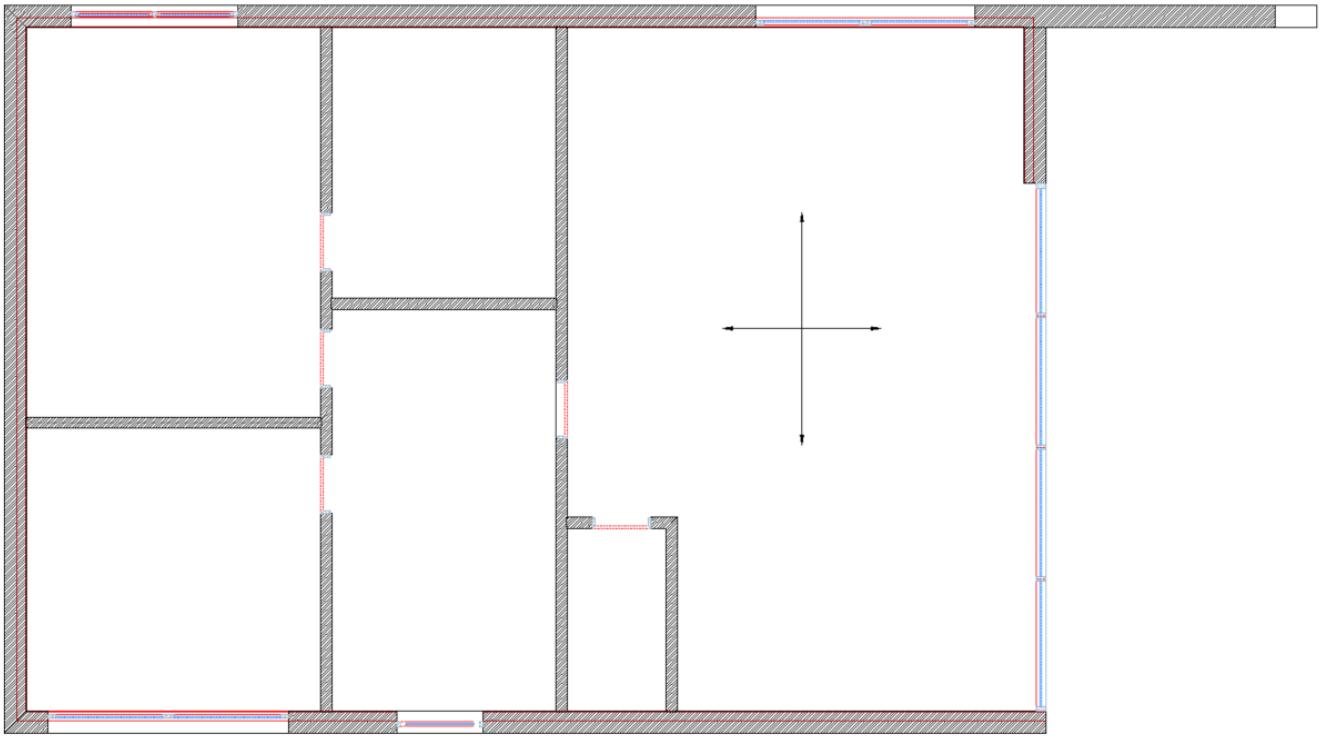

2.7.13 Customizing BIM quantities

Commands: BimProperties (6.7.38) **Overview:** In this lesson, you will learn how to make user-defined quantities. **Lesson Objectives** After this lesson, you will be able to:

- Understand the difference between Core quantities and quantities
- Create your own user-defined quantities

About

Entities have a set of properties which can be viewed in the Properties Panel. If an entity has been assigned a certain BIM classification or Type (e.g. Wall or Slab), additional properties will be displayed such as IFC Common properties and Base quantities. Which properties are displayed in the panel is managed in the BIM Properties dialog, which is opened by the BimProperties (6.7.38) command.

Namespaces

In the BIM Properties dialog, by default three namespaces are available: **IFC2x3** (1), **Quantity** (2) and **User** (3). The IFC2x3 namespace contains properties that are defined by the IFC2x3 schema (2.11.3). This contains both common properties (e.g. Wall Common properties such as Fire Rating and Acoustic Rating), and Quantities (e.g. Wall Quantities – Nominal length (4)). These Quantities are based on so-called Core quantities (5) of the solid, see Core quantities. The Quantities namespace contains some hard-coded quantities of BIM objects also based on the Core quantities, much like in the IFC2x3 namespace. **Note:** This Quantities namespace is deprecated. It has been replaced by the Quantities in the IFC2x3 namespace, however it is still available in the Properties dialog for backward compatibility with versions V20 and older. The User namespace exists for the user to create their own property definitions. See also the Procedure article Custom Properties (2.7.11) for more information on custom properties. It is also possible to import namespaces, e.g. the IFC4 namespace. This can either be done by clicking the Import button (6) on the bottom left. (2.572 on the next page) **Note:** using this method the namespace will only be imported for this particular project. If you want namespaces to be imported over all your projects, open the Settings dialog and under BIM > General > Default properties path you can add a new path. By default, it should take you to **C:\Program Files\Bricsys\BricsCAD Vxx en_US\Support**, where you can find for instance the bimproj_IFC4.xml containing the IFC4 namespace.

Core quantities

Core quantities are quantities of solids that are calculated based on the geometric features of that solid, and that can be used in user-defined quantities. These core quantities are also the basis for the quantities defined in the IFC2x3 and IFC4 (2.11.3) properties as described in the previous section. For example, under Wall Quantities in the IFC2x3 namespace, the Nominal Height of a wall is defined as the ZDimUpBoundingBox of the solid, which is a Core quantity. A full list of Core quantities can be found below.

Core Quantity	Description	Measure	Type
NumberOfPlies	Number of plies in the attached composition		Integer
XDimUpBoundingBox	X dimension of the bounding box found with global Z axis rotation freedom	Length	Real
YDimUpBoundingBox	Y dimension of the bounding box found with global Z axis rotation freedom	Length	Real
ZDimUpBoundingBox	Z dimension of the bounding box found with global Z axis rotation freedom	Length	Real
XDimFreeBoundingBox	X dimension of the bounding box found with 3D rotation freedom	Length	Real
YDimFreeBoundingBox	Y dimension of the bounding box found with 3D rotation freedom	Length	Real
ZDimFreeBoundingBox	Z dimension of the bounding box found with 3D rotation freedom	Length	Real
DistanceBetweenMajorSurfaces	Distance between major surfaces	Length	Real
FirstMajorSurfacePerimeter	Perimeter of the first (largest) major surface	Length	Real
SecondMajorSurfacePerimeter	Perimeter of the second major surface	Length	Real
LinearAxisLength	Length of the linear element's axis	Length	Real
VariablePlyThickness	Thickness of a variable ply	Length	Real
FirstMajorSurfaceNetArea	Area of the first (largest) major surface after subtracting openings	Area	Real
FirstMajorSurfaceGrossArea	Area of the first (largest) major surface before subtracting openings	Area	Real
SecondMajorSurfaceNetArea	Area of the second major surface after subtracting openings	Area	Real
SecondMajorSurfaceGrossArea	Area of the second major surface before subtracting openings	Area	Real
IsMajorSurfacesParallel	Indicator if the major surfaces are parallel		Boolean
TotalSurfaceNetArea	Area of the solid's surfaces after subtracting openings	Area	Real
TotalSurfaceGrossArea	Area of the solid's surfaces before subtracting openings	Area	Real
FootprintNetArea	Area of the bottommost solid's surfaces after subtracting openings	Area	Real
FootprintGrossArea	Area of the bottommost solid's surfaces before subtracting openings	Area	Real

ProjectedNetArea	Area of the solid's surfaces projected to global XY plane after subtracting openings	Area	Real
ProjectedGrossArea	Area of the solid's surfaces projected to global XY plane before subtracting openings	Area	Real
CrossSectionNetArea	Area of the cross section for linear elements after subtracting openings	Area	Real
OuterSurfaceNetArea	Area of the outer surface for linear elements after subtracting openings	Area	Real
NetVolume	Volume of the solid after subtracting openings	Volume	Real
GrossVolume	Volume of the solid before subtracting openings	Volume	Real

User-defined quantities

In the User namespace it is possible to create custom properties inside a custom property set using the Property (7) button, see Procedure article Custom Properties (2.7.11). It is also possible to create user-defined quantities, using the Value (8) button. In the image below, a user-defined quantity was created in a custom property set (9). This user-defined quantity (or Value Definition) has the following attributes:

- ID (10): a unique identifier
- Label (11): the name of quantity which will show up in the properties panel. This can be the same as the ID, however the **ID must be unique**.
- Description (12): a description of the quantity
- Type (13): the type of the quantity. Typically, a quantity will be defined as a Real value.
- Measure (14): the measure of the quantity, i.e. is it a length value, an area, volume or mass?
- Formula (15): the actual expression of the quantity. Here Core quantities can be used, as well as mathematical expressions as defined in Procedure article Working with Parameters and Constraints (2.5.24).

In this example, a user-defined quantity is defined that displays half the thickness of a wall, which is calculated as **DistanceBetweenMajorSurfaces/2**. (2.573 on the following page)

Procedure: creating a user-defined quantity

In this part you will learn how to make user-configurable quantities. By way of example, we will define a quantity of Spatial objects such as a room. The quantity will be the Compactness which can be calculated as the volume of the space divided by the sum of the areas on all sides of the space. (2.574 on the next page)

1. Open the BIM Properties dialog by typing BIMPROPERTIES in the command line.
2. Set the User namespace as current namespace.
3. Create a new Property Set by clicking the Set button (16), and give it a name (17).
4. Assign the Property Set to one or more categories (18). In this example we will assign it to spatial elements.
5. Create a new Value Definition by clicking the Value button (19).
6. Give this Value Definition an ID and a Label, e.g. 'Compactness'.
7. **(Optional)** Give this Value Definition a description.
8. Assign the correct Type to this Value Definition. Because our Value Definition will be based on a calculation of two Real values, this will also be a Real value.
9. Assign a Measure to the Value Definition. Because the result of the calculation will be a volume divided by an area, we will end up with a Length measure.
10. Fill in an expression in the Formula field. The volume of a space is a Core quantity with the name GrossVolume. The sum of areas of the space on all sides is also a Core quantity with the name TotalSurfaceGrossArea. Hence, we can define the **Compactness = GrossVolume/TotalSurfaceGrossArea.** (2.575 on page 2133)
11. Click OK to close the BIM Properties dialog.
12. Create a volume that represents a space, either by creating surrounding elements like walls and a slab, and by defining a space inside using the BimSpace (6.7.45) or Bimify (6.7.23) commands, or by creating a solid and using BimClassify (6.7.12) to classify it as a Space.
13. Select the space. In the Properties panel you should now see your user-defined property under a separate property set.

2.7.14 Creating and editing BIM Spaces

Command: BimSpace, (6.7.45) BimUpdateSpace (6.7.53), Bimify (6.7.23) **Overview:** In this lesson, you learn how to create BIM Space entities from enclosed spaces. **Lesson Objectives** After completing this lesson, you will be able to:

- Define Space areas
- Define Spaces with linear elements
- Edit BIM Space entities

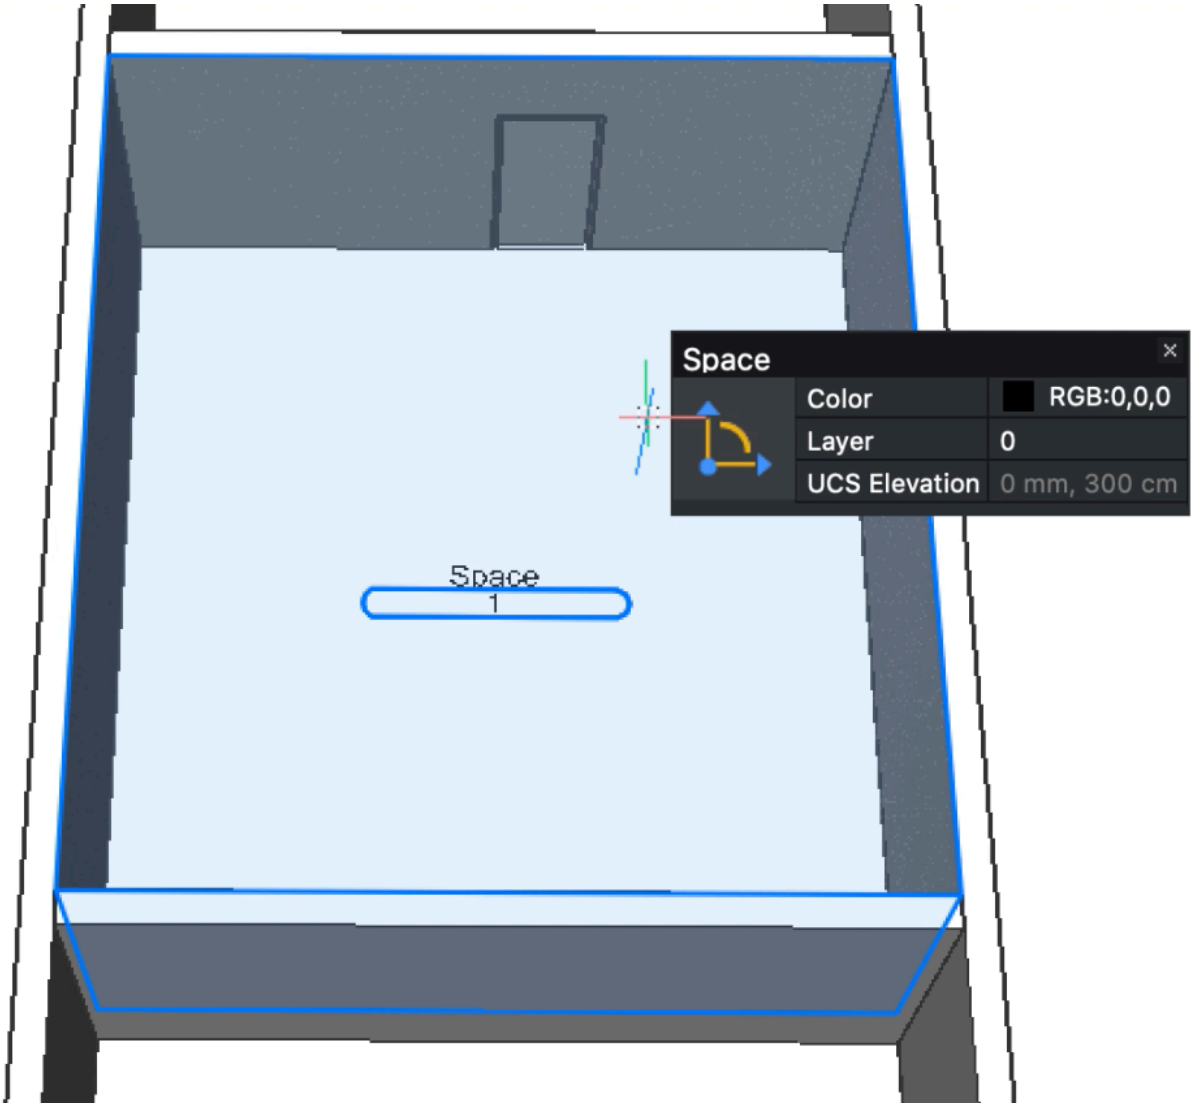
About

You can create BIM Spaces from enclosed spaces. When the wall elements enclose a space in your model, you can use the **BimSpace** tool to define a BIM Space. These spaces are solids so they can be easily manipulated. The 3D space geometries added to the current model are associated with space tags. The space tag is a block that contains a hatch and attributes. The default attributes of the Space tag include a space name and a space number. The values of each attribute can be changed using the properties panel.  **Create space**  **Edit space** For more information about this command, visit the Command Reference article BimSpace (6.7.45).

Defining a BIM space

1. Select the **Space** tool under **Home | Classify | Space or** type **BimSpace** in the commandline. **You are prompted: Pick a point inside the space or [Edit];**
2. To define a BIM space, pick a point inside the space area in your BIM model.
3. Move the cursor inside the space area to pick a point, the **Dynamic UCS** enables to define the bottom plane of the space. A green checkmark will appear next to the cursor to indicate a possible location. A red cross will appear if the plane isn't available.
4. In this plane, an area enclosed by wall elements or any space bounding elements is found and a space tag is placed in the center of the space. **Space Bounding elements** can be Walls, curtain walls, slabs, columns, but also hatches and polylines can be counted as space bounding elements.
(2.576 on the next page)
5. Edit the properties of the BIM Space in the properties panel. Change the representation from solid to footprint for a less notable visualization.

Figure 2.576



Procedure: Creating BIM Spaces from virtual boundaries

There are cases in which a virtual boundary is needed. E.g. separate parking spaces, large auditorium spaces for energy analytics, etc.

1. Divide the Space with linear entities. This can be hatches or lines. (2.577 on the facing page)
2. Select the dividing elements (the red line).
3. Classify them as a space bounding element. **Home | Classify | Wall. Or** in the Quad under Bim.
4. Type BimSpace in the commandline and pick a point inside the space. (2.578 on page 2138)

Note: If the line doesn't divide the space, go to the properties panel and BIM, check if **Space bounding** is turned on.

Figure 2.577

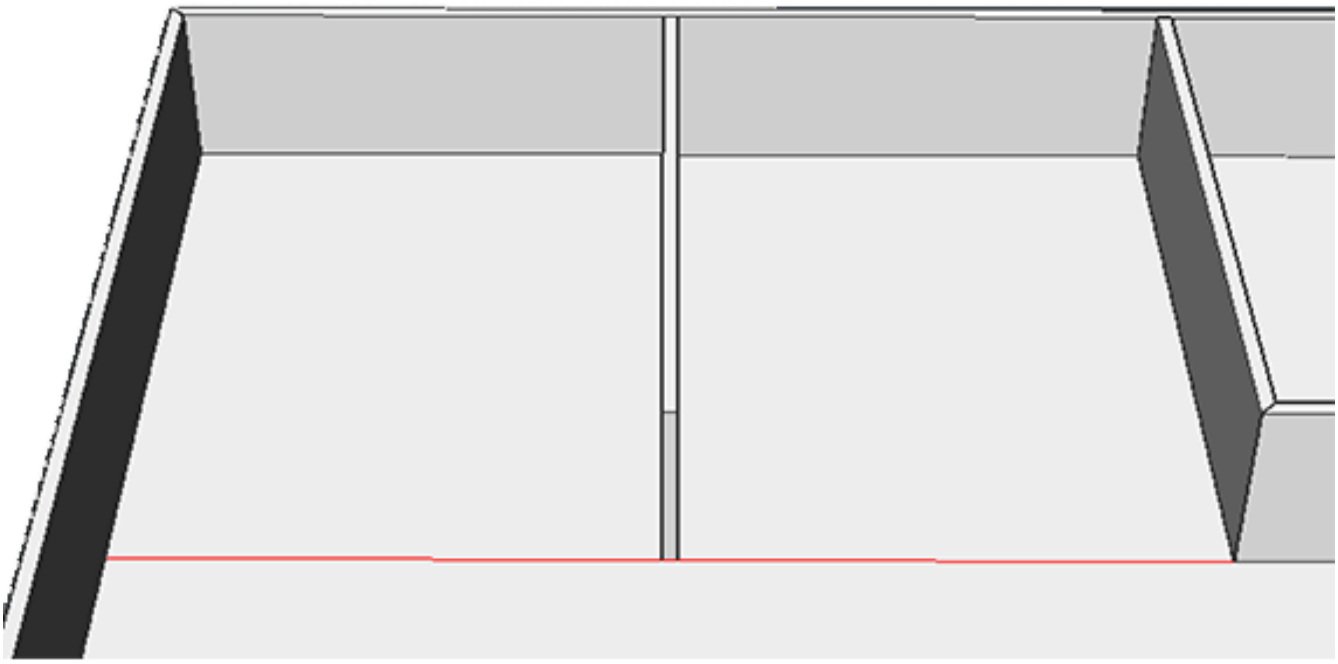


Figure 2.578

Creating BIM Spaces automatically

Bimify (2.9.1) and QuickBuilding (6.7.40) create BIM spaces and automatically assign information to them. E.g. the story and building of the space (see BimSpatialLocations (6.7.63)). The commands will search for space bounding elements and create spaces wherever possible. These spaces act like manually made spaces and can be edited according to your own needs.

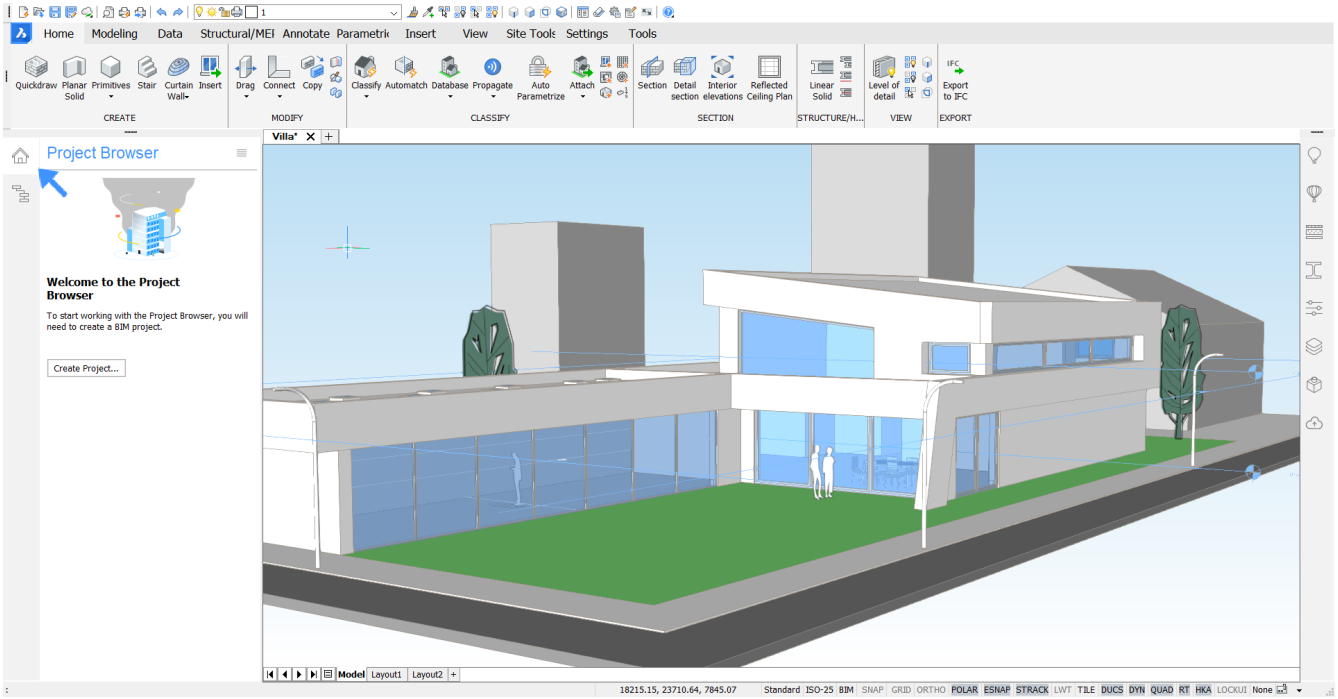
2.7.15 Project Browser

Commands: DataExtraction (6.10.4), BIMSectionUpdate (6.7.43), BIMSectionOpen (6.7.49) **Overview:** The BIM Project Browser allows you to navigate easily through an entire project; models, sections, drawings and schedules.

The Project Browser panel

You can find the Project Browser panel on the left-hand side of the screen. (2.579 on the facing page) **Note:** If the Project Browser doesn't display in the panel, right-click in the panel and select Panels > **BIM Project Browser**.

Figure 2.579



Create a BIM project

To create a BIM project, you must select one or more model drawings.

Project

1. Click the **Create Project...** button in the **Project Browser.** A dialog box appears. (2.580 on the next page)
2. **(Optional)** Click the Path list button and select a parent folder. (2.581 on page 2143)
3. **(Optional)** Type a name in the Name field (the default name is the name of the parental folder).

Cancel

Library The Project Library can either be external or embedded. Sharing the project library means that you can use the same library over different drawings, this is called an external library. The shared library is stored in an external BIM Database File with the .bsyslib extension. An embedded library stores the Project Library in the drawing file.

To make an external library: **Note:** by default, the library is set to 'Embedded'.

1. Go to the **Library** tab. Enter a name for the Project library (the default name is project.bsyslib). ===ERROR WITH DOWNLOADED IMAGE===
2. Click **OK** to display the Sheetset Setup dialog box.

Sheetset Setup

Sheetset: Shows the path of the sheetset file. **Template:** Shows the path of the current template. Click **Browse** ( ) to change the template. **Layout:** Selects which layout (different paper sizes) the section results will be generated.

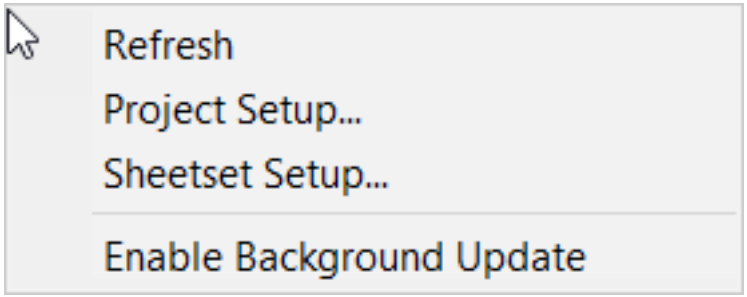
1. The **Sections** tab lists all sections. For each section with an empty Current Destination field, a viewport and sheet view are generated. ===ERROR WITH DOWNLOADED IMAGE===
2. Click **Sheets** to preview each sheet (within the selected layout). ===ERROR WITH DOWNLOADED IMAGE=== **Note:** When the viewport is larger than the layout, it displays in red. ===ERROR WITH DOWNLOADED IMAGE===
3. Click the **Configuration** tab. Slowly double-click (or click and hit Space/Enter) to change the properties. Under **Sheets Folder** you can change the name of the folder where the sheets will be stored. ===ERROR WITH DOWNLOADED IMAGE===
4. Click **Create Sheets**. An overview of the project displays and the sheets are generated. **Note:** The drawings with an orange fill circle icon are out of date. Right-click on them and select **Update** to match changes in the models included in the project. ===ERROR WITH DOWNLOADED IMAGE===

Editing a project

Click on the **Menu** button ( ). A dialog box displays: (2.584)

- **Refresh:** Refreshes the Project Browser to match changes in the model.
- **Project Setup...:** Opens the Project Setup dialog box.
- **Sheetset Setup...:** Opens the Sheetset Setup dialog box.
- **Enable Background Update:** Calculates section results automatically (without interrupting user workflow). Sections are assigned a color; Queued: blue, Outdated: red and In progress: green.

Figure 2.584



Creating Schedules

Tutorial: How to create Schedules Click here (2.12.3) to watch Click here (2.13.16) for more information about **Schedules**.

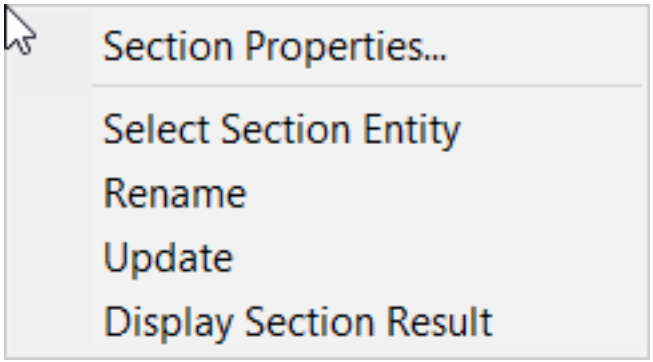
Working in the Project Browser

Right-click an item in the BIM Project Browser to display a context menu.

Sections (2.913 on page 2509)

- **Section Properties...:** Opens the Section Properties dialog box.
- **Select Section Entity**: Selects the section entity in the project model drawing.
- **Rename**: Renames the section entity.
- **Update**: Recalculates the section result.
- **Display Section Result**: Displays the section result in the corresponding sheet and zooms in on its viewport. (If not already open, the drawing is opened.)

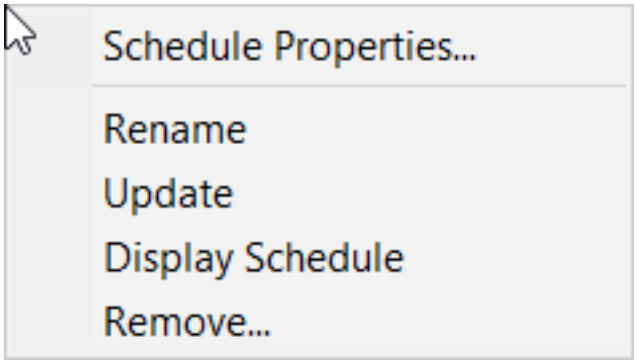
Figure 2.585



Schedules (2.586)

- **Schedule Properties...:** Opens the Schedule Properties dialog box.
- **Rename**: Renames the schedule
- **Update**: Recalculates the schedule content when the source data in the model file have been modified.
- **Display Schedule**: Displays the schedule in the resulting drawing. (If not already open, the drawing is opened.)
- **Remove...**: Displays a dialog box:

Figure 2.586



Sheets (2.587)

- **Sheetset Properties...:**
- **Sheetset Setup...:** Opens the Sheetset Setup dialog box.

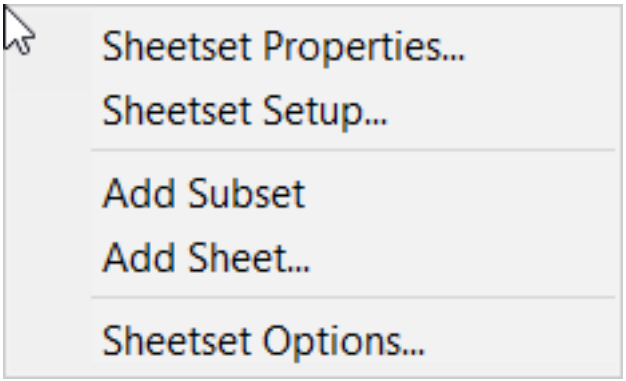
- **Add Sheet...:** Adds a new sheet in a subset in the Sheets tab.
- **Sheetset Options...:** Opens the Sheet sets tab in the Settings dialog box.

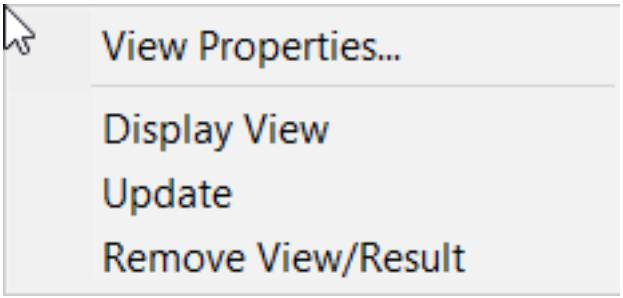
Figure 2.587



Sheet Views (2.588)

- **View Properties…:** Opens the Sheet View Properties dialog box.
- **Display view**: Displays the corresponding result and zooms in on its viewport.
- **Update**: Updates the sheet view = executes the BimSectionUpdate (6.7.43) command for the related BIM section.
- **Remove View/Result:** Removes the view and result from the corresponding sheet.

Figure 2.588



Model drawings Context menu of a currently open model: ===ERROR WITH DOWNLOADED IMAGE=== Context menu of a currently closed model: ===ERROR WITH DOWNLOADED IMAGE===

- **Model Properties...:** Opens the Model Properties dialog box.
- **Close/Open Drawing**: Closes or opens the model.
- **Remove from Model List**: Removes the drawing from the project model drawings.

2.7.16 Spatial Locations

Commands: BimAttachSpatialLocation, BimSpatialLocations (6.7.9) **Overview:** In this lesson, you will learn how to create spatial locations and assign them to building elements. **Lesson Objectives** After completing this lesson, you will be able to:

- Create spatial locations using the Building & Story manager.
- Set up building and story information about your building elements.
- Edit existing Spatial Locations.

Tutorial: How to add Building & Story information Click here (2.6.2) to watch

About BimSpatialLocations

Spatial locations allow you to specify building and its stories in a project. In BricsCAD, a BIM model file can contain one site and multiple buildings and a building can contain multiple stories. When the entities are classified as a building element in the project, these classified entities have a **Building** and a **Story** property. Every building element in the BIM model resides in a particular story within a particular building.  For more information about this command, visit the Command Reference article BimSpatialLocations (6.7.9).

Procedure: Assigning a building and story to a building element

1. Launch the BimSpatialLocations (6.7.9) command.
2. Click the **New Building** icon () to add a new building to the model.
3. Fill out the properties grid to specify a new name or value of the existing property.
4. Click the **New Story** icon () to add a new story in the selected building.
5. Fill out the properties grid to specify a new name or value of the existing property.
6. **(Optional)** Click the **Delete** icon (✕) to remove the selected building or story.
7. **(Optional)** Click **Import Spatial Locations button** () to import a spatial location from a .txt file. (6.522 on page 3805)
8. Select building element(s) in the drawing area to associate them with the appropriate spatial locations. The properties of the selected building elements display in the Properties (1.15.4) panel.
9. Do the following to assign the building and story to these building elements:
   - Expand the **BIM** section in the **Properties** Panel.
   - Click the **Building** field, then use the arrow to select a building.
   - Click the **Story** field, then use the arrow to select a story. The building elements are associated with the selected building and story. (2.590 on page 2156)

Viewing the Spatial Locations in the Structure browser

The Structure browser (2.7.18) allows to view all of the entities in a drawing. By default, the structure of the building elements is organized in a particular form. Building elements are grouped by Building, Story, BIM type, and by composition respectively. This organization can be fully configured. Right click in the structure browser and click **Configure**, a new window will open. See the StructurePanel (6.27.54) command for more info. (2.591 on the following page) If there is no BIM Building or BIM Story in the structure browser, you can add them manually. See Structure Panel (1.32.15) for more info.

About BimAttachSpatialLocation

Assigning new Spaces can be done using the BimSpace (6.7.45) command. Spaces are not always assigned to the according buildings because they don't have a spatial location yet. Use the **BimAttachSpatialLocation** command to assign a spatial location to spaces. For more information about this command, visit the Command Reference article BimAttachSpatialLocation (6.7.9). (2.592 on the next page)

2.7.17 Physical Materials

Command: BLMaterials (6.7.58) **Overview:** In this lesson, you will learn how to make and edit materials.

Lesson Objectives

The **Physical Materials** dialog box allows you to:

- Create new materials
- Edit materials
- Copy materials between the Project and Library databases
- Create single-ply compositions
- Delete materials

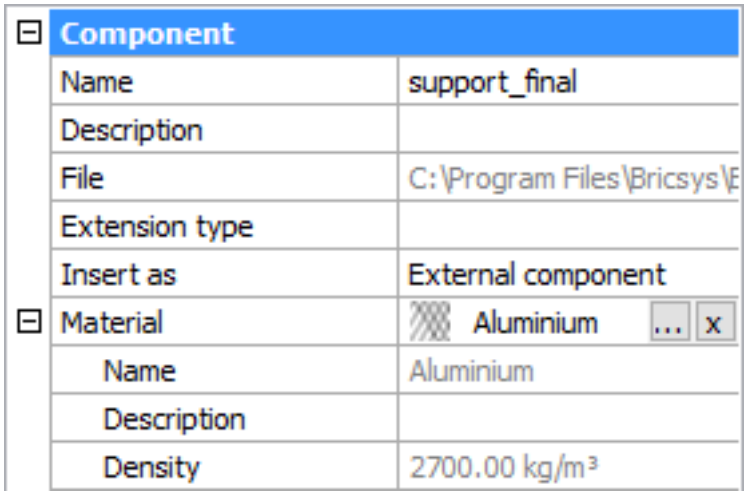
Tutorial: How to add and create Compositions Click here (2.6.1) to watch.

Opening the Physical Materials editor

Do one of the following:

- Launch the BLMATERIALS (6.7.58) command.
- Click the **Browse** button (...) of the **Material** property of a component in the Mechanical Browser (3.3.2). (2.594)

Figure 2.594



Creating physical materials

You can create physical materials in either the Project or the Library database. You can create new materials from scratch or copy them from an existing material.

Creating a physical material from scratch Select a material in either the **In Project** or the **In Library** material list. Do one of the following:

1. Click the **New Material** button () on the **Physical Materials** dialog.
2. Right-click and choose **New Material** in the context menu.

A material named **New** is added to the selected database. Now you can edit the new material.

Adding a physical material as a copy of an existing material Select a material in either the **In Project** or the **In Library** material list. Do the following:

1. Right-click on the material you want to copy and choose **Duplicate** in the context menu.
2. A material named **<existing_material>-2** is added in selected database.
3. Adjust the copy of the material.

Editing a physical material

The various settings of a physical material definition are divided into three groups under three tabs on the Physical Materials (2.7.17) dialog:

- **Identity:** name, Class and Description of the material.
- **Appearance:** the BIM Materials layers the composition is composed of.
- **Properties:** properties of building material such as **Cost, Manufacturer, Thickness**...

Select the material you want to edit in either the **In Project** or in the **In Library** list on the **Physical Materials** dialog.

Identity tab page (2.595 on the facing page)

1. Type a **name** for the material.
2. Select a **Class** from the drop-down list*.
3. **(Optional)** Type a description.

* Click the Browse button () to open the **Material Classes** dialog where you can create new material classes. (2.596 on page 2166)

Appearance tab page (2.597 on the following page)

Section settings The Section settings define the hatching of the section boundary lines.

1. Click the **Hatch Type** button and select the type of the hatch: **None, Solid, Linear, Predefined** or **Custom.**
2. Do one of the following to select a predefined or custom hatch pattern:
   - Click the **Hatch** preview and select the pattern in the **Hatch Pattern** dialog box.
   - Click the **Hatch Pattern Name** button and select the pattern in the list.
3. Define the **Scale.** The final pattern scale in a section is the product of the **Scale** setting of the physical material and the value of the **Scale** property of the BIM section. As a result, the printed scale of the hatch pattern is independent of the section plane scale.
4. Set the **Rotation** angle.
5. In the **Layer** field, either type a name or click the arrow button and select a layer in the list.
6. Optionally, check the **Annotative** option.

Elevation settings The Elevation settings define the surface hatching of the section background. See Section settings above, except for the **Scale** setting. The elevation hatch is independent of the **Scale** property of the BIM section.

3D settings The 3D settings define the rendering material. Double-click the preview image and select a material in the **Select Render Material** dialog box.

Properties tab page (2.598 on the next page)

1. Edit the **Tags** field: tags are separated by commas. Tags are case sensitive. Click the **Browse** button () to open the **Tags** dialog. (2.599 on page 2171)
2. Click the **New Item** button () to add a new tag at the bottom of the list.
3. Select a tag in the list and click a tool button:

-  : edit the selected tag
-  : delete the tag
-  : move the tag up
-  : move the tag down

4. **(Optional)** Expand the **Information** properties and fill out the necessary fields.
5. **(Optional)** Expand the **Physical** properties and specify the physical properties of the material.
6. Expand the **BIM** properties.
   - **Union Section:** select **Yes** to remove connection lines in sections between different solids of this material. Select **No** to keep the connection lines.
   - **Union Elevation**: select **Yes** to remove connection lines in elevations between different solids of this material. Select **No** to keep the connection lines.
   - Select a **Function** from the drop-down list.
   - **Variable Thickness**: select **Yes** to allow a variable thickness. Select **No** to not allow a variable thickness.
   - Type a default thickness in the **Thickness** field.
7. Click **OK**.

1. On the **Physical Materials** dialog box, select the material(s) in the **Project** or **Library** database.
2. Click **Delete**.

Note: you cannot delete materials that are used in a composition or a mechanical component.

2.7.18 Structure Browser

Command: StructurePanel (6.27.54) **Overview:** In this lesson, you learn how to organize your entities in the structure tree, then view them on the Structure Browser. **Lesson Objectives** After completing this lesson, you will be able to:

- Configure the structure tree.
- Query in the Structure Browser.
- Create a new configuration file.
- Filter, group and sort entities in the Structure Browser.

Tutorial: How to use Structure Browser Click here (2.6.8) to watch

About

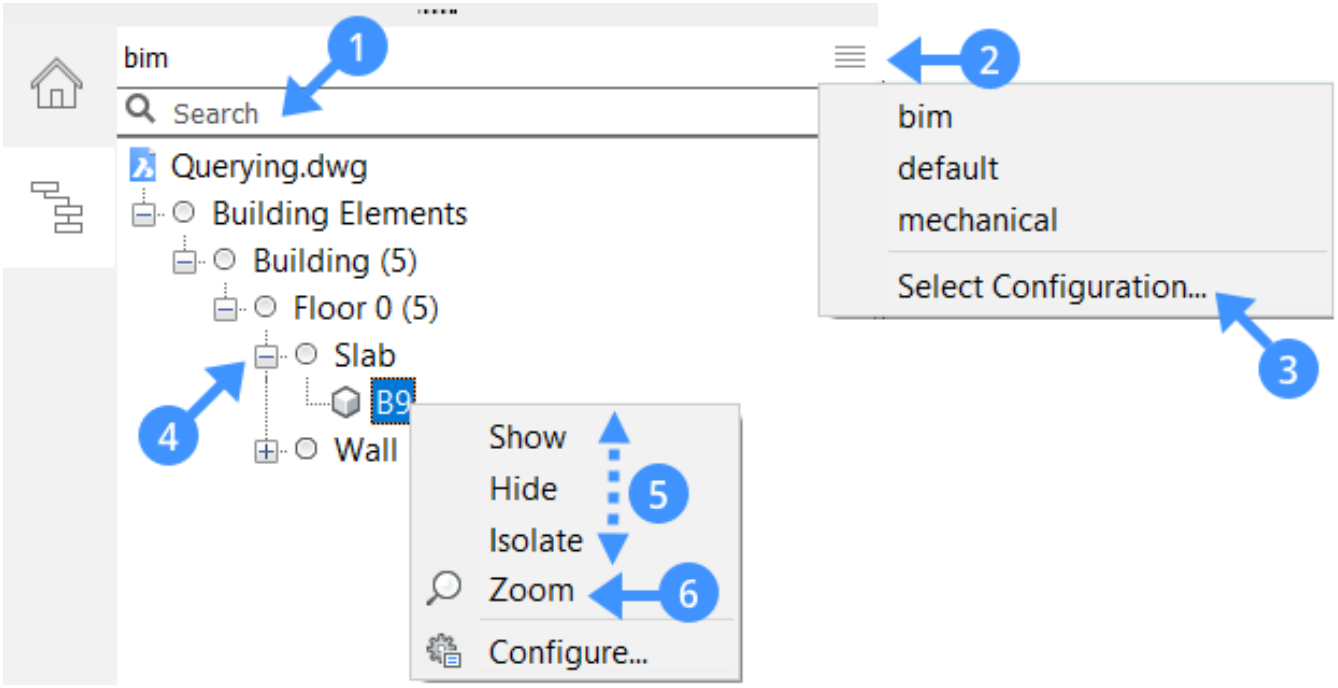
The structure browser is an interactive tree that displays the entities in the current model. Using the configurable structure tree on the Structure Browser the BIM model can be organized in a way that you want to view the elements. Once you configured the tree, you can easily save this structured tree as a .cst file. By default, the .cst files are stored in the **Support Folder**.  Place the cursor over a toolbar or ribbon panel, then right-click and choose **Structure** in the context menu. Or type **structurepanel** in the command bar, then press Enter.

Procedure: Using the structure browser

1. Open the structure browser. By default, the structure browser displays on the left-hand side on your screen. With a search field at the top of the panel (1).
2. Click the horizontal stripes button (2) to load a configuration file in the list. Click 'Select Configuration...' to select a .cst file, which specifies a configuration (3). The current configuration displays on the left. Based on the selected file the BIM model will be organized in a tree-structure.
3. Click the expand/ collapse icon (4) of a node to expand or collapse the node. Right-click on a group name to select 'Expand All' or 'Collapse All' and expand or collapse all the subnodes at once. You can Show, Hide or Isolate the entities, selected in the structure browser, in your model space, by right-clicking on the selected names (5). This context menu also provides you to zoom (6) into a specific entity in the model. The following illustration shows the Structure Browser.

(2.602 on the next page)

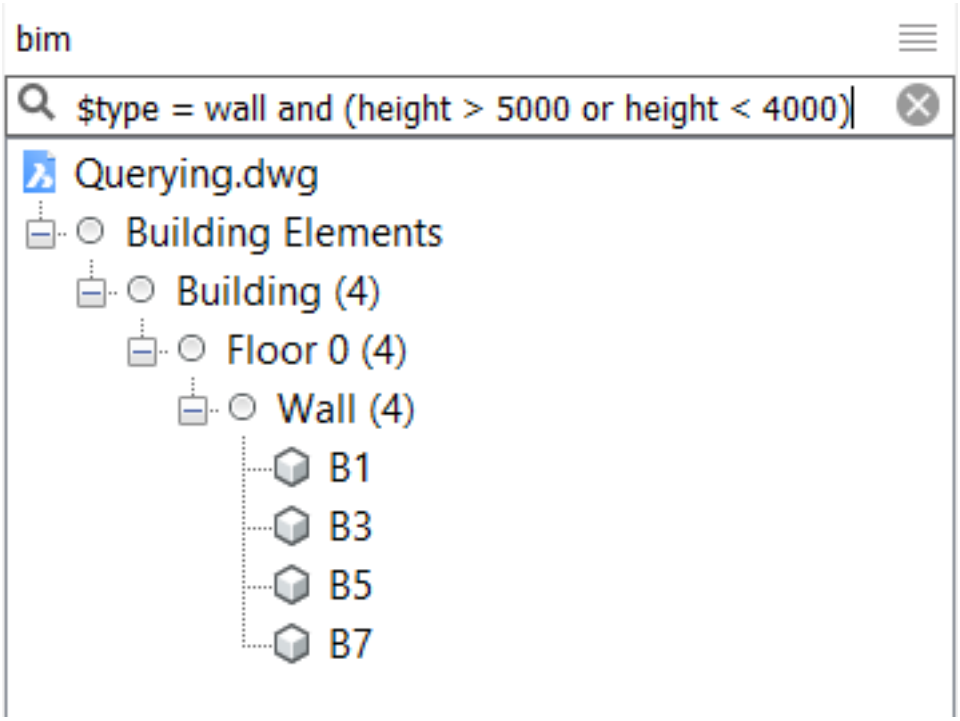
Figure 2.602



Procedure: Querying in the structure browser

1. Typing something in the Search field at the top of the structure browser will issue a simple Text search: e.g. if you type 'wall' in the search field and press **Enter**, the structure browser will be filtered to everything with 'wall' in its name, including walls and curtain walls.
2. Text searches can be useful for a quick search, but more powerful queries are possible using expressions.
3. An expression starts with the **$** E.g. if you enter **$type = wall** and press **Enter,** the browser will be filtered on entities that have the BIM type = wall. Thus, using this expression, the curtain wall doesn't show up in the browser anymore.
4. Expressions can be more complex, such as filtering on multiple properties. E.g., you can enter **$type = wall and height > 5000** to filter on all walls with a height over 5000 mm.
5. Logical expressions can be nested using brackets: **$type = wall and (height > 5000 or height < 4000).** **(2.603 on the following page)**

Figure 2.603



Procedure: Managing the tree-structure

The tree structure of the Structure browser represents the hierarchical set of rules in a graphical form. Each rule has a filter property, a grouping property, and a sorting property. Organizing the properties in the Structure Browser enhances the performance of your project while querying the entities among others. When you have a tree for your BIM model you can establish a hierarchy across its building element types, buildings, stories, etc. You can use the hierarchy to manage the properties at various levels of the data display. Do the following to configure the tree-structure:

1. Right-click on the name of your drawing in the Structure Browser, then choose Configure in the context menu. The **Configure Structure Tree** (7) dialog box displays.

2. Select any existing rule in the structure tree, then click the **Add icon** (8) or right-click and choose Add Rule in the displayed context menu. This menu can also be used to delete and rename the existing rule. The new rule is added below the previously selected rule. Type a new name for the newly created rule by clicking its name field (9).

3. Select the **Group** (10) node of the rule, then use the Add icon or right-click and choose **Add Grouping Property** (11) in the context menu. The **Select Property** dialog box displays. Select a property on the list that you want to use to group the properties in your Rule setting. Then, click the OK button. The new property is added to the Group node. If you use the Filter node to add a property, the selected property will be added in this node.

4. To move an item in the tree, select the item, then click the **Move Up** (12) or **Move Down** (13)

5. Select the **Show/Skip** (14) tab to sort the entity types or exclude them on the Structure Browser.

6. Select the **Options** (15) tab to set the entities action in the model using the structure tree. You can here specify whether or not selecting an entity in the Structure Browser also selects the entity in the model space.

7. Do one of the following to save the configured tree:

   - Click the **OK** (16) button.
   - Click the **File** (17) menu in the dialog box and choose one of the available options on the list (18).

   The following illustration shows the Configure structure tree dialog box. (2.604 on the next page)

Open (19)	Opens a file dialog to select another .cst configuration file.
Save (20)	Saves the current configuration and keep the file dialog open.
Save as (21)	Saves the current configuration under a different name and keep the file dialog open.

Procedure: Managing the tree-structure with custom properties

In BricsCAD, the user-defined/custom properties are available to add in the Select Property dialog using the GUI. The select property dialog provides a list of dynamic properties for the drawing based on the current workspace (1.17.11). Note that custom properties (2.7.11), through the select property dialog box, can be used to group the tree structure. Do the following to group the tree-structure using the existing custom properties:

1. Right-click on the name of your drawing in the Structure Browser, then choose Configure (25) in the context menu. (2.606) The **Configure Structure Tree dialog** box displays.

2. Select the **Group** node of the rule, and click the **Add rule or property** ( )icon. **Or** right-click on the Group node and choose **Add Grouping Property** in the context menu. The Select Property dialog box displays (see below image for the select property dialog). If you have custom properties, these properties will be shown under **Extensions** (26) and grouped by its namespace.

3. Click the expand/collapse icon of a node to expand and collapse the node. The following image shows the IFC 2X3 (27) and User (28) namespaces in the Select Property dialog. For example, the User namespace is expanded to display the property set (29) and properties (30) that are in this node. (2.607 on the following page)

5. Select the property to use for grouping in the tree structure, and press OK. The property is added (31) to the group node.

6. Press OK (32) to use the property for grouping entities in the Structure Browser. (2.608 on page 2181)

2.8 Design Assistance

2.8.1 Advanced Modeling with Propagate

In this video series we will create a detailed model of a pitched roof structure, making extensive use of the Propagate tool and other direct modelling tools. Youtube We start off with the rough shape of our building; materials have already been applied to the different building elements. We'll turn on 'Display Composition' to be able to 'push-pull' the different composition plies. Using 'Connect with nearest' we can easily connect these plies to each other. We will create a detail locally, and then later Propagate this detail over the entire perimeter of our roof. This detail includes a gutter, some coverings, a concrete ring beam and a wooden beam. We will use 'Propagate Planar' to copy this detail. However, to make sure Propagate knows which detail to copy exactly, we will need to activate a section that cuts through all involved detail objects. For this reason, we will move this section plane slightly further into the model, to make sure it includes everything we need. We are prompted to the select the base solids. These are the solids that define the situation where this particular detail should be applied. In this case it's the floor slab, the roof slab and the wall. After pressing 'Enter' we are prompted to the select the detail objects. These are the objects that we wish to propagate or copy throughout the model, in this case the wooden beam, the concrete ring beam, the two covering elements and the gutter. After pressing Enter, a 2D detail is constructed. It is an extrusion of this detail that will be applied over the perimeter of the roof. Let's press Enter. 'Propagate' has now scanned the entire drawing for locations where this detail can be applied. A green check mark means that this detail will be applied when pressing Enter. The blue question mark means that the detail will not be applied, in this case because the original detail was only modelled locally; we will click it so it is replaced by an adapted extrusion, to make sure the detail is applied over the entire length of the wall. After pressing Enter, this detail is applied over the entire perimeter of our roof. Youtube Let's create a new section to design the connection of the roof with the end walls; we want the facing brick to protrude further into the roof structure. We will use 'Propagate Planar' to copy this detail to the other connections. The base solids are the roof slab and the wall. There are no detail objects in this case. We'll press Enter to accept the constructed 2D detail, and press Enter again to accept the three suggestions. We see now that the four corners of the roof are not what they are supposed to be; We can solve this detail once, and again use 'Propagate' to copy it to the other corners as well. We'll temporarily hide the gutter and these covering elements. We'll make smart use of 'push-pull' and other direct modelling tools to design this corner correctly. We've made sure that the insulation layers of both walls and the roof are now connected properly. We'll finish this corner by creating ends for the gutter and the covering elements. Now that we designed this corner correctly, we want to copy this situation to the other three corners. We will use the 'Propagate' command for this again. The base solids are the two walls, the roof slab, the gutter and the covering elements. These solids define the locations where this detail can be applied. The detail solids are the end caps of the gutter and the covering elements. These objects will be copied to the other locations. We will propagate this detail as a copy by entering 'C' in the command line or by clicking 'As Copy' in the context menu. The three other corners are suggested to copy this detail to. We'll accept by pressing Enter. Youtube Let's create a new layer and move the four roof slabs to this layer, so we can easily toggle their visibility. Note that we can change their layer using the rollover tips. We'll create the rafters by extruding this boundary and slicing the resulting solid. For this next step, we will temporarily turn off the subtract behaviour of 'push-pull' by going to the settings and typing in 'pushpull'. If we now push-pull this rafter so that it goes through the insulation layer of the wall, we see that this volume is not subtracted from the wall. This is an interference that we will solve later. Now that we've specified where the rafter ends, we want to copy this to the other side as well. We'll do this with 'Propagate Linear'. The base solids are the wall and the rafter. We want to specify where the rafter ends, so we will use its end face as detail object. By pressing Enter we see that the rafter on the other side of the roof now also has the correct geometry. We will copy these two rafters to the other end of the roof, again by using 'Propagate Linear'. You could view these two rafters as elements connecting the two concrete ring beams. Thus, our base solids are the ring beams, and our detail objects are the two rafters themselves. We'll choose to copy this detail as a copy, and accept the highlighted suggestion. Note that a small exclamation mark appears to indicate that an interference will be introduced when applying this suggestion. Next, we'll copy these rafters and repeat this copy, so that the entire length of the building is covered. Finally we will slice the rafters to make an L-shaped roof. Youtube Let's create some more wooden trusses. We'll use the 'Linear Solid' tool and select the profile in the model by clicking one of the rafters. Using the Manipulator we can easily shift this member so that it connects properly to the rafter and the beam. Remember: you can call the Manipulator by holding down the left-mouse button slightly longer when selecting an entity. We want this collar tie to be cut off diagonally, like we did on the other side. Instead of using 'slice' we can again use 'Propagate Linear'. The base solids are the collar tie and the rafter; there are no detail objects in this case. We will also use 'Propagate Linear' to copy these wooden members to the rest of our building. You could view these members as a connection between the beam resting on the ceiling slab, and the rafter. Thus, our base solids are this beam and the rafter, whereas the detail objects are the members we just modelled. 'Propagate' provides a suggestion for every location where a rafter meets this horizontal beam. Notice again the exclamation marks, indicating the interferences between the objects that will be copied, and the already existing entities. We'll press Enter to accept this. The same technique can be used to copy this member connecting the two rafters. We will now create a ridge beam and again propagate this beam so it is placed between every two pairs of rafters. Finally we will clean up the interferences. We want our rafters and wooden members to go through the insulation layer of the wall, so we will subtract these volumes from the wall. Now we'll use 'Propagate' again to copy the connection of these elements. Our base solids are the wall, the

2.8.2 How to automate classification with "BIMIFY" in BricsCAD BIM

https://www.youtube-nocookie.com/embed/k3f1m-FWD_0 This video shows how BIMIFY can turn your conceptual model into a BIM model. Automatically detect IFC classifications, spatial locations, rooms and more. Back to Tutorial Overview

2.8.3 How to use Propagate Linear

https://www.youtube-nocookie.com/embed/ICDBTDb0xH8 This video shows how Propagate Linear can be used to quickly and easily copy detailed connections of steel members to other applicable locations in the model. Back to Tutorial Overview

2.8.4 How to use Propagate Pattern

https://www.youtube-nocookie.com/embed/rY_B4-JeTiU We can use Propagate to copy objects over a certain pattern. In this example we'll create a pattern of skylights in this roof. We'll launch Propagate Pattern. First, we'll select the base solid, which is the roof in this case. Next we'll select the detail. We want to create a pattern of skylights, so we'll select this skylight as our detail object. Hovering over the suggestion icon, we can see there are two options. The first option is to propagate to similar locations. In this case this will be the four corners of the slab. The second option is to create a grid on top of this slab, by adding rows and columns. We can explode this suggestion so we can individually toggle the different suggestions. In this case we'll use this to create a seemingly random pattern. Finally we'll press Enter to accept. If a Grid is drawn on top of the base solid, then this grid will be detected and a third option will automatically be presented: create a pattern according to this grid. Again, the two options that were available in the previous example are also available here. Now a third option is available: propagate along this Grid. We can again explode to have control over the individual suggestions. Back to Tutorial Overview

2.8.5 How to use Propagate Planar

https://www.youtube-nocookie.com/embed/Lmqh0-jreNI This tutorial shows how Propagate Planar can be used to easily copy a detailed wall-slab connection to other applicable locations in the model. Back to Tutorial Overview

2.8.6 How to use Propagate Edges

https://www.youtube-nocookie.com/embed/kAZnvUNxrgI This video shows how Propagate Edges can be used to easily copy the design of a wall cap to all wall edges of the model. Back to Tutorial Overview

2.8.7 How to use Propagate Corner

https://www.youtube-nocookie.com/embed/k_1k-7Tjwro This video shows how Propagate Corner can be used to fix modelling issues that were created in an earlier stage of the modelling process. Back to Tutorial Overview

2.9 Design Assistance

2.9.1 Using Bimify

Command: Bimify (6.7.23) **Overview:** In this lesson, you will learn how to use Bimify to automatically classify elements. **Lesson Objectives** After completing this lesson, you will be able to automatically:

- Classify 3D solids or block references
- Attach BIM Profiles to linear solids
- Assign spatial locations to building elements
- Create BIM Spaces
- Detect internal or external walls
- Add elevation views (front, left, right and back) and 1 plan section per floor

Tutorial: How to automate classification with "Bimify" in BricsCAD BIM Click here (2.8.2) to watch

About Bimify

Bimify analyzes a model and will automatically classify spatial locations, spaces, buildings, and stories. It also detects and classifies the external and internal walls. Bimify can automatically detect whether a model is an Architectural, Structural or MEP model. BricsCAD uses this information during the autoclassification process. Define this information before you launch Bimify, to improve the accuracy of the automatic classification. The solids are auto-classified as columns, beams or members. If their profiles match a definition in the profile library, the profile name will be automatically added to the entity's properties as meta-data. If no matching profile definition is found, a new one is created in the library. Bimify can be used in a model that has both classified and unclassified entities. The classified entities are also linked to the appropriate spatial locations.  For more information about this command, visit the Command Reference article Bimify (6.7.23).

Procedure: Bimify your entire drawing

Choose Bimify (6.7.23) from the Quad **or** type Bimify in the command line and choose **Entire model**. When the Bimify process is completed, an overview of the result (1) is provided in the Prompt History panel. (2.609 on the facing page) Bimify creates new spatial locations if necessary. (2.610 on the next page) (2.611 on the facing page) (2.612 on page 2192) **Left to right: Before Bimify: The structure tree displayed only 3D solids (2). After Bimify: the entities are sorted into their corresponding building, story (3) and building element type (4). Note:** The structure browser can be customized to control the content of the tree. (2.613 on page 2192) **The profile data of a beam in the properties panel (5). Bimify recognized the profile of these model elements as structural members and detected the axis location of the profile.** The elevation views and floor plan sections are created last. (2.614 on page 2193) **This building contains front (6), Left (7), Right (8) and Back (9) views as well as a floor plan (10).** For this simple building, one room and 4 external walls have been detected. (2.615 on page 2193) **The BIM room (11) and "Is External" (12) property under the Wall Common properties.** If you choose to use the 'Advanced' option of Bimify, a dialog box will appear: (6.365 on page 3680)

Discipline	(2.621 on page 2200) Defines the discipline of the drawing manually. This information helps improve the accuracy of Bimify.
Classification	Classifies 3D solids and Block References automatically.
Structural/MEP profiles	Assigns columns, beams, members or flow segments profiles if available in the BricsCAD profile library. This option is available when **Classification** is selected only.
Spatial Information	Assigns spatial locations such as buildings and floors, detects spaces and identifies internal and external walls. This option is available when **Classification** is selected only.
Sections	Creates an elevation view and a plan section per floor. This option is available when **Spatial Information** is selected only.

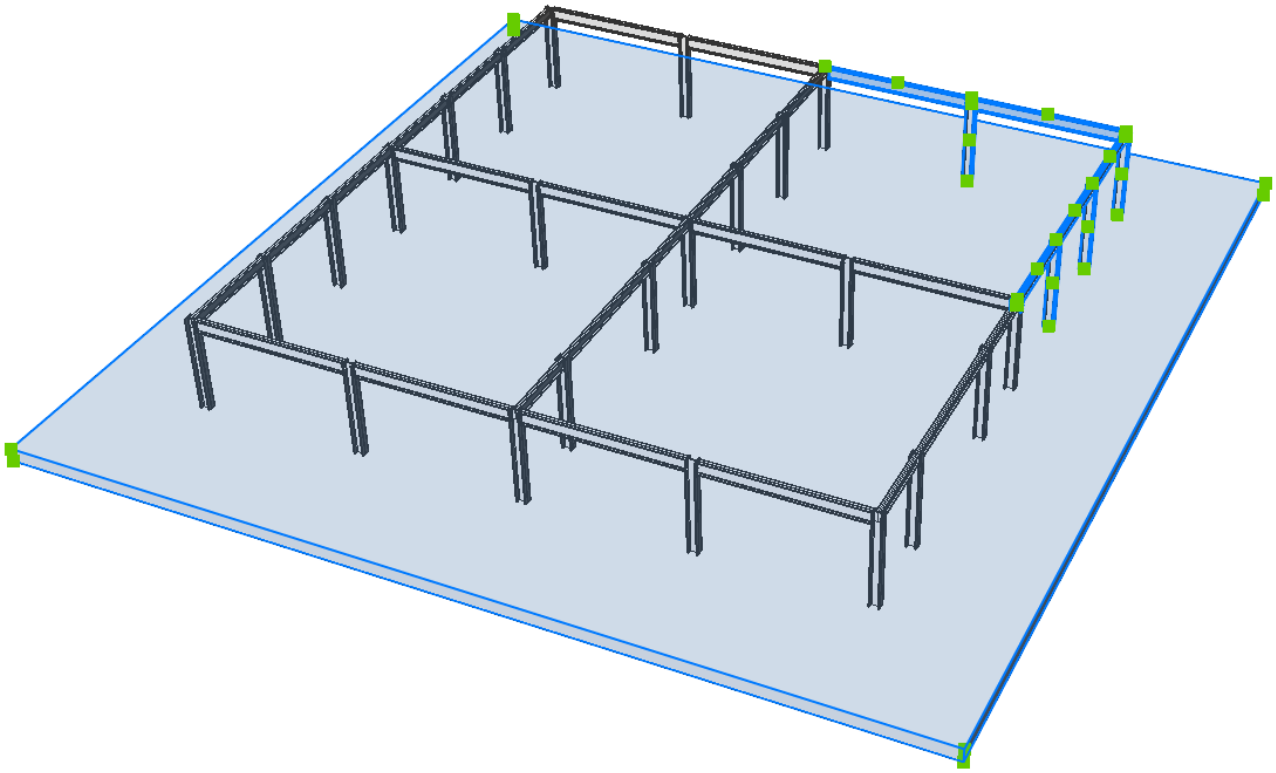
Note: To disable the autoclassification option for solids or blocks simply uncheck the related checkbox. By default, all checkboxes are ticked. However, BricsCAD remembers your previous settings. Ticking the Spatial Information checkbox automatically includes the Classification option. This information is needed to detect the other elements.

Procedure: Bimify a selection of your BIM Model

1. Select the part of your drawing you want to Bimify. (2.617 on the next page)
2. Type **Bimify** in the command line and type in **A** for Advanced. A dialog box displays: (2.618 on page 2198)

Figure 2.617



Note If you only select a part of your model, only solids, blocks and profiles can be classified. BricsCAD can only detect entities like stories, spaces, and sections when the whole drawing is selected.

3. When the Bimify process is completed, an overview of the result is provided in the Prompt History panel. (2.619 on page 2199) **Bimify classified the selected part of the model. No sections for floor plans or elevations are created.** (2.620 on page 2200) **This is the result if Bimify was launched on the whole drawing and all the boxes in the Dialog Box were checked. The entire model is classified additionally there are sections for the floor plan and the 4 elevations of the model.**

2.9.2 Using Propagate

Command: BimPropagate (6.7.30)

About

BIMPropagate can be used to copy details throughout your model. It maps details related to selected reference solids to similar solids in the model. Anytime a certain detail is needed in multiple locations in the model (e.g. a connection between steel members, a wall-slab connection, a roof edge detail, …) chances are the quickest way to solve it is by using BIMPropagate.  For more information about this command, visit the Command Reference article BimPropagate (6.7.30).

The Five Flavors

Before getting into the BIMPropagate workflow it is important to note that there are five variants of BIMPropagate, each working on a limited set of situations. These five variants (or flavors) were designed to guide new users through the process of BIMPropagate. The tool has so many different uses that it can seem overwhelming to a new user; these variants help keep the tool more clear and concise, as they are designed for more specific use cases. However, they are still distillates from original BIMPropagate command, so every problem you can solve with a particular flavor you can **also** solve using the standard BIMPropagate command. A more advanced user will even be able to solve problems that can not be solved by any of the particular flavors. The BIMPropagate variants are:

-  BimPropagatePlanar (2.9.5): Propagation of connections between planar elements such as walls, slabs and roofs.
-  BimPropagateLinear (2.9.3): Propagation of connections between linear elements such as beams, columns, pipes and ducts, and maximum one planar element.
-  BimPropagatePattern (2.9.4): Propagation of a single element or group of elements on a flat surface to multiple locations and grids; can be used to propagate light fixtures, light switches, windows, air diffusers, columns on a grid
-  BimPropagateEdges (2.9.6): Propagation along the edge of a planar solid; can be used to propagate railings, gutters, borders, wall caps, etc.
-  BimPropagateCorner (2.9.7) Propagates details connected to multiple planar reference solids coming together in one node.

The general workflow of BIMPropagate consists of two major steps: defining the detail volume, and choosing where to apply this detail.

Figure 2.622

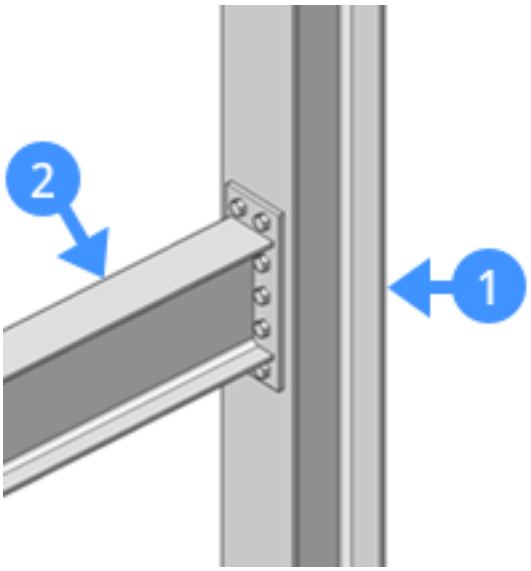

Figure 2.623

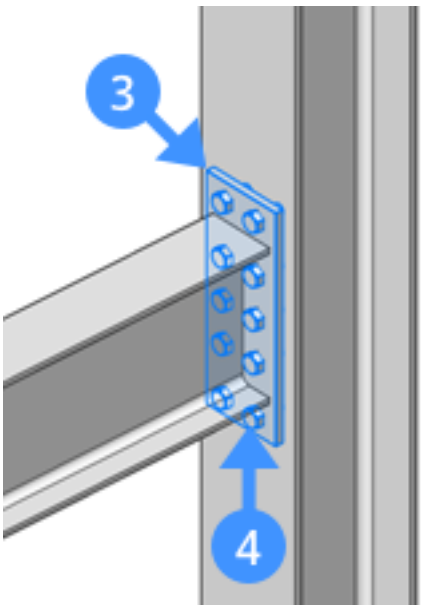

Defining the detail volume

You are prompted: Select reference solids. These will not be copied, but used to match other locations. [selection options (?)]:: **The first step** of every propagation is specifying the **reference solids**. These are the solids that define the situation where this particular detail should be applied. For instance, the image below shows a column-beam connection using an end plate and several bolts. This detail was modelled for this particular beam connecting with this particular column, and now we want to propagate this detail for every situation where a column and beam of these types come together. Thus, the reference solids in this case will be the column (1) and the beam (2). Later in the process, PROPAGATE scans the model for situations where similar solids occur, and tries to map the detail onto these locations **(2.622) Note**: this is an example of a situation that can be solved by BimPropagateLinear (6.7.33). Press **Enter** to stop selecting reference solids. **The second step** is specifying the detail objects or sub entities. These are the objects that you wish to propagate or copy throughout the model. They can be solids, block references or even faces (e.g. a hole in the reference solid can be propagated by selecting its faces). **You are prompted:** Optional. Select detail objects (solids, block references, faces, edges,...) to be copied. [selection options (?)]: In the example at hand the detail objects will be the end plate (3) and the bolts (4). (2.623) **Note** that in some cases detail objects are not even required. Let's say we want to propagate the connection between the floor slab and the wall shown in the image below. Our reference solids are then the floor slab (5) and the wall (6), and no detail objects are required. In this case you can skip this step by pressing Enter or right click. (2.624 on the next page) If we were to model extra solids in this connection (e.g. an insulation block or a skirting board), these extra solids would then be detail objects. **Note**: this is an example of a situation that can be solved by BimPropagatePlanar (6.7.36). Once the **reference solids** and the **detail objects** are specified, a detail volume is defined automatically. The visual style (6.31.15) is temporarily set to X-ray, and the view is automatically zoomed in onto the detail volume. Everything that is inside this volume and is either a detail object or part of a reference solid will be copied to the other locations when executing propagate. A detail volume can be either a **3D volume**

Figure 2.624

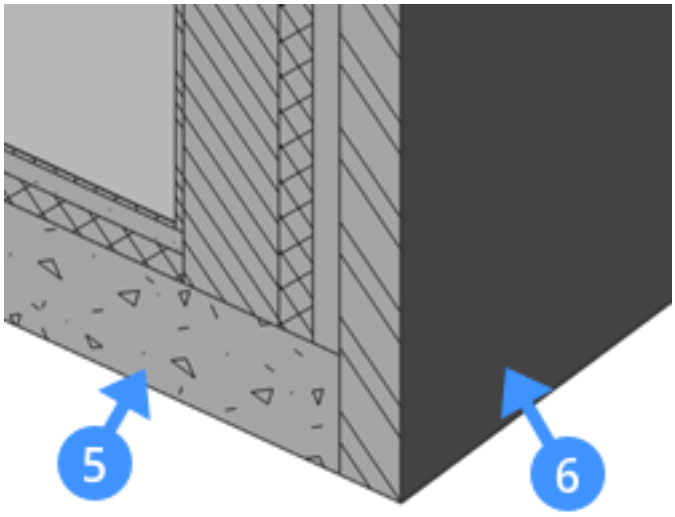

Figure 2.625

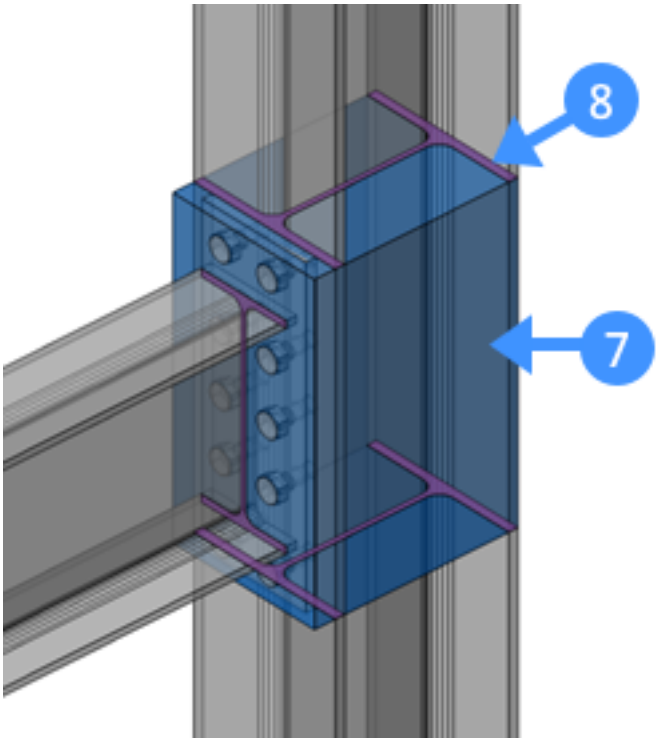

Figure 2.626

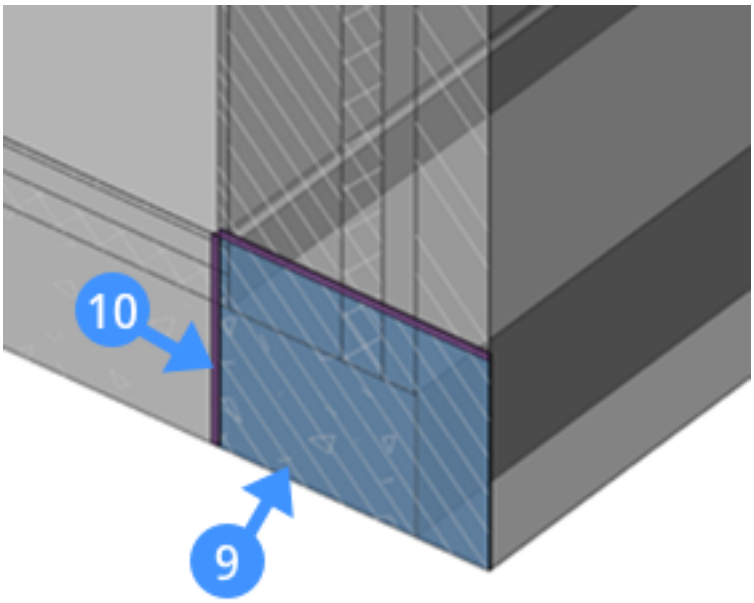

Figure 2.627

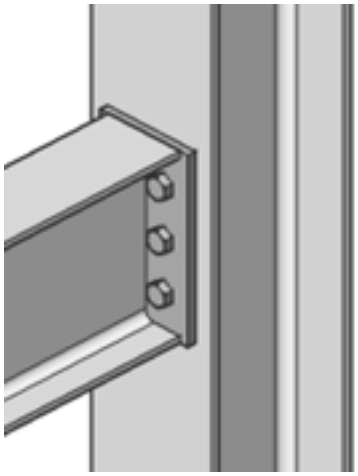

- If you want to replace an already existing detail with a new detail that is **smaller** than the original one. For example, we want to replace the previously proposed column-beam connection by the following: (2.627) In this case, we will have to inflate the detail volume (11) so that it is larger than the original detail: (2.628 on the next page)
- You might want to include a larger part of the reference solid, for example to connect with target solids that are further apart. In the image below, we want to propagate the connection between the **red** and the **yellow** beam, so that the **yellow** and the **green** beam have a similar connection. (2.629 on the facing page) To achieve this, we need to inflate the detail volume so that it overlaps the end faces of the red and the yellow beam. (2.630 on page 2206)

Once the detail volume includes everything you want to propagate, you can go over to the second step: choosing where to apply the detail. For 3D detail volumes there is one last choice to make: Propagate the detail as a Block or as a Copy. If you choose to propagate the detail as a block, then it will group all detail objects into a new Block Definition and copy around references to this Block Definition.

Figure 2.628

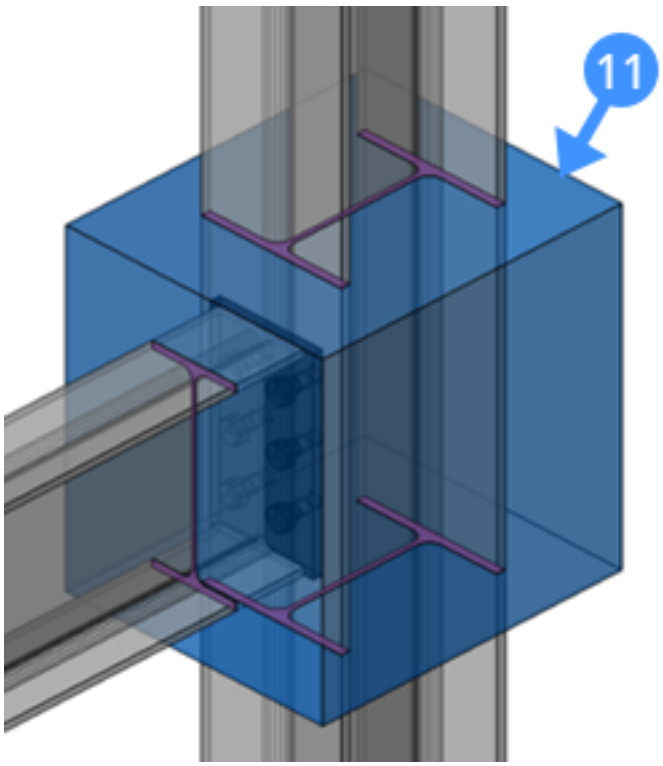

Figure 2.629

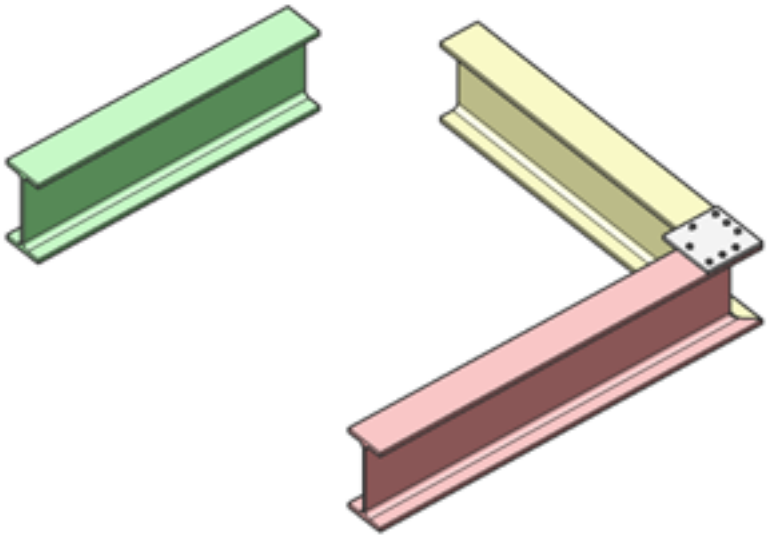

Figure 2.630

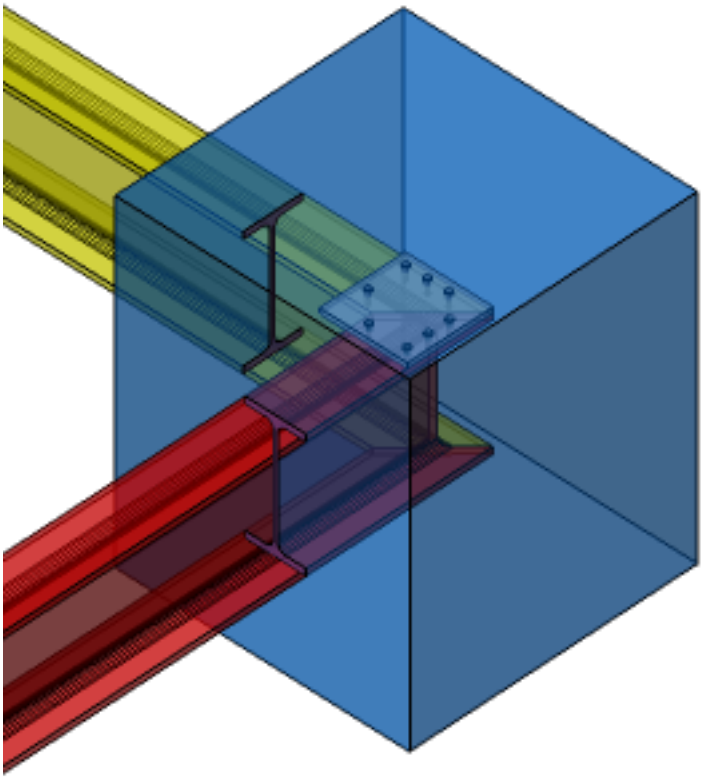

Choosing where to apply the detail

You are prompted: Accept or reject suggestions by clicking on the tick. Then [Apply/Cancel] <Apply>: In this step the view zooms out showing all the possible suggestions on screen. Each suggestion is a location where this detail could be applied, and is indicated by one of the following icons (or widgets):

	The detail will be applied
	The detail will not be applied; it was manually toggled off by the user
	The detail will not be applied, because of one of several possible reasons. Hovering over the icon will provide more information
	The detail will be applied, but interferences were detected
	The detail will be applied, but there are several alternatives. Hovering over the icon will allow you to cycle between alternatives

Hovering over a widget reveals some more information. Clicking a widget changes its status: you can toggle suggestions individually by clicking their respective widgets. Pressing Enter will then apply all the widgets as they are shown at that point: suggestions with a green checkmark will be applied, others will not be applied. (2.631 on the facing page)

A suggestion also shows a preview of what the detail will look like. In the images below, you can both see the widgets (12) and the previews (13). (2.632 on page 2208) Widgets can also be **selected** using a window selection.

2.9.3 Propagate Linear

Command: BimPropagateLinear (6.7.33)

Tutorial: How to use Propagate Linear Click here (2.8.3) to watch

About

BimPropagateLinear is one of the five Propagate flavors. It can be used to copy detailed connections between two or more linear solids. Common examples are column-beam connections or column-slab connections. For a more in-depth explanation of the general principles of Propagate, read this article on Propagate (2.9.2).  For more information about this command, visit the Command Reference article BimPropagateLinear (6.7.33).

Procedure: Propagating a column-beam connection

1. Consider the following situation of four columns and two beams. Two of the connections have been designed with an and plate and bolts trough the column flanges (1). One connection has been designed with a diagonal member for additional rotational stiffness (2). The last connection has not been designed yet (3). (2.635 on the facing page) (2.636 on the next page)
2. We can now use Propagate Linear to copy one of the details to the other locations. In this example we will copy connection 2 to all four locations. We will launch **BimPropagateLinear**.
3. **You are prompted:** Select the linear or planar reference solids that form the connection. The connection detail will be copied to similar solids. [selection options (?)]: At least one should be linear.
   Select the column and the beam that are connected by the diagonal member, and press **Enter.**
4. **You are prompted:** Optional. Select detail objects (solids, block references, faces, edges,...) to be copied as part of the connection. [selection options (?)]: Select the diagonal member and press **Enter**. A detail volume is created that completely encompasses the diagonal member and parts of the column and beam.
5. **You are prompted:** Blue: detail area to be copied. Purple: reference contact area. Accept? [yes, copy as Block/yes, plain Copy/No/Inflate first/Save detail/save detail to Library] <yes, copy as Block>: You can choose to propagate this detail as a block to keep the file smaller and more manageable, or as a copy. Inflating the detail is not necessary in this case. For more information on inflating, read the article on Propagate (2.9.2). Choosing 'No' will exit the command. Press **Enter** to accept.
6. BimPropagateLinear now scans the entire drawing for similar locations. When this is done, the view is zoomed out to show all possible locations. Every suggestion is highlighted and a widget is displayed: **You are prompted:** Accept or reject suggestions by clicking on the tick. Then [Apply/Cancel] <Apply>: (2.637 on page 2212) A green check mark means that this suggestion will be applied when pressing Enter. A question mark means that it will not be applied due to one of several possible reasons. Hovering over the widget will reveal more information. In this case it says "**Existing details detected. Suggestion will not be applied. Click to change."** We want to replace the bolted connection by this diagonal member, so we click both the blue widgets so they turn into green check marks.
7. If we now press **Enter**, all connections should be replaced by the diagonal member.

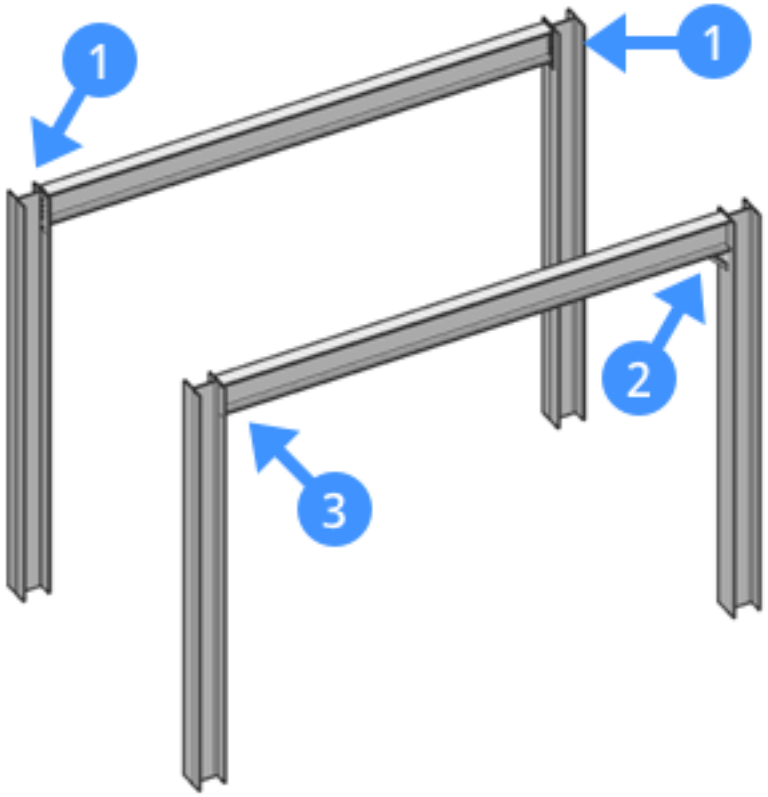

Figure 2.636

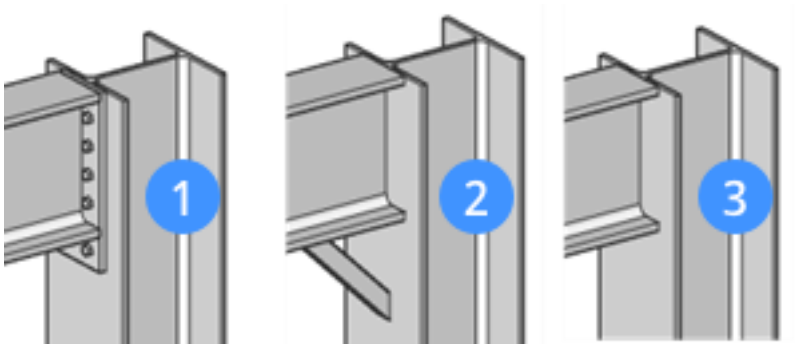

Figure 2.637

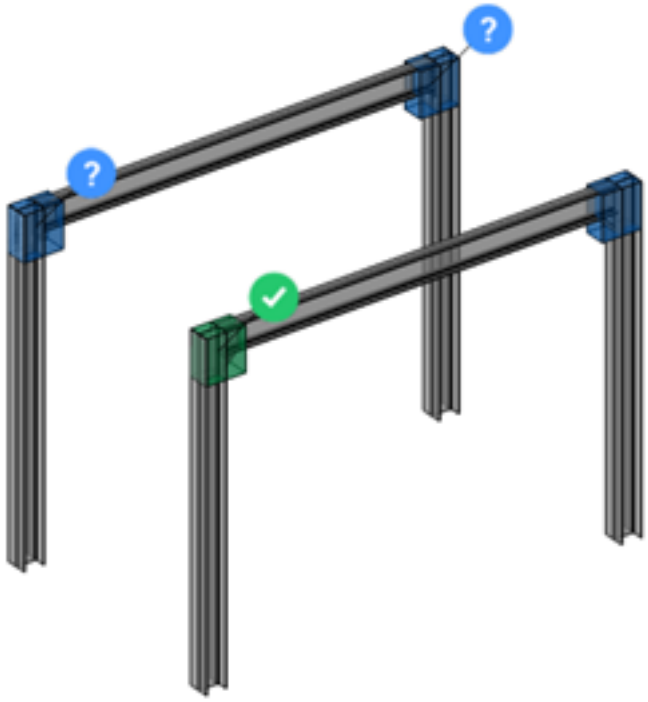

2.9.4 Propagate Pattern

Command: BimPropagatePattern (6.7.34)

Tutorial: How to use Propagate Pattern Click here (2.8.4) to watch

About

BimPropagatePattern is one of the five Propagate flavors. It can be used to copy objects to similar locations or over a certain pattern or grid on top of a planar solid. Common examples are columns on a grid or windows in a wall. For a more in-depth explanation of the general principles of Propagate, read this article on Propagate (2.9.2).  For more information about this command, visit the Command Reference article BimPropagatePattern (6.7.34).

Procedure: Propagating columns on top of a slab

1. Consider the following situation: a column (1) is placed on top of a slab (2). There is also a grid drawn on top of this slab (3). (2.638 on the next page)
2. We want to place this column on specific axis intersections. We could manually copy the column, but Propagate allows us to do this faster. Let's launch **BimPropagatePattern.**
3. **You are prompted:** Select planar reference solid to which the detail is related. The detail will be copied to similar solids. [selection options (?)]: Select the slab, and press **Enter.**
4. **You are prompted:** Select detail objects (solids, block references, faces, edges,...) to be copied. [selection options (?)]: Select the column, and press **Enter.**
5. A 3D detail volume is created. **You are prompted:** Blue: detail area to be copied. Purple: reference contact area. Accept? [yes, copy as Block/yes, plain Copy/No/Inflate first/Save detail/save detail to Library] <yes, copy as Block>: Inflating the detail is not necessary in this case. For more information on inflating, read this article on Propagate (2.9.2). Choosing 'No' will exit the command. Press **Enter** to accept.
6. A widget appears. Hovering over this widget reveals a flyout menu with several options: (2.639 on the following page)
   - **Bim Grid**: this is the grid that was drawn on top of the slab. Choosing this option and pressing Enter will copy this column to every axis intersection of this grid.
   - **Similar Location**: this will copy the column to similar locations on this slab; in this case the four corners of the slab.
   - **Grid**: this allows you to create your own grid of columns on top of this slab. You can choose to add or remove rows and columns. These rows and columns will always be evenly spaced.
7. We'll choose the Bim Grid option. Clicking this will expand the menu further; we now have the option to Explode. This will create a separate widget for each instance of this column, giving you more control over which suggestions you wish to apply (in this case which axis intersection you wish to place a column). We can now manually turn off suggestions: (2.640 on the next page) (2.641 on page 2215)

Figure 2.638

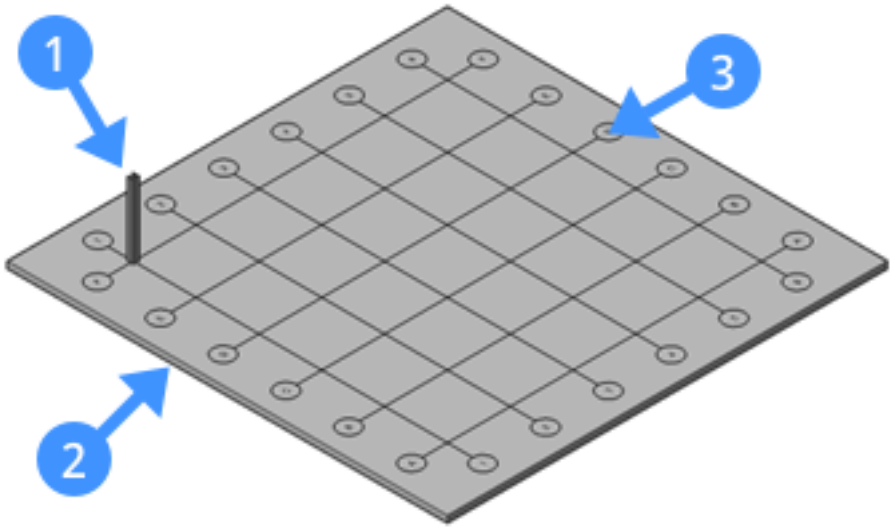

Figure 2.639

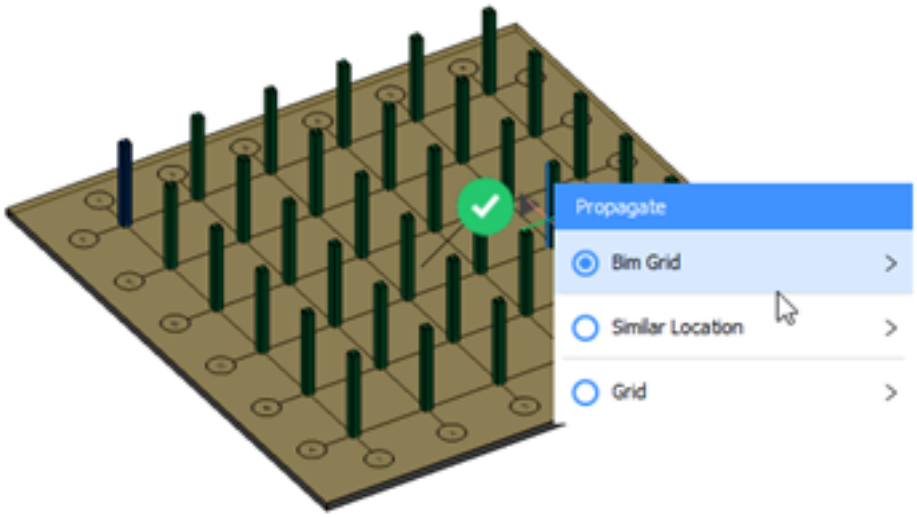

Figure 2.640

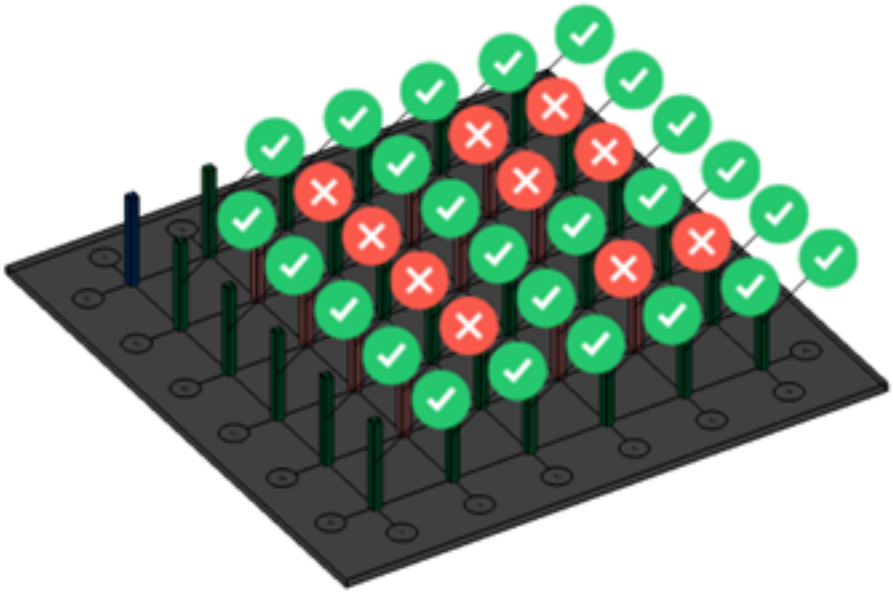

Figure 2.641

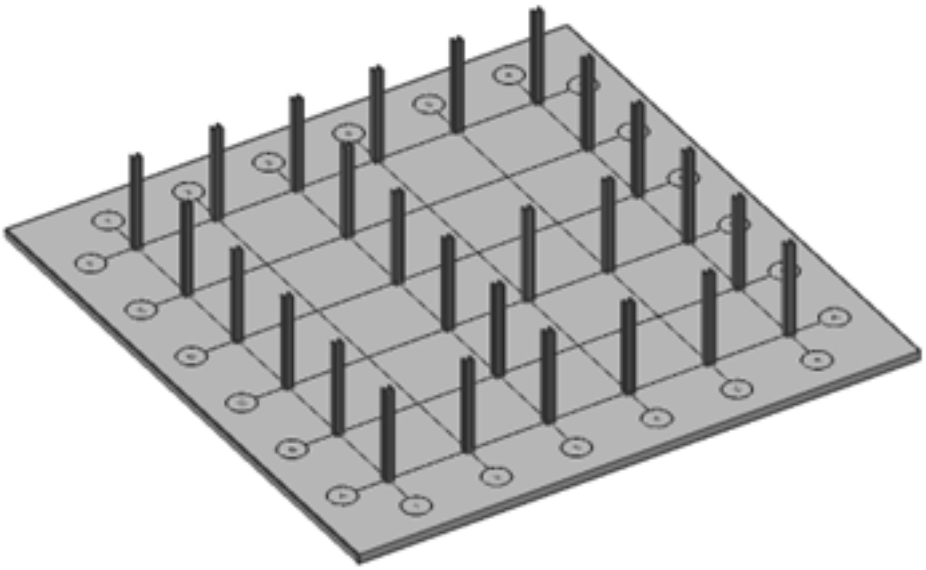

2.9.5 Propagate Planar

Command: BimPropagatePlanar (6.7.36)

Tutorial: How to use Propagate Planar Click here (2.9.5) to watch

About

BimPropagatePlanar is one of the five Propagate flavors. It can be used to copy detailed connections between two or more planar entities. Common examples are wall-slab connections or wall-wall connections.  For a more in-depth explanation of the general principles of Propagate, read this article on Propagate (2.9.2).

Procedure: Propagating a wall-slab connection

1. Consider the following situation of four walls and one slab, created with **QuickDraw.** (2.642)
2. The four walls were given a composition, as well as the floor slab. Without any further editing or modeling, creating a vertical section through the building will show the connection one of the walls (1) and the slab (2) to be something similar to the following image. (2.643 on the facing page)
3. While this section is active, we can Push/Pull the different ply faces to obtain the desired connection between the wall and the slab: (2.644 on the next page)
4. We can detail this connection even further, for example by locally adding a skirting board (3). This was done by simply drawing a box and classifying this solid as a Building Element. (2.645 on the facing page)
5. Now that we have this detailed connection, we want it to be applied to every location where a wall and slab of this type come together. Let's deactivate the section and launch **BimPropagatePlanar.**
6. **You are prompted:** Select planar reference solids that form the connection. The connection detail will be copied to similar solids. [selection options (?)]: Select the wall and slab, and press Enter.
7. **You are prompted:** Optional. Select detail objects to be copied as part of the connection. [selection options (?)]: Select the skirting board solid, and press Enter.
8. **You are prompted:** The detail section varies too much along the extrusion direction. In this particular case, BimPropagatePlanar cannot find a solution: because the skirting board is not modeled along the entire length of the wall, BimPropagatePlanar finds contradicting detail volumes. This problem can be solved easily by activating a section where the skirting board is present (e.g. the section we used earlier to create this detail) and trying again. If we now follow the same steps as before, BimPropagate finds a detail volume as shown in the image below. (2.646 on page 2218)
9. **You are prompted:** Blue: detail area to be copied. Purple: reference contact area. Accept? [Yes/No/Inflate first/Save detail/save detail to Library] <Yes>: Inflating the detail is not necessary in this case. For more information on inflating, read the article on Propagate (2.9.2). Choosing 'No' will exit the command. Press **Enter** to accept.

Figure 2.642

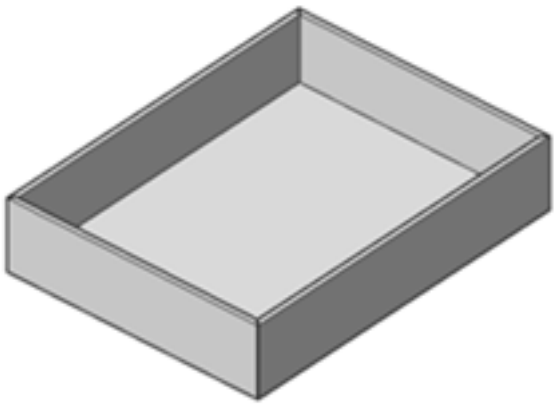

Figure 2.643

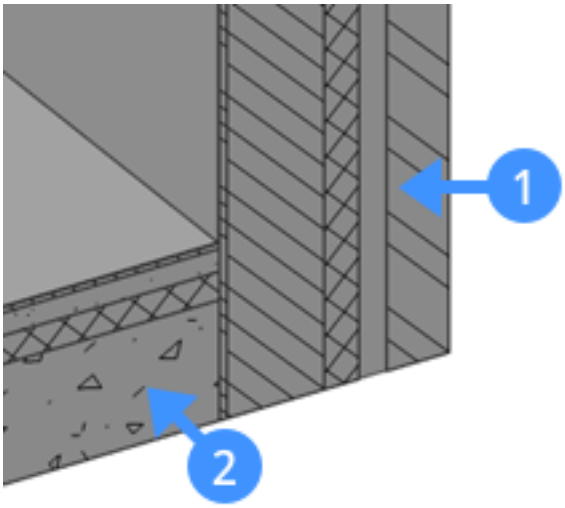

Figure 2.644

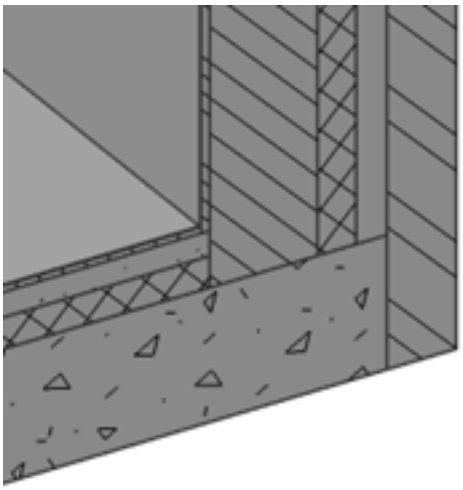

Figure 2.645

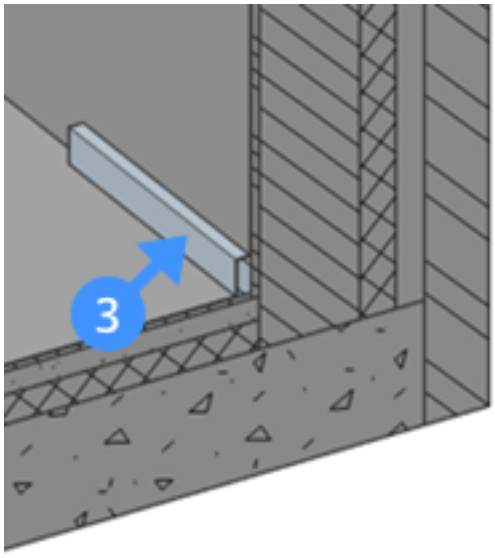

Figure 2.646

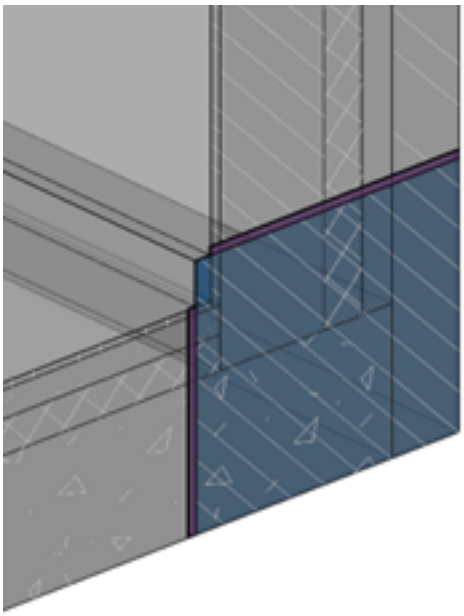

Figure 2.647

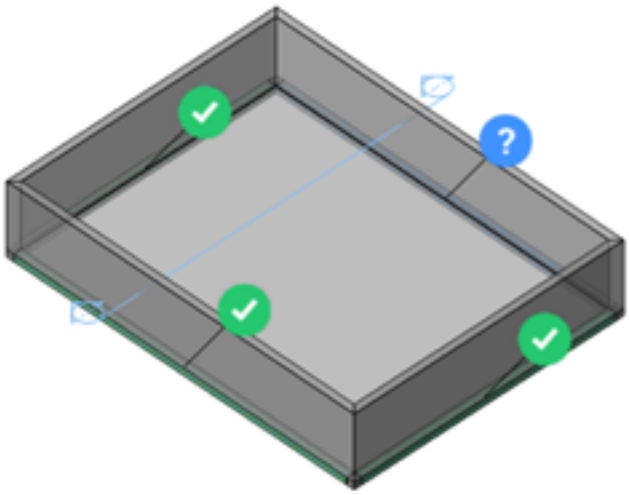

10. **BimPropagatePlanar** now scans the entire drawing for similar locations. When this is done, all sections are deactivated and the view is zoomed out to show all possible locations. Every suggestion is highlighted and a widget is displayed: **You are prompted:** Accept or reject suggestions by clicking on the tick. Then [Apply/Cancel] <Apply>: (2.647) A green checkmark means that this suggestion will be applied when pressing Enter. A question mark means that it will not be applied due to one of several possible reasons. Hovering over the widget will reveal more information. In this case, it says **"Location of original detail. Click to replace original detail by adapted extrusion".** Because we modeled the skirting board only locally, we should replace the original detail by an adapted extrusion so that it covers the entire length of the wall. Clicking the widget will turn it into a green checkmark.

11. Press **Enter** to complete the command. Now all four walls should have this particular connection with the floor slab, including the skirting board.

2.9.6 Propagate Edges

Command: BimPropagateEdges (6.7.44)

Tutorial: How to use Propagate Edges Click here (2.8.6) to watch

About

BimPropagateEdges is one of the five Propagate flavors. It can be used to copy details along edges of planar solids. A common example is a wall cap along the edges of a flat roof. For a more in-depth explanation of the general principles of Propagate, read this article on Propagate (2.9.2).  For more information about this command, visit the Command Reference article BimPropagateEdges (6.7.44).

Procedure: Propagating a wall cap

1. Consider the following situation of a one-story building with a flat roof. (2.648)
2. Let's create a vertical section plane to cut through our building and take a look at where the wall (1) and the roof slab (2) come together. (2.649 on the following page)
3. We want to create a capping (3) on top of this wall to get the following result: (2.650 on the next page) We can start by creating this locally on top of one wall, either by using direct modelling tools or inserting a block from somewhere else and exploding it. In our section it might look like this: (2.651 on page 2221)
4. Now we can use Propagate to copy this detail over to all applicable locations. Let's deactivate the section and launch **BimPropagateEdges.**
5. **You are prompted:** Select planar reference solid to which the edge detail is related. The detail will be copied to edges of similar solids. [selection options (?)]: Select the wall on top of which the capping was modelled, and press **Enter.**
6. **You are prompted:** Select detail objects to be copied. These should be solids or faces that are parallel to an edge of the reference solid. [selection options (?)]: Select the objects that make up the capping, and press **Enter.**
7. **You are prompted:** Blue: detail area to be copied. Purple: reference contact area. Accept? [Yes/No/Inflate first/Save detail/save detail to Library] <Yes>: Inflating the detail is not necessary in this case. For more information on inflating, read this article on Propagate (2.9.2). Choosing 'No' will exit the command. Press **Enter** to accept.
8. **You are prompted:** Propagated to edges with similar orientation only? [Yes/No] <Yes>: Choosing **Yes** will only apply this detail to edges with a similar orientation, in this case wall edges that point upwards. Press **Enter** to accept.

Figure 2.648

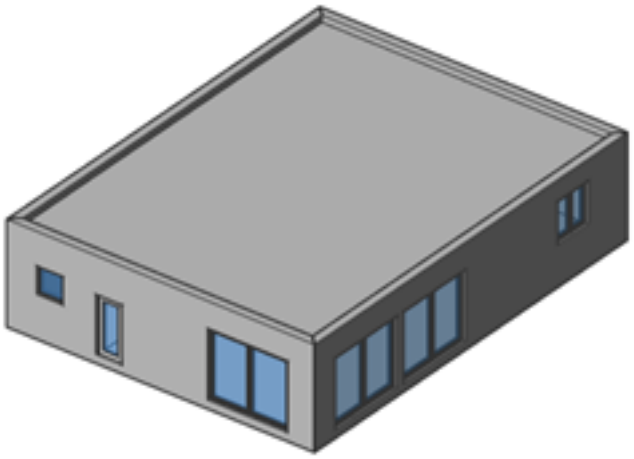

Figure 2.649

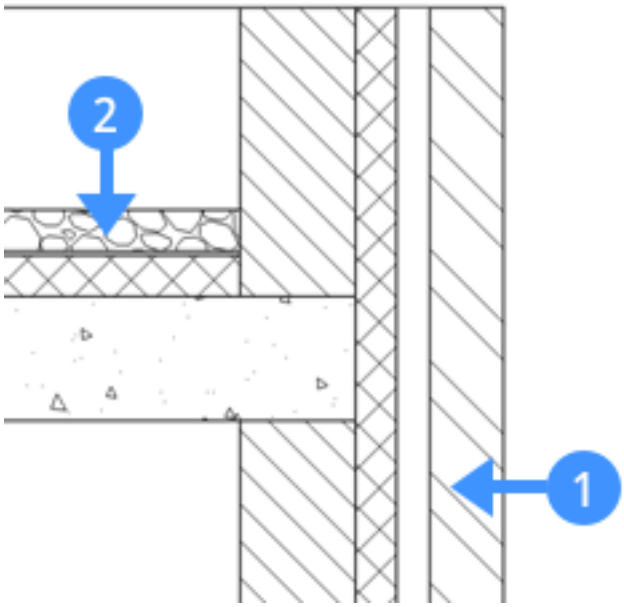

Figure 2.650

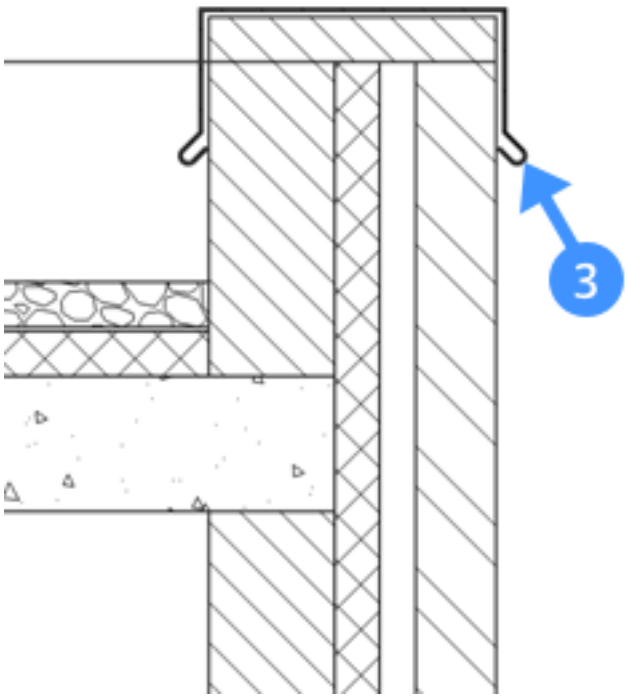

Figure 2.651

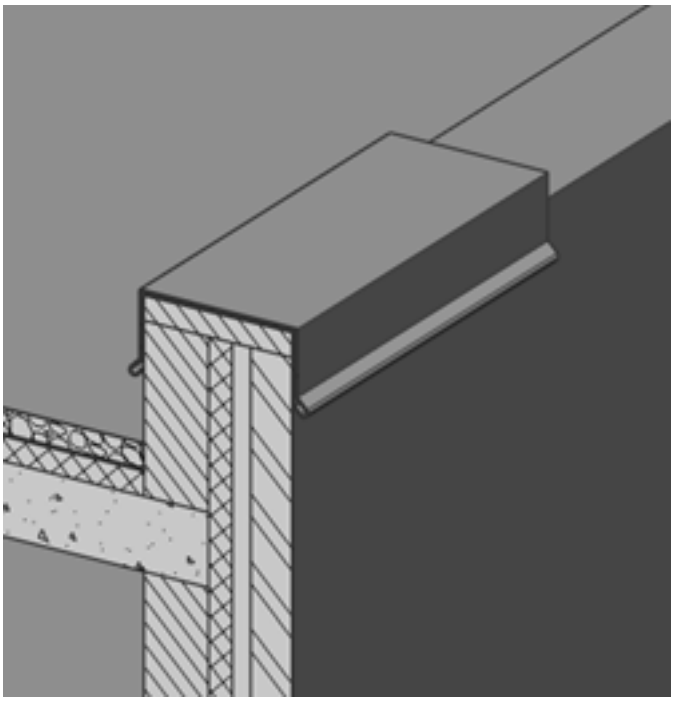

Figure 2.652

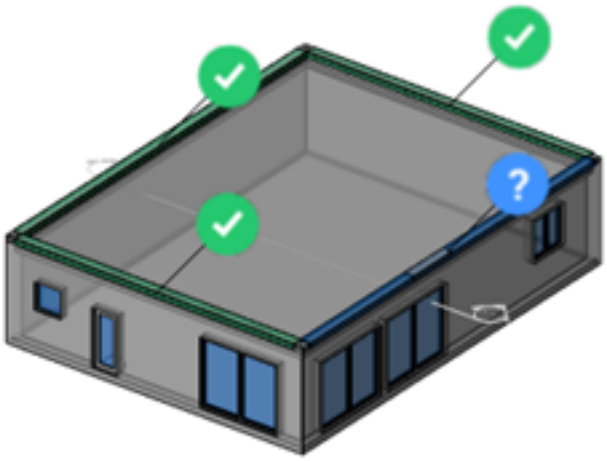

9. **You are prompted:** Choose location of detail relative to edge: [Outside reference solid/Inside reference solid] <Outside reference solid>: This option controls whether the detail will be placed inside or outside (on top of) the base solids. When placed inside, the detail is subtracted from the base solids.

10. BimPropagateEdges now scans the entire drawing for similar locations. When this is done, the view is zoomed out to show all possible locations. Every suggestion is highlighted and a widget is displayed: **You are prompted:** Choose next action [Apply all/Cancel] <Apply all>: (2.652) A green check mark means that this suggestion will be applied when pressing Enter. A question mark means that it will not be applied due to one of several possible reasons. Hovering over the widget will reveal more information. In this case it says "Location of original detail. Click to replace original detail by adapted extrusion". Because we modelled the wall cap only locally, we should replace the original detail by an adapted extrusion so that it covers the entire length of the wall. Clicking the widget will turn it into a green check mark.

11. Press **Enter** to complete the command. Now all four walls have this wall cap and the corner connections are created automatically.

2.9.7 Propagate Corner

Command: BimPropagateCorner, (6.7.31) Propagate (2.9.2)

Tutorial: How to use Propagate Corner Click here (2.8.7) to watch

About

BimPropagateCorner is one of the five Propagate flavors. It can be used to propagate details connected to three planar base solids (i.e. corners). Common examples are **exterior wall-interior wall-slab** connections or **exterior wall-interior wall-roof** connections. For a more in-depth explanation of the general principles of Propagate, read this article on Propagate (2.9.2).  For more information about this command, visit the Command Reference article BimPropagateCorner (6.7.31).

Setting the foundations

In this example the 4 exterior walls, 5 interior walls, and floor slab have already been assigned a composition. (2.653 on the facing page) First you must connect the 3 planar types of connections separately. For a detailed explanation of how to do this, read the article **PropagatePlanar (2.9.5).** You should now have the following connections:

(2.658 on page 2227)	(2.659 on page 2228)	(2.660 on page 2228)
Exterior wall - Floor slab	Exterior wall - Interior wall	Interior wall - Floor slab

The nodes where the exterior wall, interior wall, and floor slab come together can't be correctly propagated using **PropagatePlanar**. Instead, use **PropagateCorner. PropagateCorner** can propagate details connected to three planar base solids (i.e. corners). (2.654 on the facing page)

Figure 2.653

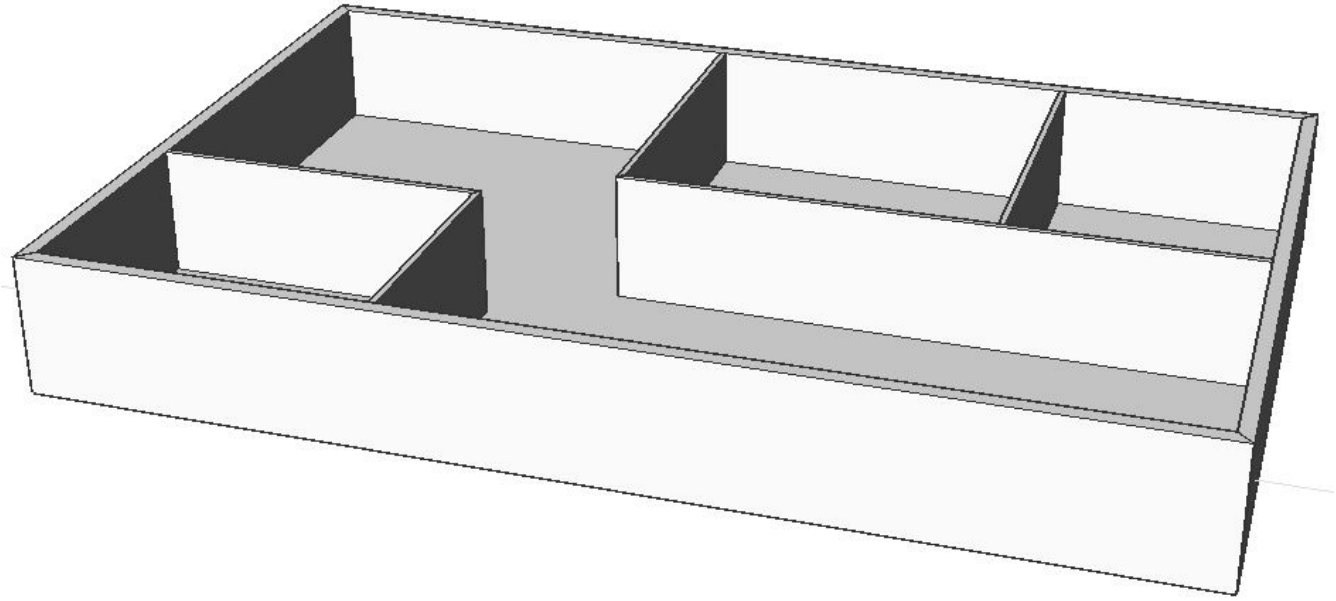

Figure 2.654

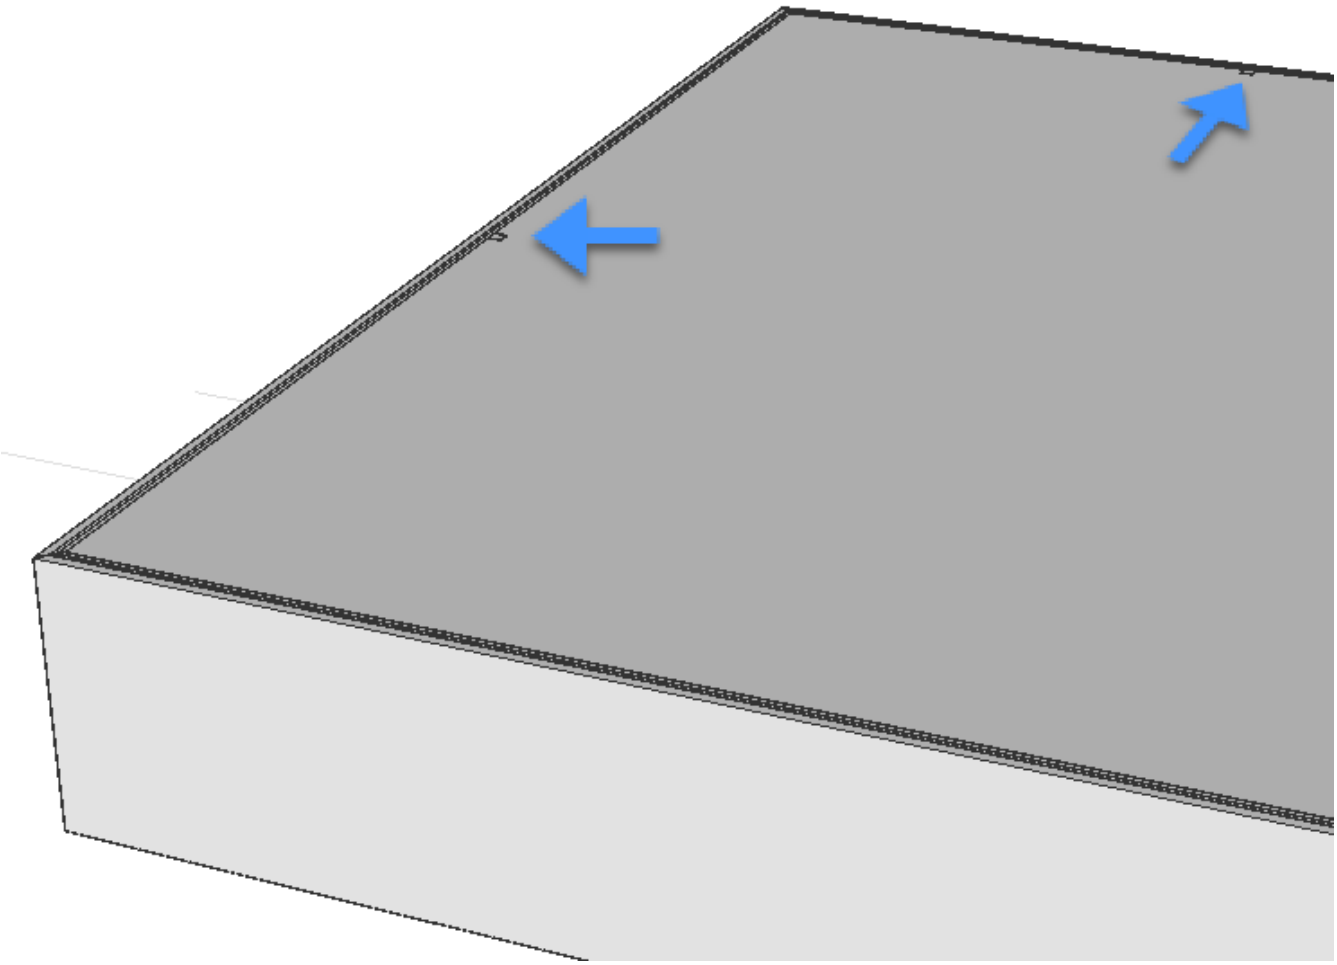

Propagate corner

1. Launch **BimPropagateCorner You are prompted:** Select at least three planar reference solids that form a 3D corner. The detail will be copied to similar corners. [selection options (?)]:
2. Select the exterior wall (1), the interior wall (2), and the floor slab (3).
3. Press **Enter** to accept. (2.655 on the next page) **You are prompted:** Optional. Select detail objects (solids, block references, faces, edges,...) to be copied as part of the corner detail. [selection options (?)]: If you have extra solids in your detail, i.e. an insulation block, you can select this as an extra detail object and it will be copied to the other nodes when using **PropagateCorner**.
4. Press **Enter** when ready. **Note:** if you don't have any extra details, just press **Enter** to continue.
5. The volume that will be propagated is encased in a purple box. **You are prompted:** Blue: detail area to be copied. Purple: reference contact area. Accept? [Yes/No/Inflate first/Save detail/save detail to Library] <Yes>:
6. Press **Enter** to accept the detail. (2.656 on page 2226) **Note:** PropagateCorner shows a 3D volume instead of a 2D section.
7. **BimPropagateCorner** now scans the entire drawing for similar locations. When this is done, the view is zoomed out to show all possible locations. Every suggestion is highlighted and a widget is displayed. A green checkmark means that this suggestion will be applied when pressing **Enter**. (2.657 on page 2227) **You are prompted:** Choose next action [Apply all/Cancel] <Apply all>:
8. Press **Enter** to complete the command. The nodes where the exterior wall, interior wall, and floor slab come together should now be propagated correctly.

2.9.8 Parametrize details

Command: BimParametrizeDetail (6.7.28) **Overview:** In this lesson, you will learn how to use the BimParametrizeDetail command to parametrize a detail and make it applicable to a wider range of target situations. **Lesson Objectives** After completing this lesson, you will be able to:

- Parametrize and edit a wall-slab connection.
- Parametrize and edit a linear connection: structural beams, HVAC ducts, piping, etc.
- Propagate parametrized details in a project.

About BimParametrizeDetail

Use the BimParametrizeDetail command to automatically generate parameters for a saved detail. Standard parameters such as angles, offsets in different directions and tolerance parameters are created. These parameters mean you can propagate details to target situations similar to the example below. The automatically generated parameters form a framework that can control the position and shape of the reference solids. You can extend this framework adding custom constraints. You can evaluate the effect of these changes by animating the parameters from the **Mechanical Browser**. You can add custom constraints to link detail objects to the reference solids and to each other. You can also use the framework parameters in the expression of those constraints.

Parametrize and Edit a Wall-Slab Connection Detail

1. To open the .dwg file of the detail you want to parametrize click on the detail in the Details Panel (2.9.9). The detail dialog box displays: (2.661 on the following page)
2. Click **Parametrize**, or click **Open** and run BimParametrizeDetail (6.7.28). The detail .dwg file will open and the detail will be parametrized. (2.662 on page 2231)
3. Open the **Mechanical Browser**.
4. Click the **Mechanical Browser** button on the right of the screen. (2.663 on page 2232)
5. If the **Mechanical Browser** button isn't visible yet, move the cursor to the toolbar or ribbon panel and right-click. A context menu displays. Expand the **Panels** option. Select **Mechanical Browser** in the context menu. (2.664 on page 2233)
6. Once you have clicked on the **Mechanical Browser** button, the **Mechanical Browser** displays: (2.665 on page 2234) **Note** You can also use the MechanicalBrowserOpen (6.8.32) command.
   - 1: **Group by entity** Group the parameters and constrains by entity.
   - 2: **Group by type** Group the parameters and constrains by type.
   - 3: **Sort** Sort alphabetically.
   - 4: **Settings** An options menu will display: (2.666 on page 2235)
   - 5: **Show search (Ctrl+F)**: Show or hides the search bar.
   - 6: The name of the parametrized detail.
   - 7: **Parameters** Right-click on a parameter to open a context menu: (2.667 on page 2235)
     - **Delete** Delete the selected parameter.
     - **Create Design table** Create a design table (1.27.6) to drive parametric block parameters.
     - **Animate** the detail parameters.
     - **Collapse all** Collapse the whole **Mechanical Browser**.
     - **Expand All** Expand the whole **Mechanical Browser**.
   - 8: **Tolerance Parameters** The maximum and minimum variation of an angle, thickness or dimension from the original parameter value.
   - 9: **Bodies** Display the bodies in the model.
   - 10: **Constraints** The constraints you can delete, modify or add.
   - 11: **Component** The properties of the detail file.
7. **Note** Some default constraints are generated that link the detail volume and the detail objects to the reference solids. You can delete and replace them with other constraints.
8. Edit the parameters. The parameters that were generated have specific values to ensure the detail looks exactly as it was created. If you change these values, the detail will change. **For example:**
   - Change the **Thickness_Ply1_Wall_30_31** parameter from 40 to 70 (in the **Expression** field). The new detail is visibly different in the model space:

Propagate

3. Open the **Mechanical Browser**: (2.671 on page 2240) **Note:** For connections between linear reference solids, only the framework parameters are automatically generated. You must manually add constraints to specify the behavior of detail objects in relation to the reference solids. In this example, three coincidence constraints have been manually added: two to make sure that the connection planes of the triangular steel plate maintain coincident with the flanges of the steel column and girder, and one to make sure that the end section of the girder maintains coincident with the column flange. You can add coincidence constraints before or after the parametrize tool. If you add the coincidence constraints after you can see how the reference solids change with new parameters. This makes it clear which constraints have to be added to make all detail objects move correctly.
4. Edit parameters. The parameters that were generated have specific values that make sure the detail looks exactly as it was created. If you change these values, the detail will change. **For example:**
   - Change the **Angle2_Beam_2E** from -28.1931013282 to -40. The column and the girder change in the model space. A warning pops up: (2.673 on page 2241) This is because the **AngularTolerance** parameter was set to 10. The **AngularTolerance** parameter automatically changed to 11.8069 because you have changed the **Angle2_Beam_2E** by 11.8069 degrees. Click **OK**.

Before	**After**
(2.684 on page 2249)	(2.685 on page 2250)

   - Change the **Offset1_Beam_2E** 0 to 200. You see the girder moves 200 mm downwards. A warning pops up: (2.673 on page 2241) This is because the **OffsetTolerance** parameter was set to 31. The **OffsetTolerance** parameter automatically changed to 200 because you changed the **Offset1_Beam_2E** parameter by 200 mm. Click **OK**.

Before	**After**
(2.686 on page 2251)	(2.687 on page 2252)

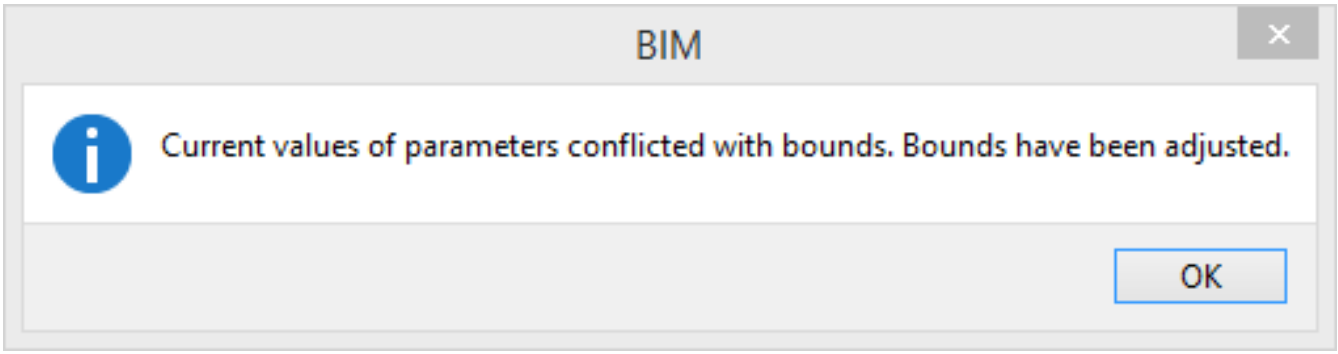

Figure 2.673

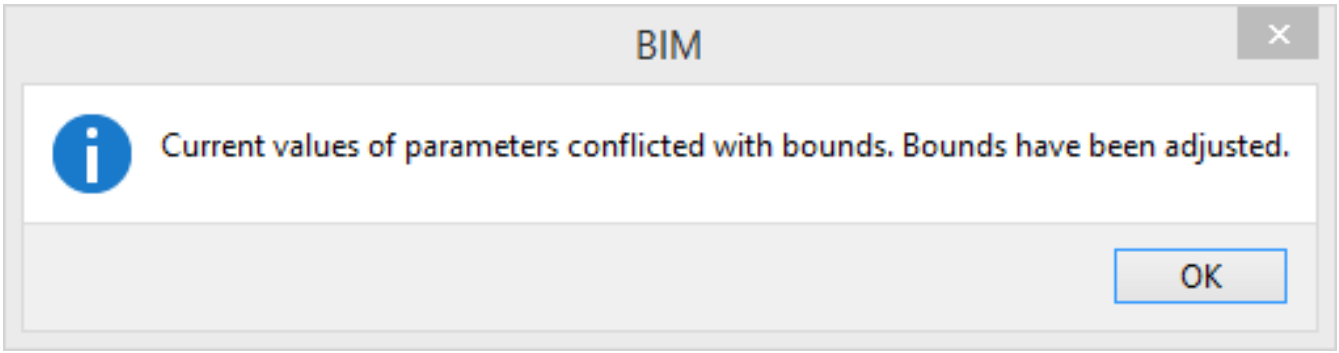

Propagate a Detail in a Project

There are different methods to Propagate a detail:

- With the Details Panel (2.9.9): propagate a detail from the project on all similar connections in the project.
- With the BimPropagateFromFile (6.7.35) command: propagate a detail from a file.

Fewer suggestions are given by the propagate command for a detail that is not parametrized. This is because a detail that is not parametrized has fewer possible locations. For example: if a non-parametrized detail of a wall-slab connection is propagated, BricsCAD BIM won't be able to propagate this detail to a wall-slab connection when the composition is different or a particular ply in the wall differs 10 mm from the corresponding ply in the wall of the original detail. To solve this problem parametrize the detail. The **Propagate** command can adapt a detail with parameters to situations that differ from the original (eg: another corner, a smaller profile, etc.). You can decide how much the connections can differ from the original with the tolerance parameters. Different tolerance parameters:

- **Angular** Sets the tolerance on angle parameters of the detail in degrees. Angles in the target situation cannot deviate more than this tolerance value from the original angles in the detail.
- **Dimension** Sets the tolerance for the profile dimensions of linear reference solids in the detail. Profile widths and heights in the target situation cannot deviate more than this tolerance from the original widths and heights in the detail.
- **Offset** Sets the tolerance for offset parameters of the detail. Offsets in the target situation cannot deviate more than this tolerance from the original offsets in the detail.
- **Thickness** Sets the tolerance for the total thickness of planar reference solids in the detail. Thicknesses in the target situation cannot deviate more than this tolerance from the original thicknesses in the detail.

In the following project, there are a lot of similar connections present. However, the angles of the connections vary and the lower beam in the truss and has a different profile size than the upper beam. (2.674 on the next page) Propagate a detail in the project: (2.675 on the following page) The **Mechanical Browser** displays the parameters. The **AngularTolerance** parameter is set to 0 degrees, the detail will only propagate to connections with exactly the same angle. (2.676 on page 2243) Change the **AngularTolerance** parameter to 45 degrees. The detail will propagate to all the similar connections. This is because none of the connections exceed the tolerance value. (2.677 on page 2243) (2.678 on page 2244) (2.679 on page 2244)

2.9.9 Details Panel

Overview: In this lesson, you will learn how to use the Details Panel. **Commands:** DetailsPanelOpen (6.10.52) and DetailsPanelclose (6.10.44) **Lesson objectives** After completing this lesson, you will be able to:

- Open the Details Panel
- Organize saved details
- View details
- Add tags to details
- Search for details in the library
- Propagate details
- Adjust details
- Save details to the Details Panel
- Share a details folder

Opening the Details Panel

Execute the DETAILSPANELOPEN (6.10.52) command. or

1. Place the cursor on a toolbar or ribbon panel and right-click. A context menu displays.
2. Expand the **Panels** option.
3. Select **Details** from the context menu. (2.688 on the next page)

The Details panel displays and the **Details** button () is added to the collapsible panelset a the right hand side of the BricsCAD application window. (2.689 on page 2255) Click on the **Details** button () to expand/collapse the Details panel.

Saving details to the Details Panel

After you created a new detail, it's possible to save it to the **Details** Panel. This way you can use the same detail in other files as well. Use the command BIMCREATEDETAIL (6.7.14).

View a Detail

1. Click on the category of the detail you want to view. The details assigned to that category display. (2.690 on the next page) (2.691 on the facing page)
2. Click on the detail you want to view. The detail dialog box displays: (2.692 on page 2258)
   - Edit the thumbnail image:
     - Click the Pencil icon (). The detail dwg opens. The CREATETHUMBNAIL command is launched.
     - Use view commands (zoom, pan, rotate) to adjust the view.
     - Choose **OK** or press Enter to save the thumbnail.
3. Parametrize: Opens the .dwg detail file and executes the BIMPARAMETRIZEDETAIL (6.7.28) command.
4. Open: Opens the .dwg file of the detail.
5. **Tags**: Add general tags.
6. **Reference solid tag**s: Click the down arrow to display the tags. You cannot add reference solid tags; you can only delete the existing tags
7. **General tags:** Click the down arrow to display the tags.
8. **Save** : Saves the changes and closes the detail dialog box.
9. **Propagate** Propagates the detail. See the BIMPROPAGATE (6.7.30) command.
10. **Cancel**: Closes the detail dialog box without saving.
11. Change the thumbnail image of the detail.ags

Tags can be added to each detail. These are used to search for a specific detail in the library. There are two different tag categories:

- **Reference solid tags**: Tags that identify an individual reference solid from the detail.
- **General tags**: Tags that generally identify the detail.

During the BimCreateDetail (6.7.14) command, tags are automatically generated for the detail. You can delete unrequired tags and add new tags. New tags can only be **General tags.** You can add tags during the BimCreateDetail (6.7.14) command or at any moment after the detail has already been created. To add tags during the BimCreateDetail refer to the BimCreateDetail (6.7.14) article. To add tags at another moment see below.

Managing tags

1. In the **Details Panel**, click on the detail you want to adjust. The detail dialog box displays.
2. Expand the **Reference solid tags** category. You can only delete these tags, you cannot add new tags.
3. Click in the **Tags** field and type the name for the new tag, then click the **Add** button to add General tags The new tag is added to the **General tags** category in an orange box. Repeat this procedure to add more tags.
4. Click the **Save** button to save the changes and close the detail dialog box.

Searching details with tags In the **Details Panel,** you can search the library for specific details using tags. You can add one or more tags at once to your search query to select all matching details.

1. Click the search bar in the **Details Panel** and type in a search string. The matching tags display: **Reference solid** tags and the **General** tags. (2.693 on the following page)
2. Do the following:
   - **General tags**: Click the desired tag .
   - **Reference solid tags**:
     - To add the tag to a reference solid that is not yet in your search query: click the plus sign next to the required tag.
     - Add the tag to a reference solid that is already in your search query: click the number of the required reference solids next to the tag. Once these tags have been added to your search query, they will appear at the bottom of the **Details Panel** under the right tag category. The filtered search results display. (2.694 on page 2261)

Create detail

Editing a Detail

1. Select the detail you want to edit.
2. Click the **Open** button. The .dwg file of the detail opens in a separate drawing tab.
3. Make the necessary adjustments to the detail.
4. Save the detail .dwg file. The detail is updated in the **Details Panel**.
5. The existing details won't be updated automatically. To Replace the existing details by the new one, follow the steps above to propagate a detail.

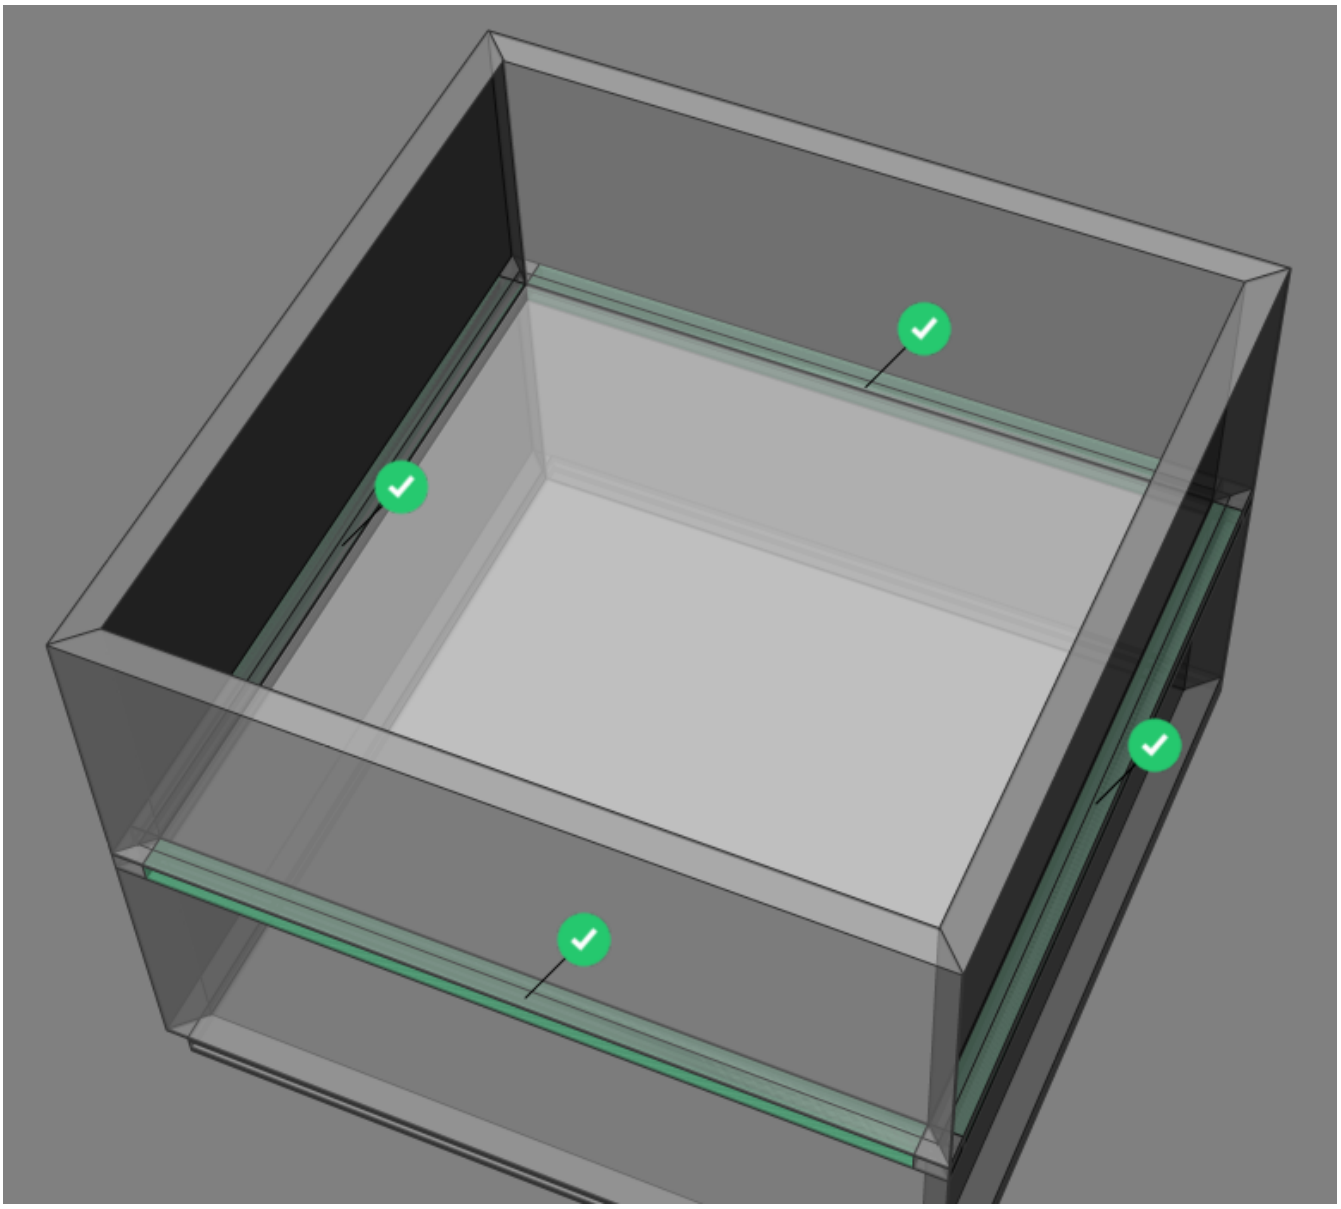
To propagate a detail

You can propagate a detail to all of the similar connections in your project. Do one of the following: Drag and drop the detail from the library into the drawing. or

1. Select the detail in the library. The Detail dialog box dispays.
2. Click the **Propagate** button.

To apply all suggestions, hit Enter. To reject a suggestion click on the checkmark. A red cross icon replaces the checkmark. Click the icon again to accept the suggestion. Press Enter to accept. (2.695 on the facing page) You can also propagate a detail in your project using the BimPropagateFromFile (6.7.35) command. This command allows you to propagate detail files that are not in the library.

Figure 2.695



Sharing details

You can save details as a dwg-file and share the details folder/library. Save the detail drawings at the correct location which will then display in the details panel.

1. If you want to make a new detail to share, you can create a new detail first, as is explained above. The following steps apply both to new details as well as existing details.
2. All the details you have created are automatically saved in the folder, and its subfolders, which is set through the DETAILSPATH system variable. By default this is **C:\ProgramData\Bricsys\Details**. (2.696 on the next page) Then click on the three dots next to the existing name in the Path List to change the location. (2.697 on page 2267)

Tool palettes

You can also create a additional paths. Click the **New** icon (), then click on the three dots of the new row to add a path for the Details library.

3. If you want to share a folder, go to the file explorer on your computer and follow the path to the details folder. If you haven't created any details yet, this folder only contains the folder '.resources'. If you have created some details, you can find the same folders here as in your Details Panel. (2.698 on the next page)
4. Copy the folder that you want to share and turn it into a zip file. This zip file can be shared with others.
5. If you receive a zip file you should unpack it and copy the folders containing the details to the folder **C:\ProgramData\Bric**
   Note: make sure the details are saved in a folder that you place in the detail folder. If you just place the dwg files in your details folder, they will not appear in your Details Panel.
6. To load the new details in your library panel, go to the details panel, open the menu and click **Generate thumbnails**. The new details folders will appear in your Details Panel. (2.699 on the facing page)

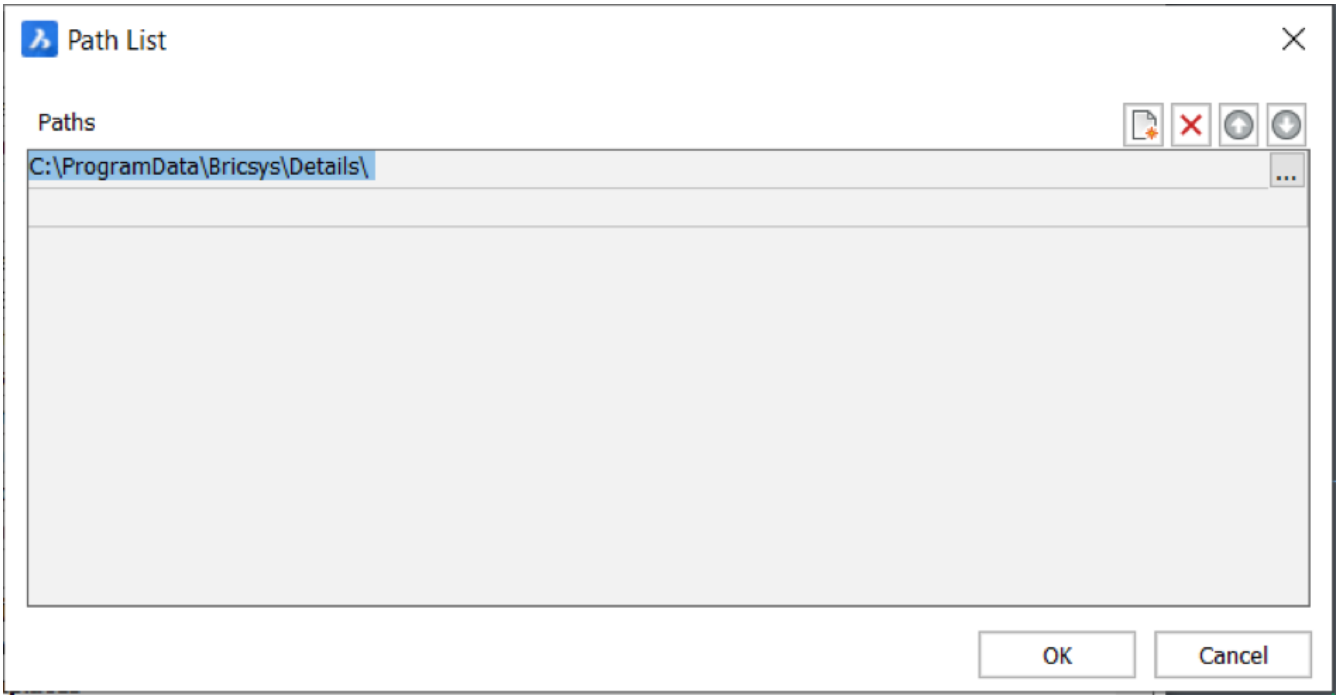

Figure 2.698

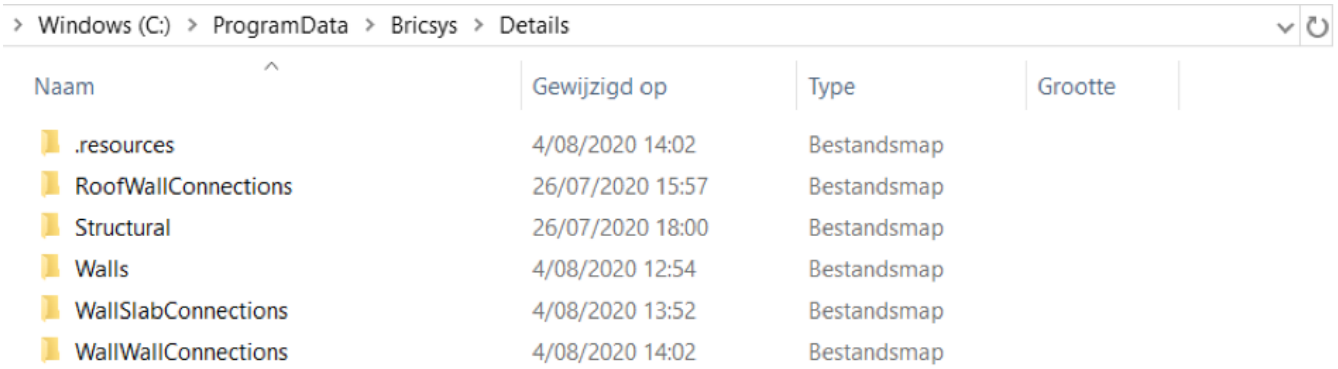

Figure 2.699

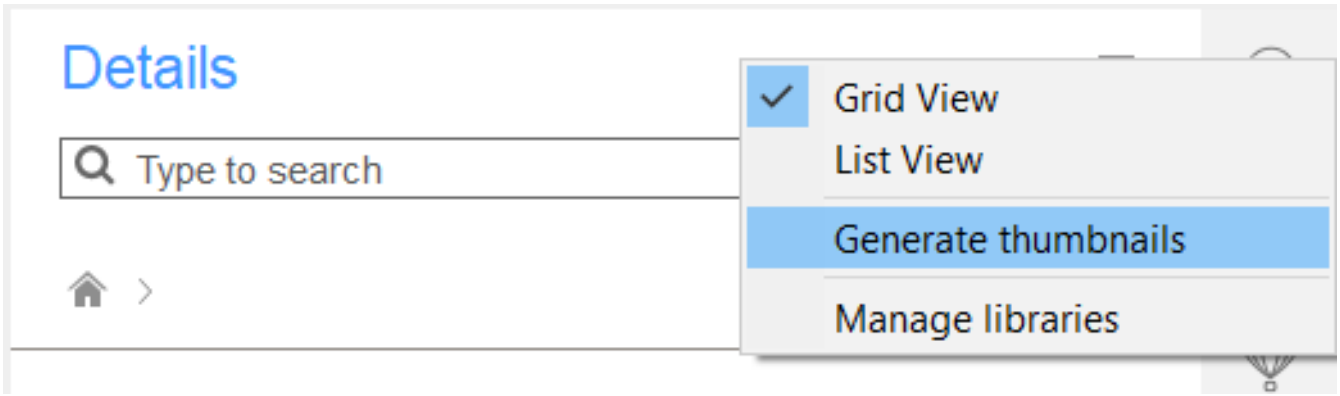

2.9.10 Rhino/Grasshopper Integration

Command: Rhino, Grasshopper, ToGrasshopper **Overview:** You can use Rhinoceros3D (a.k.a. "Rhino") and Grasshopper to create parametric, NURBS-based geometry inside of BricsCAD. To use this integration, you will need a "Rhinoceros 7" license or trial license, the Grasshopper-BricsCAD Connection, and a BricsCAD BIM V21 license or trial license. Detailed info can be found in the "Installing Rhino/Grasshopper Connection" section below. Rhino creates NURBS geometry, and Grasshopper adds scriptable parametric controls that can drive that geometry. This combination of tools allows the iterative, algorithmic design of CAD and BIM geometry.

About

Rhinoceros3D is a 3D modeler developed by Robert McNeel & Associates of Seattle, Washington USA. Rhino is used to create, edit, analyze, document, render, animate and translate NURBS* curves, surfaces, solids, point clouds and polygon meshes. Grasshopper is a visual programming language environment that runs within the Rhinoceros 3D computer-aided design application. It is tightly integrated with Rhino's 3D modeling tools.

Installing Rhino/Grasshopper Connection

1. Download Rhino 7 from https://www.rhino3d.com/download. **Note:** Since the releases of BricsCAD V21 and Rhino 7, you can use the Rhino/Grasshopper Connection within BricsCAD with trial license keys of both BricsCAD BIM V21 and Rhino 7. Keys for older versions of Rhino will not work for this integration.
2. Download the Grasshopper-BricsCAD Connection from the BricsCAD Application Store: https://www.bricsys.com/applications/a/?rhino-grasshopper-connection-for-bricscad-a1353-a12360. The installer copies all required files to the 'Program Files\Bricsys\Grasshopper-BricsCAD Connection' folder. **Note**: The Grasshopper-BricsCAD Connection currently available from the Application Store will only work within BricsCAD BIM V21, not within older versions.
3. Restart BricsCAD V21.
4. To launch Grasshopper or Rhino, open and save a new drawing. Then use the buttons in the new tab that is displayed in the ribbon or launch with the Quad.

To launch a Grasshopper file from BricsCAD

1. Open an empty BricsCAD file.
2. Save it.
3. Open Grasshopper with the button in the new Grasshopper tab inside BricsCAD.
4. You can close the Rhino pop-up window. Rhino will continue to work in the background.
5. In the File tab of Grasshopper, choose 'New document' to open a new and empty Grasshopper script.
6. Choose 'Open document...' to open an existing Grasshopper script. You can use any script you made with Grasshopper in the past and open it in BricsCAD, as long as the input geometry from another program has been internalized. (To internalize data right-click the input geometry component and hit 'Internalise data'.)
7. The geometry you created with the script should now pop-up in your BricsCAD model space, displayed in red. Make sure you don't close the Grasshopper window, otherwise the preview geometry will disappear, as the Grasshopper document is closed.
8. If your Grasshopper script is open and you still don't see the preview geometry, it probably means your Grasshopper file is linked to the wrong BricsCAD document. To link it to the correct one, see 'To link a Grasshopper file with a BricsCAD file'.

To link a Grasshopper file with a BricsCAD file By default, the BricsCAD file that the Grasshopper document will link to is the one that was active when you launched Grasshopper from BricsCAD. If you want to link it to another BricsCAD file, you need to:

1. Make the target BricsCAD drawing the current drawing (i.e. the one you see in the model space window of your current session).
2. Link the Grasshopper script to this open drawing. You do that by clicking the Link icon  in the bar just above the Grasshopper canvas that contains the script that you are trying to link.

To launch a sample file The sample files are provided with the Grasshopper-BricsCAD Connection. They can show you what is possible with the Connection. They are stored in the 'Program Files\Bricsys\Grasshopper-BricsCAD Connection' folder.

1. Open up a sample .dwg file by opening a .dwg from the 'Program Files\Bricsys\Grasshopper-BricsCAD Connection' folder.

2. You will get a warning that the file is read-only. This happens because the document is located in a secured folder. Click 'Yes' to open as read-only. **Optional**: If you don't want this warning, or if you want to edit the file, copy-paste the sample files into one of your own folders and open them from there instead.
3. From inside Grasshopper, choose File > Open Document. Go to the 'Program Files\Bricsys\Grasshopper-BricsCAD Connection' folder again.
4. Choose the .ghx-file with the same name as the .dwg file.
5. The sample file now opens and you should see red preview geometry in your BricsCAD model space. Make sure you don't close the Grasshopper window, otherwise the preview geometry will disappear, as the Grasshopper document is closed. If your Grasshopper script is open and you still don't see the preview geometry, it probably means your Grasshopper file is linked to the wrong BricsCAD document. To link it to the correct one, see 'To link a Grasshopper file with a BricsCAD file'.
6. You can play around with the input sliders in the Grasshopper script.
7. If you are happy with your model and would like to convert the preview geometry into real BricsCAD geometry, you can 'bake' the geometry into BricsCAD. You do that by selecting all the 'Bake Building Element' components (Shift-clicking them all) and pressing the Bake button .
8. A pop-up window appears, just click 'OK' to accept.
9. The geometry is now converted into real BricsCAD geometry, even with BIM data attached to it.
10. You won't be able to save your changes to your files, as they were read-only. So discard your changes or save the files as new ones in a different location.

Customizing the Rhino/Grasshopper Connection

The code for the Rhino/Grasshopper Connection is 100% open-source and is available at `https://github.com/Bricsys/rhino.inside-bricscad`. This allows you to fully customize your Connector by coding to your heart's content (assuming, of course, that you know how to code).

Uninstall the Rhino/Grasshopper Connection

1. Launch 'Add or Remove Programs' in Windows.
2. Search for 'Grasshopper-BricsCAD connection'.
3. Hit 'Uninstall'.

How to draw a box in Rhino and bake into BricsCAD via Grasshopper

1. Open a new BricsCAD file.
2. Save the file.
3. In BricsCAD, click on **Grasshopper > Rhino**.
4. Draw a Rhino box by typing **BOX** in the Rhino command line. (This works in the same way as the BricsCAD **Box** command).
5. Click for the first corner of the base.
6. Click for the other corner of the base.
7. Click to define the height of the box. (2.700 on the next page)
8. To open a new Grasshopper script, inside the Grasshopper environment, click on **Grasshopper > Grasshopper** then click on **File > New document**. (2.706 on page 2275)
9. Save the file.
10. Drag and drop the **Params > Geometry > Brep component** onto the Grasshopper canvas.
11. Right-click on the component and select **Set one Brep**. (2.702 on page 2271)
12. Go to the Rhino canvas and select your cube.
13. The Brep component will change color from orange to grey. If you close the Rhino window and return to the Grasshopper window, a preview of the cube will display in the BricsCAD model space.
14. Drag and drop the **BricsCAD > Building Element > Bake Geometry component** onto the Grasshopper canvas.
15. To link the two components click and drag from the Brep component's right dot to the BricsCAD Bake component's left dot. (2.703 on page 2272)
16. Right-click onto the Bake Geometry component and choose **Bake into BricsCAD**. (2.704 on page 2272) The following dialog displays. Here you can choose the destination Layer, Material and Color: (2.705 on page 2273)
17. Click **OK**. The box is baked as a solid into BricsCAD.

How to draw a box in Grasshopper from a BricsCAD rectangle

1. To open a new Grasshopper script, click on **Grasshopper > Grasshopper** and clicking on **File > New document** inside the Grasshopper environment. Save the file. (2.706 on the next page)
2. Open a new BricsCAD file in a **meter template** and save it.
3. To link the new script to the open .dwg file hit the Link button in the Canvas Toolbar. (2.707 on the facing page)
4. Go to the BricsCAD model space and draw a rectangle. **Note**: Use a polyline to create irregular geometry.
5. Drag and drop the **BricsCAD > Input geometry > Curve component** onto the Grasshopper canvas.
6. Right-click onto the Curve component and choose **Set One BricsCAD Curve**.
7. Go to the BricsCAD model space and select the rectangle. **Note**: Save time with the Quad: select the curve in BricsCAD and then select **ToGrasshopper** under the Grasshopper tab of the Quad. A Grasshopper component appears in the upper left corner of your Grasshopper canvas.
8. Link the Curve component to a **Surface > Freeform > Boundary Surfaces component**
9. Link this to a **Surface > Freeform > Extrude component**.
10. In the Direction input of the Extrude component link a **Vector > Vector > Unit Z component** with **Params > Input > Number Slider component**. Set this to the height of your box, 17 for example. **Note**: you can edit the range and preciseness of the slider by right-clicking the component and selecting 'Edit...'. A dialog box pops up where you can set the digits and min and max value of the slider. (2.708 on page 2276)
11. You now have drawn a box in Grasshopper, using BricsCAD geometry as an input!

Figure 2.706

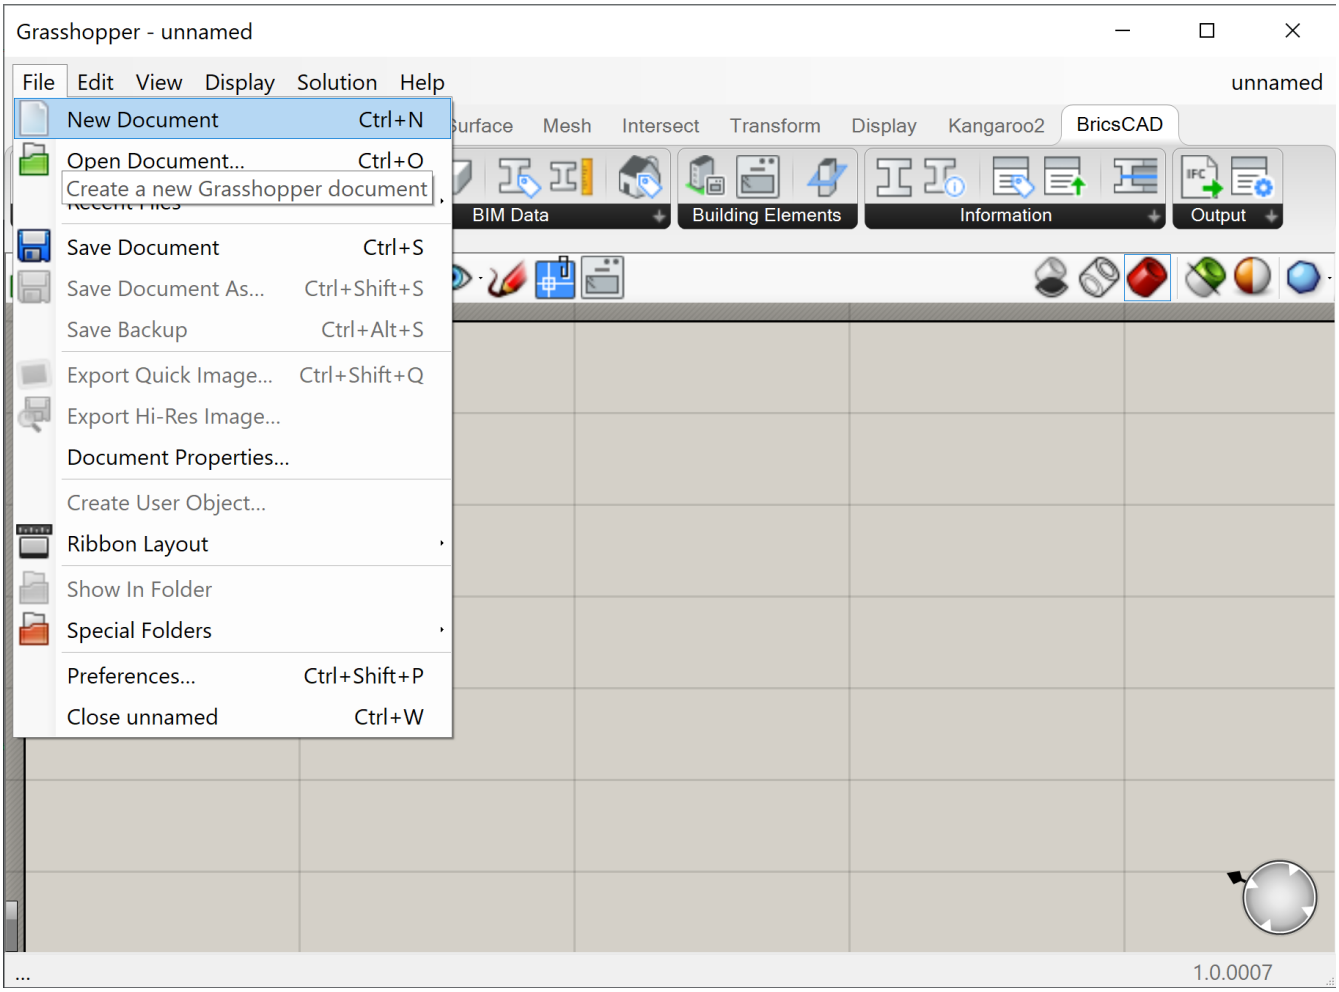

Figure 2.707

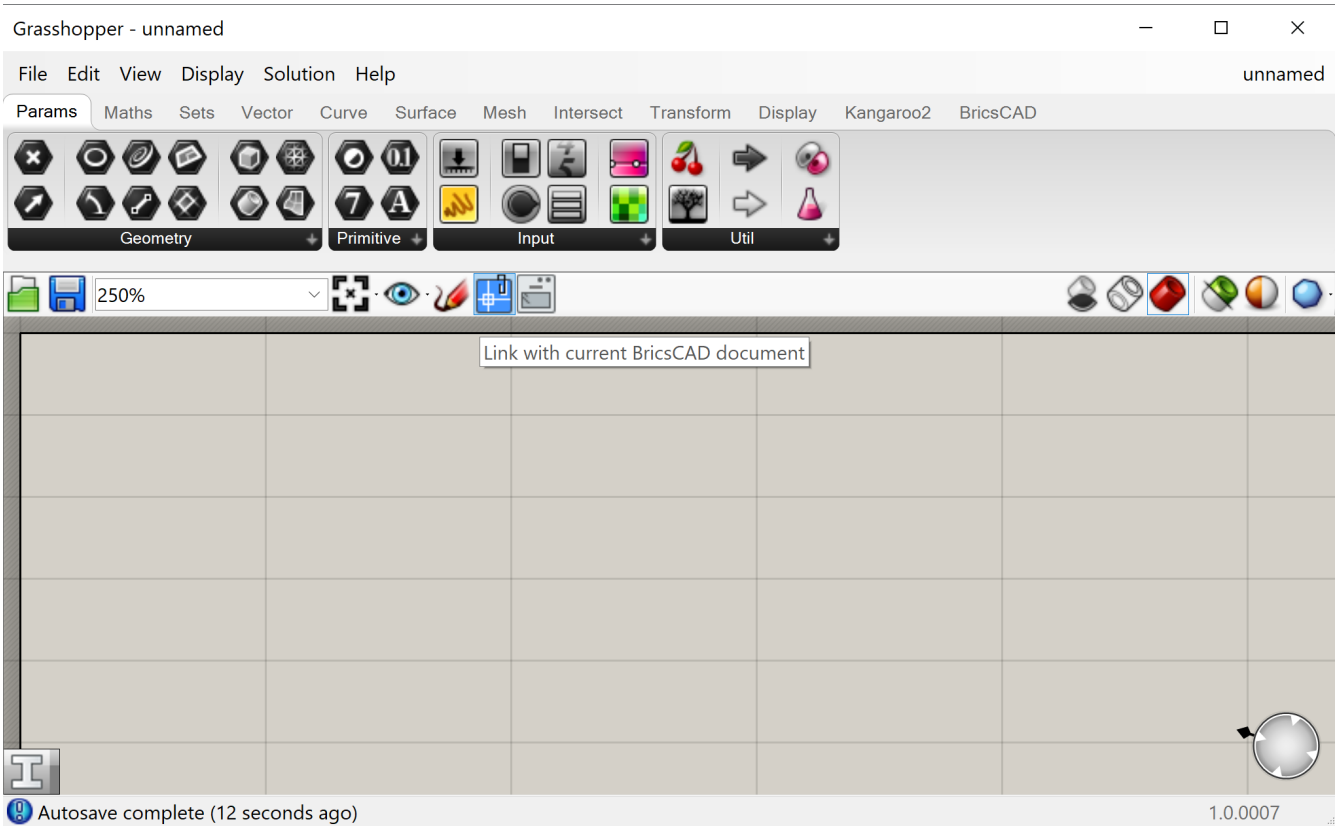

Figure 2.708

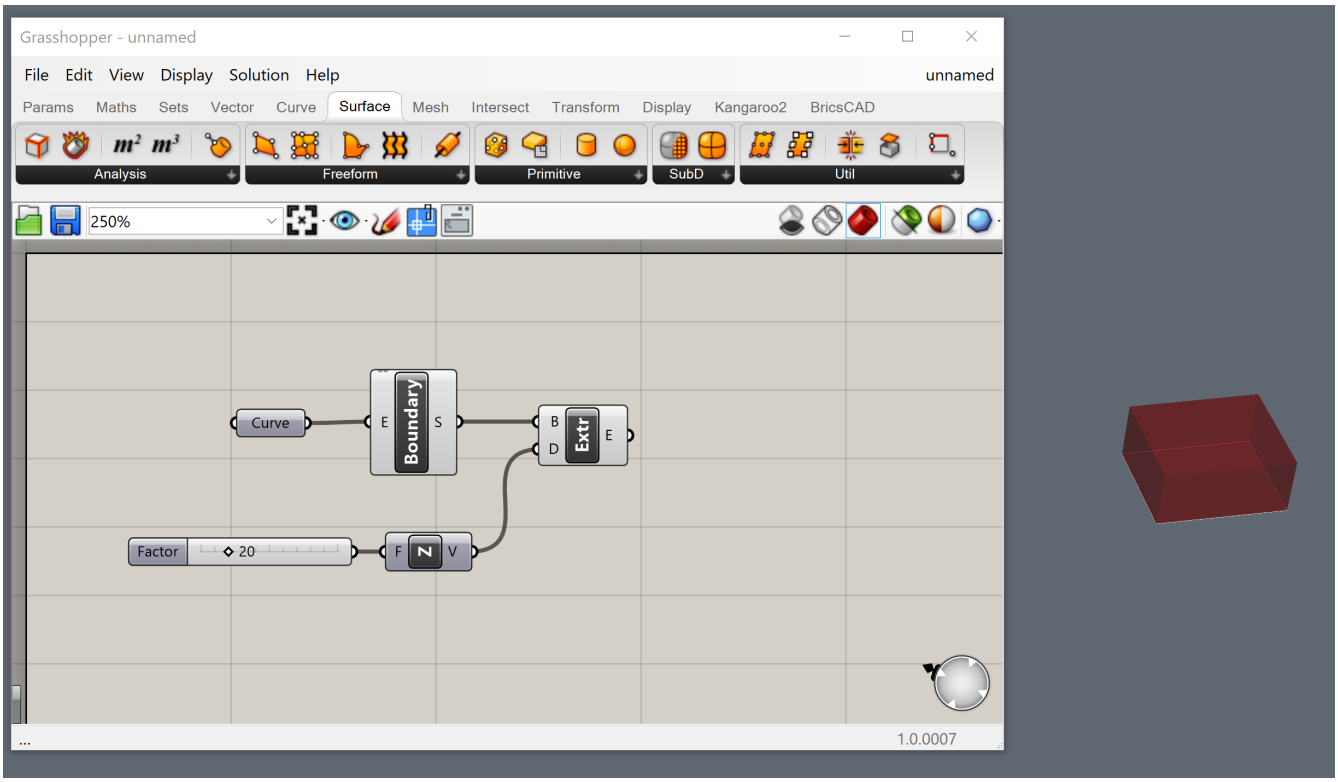
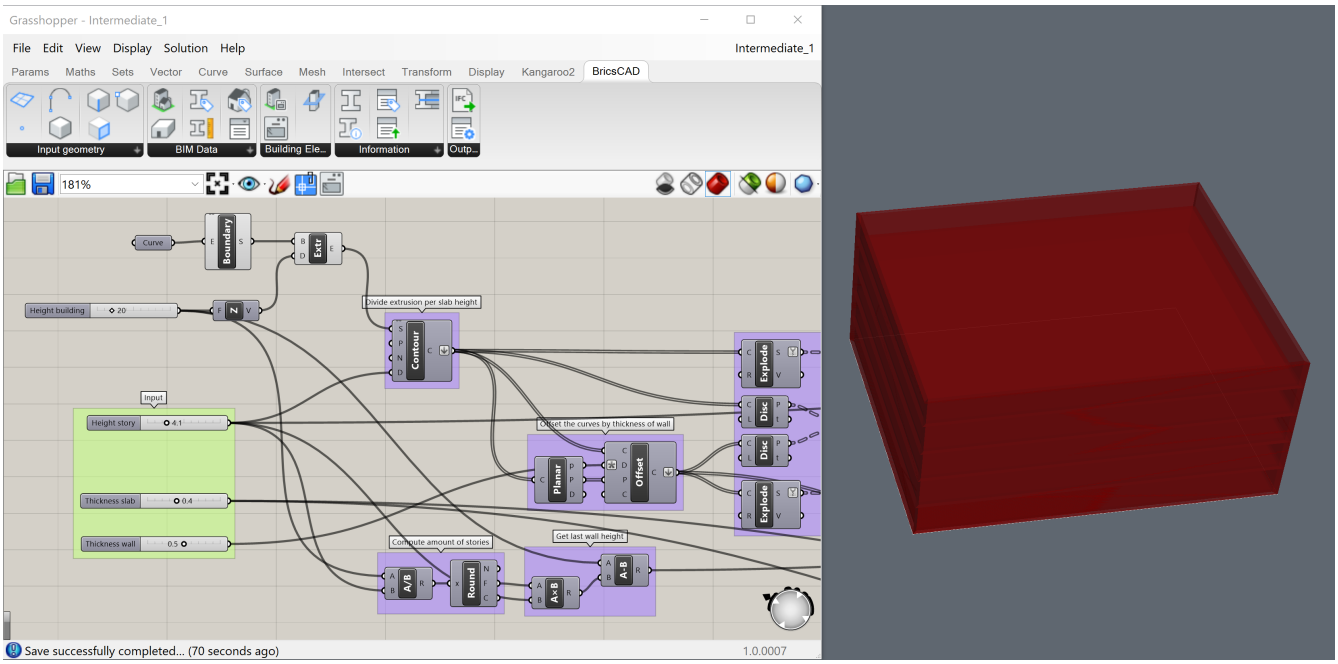


How to split up a box into different floors using Grasshopper

1. Add the 'Start_1.ghx'-code to your previous Grasshopper script.
   - You do that by downloading the zip file at the bottom of this page and extracting its content.
   - Then open the 'Start_1.ghx' file by going to **File > Open Document...** in your Grasshopper window.
   - You can now select all of the Grasshopper code by hitting **Ctrl+A** on the keyboard and copy it using **Ctrl+C**.
   - Then switch back to the document you were working on in the previous procedure by going to the upper right corner of the Grasshopper window and clicking on the title of the current document (Start_1).
   - You then get a drop-down of all the active Grasshopper scripts, so open the one you saved in 'How to draw a box in Grasshopper from a BricsCAD rectangle'.
   - Now click on the canvas and hit **Ctrl+V** to paste the 'Start_1.ghx'-code.
2. Right-click to name to rename the number slider from the previous procedure to 'Height building'.
3. Link this number slider to input A from the Division component in the 'Compute amount of stories'-group and to input A from the Subtraction component in the 'Get last wall height'-group.
4. Link your extrusion to the Shape input of the Contour component. (2.709 on the facing page)
5. Do some cleaning up of the file:
   - Drag the green 'Input' group to the front of your canvas.
   - Add the 'Height building' slider to the group by selecting the component and then right-clicking on the group and choosing 'Add to group'.
   - Put off the preview for your Boundary and Extrusion components: select the components (Shift-click them) and right-click on an empty space of your canvas and choose 'Preview Off'.
6. **(Optional)** For intermediate files that already have these changes, use 'Intermediate_1.ghx' and 'Intermediate_1.dwg'. (Located in the zip file at the bottom of this page.)
7. The script you just made allows you to:
   - Divide the extrusion per slab height, using the **Contour component**.
   - **Offset** the curves by the thickness of the walls.
   - Make the bottom surfaces of the walls (the surfaces are split into lower floor walls and roof walls).
   - Compute the last wall height.
   - **Extrude** the surfaces into roof, slabs, and walls.
   - Adapt the height of the building, the height of the stories, and the thickness of the slabs and walls, by using the sliders in the green **Input group**.

Figure 2.709



8. Add 3 **BricsCAD > Building Element > Bake Building Element components** to the end of your Grasshopper script.
9. Attach the extruded elements (the Flip components) to the Geometry input nodes of the Bake Building Element components:
   - Connect the extruded lower floor walls and extruded roof walls to one Bake Building Element component. (Hold Shift while connecting multiple nodes to one input node).
   - Connect the extruded lower floor slabs to another Bake Building Element component.
   - Connect the extruded roof to the remaining Bake Building Element component.
10. Add the following components to your canvas from the **BricsCAD > BIM Data** category: 1 **Buildings**, 1 **Stories,** and 3 **BIM Types components**.
11. Attach Buildings to the Building input of the Stories component and attach this to the Spatial Location input of all the Bake Building Element components.
12. Attach BIM Types (set respectively to BimWall, BimSlab, and BimRoof in the selection menu) to the Element Type input of the Bake Building Element components of the extruded walls, the slabs, and the roof respectively.
13. The following warning will display: **'Input parameter Building failed to collect data'.** This is because, when no buildings are defined in the BricsCAD drawing, Grasshopper fails to collect input. (2.710 on the next page)
14. To make spatial locations, for the component to detect, go to BricsCAD and click on **Home > Classify > Spatial Locations**.
15. Add a building and a few stories (more stories than you want to divide your building into). (2.711 on the following page)
16. Go to Grasshopper and right-click the Buildings component and put it onto 'Dropdown List' instead of 'Check List'. (2.712 on page 2279)
17. Select the newly made building in the dropdown.
18. Shift-select all the **Bake Building Element components** and choose the **Bake** option from the Canvas Toolbar. Click **OK** to accept the Layer, Material, and Color.
19. The drawing will now have different floors. **Note:** Check the properties to see that the geometry is correctly classified as Wall, Slab or Roof. These elements will also have a spatial location assigned to them. (2.713 on page 2280)
20. The last input geometry will be baked onto all remaining stories as there are now more stories than geometry. To correct this, select a correct subset of the stories to assign. Bake the geometry in BricsCAD and the stories will be correct. No 'duplicate' geometry will be baked. You can see how it's done by opening the 'End_1.dwg' and then opening the Grasshopper file 'End_1.ghx' that is linked to the 'End_1.dwg'.
21. You have now successfully created a building! If you want to see the result of the baked building, check the file 'End_1_Baked.dwg' or bake it yourself. (2.714 on page 2280)

How to add a railing to the top of the building

We will continue with the building made in the previous procedure. So open the 'End_1.dwg' and then open the Grasshopper file 'End_1.ghx' that is linked to the 'End_1.dwg'.

1. Add the 'Start_2.ghx'-code to the Grasshopper canvas.
   - You do that by downloading the zip file at the bottom of this page and extracting its content.
   - Then open the 'Start_2.ghx' file by going to **File > Open Document...** in your Grasshopper window.
   - You can now select all of the Grasshopper code by hitting **Ctrl+A** on the keyboard and copy it using **Ctrl+C**.
   - Then switch back to the document you were working on in the previous procedure by going to the upper right corner of the Grasshopper window and clicking on the title of the current document (Start_2).
   - You then get a drop-down of all the active Grasshopper scripts, so open 'End_1.ghx'.
   - Now click on the canvas and hit **Ctrl+V** to paste the 'Start_2.ghx'-code.
2. Link the 'Extrude Roof'-group's end component to the Brep input of the Deconstruct Brep component of the 'Select top face of roof'-group. (2.715 on the following page)
3. The script does the following:
   - The 'Select top face of roof'-group will select the top face of the roof.
   - The remaining script will take that face and use it to make the baselines for the railing.
   - It will then make the axes of the supporting columns and beams.
   - It will also calculate half of the height of the beam profile.
   - There is still a profile required, however, to complete this step and the following one. We will, therefore, create a profile from step 6 onward.
   - With that profile and the axes, the beams and supporting columns are made as extrusions.
4. The intermediate result is found in the 'Intermediate_2.ghx' and 'Intermediate_2.dwg' files. (Located in the zip file at the bottom of this page.)
5. **(Optional)** Skip the 'Select top face of roof'-group and replace it with a **BricsCAD > Input geometry > Face component**. Set to the top face of the roof slab in your BricsCAD baked building. (Do this by right-clicking on the component, click on 'Set one BricsCAD face' and select the face in the BricsCAD drawing). Connect this Face component with a **Params > Geometry > Surface component** and connect this surface to the correct inputs.
6. Go to **BricsCAD > BIM Data**. Drag the **Profile Names** and the **Profile Sizes** components onto the canvas.
7. Select 'HEA' from the dropdown in Profile Names. This dropdown displays all the names of the profiles in the Profile Library of BricsCAD.
8. Link the component to the input ProfileName of the Profile Sizes component. (2.716 on the next page)
9. Link the Profile Sizes component to the input node 'List' in a **Sets > List > List Item component**, where i is set to '4' (right-click on the **i** input and 'Set integer' to **4**). This List Item lets you pick one size from the list with all available profile sizes for the Profile Name linked to it. **Note:** If you link a **Params > Input > Panel component** to the Profile Sizes output, you will see that the index 4 stands for size 160. (2.717 on the following page) Link the Profile Names and List Item components to the **BricsCAD > Information > Library Profile component**, to get an HEA 160 profile as an output. (2.718 on the next page)
10. To get the curves that make up this profile, attach a **BricsCAD > Information > Profile Info component** to the Library Profile. One of the outputs created is the Profile Curves as tree.
11. Attach a **Surface > Freeform > Boundary Surfaces component** to the Profile Curves output node. This is to later extrude the surface as a solid, instead of the lines as a surface. (2.719 on page 2283)

Figure 2.715

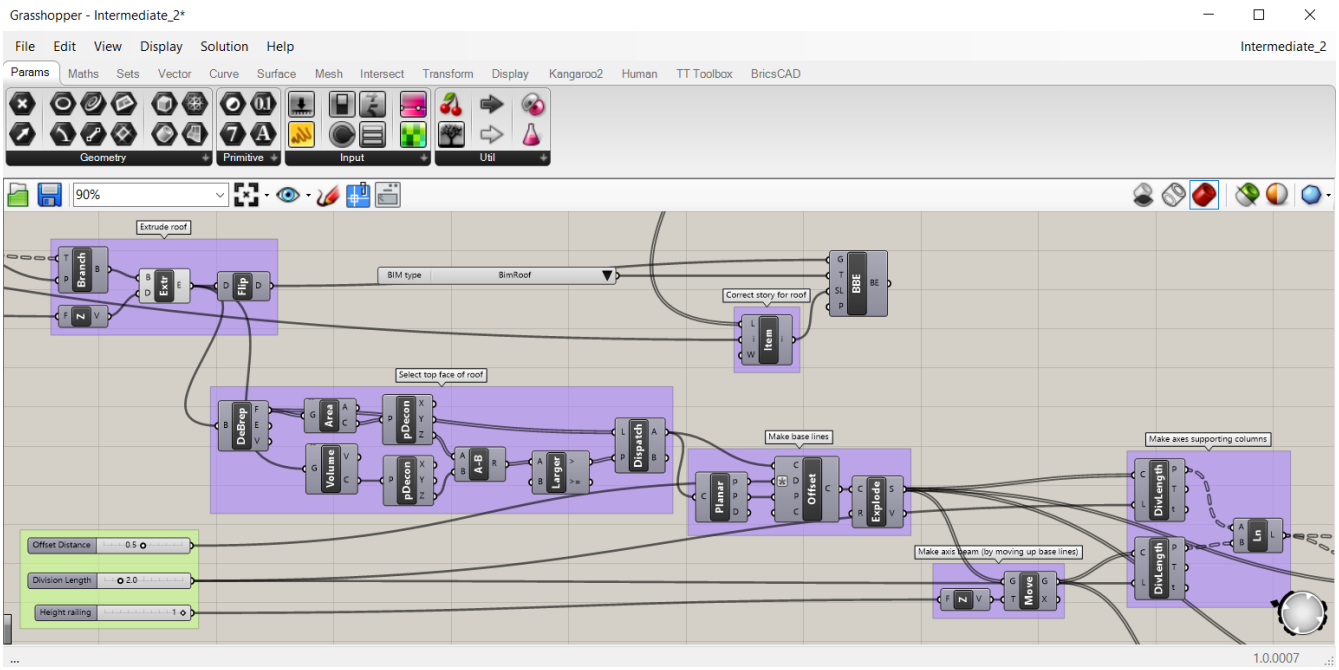

Figure 2.716

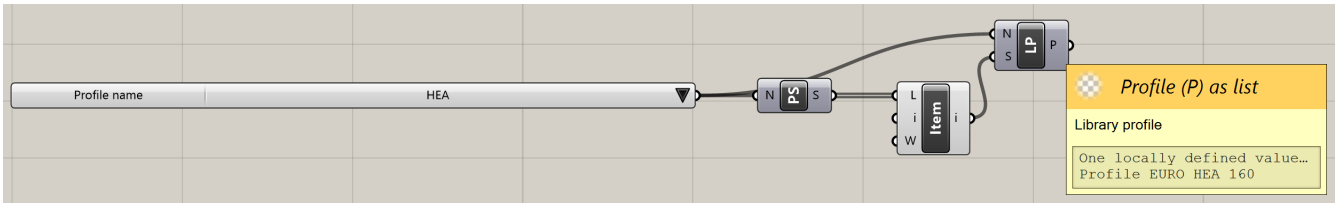
Figure 2.717

Figure 2.718



12. To group together the components just created, select them (with a selection box) and right-click on 'Group'.
13. **(Optional)** To rename the group, right-click on the purple rectangle. Rename the group in the upper text box, e.g. to 'Make profile'. (2.720 on the next page)
14. The Boundary Surfaces component should now be linked to the Content input of the Bounding Box component of the 'Calculate half of height of beam'-group. The Boundary Surfaces component should also be linked to the two Profile inputs of the Extrude components in the groups 'Make supporting columns' and 'Make beams'. The extrusions should now show you a railing with HEA 160 beams and columns. (2.721 on the following page)
15. To bake those beams and columns into BricsCAD attach two **BricsCAD > Building Elements > Bake Building Element components** to the Grasshopper canvas.
16. Do the following:
    - Set the Geometry input to the extrusions.
    - Set the Element Type input to a **BricsCAD > BIM Data > BIM Types component**, which is set to BimColumn for the column extrusions and to BimBeam for the beam extrusions.
    - Set the Spatial Location input to the same as the roof.
    - Set the Profiles input to the Library Profiles component from the 'Make profile'-group.
17. You now successfully created a railing on top of your building. (The full script to do this is in the 'End_2.ghx' file at the bottom of this page, which is linked to the 'End_2.dwg'.)
18. Bake into BricsCAD. The profiles are now set to the one in the Grasshopper script. You can still modify the connections of the beams in the corners by using L-Connect in BricsCAD. (To see the finished building with the railing on top of it, check out the 'End_2_baked.dwg' file at the bottom of this page.)

Figure 2.719

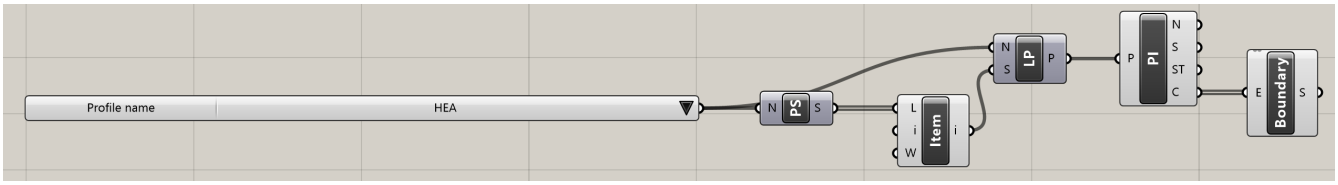


Figure 2.720

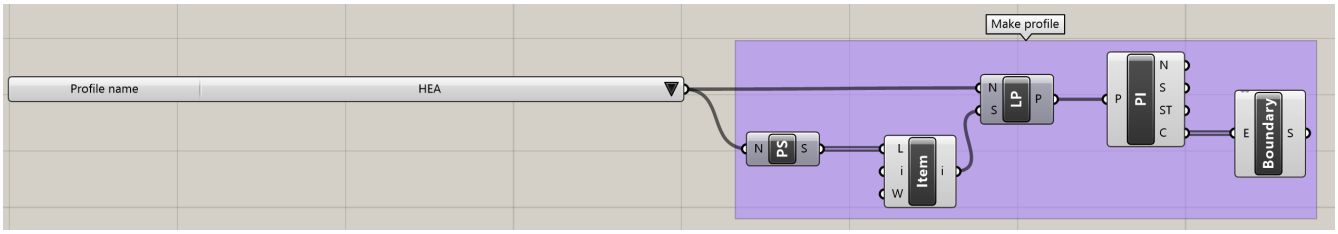

Figure 2.721

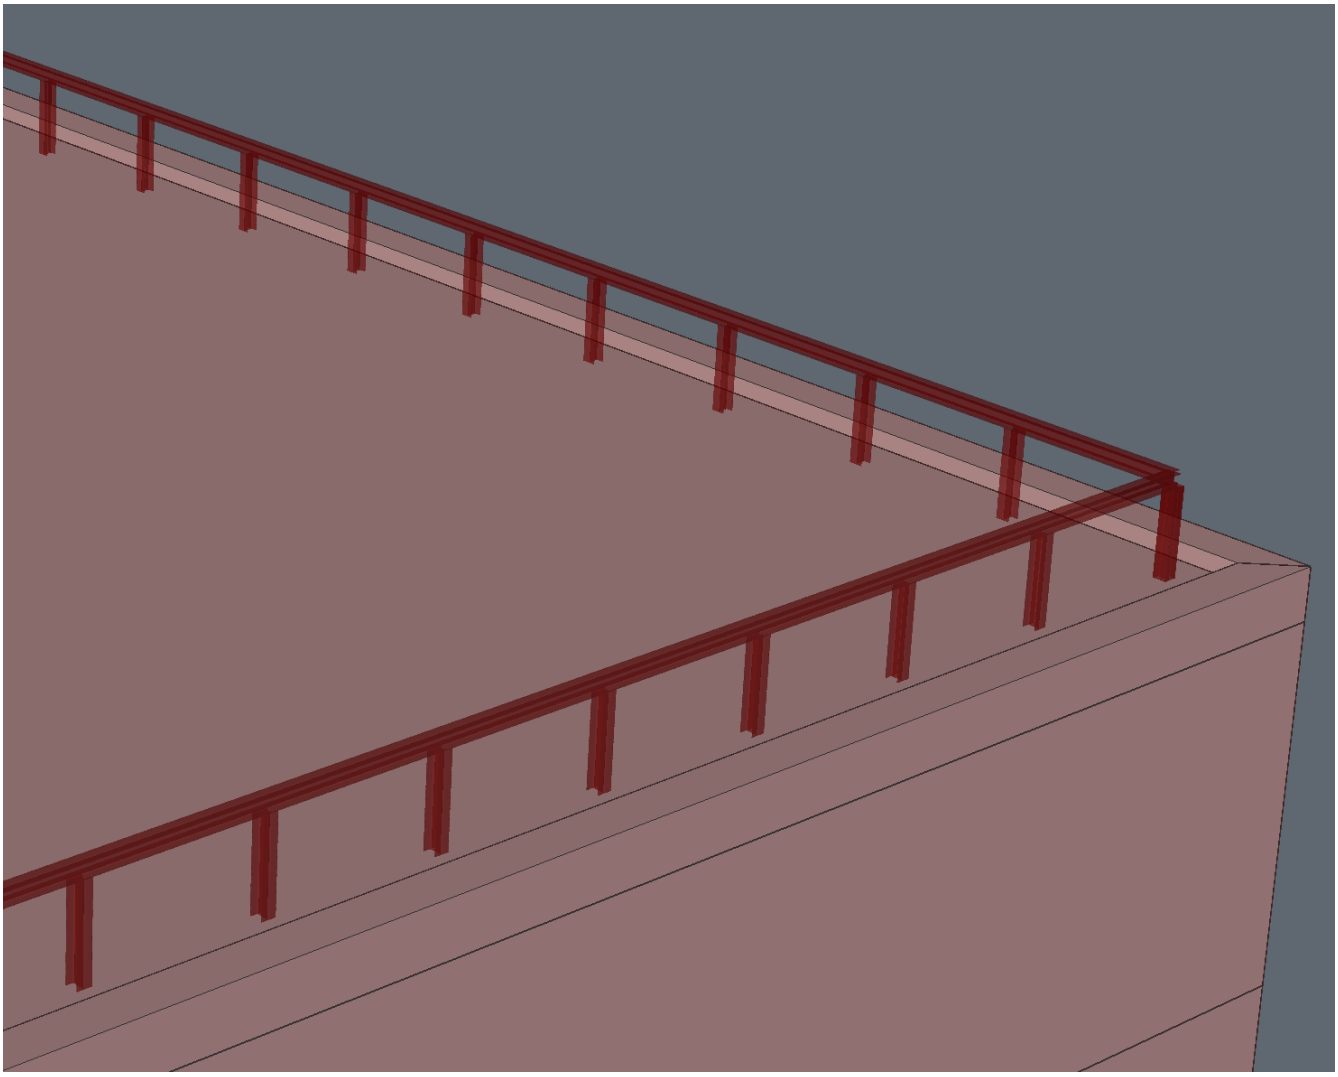

Procedure: Add information to a baked model

We will continue with the building made in the previous procedure. So open the 'End_2.dwg' and then open the Grasshopper file 'End_2.ghx' that is linked to the 'End_2.dwg'.

1. Add the 'Start_3.ghx' code to the canvas.
   - You do that by downloading the zip file at the bottom of this page and extracting its content.
   - Then open the 'Start_3.ghx' file by going to **File > Open Document...** in your Grasshopper window.
   - You can now select all of the Grasshopper code by hitting **Ctrl+A** on the keyboard and copy it using **Ctrl+C**.
   - Then switch back to the document you were working on in the previous procedure by going to the upper right corner of the Grasshopper window and clicking on the title of the current document (Start_3).
   - You then get a drop-down of all the active Grasshopper scripts, so open 'End_2.ghx'.
   - Now click on the canvas and hit **Ctrl+V** to paste the 'Start_3.ghx'-code.

   (2.722 on the next page)
2. This code has some post-baking settings of classified and baked beams and columns:
   - The script uses the **Get Properties Names component** to display the BIM properties in the **Property Category** 'Bricsys'.
   - In those properties, it selects item 1 for the columns and item 0 for the beams, 'ColumnType' and 'BeamType' respectively.
   - To conclude, it sets the properties to the value specified in the **Panel components**, using the **Set Property Value components**.
3. To make the script work, bake the two **Bake Building Element components** that make up the railing.
4. Now link the Building Element output of the **Bake Building Element components** to the respective Building Element input of the **Get Properties Names components**.
5. Also, link the Building Element output of the **Bake Building Element components** to the respective Building Element input of the **Set Property Value components**.
6. If you now select a column in BricsCAD and open its Properties, the ColumnType will be set to 'Steel column'. When you change the value of the **Panel component**, the Properties in BricsCAD change in real-time.
7. The resulting script: 'End_3.ghx' can be found in the zip file, located at the bottom of this page. It works with the 'End_3.dwg' file in which nothing is yet baked. Bake all the Building Elements, to get the post-baking settings. (2.723 on the following page)

Figure 2.722

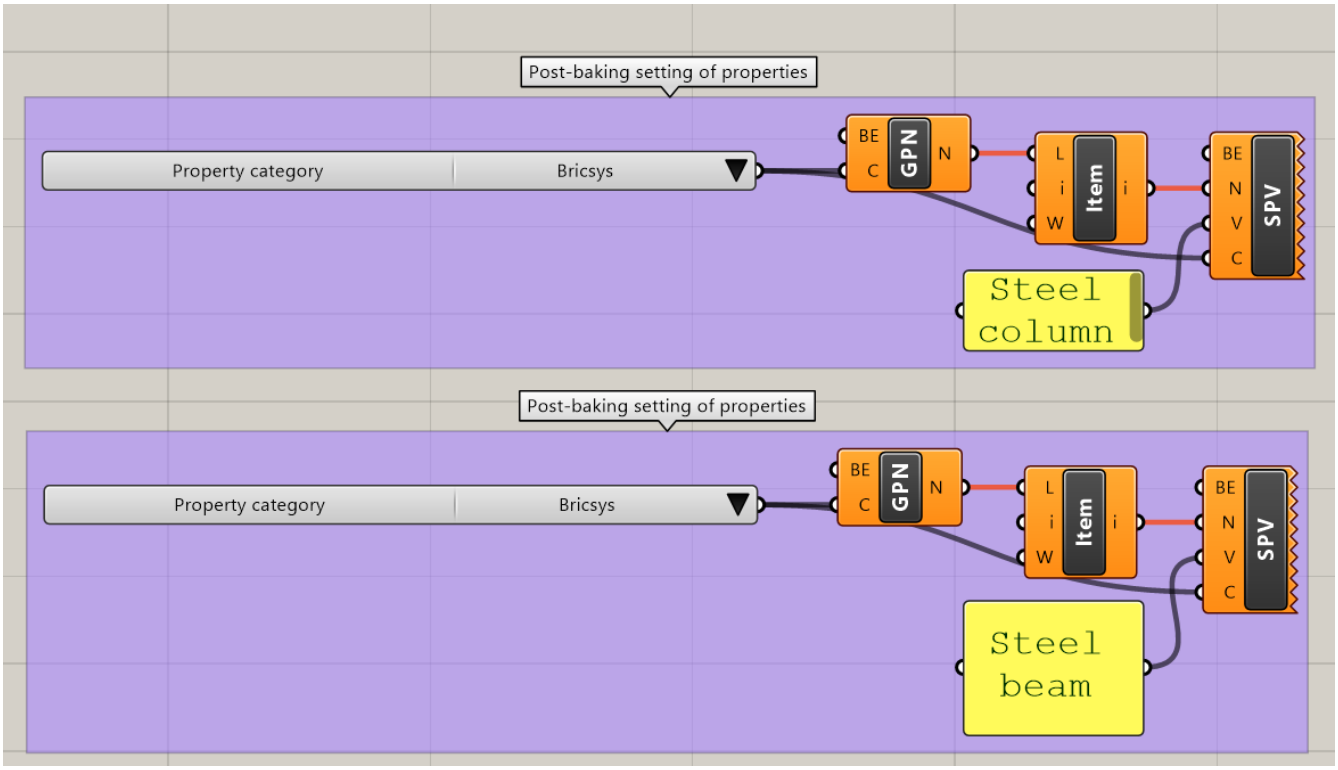

Figure 2.723

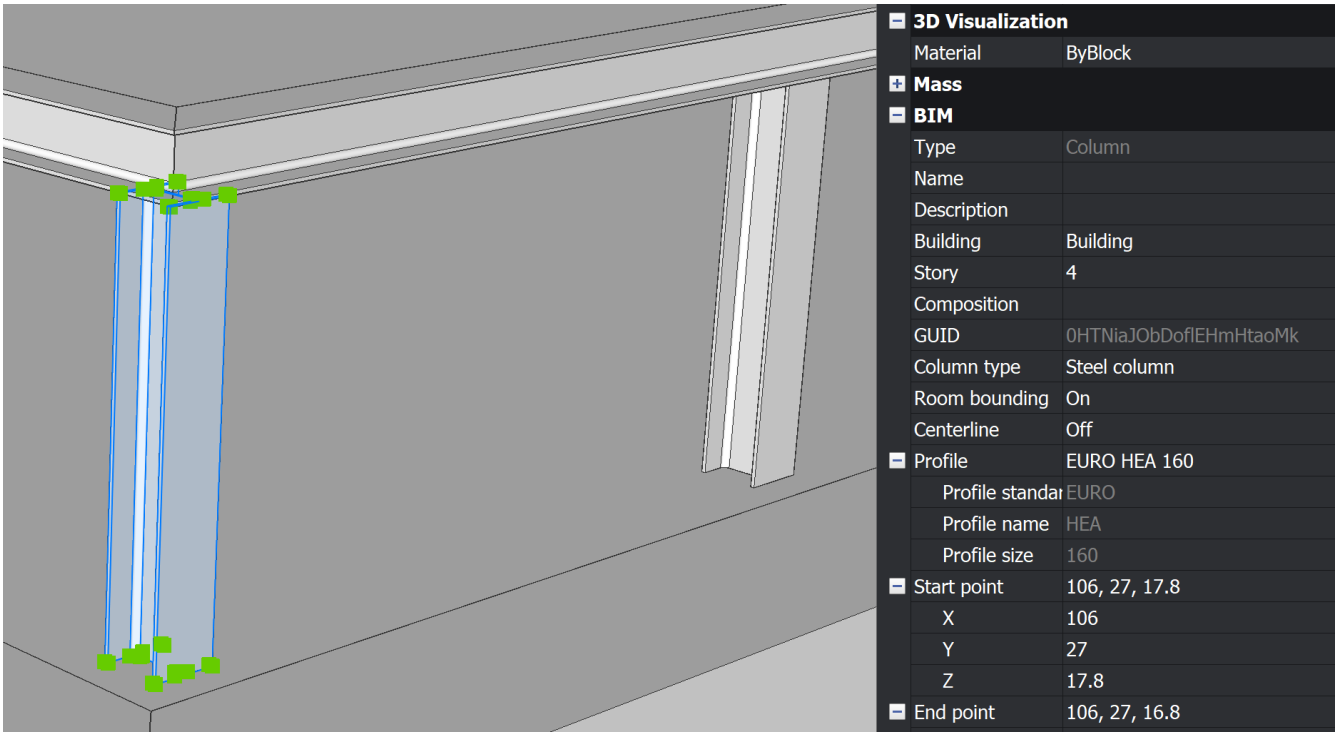

The BricsCAD toolset in Grasshopper

Icon	Name	Description
	Plane	Represents a plane in BricsCAD.
	Point	Represents a point in BricsCAD.
	Curve	Represents a BricsCAD curve.
	Entity	Represents a BricsCAD entity.
	Edge	Represents a BricsCAD edge.
	Face	Represents a BricsCAD face.
	Vertex	Represents a BricsCAD vertex.
	Buildings	Provides a name picker for all the buildings present in Spatial Locations in BricsCAD.
	Stories	Returns all the stories attached to the input building.
	Profile Names	Provides a name picker for all the profiles present in Profiles in BricsCAD.
	Profile Sizes	Returns all the sizes attached to the input profile.
	BIM Types	Provides a type picker for all the BIM Types available in BricsCAD.
	Property Categories	Provides a category picker for all the property categories available in BricsCAD.
	Bake Geometry	Bake the Grasshopper geometry into the current BricsCAD drawing, while disregarding the BIM data attached to it. The output of Bake Geometry is a reference to the baked building element without BIM data.
	Bake Building Element	Bake the Grasshopper geometry into the current BricsCAD drawing, while adding BIM data to it. The output of Bake Building Element is a reference to the baked building element with BIM data.
	Elements on Spatial Location	By default, returns all the building elements present in BricsCAD. When using input parameters, returns the building elements filtered by element type and/or spatial location

	Library Profile	Returns a profile from the library, according to the given name and size.
	Profile Info	Returns the information (name, size, standard and curves) of the specified profile.
	Property Names	Returns the property names, attached to a building element, in the specified property category.
	Property Value	Returns the property value, attached to a building element, for the specified property name and category.
	Linear Solid Info	Returns information (axis, extrusion path and profile curves) about a linear solid present in the BricsCAD drawing.
	Set Property	Sets the property value of the building element according to the specified name, category and value.
	IFC Export	Exports the specified building elements to IFC.
	Link	Links the Grasshopper script to the open BricsCAD .dwg file.
	Bake	Bakes the geometry from the selected Bake Geometry and Bake Building Element components.

2.10 Project Collaboration

2.10.1 How to do clash detection in BricsCAD BIM

https://www.youtube-nocookie.com/embed/XmCQ8VOLcnQ This tutorial shows how the Interfere command can be used for clash detection between solids. Use the Structure browser and Layer panel for easy navigation between the collisions. Back to Tutorial Overview

2.10.2 How to import .RFA files

https://www.youtube-nocookie.com/embed/4Kff1Rzf5zA This video shows how to import .RFA files, either individually or by adding the folder location to your 'components path' so it shows up in your Components Panel.
Back to Tutorial Overview

2.10.3 How to import & export IFC files in BricsCAD BIM

https://www.youtube-nocookie.com/embed/6Q1ABXp1w2Q This tutorial shows how you can easily Import from and Export to IFC files to be able to communicate with other BIM software packages. Back to Tutorial Overview

2.11 Project Collaboration

2.11.1 BIM Collaboration Format (BCF) Panel

About BCF

The BIM Collaboration Format (BCF) is an open file format used to exchange textual comments, images, and more on top of an IFC model. This allows better communication between different parties in the BIM process. BCF makes it possible to link information such as a comment, a screenshot, a list of involved objects, and a camera viewpoint to an issue. An issue can be anything ranging from a small change in the design to clashes between different disciplines in the model. These issues can then either be saved as .bcf files or they can be managed on the cloud, using any sort of BCF cloud management system. The advantage of BCF is that it allows communication over different software packages (e.g. a BCF issue created in Solibri can be opened in BricsCAD BIM), and that it enables easy navigation through a model based on issues.

BCF files

Issues can be saved in standalone files. This is generally a more cumbersome workflow than working with a cloud system but it can be useful in case you are working offline. A .bcf file can then be imported in any BCF manager (e.g. BricsCAD BIM) to read the issues and see where in the model it applies. Note that a .bcf file cannot be created in BricsCAD BIM. For this, you will need access to another service e.g. Solibri Model Checker or BIMcollab ZOOM. This software allows you to create a .bcf file based on one or more .ifc files. You can then create issues containing:

- Comments
- Screenshots or other images
- A list of involved objects, based on GUID (Global Unique IDs) to distinguish them unambiguously
- A camera position

Using the cloud

It is generally easier to use cloud services to manage BCF issues. Currently, BricsCAD BIM supports connection to three such services: **BIMcollab, BimSync** and **BIMtrack**. If you wish to connect to these services from within BricsCAD BIM you will need an account of these services first. These allow you to create issues and manage them in real-time from anywhere. Note that it is not possible to **create** issues within BricsCAD BIM. The BCF Panel allows you to connect to these services from within BricsCAD BIM, log into your account and add comments, screenshots or change statuses of existing issues.

The BCF Panel

The BCF Panel can be opened by clicking the board pin icon on the left of your screen (1). If the icon is not there, right-click an empty space in the ribbon and under Panels (1.15.7), enable the **BIM BCF panel**. Using the panel you can either **Connect with a service** (2) or **import a BCF file** (3), as stated above. The hamburger menu at the top (4) gives you the same options, as well as refreshing the panel and clearing the sources. (2.724 on the next page) **Refreshing the panel** (5) will make sure you see the latest updates in case you are working on the cloud. **Clearing the sources** (6) will disconnect you with the cloud service in case you are online, or close the .bcf file in case you are working on an imported .bcf file. (2.725 on the facing page)

Figure 2.724

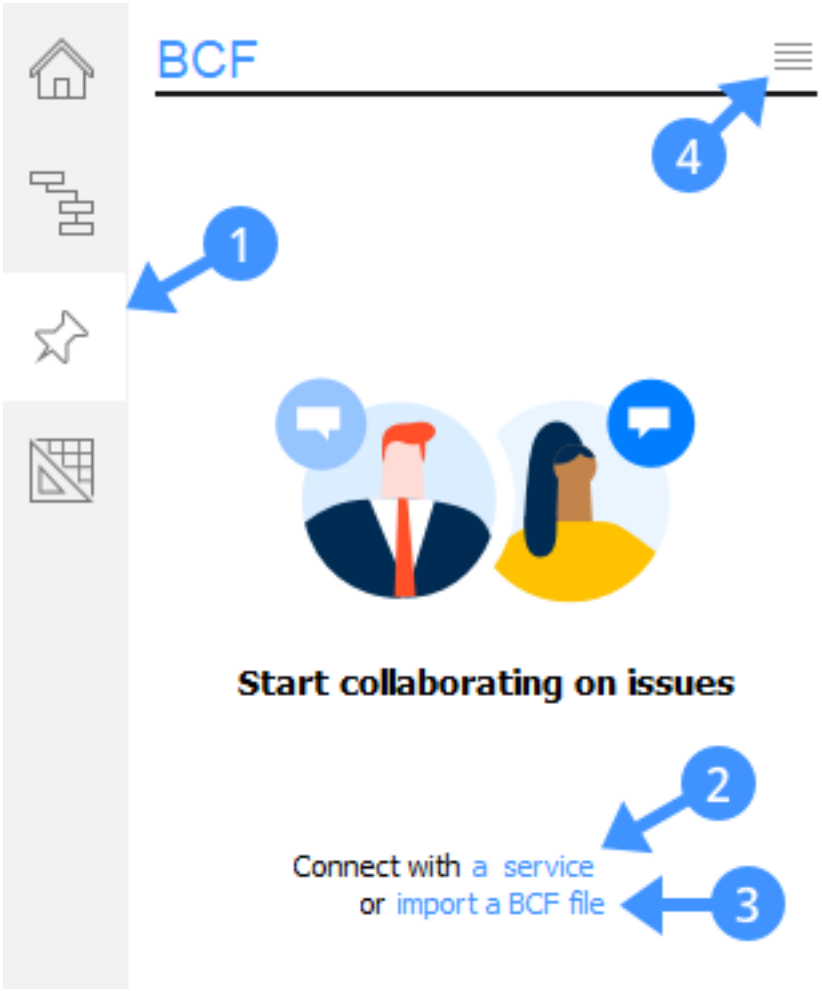

Figure 2.725

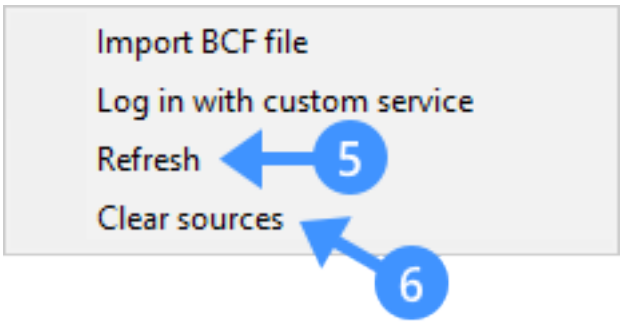

Procedure: Working with the BCF Panel

The following example will be shown with the files attached at the end of this article. If you want to follow along, open **West_str.dwg** and import **Structural_node.bcf**. When importing a .bcf file you will see the path of the currently opened file (7), a search bar that can be used to filter on issues (8) and a list of issues. In the case of this imported .bcf file, there is only one issue (9) with two associated views (10). (2.726 on the next page) Click on the issue to open it. When opening an issue you will see a button to return to the issue overview (11), some more detailed information about the issue such as status, creation date and so on (12) and different comments on this issue (13). If this comment has an associated camera position, then clicking the thumbnail image (14) will take the camera in the current drawing to this position. This is useful if you want to know where exactly the issue is and you don't want to manually search through the model. (2.727 on page 2296) When using a cloud service you are presented with some more options, such as setting statuses and adding comments and screenshots. To connect to a cloud service, click the **Connect with a service button** (2). You are prompted to enter a **Source URL** (15). The correct Source URL's for the respective services can be found in the table below.

Cloud service	**Source URL**
BIMcollab	**<space name>**.bimcollab.com *
BimSync	bcf.bimsync.com
BIMtrack	bcfrestapi.bimtrackapp.co

* Note that the Source URL for BIMcollab includes the name of the space you bought. If using a free account, use **join.bimcollab.com.** (2.728 on page 2296) The following examples will be shown on an internal cloud space so it will not be possible to follow along with these steps exactly. It is possible however to create a free account on e.g. BIMcollab. Clicking the **Log In** button should take you to a login page of the chosen service. After logging in, the source URL should be shown (16), along with a list of projects that you are involved in (17). In this example, only one project is shown with 14 issues. Left-clicking the project will open it and show a list of the issues, similar to what we saw when importing the .bcf file. (2.729 on page 2297) At the top of the panel, the current project is displayed (18). Note that now it is also possible to filter the issues on assignee (19) and status (20). This makes it easy to quickly find the issues that are relevant to you. (2.730 on page 2297) Left-clicking an issue will open it and you will see similar options as before: detailed information about the issue (12) and comments on this issue (13). However, note that at the bottom it is also possible to add bitmap images (21) or a screenshot from model space (22). You can add some textual comments as well (23). (2.731 on page 2298)

2.11.2 Bricsys 24/7 Panel

Overview: In this lesson, you will learn how to connect your BIM project with the cloud by using the Bricsys 24/7 Panel. **Lesson Objectives** After completing this lesson, you will be able to:

- Use the Bricsys 24/7 Panel inside BricsCAD BIM.
- Launch a Bricsys 24/7 project in a browser.
- Upload the current BIM model to Bricsys 24/7.
- Download and open a BIM model from Bricsys 24/7.

About Bricsys 24/7

Bricsys 24/7 helps team members to find and share their drawings. Bricsys 24/7 makes project management, a collaboration between project teams, cloud computing security, and task automation possible. A big advantage of this cloud-based service is that BricsCAD is directly linked to it by the Bricsys 24/7 Panel.

Use the Bricsys 24/7 Panel in BricsCAD BIM

1. Open the Bricsys 24/7 Panel by clicking on the Bricsys 24/7 icon in the Tool Panel on the right-hand side of the workspace. **Note:** If you do not find this icon in the Tool Panel, right-click in it and check Bricsys 24/7 in the dropdown menu. (2.732 on the next page) If you are logged out of your 24/7 account a screen will display: (2.733 on page 2301)
2. Enter your Email address and Password and press the 'Log in' button.
3. (Option) Tick the **Remember Me** checkbox to store username and password
4. Once logged on you will see an overview of your 'in the cloud' Projects, Folders, and Documents. (2.734 on page 2302) (2.735 on page 2303) (2.736 on page 2304)

(1)	**project**	The first thing you see on the 24/7 Panel when logged on, are all the projects you are assigned to.
(2)		At the top of the panel you see your project. You can go back to the overview of projects by clicking on it.
(3)	**folder**	When you open a project, a list of folders is shown.
(4)		At the top of the panel you see the folder you're in. You can go back to the overview of by clicking it.
(5)	**documents**	In a folder you find documents. On the right-hand icons are displayed: JW The profile picture or the initials from the author of the document. The document is in the cloud. Someone is currently working on the document. The document is currently uploading. JW The document is locked by someone, another person cannot change it.

2.11.3 IFC Import and Export in BricsCAD

Commands: Import (6.17.10), IFCExport (6.17.2), Export (6.13.18) **Overview:** In this lesson, you will learn how to import and export IFC files in BricsCAD BIM. **Lesson Objectives** After completing this lesson, you will be able to:

- Import an IFC model to BricsCAD.
- Export an IFC model from BricsCAD.
- Use IFC properties.

Tutorial: How to import & export IFC files in BricsCAD BIM Click here (2.10.3) to watch

About IFC

The Industry Foundation Classes (IFC) data model is designed to describe building and construction industry information. IFC is a platform-neutral, open-format file type. IFC provides interoperability between different BIM software platforms. BricsCAD BIM supports IFC2x3 and IFC4 for import and export. It is certified for IFC 2X3 coordination view 2.0. The IFC standard includes both parametric and non-parametric shapes, material definitions, metadata in the BIM file, and property sets (PSets). When you export an IFC file from BricsCAD, the properties will be exported as IfcPropertySet. These property sets contain common IFC properties. User-defined property sets can also be exported. Mechanical system layouts, structural models, and architectural models that are exported

from different IFC compliant software applications can be imported into BricsCAD BIM.

IFC2x3 vs IFC4 IFC4 is an advanced schema of IFC2x3. It is extended and overcomes certain limitations of IFC2x3. There are geometric and data improvements as well as new and changed Model View Definitions. Geometric improvements include more parametric support, more efficient handling of meshes and an improved way to add textures, lighting settings, etc. An increased number of property sets, make the IFC data model more complete and more granular. For IFC4 the coordination view has been replaced by two official Model View Definitions: the IFC4 reference view and the IFC4 Design Transfer View.

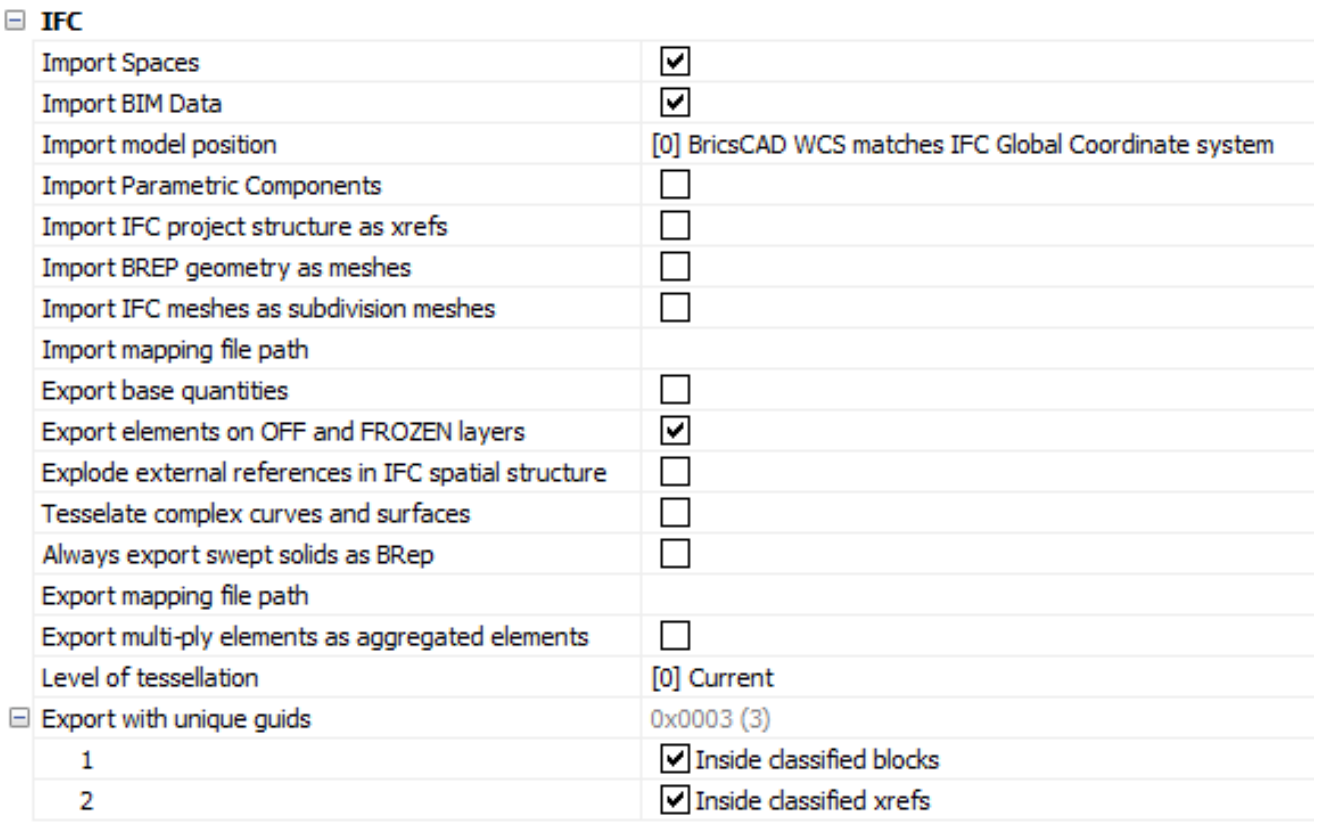
IFC import and export settings

The IFC import and export settings in the settings dialog: (2.739 on page 2308)

Import Spaces	Enable/disable the import of IfcSpace entities as BIM Spaces. If enabled, IfcSpace entities will be imported as BIM Space entities. By default, this setting is enabled.
Import BIM Data	Enable/disable the import of BIM data from different BIM platforms to BricsCAD BIM. By default, this setting is enabled.
Import model position	Controls the insertion point of the imported model. The options are: • **0**: BricsCAD WCS matches the IFC Global Coordinate system. • **1**: BricsCAD WCS matches the IFC Site Location.
Import Parametric Components	Enables/disables the import of windows and doors as parametric components.
Import IFC project structure as xrefs	Enable/disable the import of IFC project structures as separate XRef drawings. If this setting is enabled, drawing files are created as XRefs. These files correspond to each building and each story of the IFC project structure.

Import BREP geometry as meshes	Enable/disable the import of BREP geometry as meshes. If this setting is enabled, BREPs in the drawing are converted into meshes. Enable this setting to prevent BricsCAD from converting all the geometry to solids. This decreases the import time of the model significantly.
Import IFC meshes as subdivision meshes	Enables the import of polyface meshes with no limitation of the number of faces.
Import mapping file path	Allows to specify an import mapping file path, see 'Import/Export mapping of IFC files'.
Export base quantities	Enables/disables exports derived from base quantities of BIM elements. If this setting is enabled, calculated quantities (e.g. length, thickness, height) for each BIM element will be exported to IFC.
Export elements on OFF and FROZEN layers	Enables/disables the export of BIM elements that are in Off and Frozen layers. By default, this setting is enabled.
Explode external references in IFC spatial structure	Enables/disables exploded external references in IFC spatial structures. If this setting is enabled, each external reference will be divided into the elements (e.g. **IfcSite or IfcBuilding)** based on the project spatial structure. **Important note**: use the BIM Classify command to Classify Xrefs as BIM XReferences prior to doing an export with this setting enabled. Otherwise, the result will be a block per Xref.
Tesselate complex curves and surfaces	Controls whether BSpline curves and surfaces are tesselated.
Always export swept solids as BRep	Allows to export all extrusions, revolutions, swept 3D solids with clippings and subtractions using a boundary representation (BRep).
Export mapping file path	Allows to specify an export mapping file path, see 'Import/Export mapping of IFC files'.
Export multi-ply elements as aggregated elements	Enables/disables the export of building elements with multi-ply compositions as aggregated entities. If this setting is enabled, each ply material belonging to a building element (e.g. **wall or column**) is calculated and exported individually.
Level of tessellation	Controls the level of tessellation of the exported geometry. If the 'Current' faceting option is chosen, the faceting as set by FacetRes or Modeler properties is used. Choosing the 'Low', 'Medium' or 'High' options of regeneration of the facets. This makes the process longer.
Export with unique guids	Defines whether a unique GUID for nested elements should be generated upon export. 1: unique guids for inside classified blocks, 2: inside classified Xrefs, 3: to enable both inside classified blocks and Xrefs.

Figure 2.739



Import an IFC file in BricsCAD

1. To import an IFC file into your project, type **Import** into the command line. The import file dialog box displays.
2. Select the .ifc file format (1) from the **Files Of Type** dropdown list and choose the IFC model you want to import. (2.740 on the next page)
3. Click **Open** to import the IFC model. **Note:** Both IFC2x3 and IFC4 files can be imported. When the IFC file is imported the data from the imported file integrates with the BricsCAD data structure which means you can work with them right away. If the imported data contains custom properties, these property sets will be made available. You have the ability to create custom property sets and properties directly in BricsCAD BIM and associate them with imported entities.
4. **(Optional)** Change the IFC import settings using the BIM section in the Settings dialog. See 'Change IFC import and export settings'.

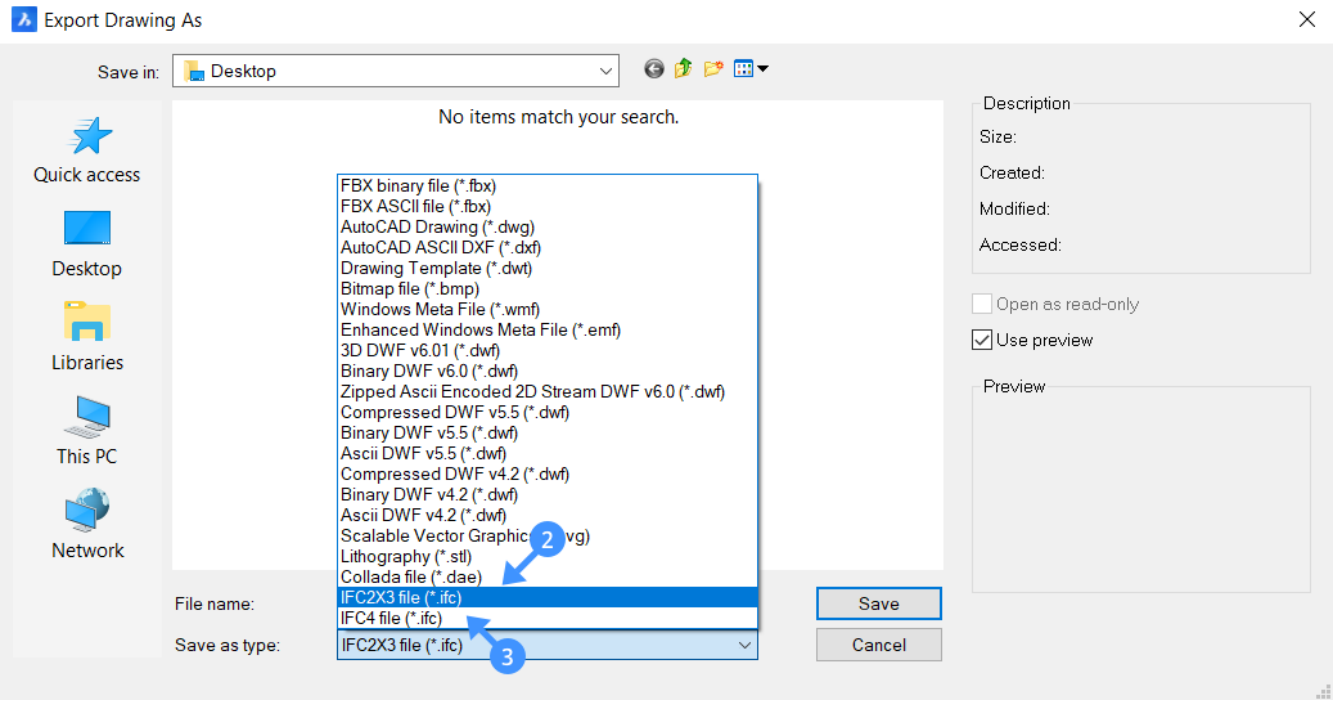
Export an IFC file in BricsCAD

1. To export an IFC file in your project, click the **BricsCAD icon** and then select **Export.** The **Export Drawing As** dialog box displays.
2. Select the desired .ifc file format in the **Save as type** list and save the IFC model in a sensible location. You have the option between IFC2x3 (2) and IFC4 (3). (2.741 on the facing page)
3. Click **Save** to export the IFC model. The exported BIM model is saved as an IFC2X3 or IFC4 file and it is now ready to use in any IFC certified application.
4. **(Optional)** Change the IFC export settings using the BIM section in the Settings dialog. See 'Changing IFC import and export settings'.

Figure 2.741



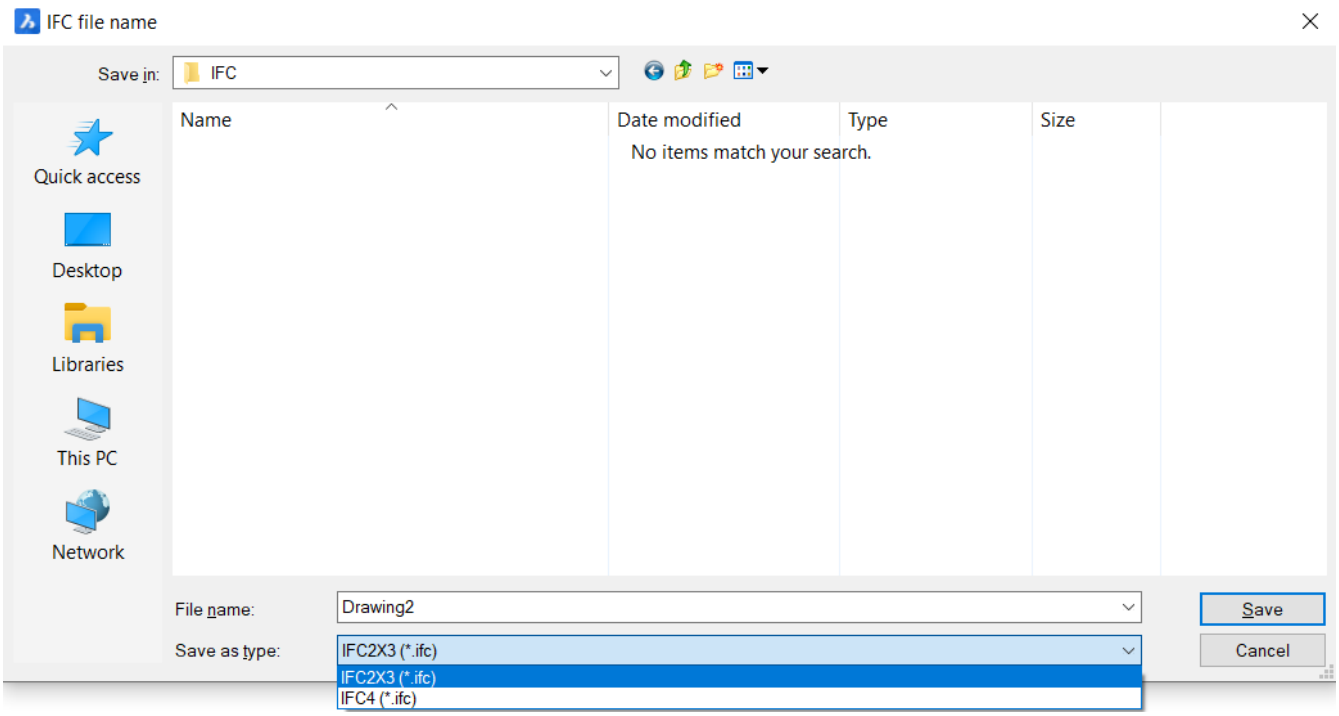
Export an IFC file only for selected entities

1. To export IFC model partially in your project, type **IFCEXPORT** in the command line **Or** press the **Export to IFC** icon in the **Home Toolbar**. **You are prompted:** Select entities to export [Entire model/selection options (?)] <Entire model>:

2. Select the entities in your model space to export as IFC and press Enter. The **IFC file name** dialog box displays: (2.742 on the next page)

3. Enter a name for the IFC file, choose the IFC format for export (IFC2x3 or IFC4) and click the **Save** button. The selected entities are exported to IFC.

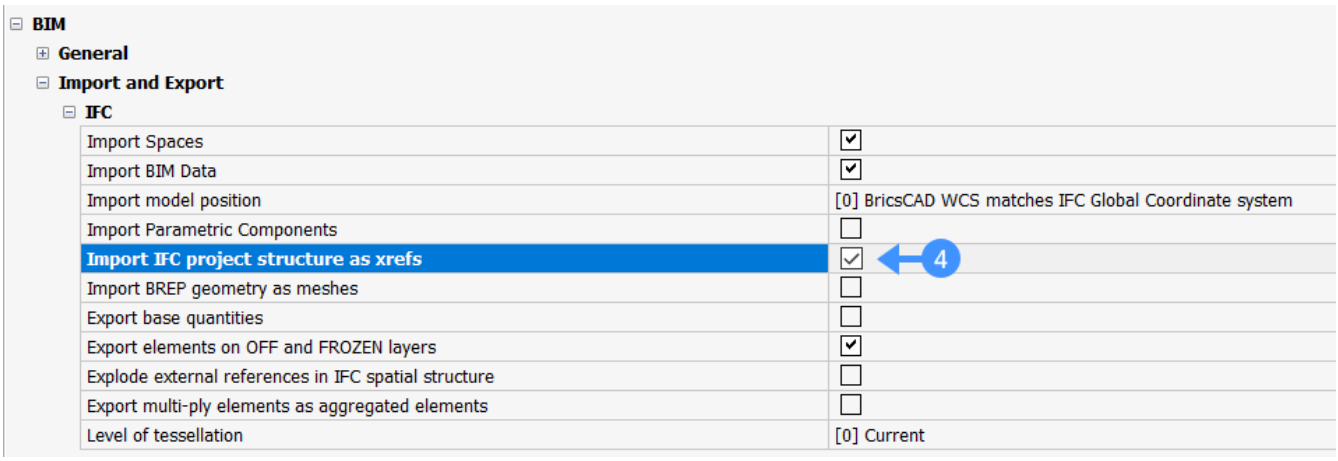
Figure 2.742



Import an IFC Project as Xrefs

1. Go to **Settings** (type **Settings** in the command line **or** go to Settings in the ribbon > Settings).
2. Navigate to BIM > Import and Export > IFC.
3. Check 'Import IFC project structure as xrefs ' box (4). (2.743)
4. Type **Import** into the command line. Specify which .ifc file you want to open and click **Open**. The drawing will now open with Xrefs made for each floor in each building. This allows you to easily split large files into smaller BricsCAD files.

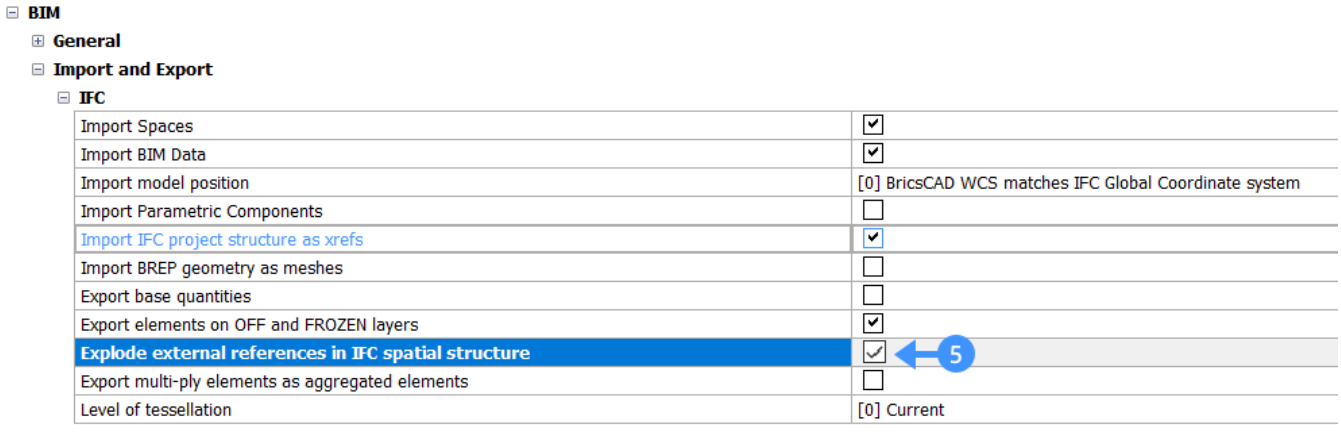
Figure 2.743



Export a BricsCAD BIM Project with Xrefs exploded

1. Use the **BIM Classify** command to Classify Xrefs as BIM XReferences. **Important note**: If you don't go through this step, your Xrefs will be exported as blocks, instead of separate entities that are part of the Xref.
2. Go to **Settings** (type **Settings** in the command line **or** go to Settings in the ribbon > Settings).
3. Go to BIM > Import and Export > IFC.
4. Check 'Explode external references in IFC spatial structure' (5). (2.744)
5. Click the **BricsCAD icon** and then select **Export**. Choose IFC2x3 or IFC4, specify the name of the exported drawing and click **Save**. The exported drawing will now have all Xref elements merged onto one Site and one Building.

Figure 2.744



Using IFC properties

1. In the ribbon go to Home > Database > Properties (6). (2.745 on the facing page)
2. Select IFC2x3 in the Namespace dropdown-menu (7). (2.746 on page 2316)
3. Search for the property you want to see in the properties list (8).
4. Set 'Visible' to 'Yes' for the section you want to see (9). Set to 'No' to hide a section.
5. In 'Categories' select the IFC Classes you wish to display (10). (2.747 on page 2317)
6. Once all properties have been set, click OK.
7. Select an object of the type/category that you just enabled the Property Set for (i.e. in this example an Energy Conversion Device). Go to the Properties Panel. Scroll down to the Properties section you just enabled.
8. Fill in the data as required (11).

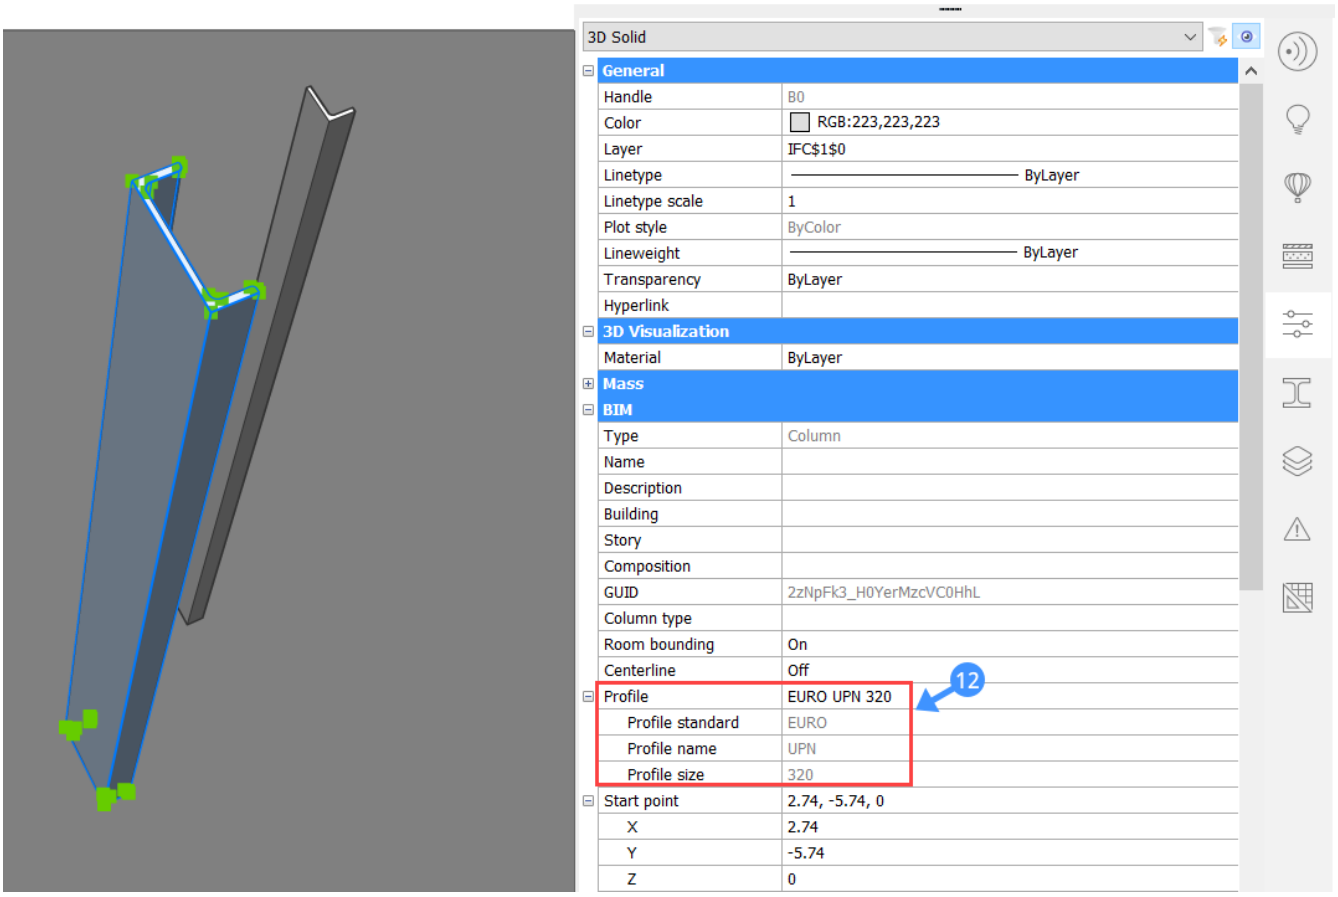
Profiles in IFC import

When importing profiles from an IFC file to BricsCAD, the profiles will be assigned with proper Profile Standard, Profile Name and Profile Size in the Properties Panel (12). (2.749 on the facing page)

Figure 2.749



Supported IFC Classes

Following IFC Classes are supported by BricsCAD BIM. These are the same categories as the classify options in the BIMClassify command. IfcWall IfcBeam IfcColumn IfcSlab IfcStair IfcStairFlight IfcRamp IfcRampFlight IfcRailing IfcCurtainWall IfcRoof IfcBuildingElement IfcSite IfcGridAxis IfcGrid IfcAnnotation IfcWindow IfcDoor IfcCovering IfcFurnishingElement IfcOpening IfcDistributionControlElement IfcDistributionPort IfcDistributionFlowElement IfcDistributionChamberElement IfcEnergyConversionDevice IfcFlowFitting IfcFlowController IfcFlowMovingDevice IfcFlowSegment IfcFlowStorageDevice IfcFlowTerminal IfcFlowTreatmentDevice IfcMember IfcFooting IfcPile IfcReinforcingBar IfcReinforcingMesh IfcTendon IfcTendonAnchor IfcPlate IfcDiscreteAccessory IfcFastener IfcMechanicalFastener IfcSpace

Exporting a structural analysis model

It is possible to export a line model of a structure using BimAnalyticalModel (6.7.6). It can either be exported to CIS/2 or to IFC. To set the export type, do one of the following.

1. Go to Settings. BIM > Import and Export > Structural Analysis Model > Export format and change the setting
2. Type **AMExportFormat** (1: IFC, 0: CIS/2)

For more information about this command, visit the Command Reference article BimAnalyticalModel (6.7.6). For more information and examples, visit the Procedure article Analytical Model (2.7.1).

Import/Export Mapping of IFC files

When you Import/Export an IFC file in BricsCAD, all entities are imported/exported according to the default mapping. It is possible to import/export elements by special mapping and to exclude entities from import/export. There are different txt configurations possible.

- **No text mapping** All entities will be imported/exported according to the default mapping.
- **Import/Export an entity by special mapping** In case of import, you first write the IFC class, followed by the BricsCAD class in which the entities should be imported. For example:

```
IfcWall BimDbColumn
```

In case of Export, you first write the BricsCAD class, followed by the IFC class in which the entities should be exported. For example:

```
BimDbWall IfcColumn
```

Note: when an IFC or BimDB entity isn't listed in the Import or Export mapping file, the default mapping will be used.

- **Exclude an entity from the Import/Export** Write the IFC or BimDb entity followed by 'skip'. For example for Import:

  ```
  IfcWall skip
  ```

  For example for Export:

  ```
  BimDbWall skip
  ```

- **Import/Export only the listed entities** List the entities that should be imported/exported followed by '* skip' on the next line. The asterisk refers to all not listed entities.

  ```
  * skip
  ```

- **Import/Export all not listed entities by the same special mapping** Write the asterisk followed by the name of the class in which the entities should be imported. For example for Import:

  ```
  * BimDbWall
  ```

  For example for Export:

  ```
  * IfcWall
  ```

- **Import/Export entities by default mapping when using the asterisk** If you used one of the two previous options to skip all entities except the listed ones or to Import/Export by special mapping, you can still Import/Export entities by default mapping. Use the same text as you use to Import/Export an entity by special mapping. Instead of writing a special mapping next to the entity, write the default class or write 'default'. For example for Import:

  ```
  IfcWall BimDbWall or IfcWall default
  ```

  For example for Export:

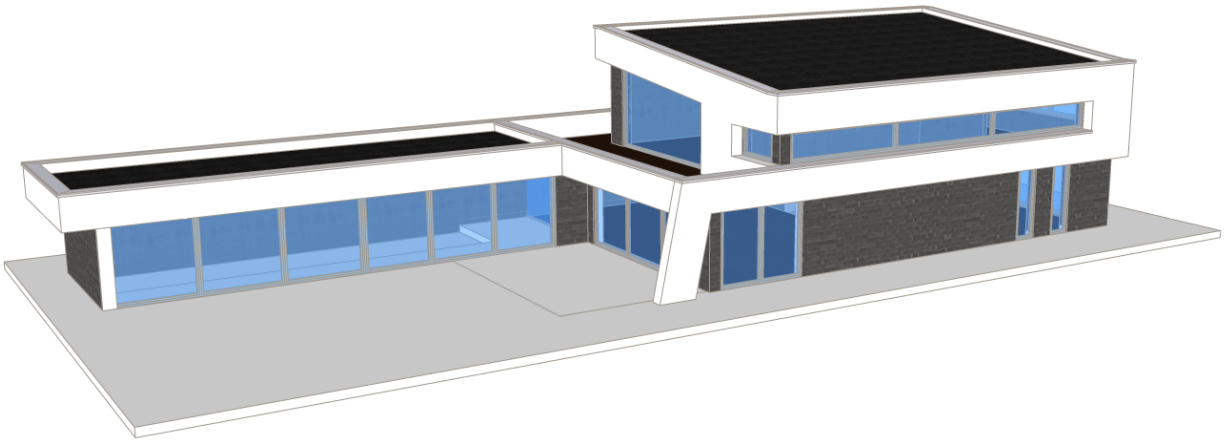
  ```
  BimDbBeam IfcBeam or BimDbBeam default
  ```

Note: use the rules explained in 'Procedure: Export Mapping of IFC Files' to create an Import/Export Mapping file.

Procedure: Export Mapping of IFC Files

1. Start from a similar model in BricsCAD with all the building elements classified. (2.750 on the next page) **Note**: If the elements are not classified, run Bimify to classify the model. For more information about this command, please read the command reference article Bimify (6.7.23).
2. The building consists of several building elements. Walls, slabs, doors, windows etc. (2.751 on page 2324) A custom Export Mapping file will be created to only export the geometry of the building without windows, doors or spaces. **Note:** If you export the file without a mapping file, all the elements will be exported in the default IFC class.
3. Open a new txt file to create the export mapping file. Use an ASCII text editor, e.g. Notepad.
4. Follow these rules to add the text in the txt file according to 'Import/Export Mapping of IFC files':
   - For export mapping, write the BimDb entity followed by the IFC entity. Separate the two words by a single Tab. Do not use a space or multiple Tabs to align the IFC classes. The lines with a space or multiple Tabs will not be used for Export Mapping.
   - Only write one command per line.

Figure 2.750



- If a composition is attached to a wall in a BricsCAD file, the wall will be exported as IfcWallStandardCase instead of IfcWall. **Note:** When a building entity is imported/exported by special mapping, the properties of the element will change according to the default properties of the new category.

5. Two categories need to be added in the txt file to create the Export Mapping File for this model.
   - Exclude windows, doors and spaces. The BricsCAD file contains normal windows and curtain walls, exclude both.

     ```
     BimDbWindow skip BimDbCurtainWall skip BimDbDoor skip BimDbSpace skip
     ```

   - Export beams by special mapping. Some walls are classified as beams in the current BricsCAD file. These have to be exported as walls.

     ```
     BimDbBeam IfcWall
     ```

   - The resulting file looks like this:

     ```
     BimDbWindow skip BimDbCurtainWall skip BimDbDoor skip BimDbSpace skip BimDbBeam IfcWall
     ```

     Note: you can also create a file where you include the entities you want to export, followed by '* skip'. This will give the same result.
6. Save the file to your computer.
7. Go to the BricsCAD file you want to Export.
8. Go through one of the following steps.
   - Type **Settings** in the commandline and press Enter. Go to BIM > Import and Export > IFC > Export mapping file path. Click on the three dots and select the mapping file on your computer. (2.752 on page 2325)
   - Type **IFCExportMappingPath** in the commandline. **You are prompted:** New value for IFCEXPORTMAPPINGPATH <"">: Copy the path of the destination file in the commandline and press Enter.
9. Type **Export** in the commandline and press Enter **or** click the BricsCAD icon in the ribbon and select Export to export the file.
10. Select the desired .ifc file format in the **Save as type** list and save the IFC model to your computer.
11. To check if the IFC file is correct you can open the file in an IFC viewer **or** you can import the file in BricsCAD without an Import Mapping file. Type **Import** in the commandline, Press enter, select the file on your computer and click **Open**. (2.753 on page 2325)

Note: The same workflow can be used to use Import Mapping of IFC Files. To use the import mapping, the model should contain BIM information. Start from a model that is divided into different IFC elements.

2.11.4 Import and Underlay Autodesk® Revit® files in BricsCAD

Command: Import (6.17.10) **Overview:** In this lesson, you will learn how to import and underlay Autodesk® Revit® files in BricsCAD. **Disclaimer:** Unless otherwise indicated, the word "Revit" used in this article refers to the Revit® software and its peripherals by Autodesk®. **Lesson objectives:**

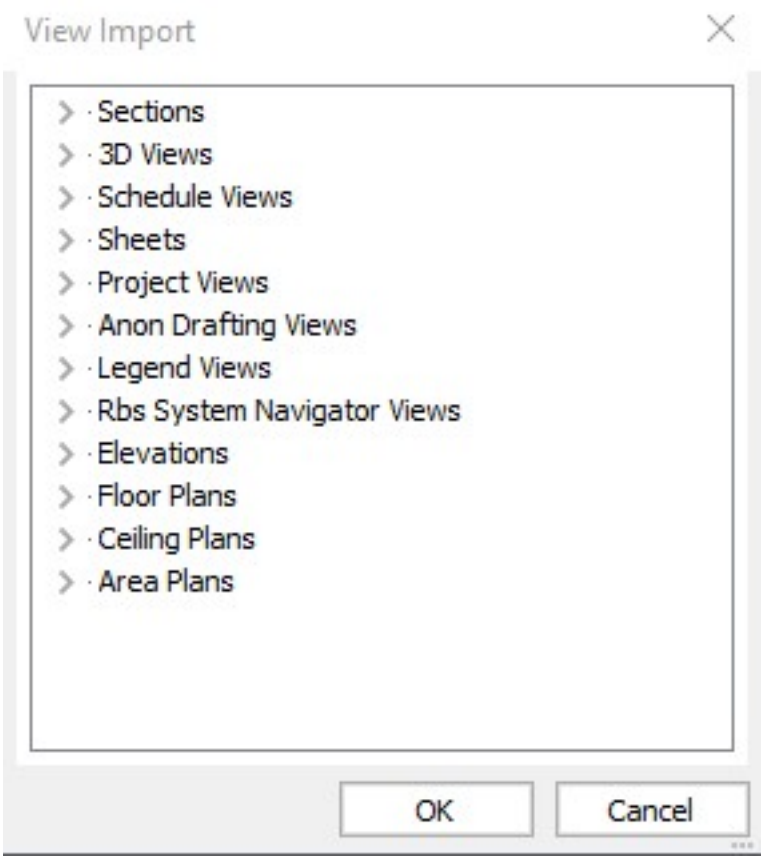
- Import a Revit model (.RVT) as solid geometries in BricsCAD.
- Import a Revit model (.RVT) as a geometry underlay in BricsCAD.
- Import a Revit family (.RFA) in BricsCAD.

Tutorial: Importing a Revit model (.RVT) Click here to watch
About Revit Import The Revit import function allows you to import .RVT files into BricsCAD as 3D solids or as a geometry underlay for referencing purposes. However, any project data and model metadata, i.e. Constraints, Wall Type structure assembly, materials etc., from the Revit model are not imported. You can also choose to import selected geometries by 3D Views, by Family Categories, by Levels or by View Worksets, depending on how the Revit project file has been set out. If you import the RVT file as a solid, only the geometry will be imported with no BIM metadata attached to it. The solids can later be classified and edited with direct modelling tools in BricsCAD. If you import the RVT file as an underlay, almost like how an XREF (2.11.7) is used, the BricsCAD model performs faster and smoother generally. This process also takes a shorter time than importing as a solid. However, the underlay model becomes an OdRvtEntity, like an uneditable, singular block. This method is particularly useful if you are looking to import the Revit model only for reference and coordination purposes, i.e. importing a Revit structural model to look for clashes with your architectural / MEP model within BricsCAD. BricsCAD V21 currently supports the import of **Revit 2015-2020** files only. If you would like to import a model created in a later version of Revit, please consider importing the model into BricsCAD as an IFC file. For more information, please visit the IFC Import and Export in BricsCAD (2.11.3) article.

Procedure: Importing a Revit file as a solid in BricsCAD

1. Open a new BricsCAD file.
2. Type **Import** in the command-line and press Enter **or** click the BricsCAD icon in the ribbon and select Import to launch the Import command.
3. The Import File dialog box pops-up. Select Revit Project (*.rvt) in 'Files of type', select the file you want to import from your folder and click **Open**.
4. **You are prompted:** Choose import mode as [Import/Underlay]: Type **I** and Press Enter to select Import.
5. **You are prompted:** Choose elements [**A**ll/by **V**iews/by **C**ategories/by **L**evels/by **W**ork**S**ets]: There are different filters to import a file. Select the filter you want to use by clicking into your desired option in the command-line or by hitting their respective letters in bold.
   - **All** All elements present within the RVT file will be imported.
   - **By Views** Select a view from the View Import dialog box and the elements will be imported based on the view's Visibility/Graphics Overrides settings in Revit. The views are structured based on their View Types. (2.754 on the next page) You can expand any relevant or applicable View Type category for the specific views. It could look like this, if the 3D Views category is expanded: (2.755 on page 2328) **Note**: Importing elements via a 2D view, ie. Floor Plans etc., only brings elements that are made visible in the Visibility/Graphic Overrides in the Revit model settings for that particular view. It does not necessarily bring elements hosted onto its corresponding level, if they are made hidden on the plan view.
   - **By Categories** You can select one or multiple built-in Categories and Element Types from the Revit Project Import dialog box. Elements of those chosen categories and element types will be imported. (2.756 on page 2329)
   - **By Levels** You can select one or multiple levels from the Import By Levels dialog box. Elements hosted to the chosen levels will be imported. (2.757 on page 2330)
   - **By WorkSets** You can select one or multiple worksets from the Import By Worksets dialog box. This method of importing works best on a workshared Revit model. It is recommended you import a Central Model to ensure you are importing the latest information in the worksets. Detaching the Central Model is optional. If you import a non-workshared Revit model, only **Workset1** is available. (2.758 on page 2331) If you import a workshared Revit model, either Central or Local, the User-Created worksets within the model will be available in the dialog. The elements which belong to this workset will be imported. (2.759 on page 2332) **Note**: The **Shared Levels and Grids** and **Workset1** worksets are created in Revit by default when Worksharing is enabled and can be managed by the Revit user.
6. If you have chosen to import by view, you do not have to specify the level of detail. The Detail Level of the selected view set in Revit will be used.

Figure 2.754



7. For the rest of the other options, **you are prompted:** Import Elements with Detail Level [Fine/Medium/Coarse] : Select the level of detail you want. Type **F** in the command-line for fine, **M** for medium and **C** for coarse and press Enter. **Note:** When selecting the level of detail, make sure you are aware of how the incoming geometries have been set out in terms of Detail Levels within the Family Elements Visibility Settings in Revit.
8. Select the View, Categories, Levels or WorkSets you want to import and click **OK**. The RVT file will be imported as 3D solid geometries.
9. Now, you can classify the solid manually or automatically and/or further edit it with direct modelling tools in BricsCAD. **Note:** Some of Revit's system families, such as walls and floors etc., are imported into BricsCAD as 3D solids, where you can further manipulate their geometries directly. This also applies to Model-In-Place components and Element Types, such as Fascias, that can be defined geometrically by a Profile. However, other system families designed with in-built constraints, i.e. stairs and curtain walls etc. are imported into BricsCAD as separate Block References. For eg., Curtain Panel and Curtain Wall Mullion Types, which make up a Curtain Wall Type in Revit, will exist as separate Block References. This also applies to all other loadable families, like furniture, placed within the Revit model. For more information, please visit the article on **Working with Blocks (1.30.3)**.

Procedure: Importing a Revit file as an underlay in BricsCAD

1. Open a new BricsCAD file.
2. Type **Import** in the command-line and press Enter **or** click the BricsCAD icon in the ribbon and select Import to launch the Import command.
3. The Import File dialog box pops-up. Select Revit Project (*.rvt) in 'Files of type', select the file you want to import from your folder and click **Open**.
4. **You are prompted:** Choose import mode as [Import/Underlay]: Type **U** and Press Enter to select Underlay.
5. Follow Steps 5-7 of the 'Procedure: Importing a Revit file as a solid in BricsCAD' above.
6. **You are prompted**: Deviation value : By default, the deviation value is 0.001. Press Enter to accept **or** type a new value and press Enter. **Note**: The deviation value defines the accuracy of the imported model. A lower value will result in a finer geometry, but it will take longer time to load.

7. The RVT file is now imported as an uneditable OdRvtEntity.

Procedure: Importing a Revit family in BricsCAD

Please refer to the article **Importing Revit RFA Families in BricsCAD (2.11.5)** for more information.

Texture and graphics of the imported geometries

Although project information and element metadata in a Revit model cannot be brought into BricsCAD (just yet), there are some aspects of the imported 3D solids, i.e. Material Color, Transparency, which can be brought over and therefore correspond to the original graphics set in the Revit. To retain the consistency of the graphical information during the import process, ensure your RGB color and transparency settings set in Revit's Material Browser are set to your desired values. In the example below, the values taken will be **RGB 149 134 119** and **0** (%) for the colors and transparency values respectively. (2.760 on the next page) If the imported element is a Revit System Family with the ability to define its structure assembly, i.e. Wall Type, and is made up of various layers of materials or functions, BricsCAD applies the color template values from the outermost materials (on both the Exterior and Interior sides) accordingly on to the corresponding geometry's faces. Let's take an example from the illustration below, the values will be derived from the materials assigned on Layers 1 and 9, which are **Cladding...** and **Plaster** respectively. (2.761 on the following page) Otherwise, BricsCAD applies the color value, and the transparency settings if applicable, to the 3D solid replacing the respective parts of the Revit Family. This also applies to those Loadable Families and Components, having loaded into the imported Revit project.

Figure 2.760

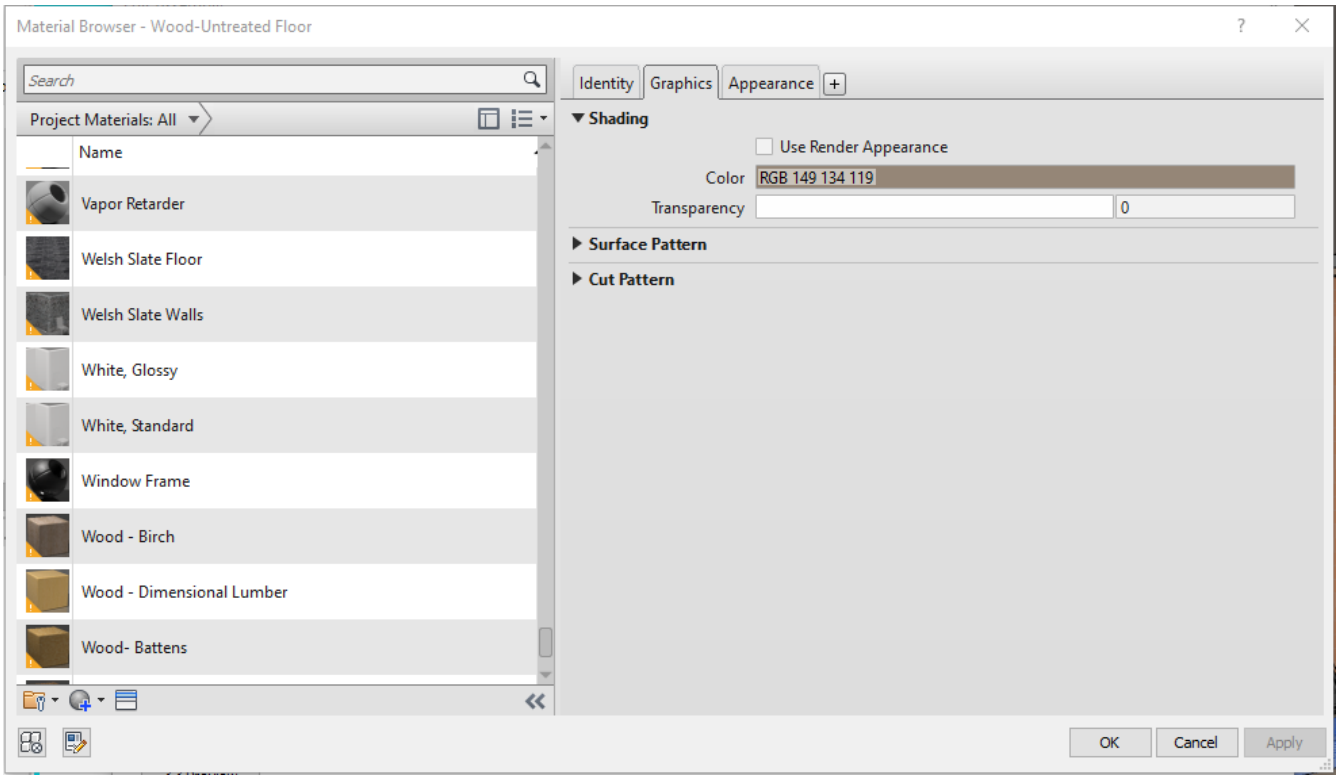

Figure 2.761

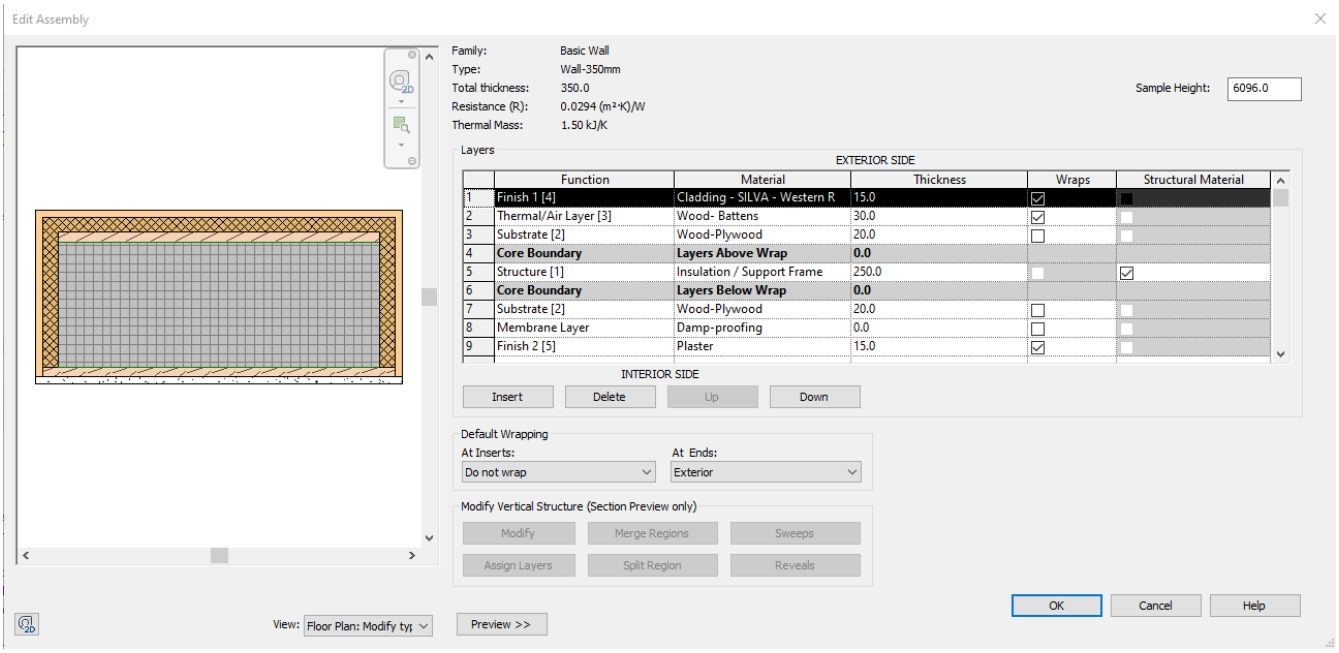

2.11.5 Importing Autodesk® Revit® Families in BricsCAD

Commands: Import (6.17.10), BmInsert (6.8.16) **Overview:** In this lesson, you learn how to import Autodesk® Revit® family files in BricsCAD BIM. **Disclaimer:** Unless otherwise indicated, the word "Revit" used in this article refers to the Revit® software and its peripherals by Autodesk®. **Lesson Objectives** After completing this lesson, you will be able to:

- Use the Import (6.17.10) command to import a Revit RFA file into BricsCAD.
- Use BmInsert (6.8.16) command to insert a RFA file as a BIM component.
- Insert RFA files from the Library panel (2.5.3).

Tutorial: How to import .RFA files Click here (2.10.2) to watch

Important notification before getting started

RFA import is a work-in-progress. See the BmInsert (6.8.16) command. BricsCAD V21 currently supports the import of **Revit 2015-2020** files only. If you would like to import a model created in a later version of Revit, please consider importing the model into BricsCAD as an IFC file. For more information, please visit the IFC Import and Export in BricsCAD (2.11.3) article.

Importing RFA family files

1. Launch the Import (6.17.10) command. The **Import file** dialog box displays.
2. Select **Revit Family (*.rfa file)** (1) in the **Files Of Type** list.(2.762 on the next page)
3. Select the .rfa file you want to import.
4. Click **Open** to import the Revit Family. When the RFA family file is imported the geometry from this file is included in BricsCAD as separate 3D solids.

Procedure: Inserting RFA family files

Notes:

- When DUCS = ON (Dynamic UCS) the RFA entity aligns with the 3D solid face under the cursor.
- When DYN = ON (Dynamic Dimensions (1.21.9)) the distances from the nearest parallel edge on the face of the 3D solid display.

Using BmInsert

1. Launch the BMINSERT (6.8.16) command. A File dialog box displays.
2. Browse to the folder where your .rfa family files are saved.
3. Select **Revit Family (*.rfa file)** (2) in the **Files Of Type** list. (2.763 on the following page)
4. Select the .rfa file you want to import. The selected file is attached to the cursor (3). (2.764 on the next page) The following illustration shows inserting a Revit family sofa when both DYN and DUCS are on. (2.765 on page 2339)
3. Do the following to place the selected RFA family file using the dynamic dimension fields:
   - Hit the Tab-key to select one of the dynamic dimension fields, then type a value and hit the Tab-key to lock the dimension. The locked dimension will turn red.
   - Repeat the previous step to lock another dynamic dimension field.
   - Optionally hit the Tab-key to adjust the dynamic dimensions.
   - Press Enter to accept the current position.

Figure 2.763

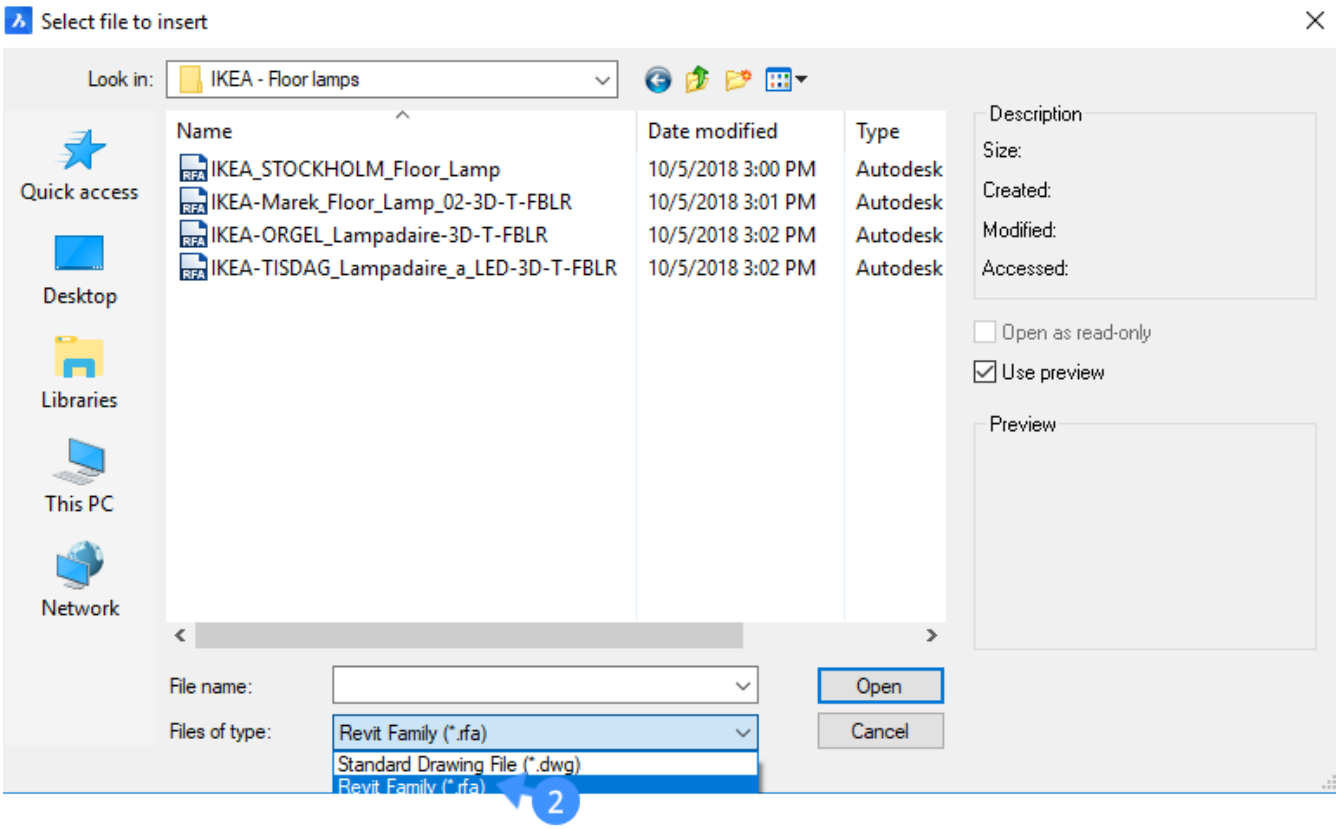

Figure 2.764

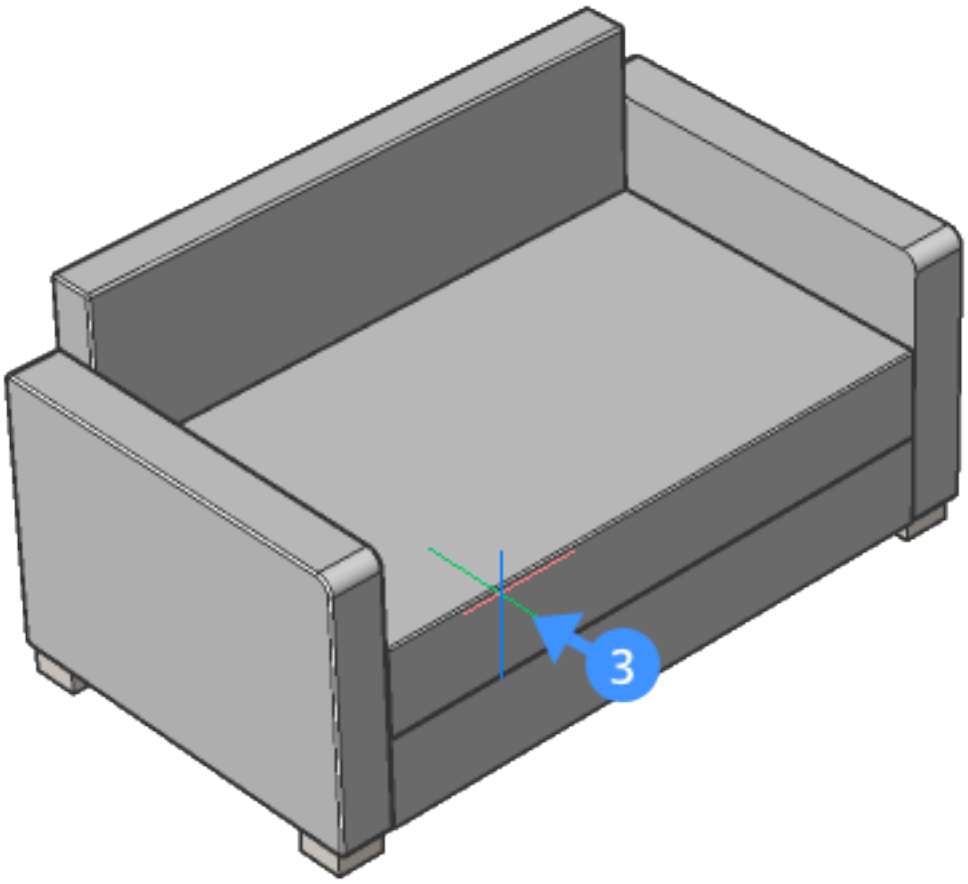

Figure 2.765

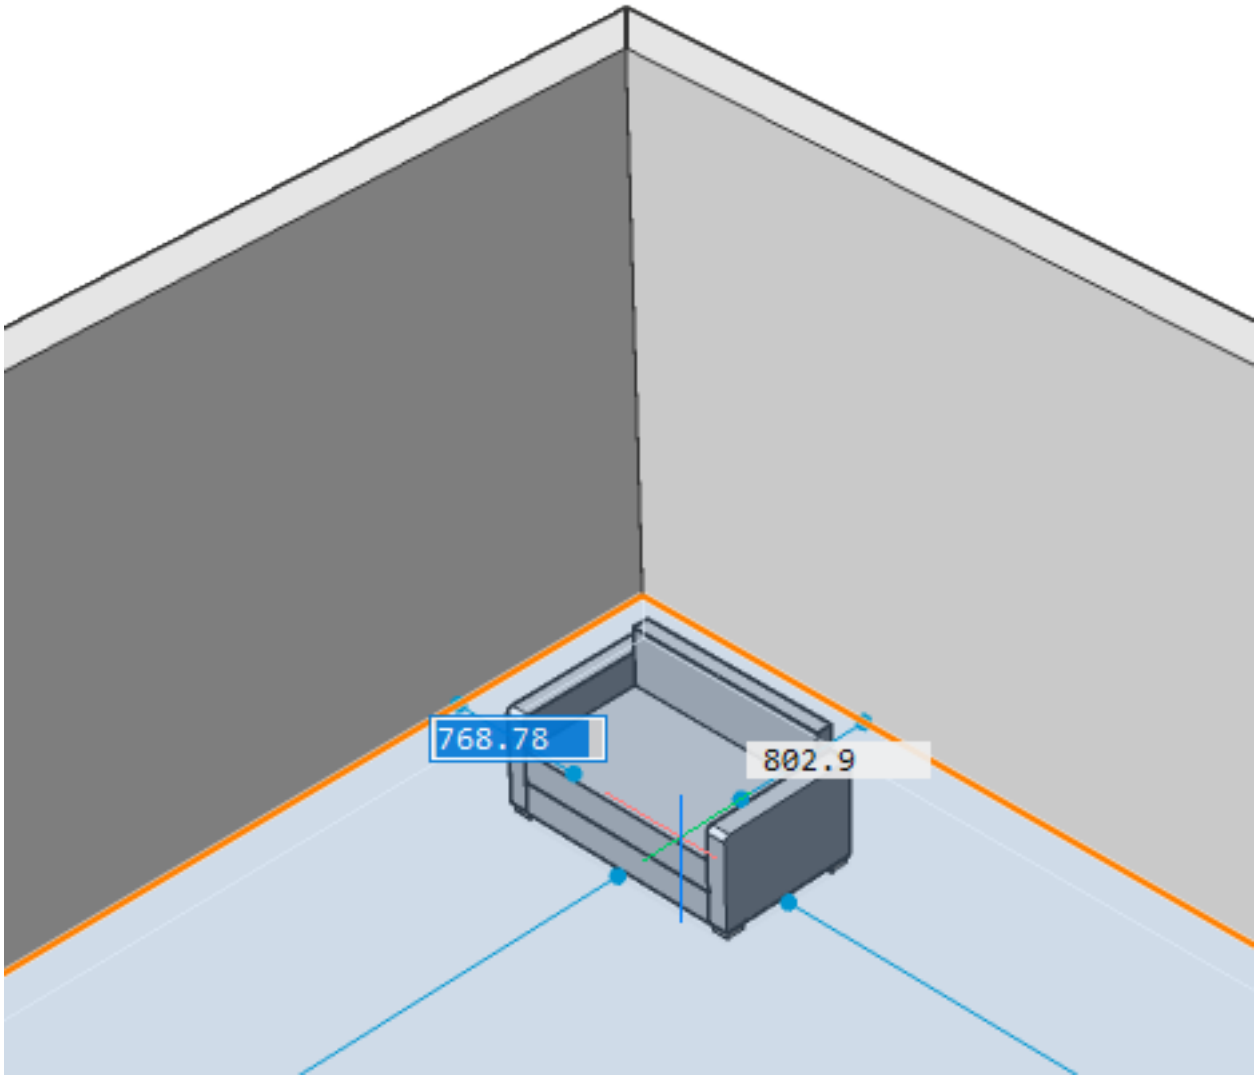

Using the Library panel

1. To insert an RFA family folder in the Library panel (2.5.3), add the RFA root folder path to the LIBRARY DIRECTORY PATH in the Settings (1.17.10) dialog box. The content of the root folder and all subfolders will be available in the Library panel. The following animated gif shows how to add the RFA root folder path to the components directory path. (2.766 on the next page) The RFA family files are ready to insert in the model space. If necessary, choose to Generate Thumbnails (6.9.26) in the hamburger menu on the Library panel.

2. Drag and drop the RFA file from the Library Panel into your model space.

2.11.6 Interference Checking

Command: Interfere (6.17.17) **Overview:** In this lesson, you learn how to do clash detection between solid models in BricsCAD BIM. **Lesson Objectives** After completing this lesson, you will be able to:

- Use the interference check tool on your existing model.
- Identify where 3D solids intersect each other.
- Remove undesired intersections among the two solid models.

Tutorial: How to do clash detection in BricsCAD BIM Click here (2.10.1) to watch

About Interference Checking

The Interference Checking tool is used during the modeling phase to find out conflicts in the model by comparing 3D solid models of building elements. Interference occurs when two 3D entities overlap in 3D space. In BricsCAD BIM, the Interfere tool helps you to find intersections between the entities that you have selected. You can also do the interference checking for all elements in your model at a time. Optionally, the tool creates interference solids after running the command. The newly created solids are placed on their own layer, as specified by the InterferenceLayer variable. Running an interference check on existing models allows you to prevent the conflicts in your entire model.  For more information about this command, visit the Command Reference article Interfere (6.17.17).

Procedure: Performing an interference check

1. Select the desired 3D solids to be checked for interference, then launch the INTERFERE command. **Note:** Multiple solids can be selected using the selection box or in the Structure Browser, depending on whether the selected entities appear when selected in the tree. The first set of entities is defined. The command line displays how many entities in total are set for interference checking e.g. Entities in set: 20. Note that **Nested Selection** option allows you to select 3D solid models that are inside blocks and external references (XRef) and once they are selected you can compare them against other entities in the selection set.

2. Select the 3D solids in the model to add them to the second set of entities. The entities in the first set are compared with the entities in the second set. **Note**: If you Press **Enter** key without selecting any solids for defining the second set of entities, the entities in the first set will be compared to each other.

3. Press **Enter** to run the interference check.

4. The interference volume is created for each collision and it is shown in a solid model. **Note:** The solids of the interference volume are displayed in red since they are placed on layer **Interference.** The default settings on the Interference Checking tool makes it easy to find the intersecting solids in the model. This setting can be changed using the prompt menu or the command line. To open it, click the Settings option in the prompt menu or type "S" while the interfere command is still active. The Interference Settings dialog box displays. The dialog box allows you to configure interference settings, which are stored in variables. The following illustration shows the Interference Settings dialog box. The table below presents each component of the dialog box. (2.767 on the facing page)

Create Interference Solids box (1)	Determines whether a solid or region of the interference is created. Check to create a solid of the interference volume or region of the interference area.
Layer (2)	Shows the current layer for interferences.
Color (3)	Shows the current layer color.

The following illustration shows the detected collision (4) between the floor slab and column. (2.768 on the next page)

5. To remove the undesired intersections, turn off the Interference layer, and perform one of the 3D solid modifying tools e.g. **BIM Drag** or **Subtract** on the interfering solid. This process will let you make the necessary corrections in your model. In the following illustration, the created solid of the interference volume is shown (5). In the second image, the intersection is fixed by subtracting the slab geometry from the column. (2.769 on page 2344) (2.770 on page 2344)

Figure 2.767

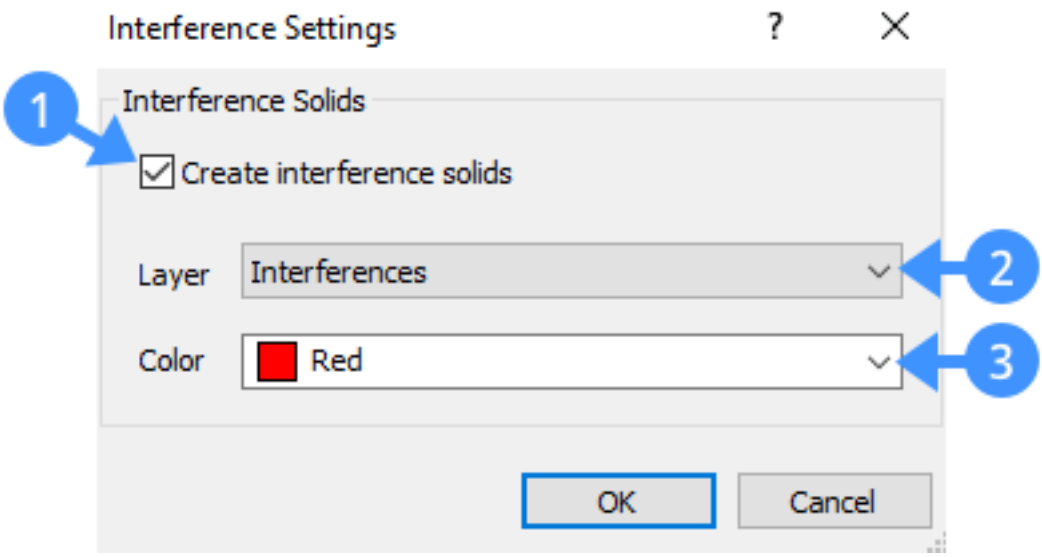

Figure 2.768

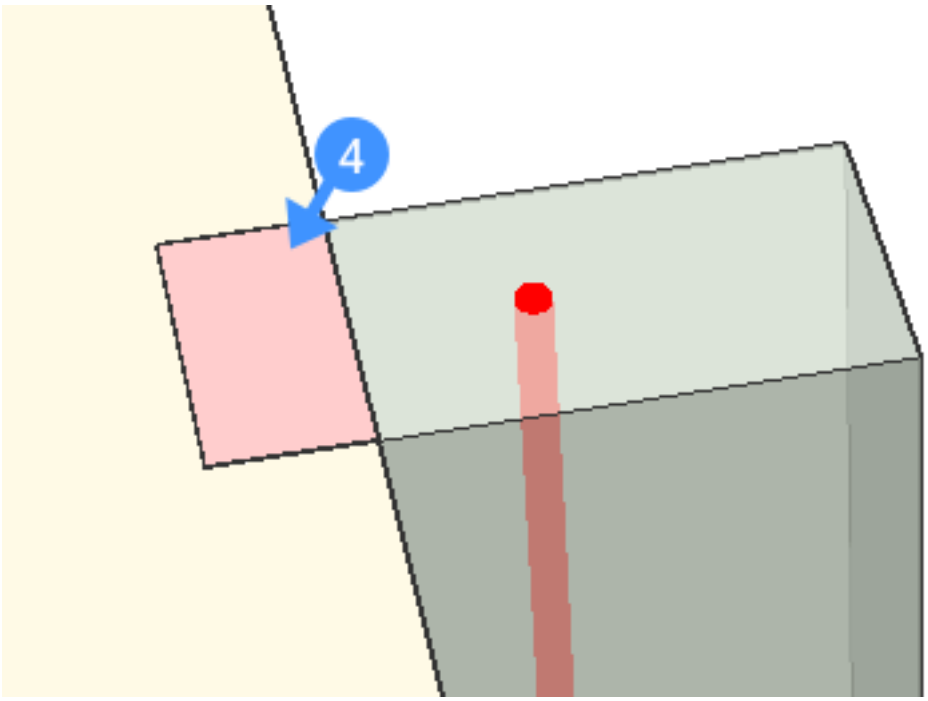

Figure 2.769

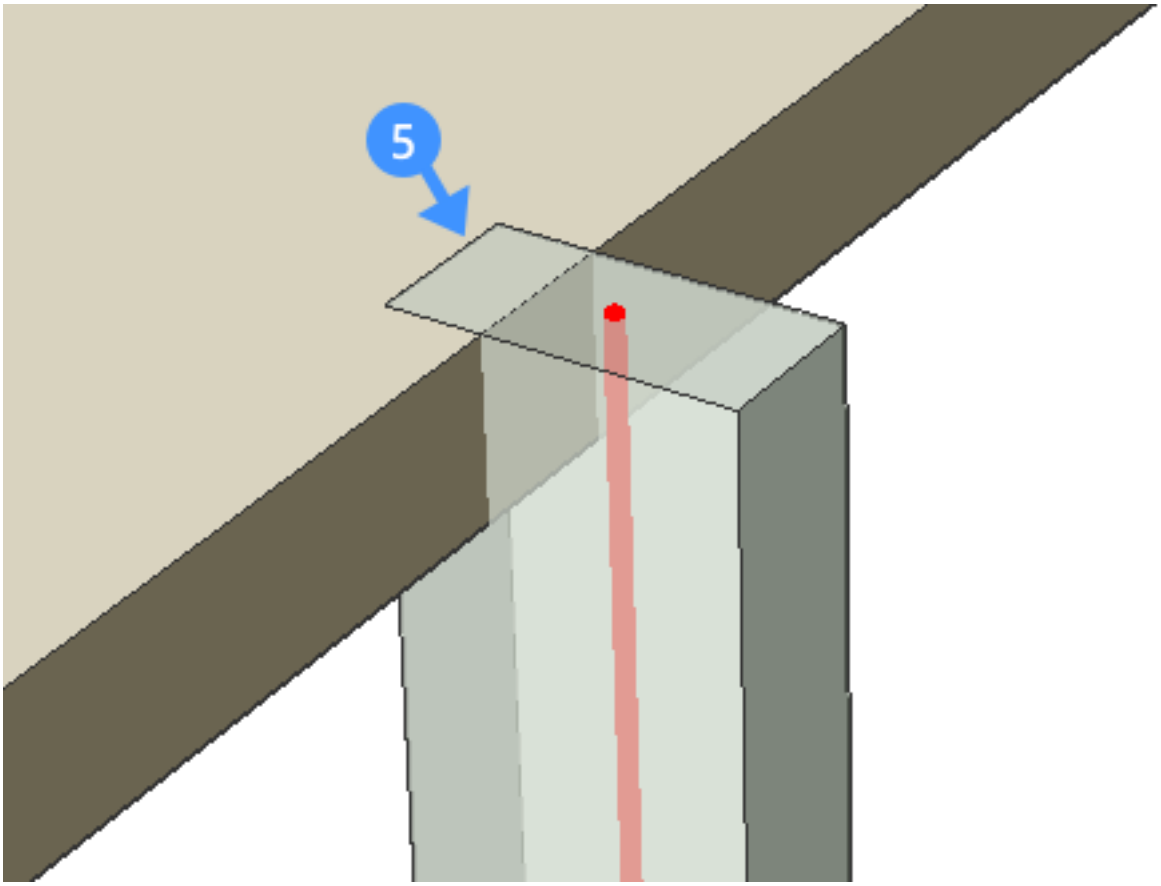

Figure 2.770

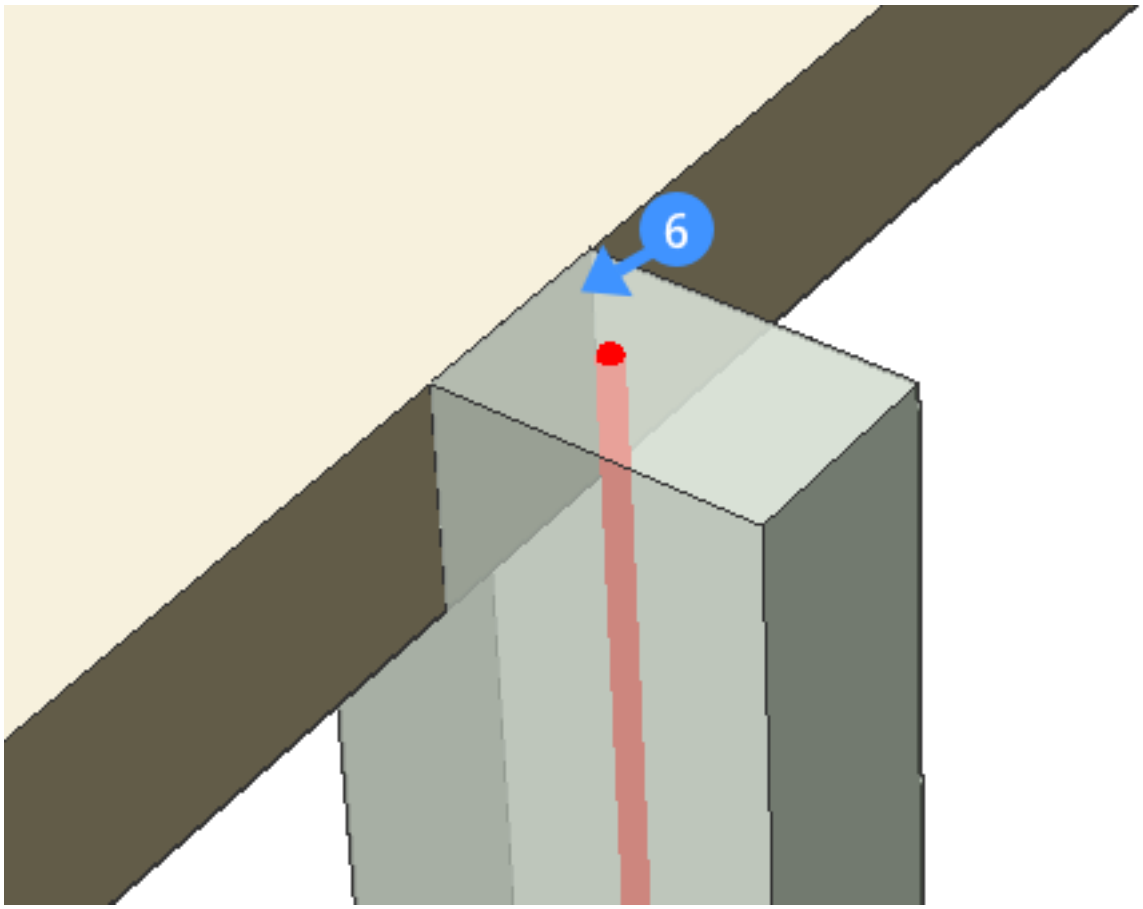

6. Run the Interfere command a second time to check whether all interferences are fixed. If there are no collisions left, the command line reports that “Solids do not interfere".

2.11.7 Using Xrefs

Command: XRef (6.13.23), XAttach (6.34.1), XOpen (6.34.5), XClip (6.34.2) **Overview:** In this lesson, you learn how to attach and detach DWG files to the current model through the Drawing Explorer. **Lesson Objectives** After completing this lesson, you will be able to:

- Attach externally referenced models to a master model.
- Unattach, reload, and unload the XRefs in the master model.

About

Using external references or Xrefs allows you to insert any model in the current BIM model. Instead of copying the model, only a reference to the source model is saved in the master model. You can attach multiple models to a single master model without increasing the size of the current model significantly. Further advantages of using the Xrefs are that the source models can be edited simultaneously by different members of the design team, and the master model can always be updated to show the latest version of each of the source models. **Note:** You can distinguish between XRef entities and entities in the current drawing using the XDWGFADECTL system variable. This system variable allows to fade the display of XRefs. You can give the values between 0 (no fading) and 90 to change the default value of the fading.

Procedure: Managing XRefs in the current drawing

1. Open the Drawing Explorer dialog box and click the External References section. The XRef preview pane displays for attaching a model or managing the existing XRefs on the list. The following illustration shows the XRef preview pane. (2.771 on page 2348)

External references (1)	Shows the External References section.
Attach XRef (2)	Attaches a model as an external reference.
Detach XRef (3)	Removes the selected XRef completely from the current model.
Reload XRef (4)	Reloads the selected XRef. This is useful when the source models have been changed, and you want to see the updated versions in the master model.
Unload XRef (5)	Unloads the selected XRef. This hides the XRef from the view.
Bind XRef (6)	Merges the source models permanently to the current drawing. Merging the XRef to the current drawing makes the XRef part of the drawing. References to the XRef disappear from the Drawing Explorer.
Insert XRef (7)	Converts XRefs into blocks.
Open XRef (8)	Opens the referenced drawing.
Detail view (9)	Displays the details of XRefs.
Icon view (10)	Displays icons of the XRefs.
Tree view (11)	Displays the relationship between XRefs in a tree-like view.

2. To attach externally referenced models, click **Attach XRef** tool button on the Drawing Explorer dialog box. The **Select Reference File** dialog box displays. The following illustration shows the Select Reference File dialog box. From this dialog box, select the DWG file you wish to attach in your main model, and then click **Open** (2.772 on page 2348) Next, the **Attach External Reference** dialog box displays. The following illustration shows the Attach External Reference dialog box. The table below presents each option of the Attach External Reference dialog box. From this dialog box, select the options you want to apply, and then click **OK.** (2.773 on page 2349)

Path field (12)	Displays the full path of the selected drawing.

Path type (13)	Includes full, relative, and no path options. **Full path:** When you move your drawing containing an XRef to another location, BricsCAD will still search for the XRef in the previous location and it will not find this XRef. **Relative path:** When you move your drawing containing an XRef to another location, the new file path will be created in the new location. The file folder will set up correctly using the same folder structure as the first one.
External reference type (14)	Includes Attachment and Overlay reference types. **Attachment:** Attaches all XRefs, including nested XRefs. For example, you have the first level of XRef "X" and this contains nested XRefs "Y" and "Z". When the attachment option is selected the first level of XRef and its nested XRefs Y and Z will be attached to the drawing. **Overlay:** Attaches only the first level of xref (X), nested xrefs (Y, Z) will be not loaded. This can also be used to prevent circular references.
Insertion point (15)	Allowsto specify the Insertion point on the screen or in the X-, Y-, Z- fields.
Scale (16)	Allows to specify the Scale on the screen or in the X-, Y-, Z- fields. Check the **Uniform Scale** option to specify the scale in the X- field.
Rotation (17)	Allows to specify the Rotation angle on the screen or in the Angle field.

Note that BIM XReference option from BIM Classify allows you to classify the model as an external reference. The identification of information will not explicitly be represented in the current model or in the project database. Such information appears after attaching the model to another project. To do so, follow the above step. The following illustration shows the BIM category in the properties panel after attaching the model that has been classified as an XRef. (2.774 on page 2349)

3. To detach an existing XRef, select the XRef you wish to detach in your main model, and then click the **Detach XRef** tool button on the Drawing Explorer dialog box. The selected XRefs are detached. **Note:** Press and hold the CTRL key to select multiple XRefs or to unselect a selected XRef.

4. Do one of the following to unload and reload an existing XRef.
   - Click the Loaded (18) column of a loaded XRef. This XRef is unloaded in your main model. To reload the XRef check the load box of this XRef.
   - Select the XRef, then click the Unload XRef (19) tool button on the Details toolbar. Select the unloaded XRef, then click Reload XRef (20) tool button. The following illustration shows the Load column, Unload XRef and Reload XRef tool buttons on the Drawing Explorer. (2.775 on page 2350)

5. To modify the attachment type, click the **Type** column of an existing XRef and switch from the Attach to Overlay or vice versa. The same process can be followed for modifying the **Saved path** of an XRef and **Found path** of an overlay.

6. Click **X** to close the dialog box. Notice that the changes that have been made appeared after you close the Drawing Explorer.

2.12 Design Documentation

2.12.1 How to add tags

https://www.youtube-nocookie.com/embed/lA2Bn0zfgvs

This video shows how to add labels to entities on a generated 2D plan or section, either automatically or manually.
Back to Tutorial Overview

2.12.2 How to create Interior Elevations

https://www.youtube-nocookie.com/embed/oPxPF9o6d68 This tutorial shows how Interior Elevations can be generated from a BIM Room, by first creating the section planes and then generating them together or individually.
Back to Tutorial Overview

2.12.3 How to create Schedules

https://www.youtube-nocookie.com/embed/OPkqYVjrNDA This video shows how the Project Browser can be used to create schedules. Either use existing .dxd files or create your own. Back to Tutorial Overview

2.12.4 How to extract data in BricsCAD BIM

https://www.youtube-nocookie.com/embed/yiRaYGwd_-8 This tutorial explains how to use the DATAEXTRACTION command and its dialog windows to extract the necessary information from your drawing. Back to Tutorial Overview

2.12.5 How to generate sections

https://www.youtube-nocookie.com/embed/gQQ8PXSZXNg This video shows how the BIM Section planes can be used to generate 2D plans and sections for your construction drawings and sheet sets. Back to Tutorial Overview

2.13 Design Documentation

2.13.1 BIM Sections

Command: BimSection (6.7.54) **Overview:** In this lesson will you learn how to create and manage plan, elevation, and section planes. How to create design documentation from these section planes will be covered in a future lesson. **Lesson Objectives** After completing this lesson, you will be able to:

- Cut through a BIM model horizontally to show the details on a floor plan
- Cut through a BIM model vertically to show the interior detail
- Display a BIM model with a vertical section outside the model
- Toggle the Clip Display property of a BIM section entity
- Control the visibility of your BIM section cuts

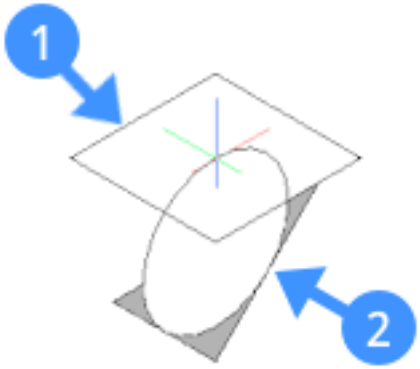
Tutorial: How to create and edit sections Click here (2.4.1) to watch

Defining a Section

In BricsCAD BIM, the **Define Section** tool allows you to create BIM section entities. The BIM section allows you to section a BIM model by a plane and thus view the interior details.  For more information about this command, visit the Command Reference article BimSection (6.7.54). When defining a BIM section, the section tracker is attached to the cursor. (2.776) The section plane (1) lies in the XY-plane of the current coordinate system (WCS or UCS). The view direction (2) is in the negative direction of the current coordinate system. **Note:**

- If **Dynamic UCS** (DUCS) is ON, the section plane aligns to the face of the 3D solid under the cursor. Hit the TAB-key to select an obscured face.
- You can press the Shift-key to lock a highlighted plane, allowing you to specify the definition point for the BIM section entity outside the face of the solid.
- The section line is parallel to the X-axis of the coordinate system (WCS, UCS or DUCS).

Figure 2.776



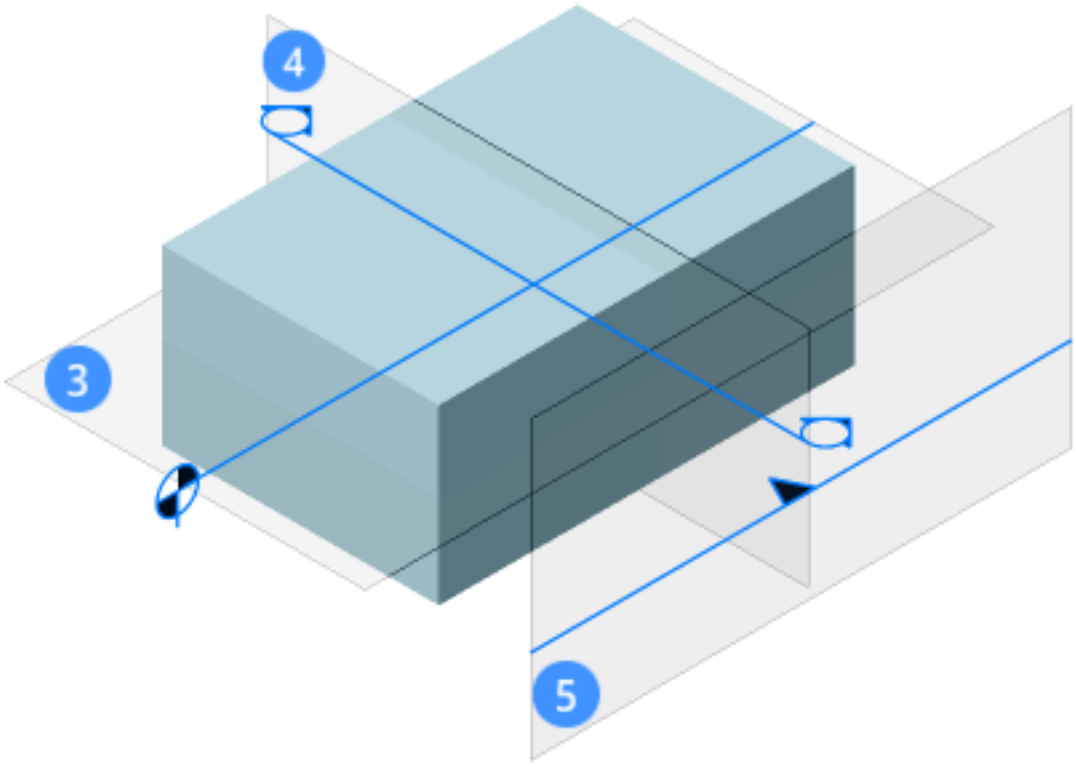
General procedure to create a BIM Section

1. Choose **Define Section** in the Model tab of the **No Selection** Quad. You are prompted: **Select a point to place section or [Detail/Interior/Scale/Reflected ceiling]:**
2. Do one of the following:
   - – To create a plan section, click a point anywhere outside the model.
   - – Hover the cursor over the face of a 3D solid, parallel to the section plane you want to create. The section tracker aligns to the face under the cursor, on the condition that DUCS is active. Left-click.
   - – Optional Hit the Shift-key to lock the highlighted plane. This allows you to start from a point outside the selected 3D solid face. Next, left-click.
3. The initial section plane displays dynamically and the 3D model is clipped accordingly. You are prompted: **Specify distance:** Do one of the following:
   - Type a value in the dynamic dimension field to offset the section from the initial position.
   - Left-click when the section plane is at the location you want it to be.

The BIM Section entity is defined. The **Section Type** depends on the direction of the section plane (horizontal or vertical) and whether it intersects with the model. (2.777 on the following page)

Plan (3)	Displays horizontal section plane
Section (4)	Displays a vertical section that cuts through the model
Elevation (5)	Displays the exterior elevation view

Figure 2.777



To create a plan section **Note:** A plan section is best defined in the WCS (World Coordinate System).

1. Choose **Define Section** in the **Model** tab of the **No Selection** Quad. You are prompted: **Select a point to place section or [Detail/Interior/Scale/Reflected ceiling]:**
2. Place the Section Tracker near the 3D model and click (6). (2.778 on the next page) The initial section plane lies in the XY-plane (Z = 0) of the current coordinate system (e.g. the WCS). The section plane displays dynamically and the 3D model is clipped accordingly (7). (2.779 on the facing page) You are prompted: **Specify distance:**
3. If Dynamic Dimension is ON, the current distance displays in a dynamic dimension field. Do one of the following:
   - Move the cursor and click when the section plane is at the desired height.
   - Use an Entity Snap to specify a point.
   - Type a value to define the offset from the initial position of the section plane.

The plan section is defined.

Figure 2.778

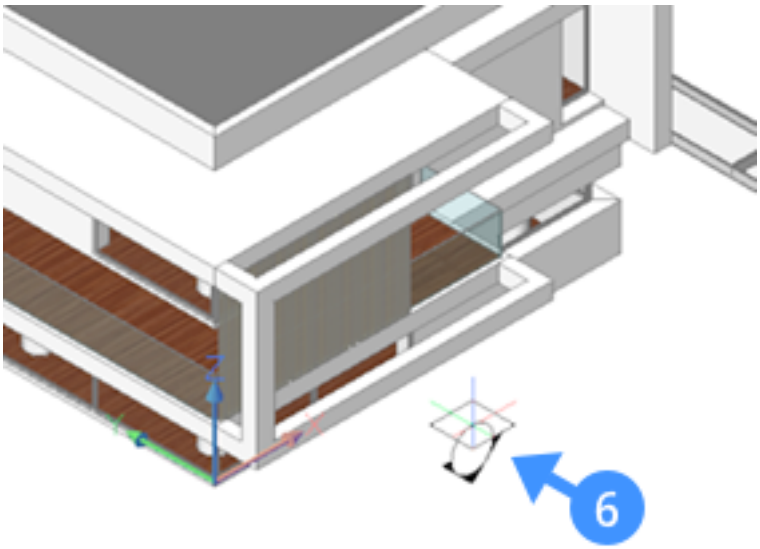


Figure 2.779

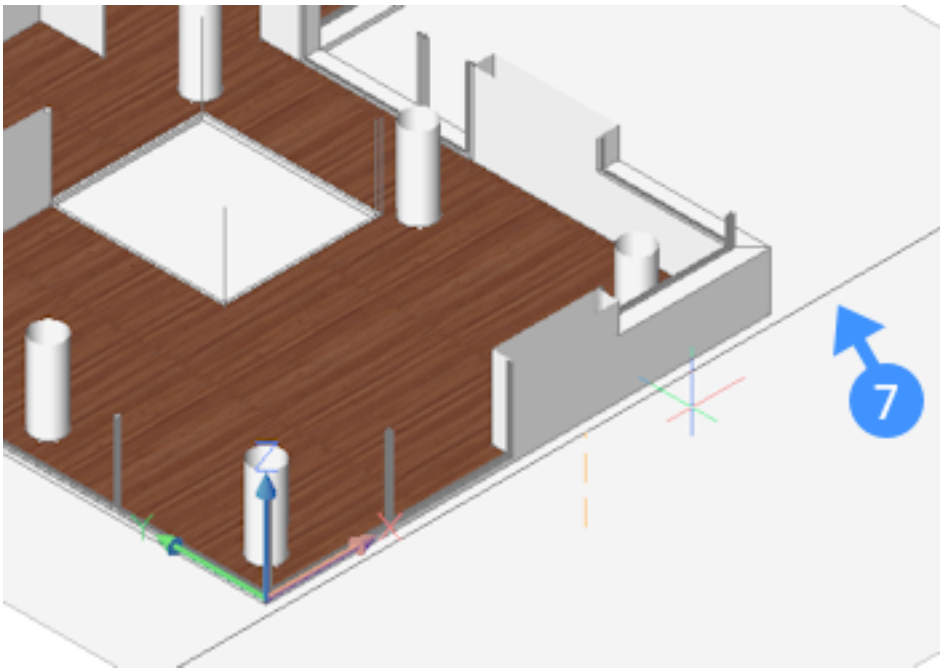

To create a cross section Make sure Dynamic UCS (1.21.20) (DUCS) is enabled.

1. Choose **Define Section** in the **Model** tab of the **No Selection** Quad. You are prompted: **Select a point to place section or [Detail/Interior/Scale/Reflected ceiling]:**
2. Place the section tracker over a 3D solid face (8) parallel to the cross-section to be defined. (2.780)
3. Click when the face highlights and move the section tracker inside the 3D model. The section plane displays dynamically and the 3D model is clipped accordingly (9). (2.781 on the facing page) You are prompted: **Specify distance:** If Dynamic Dimension is ON, the current distance displays in a dynamic dimension field.
4. Click when the section plane is at the desired location or specify a distance. The cross-section is defined.
5. (Optional) Click the section entity and hold down the left mouse key a little longer to display the Manipulator (1.32.10). Drag an axis of the manipulator to move the section.
6. (Optional) Click the **Arrow** grip to flip the view direction.

Figure 2.780

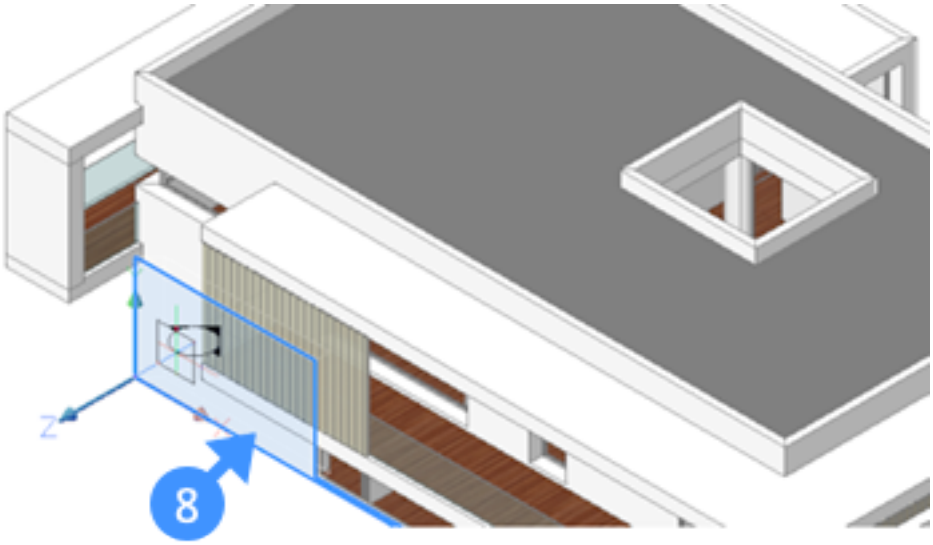

Figure 2.781

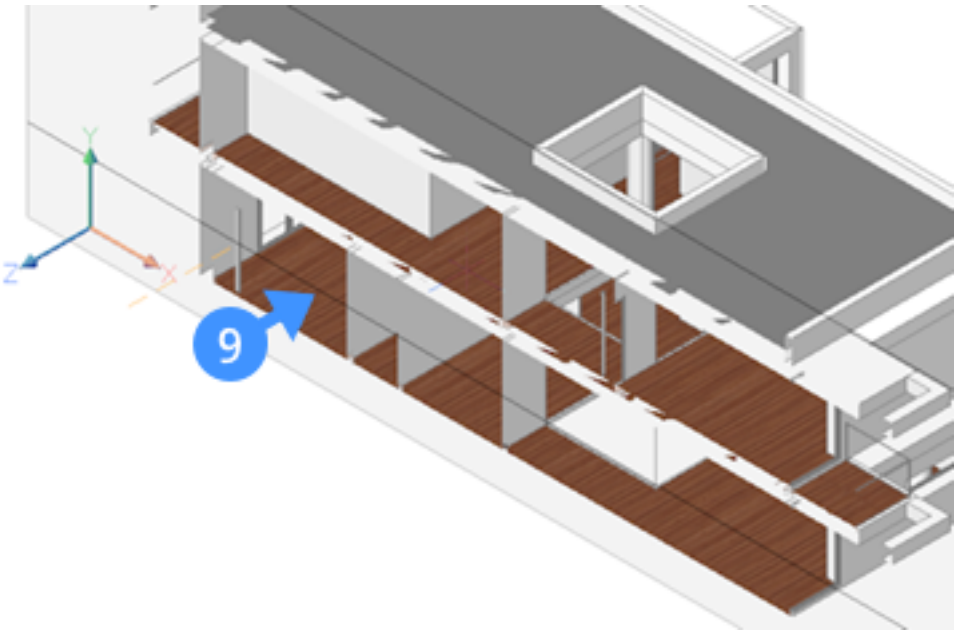

To create an elevation Make sure Dynamic UCS (1.21.20) (DUCS) is enabled.

1. Choose **Define Section** in the **Model** tab of the **No Selection** Quad. You are prompted: **Select a point to place section or [Detail/Interior/Scale/Reflected ceiling]:**
2. Place the Section Tracker over a 3D solid face (10) which is parallel to the elevation to be defined and click when face highlights. (2.782 on the next page)
3. You are prompted: **Specify distance:** Move the section tracker outside the 3D model and click to define the elevation (11). (2.783 on the following page)

Vertical sections outside the model (no geometry is sectioned) get the Elevation section type automatically.

Figure 2.782

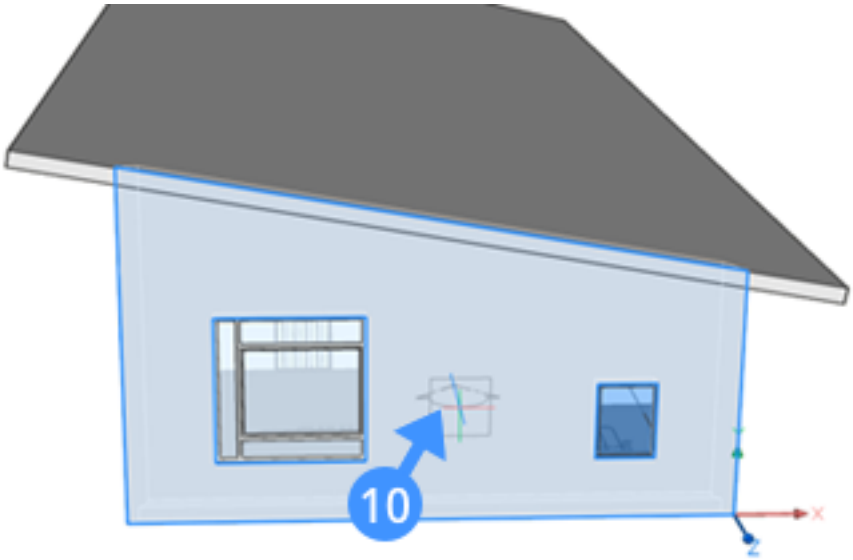

Figure 2.783

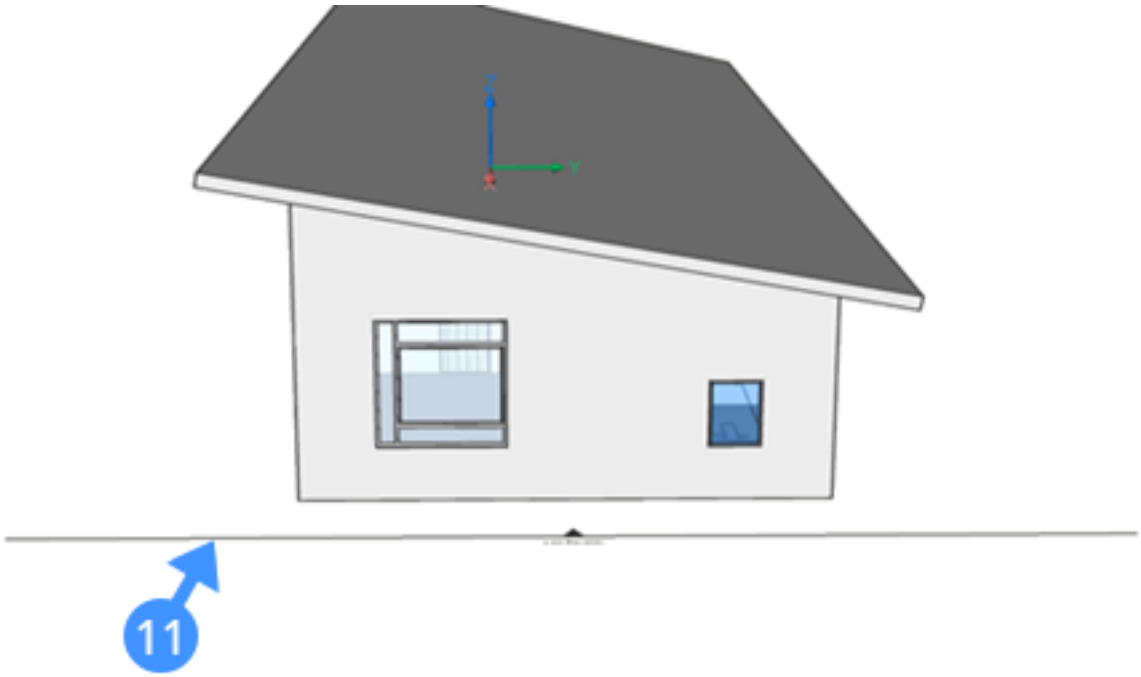

Editing the default properties of a BIM Section

The default properties of a BIM section entity are copied from the section entities in _SectionSettings.dwg in the BIM/Sections subfolder of the Support folder (6.27.59).

1. Select the BIM section in the drawing or the Structure panel (6.27.54). The section properties display in the Properties panel.
2. Define the properties of the BIM section entity. (2.784 on page 2365)

Section Entity:

Name	Type a name.
State	Click the field and select a state. The selected state determines how the section result will be clipped. The options are: Plane (default), Boundary and Volume.
Live section	Sets the live section property of the section plane. Only one section entity can have the "Live section" property ON. It is recommended to use the "Clip Display" property instead. Use this mode for visual checking only, not for 3D modeling.
Clip display (6.9.22)	Clips the 3D model. The Clip Display status can be set for multiple section entities simultaneously. As different from "Live section", entity snaps are available in the section plane.
Use lids	Closes the top faces of the clipped geometry.
Plane transparency	Sets the transparency of the section plane in rendered Visual Styles.
Plane color	Sets the fill color of the section plane in rendered Visual Styles.
Destination File	Sets the name and path of the drawing file created by the BIMSECTIONUPDATE (6.7.43) command. When the path is not specified, the section drawing is created in the folder of the 3D model.

Geometry:

Elevation	Defines the Z-value of the start point of the section plane.
Top plane	Defines the top plane of the section volume.
Bottom plane	Defines the bottom plane of the section volume.
Vertex	Defines to coordinates of the control points of the section plane. The number of vertices depends on the current section plane state. • Plane: 2 vertices • Boundary and Volume: 4 vertices. Select the field, then click the arrow buttons to select a vertex. An X indicates the selected vertex in the model.

BIM:

Name	Type a BIM name.
Description	Type a description.
Section type	Sets the BIM section type.

Callout position	Defines the position of the callout(s). The callout block and default position depend on the section type. The options are: Start (12), Mid (13), End (14) and StartEnd (15). (2.788 on page 2368)(2.789 on page 2369)(2.790 on page 2369)(2.791 on page 2369) Click the green arrow () to flip the view direction of the section.
Initial Scale	Sets the initial scale of the paperspace viewport in the generated drawing.
Layer state	Sets the layer state to be used to calculate the section.
Apply layer state	Determines whether the layer state (6.20.9) will be used to calculate the section or not. Applying a layer state allows to control which layers are ON/OFF when calculating the section result.
Project section	Controls the display of the section callouts and section line in section drawings which are perpendicular to this section.
Generate tags	Controls whether BIM tags are generated automatically.
Entity property sets	Controls whether 'per instance' entity properties can be used to generate tags. Click the Browse () button, then select the property sets in the 'Enable per-instance property' set dialog box.

To toggle the clipped display property of a BIM section entity

The **Clip Display** property of the BIM section temporarily clips 3D models. The Clip Display can be used in all modeling and editing operations on all drawing content. The following illustration shows the 3D model of a villa with a plan section (16) for the ground floor plan. (2.785 on the facing page)

To clip the 3D model, do one of the following:

- Double click the section entity.
- Select **Clip Display** from the Quad.
- Select the section plane and set the **Clip Display** property to **Yes** in the Properties panel.
- When **RT** (Rollover Tips) is selected in the Status Bar (1.15.2), place the cursor over a section entity to set the **Clip Display** property.

Note: Clip Display can be on for multiple section entities simultaneously. In the following illustration, Clip Display is turned **ON** for two BIM section entities (17,18). These section entities are in opposite view directions: section plane 18 is a plan section, section plane 17 is a reflected ceiling section. (2.786 on the next page) Option: Set the **State** property for the current section to **Volume** in the properties panel. (2.787 on page 2368) A clipped section shown in the **Volume** state (19).

Figure 2.785

Figure 2.786

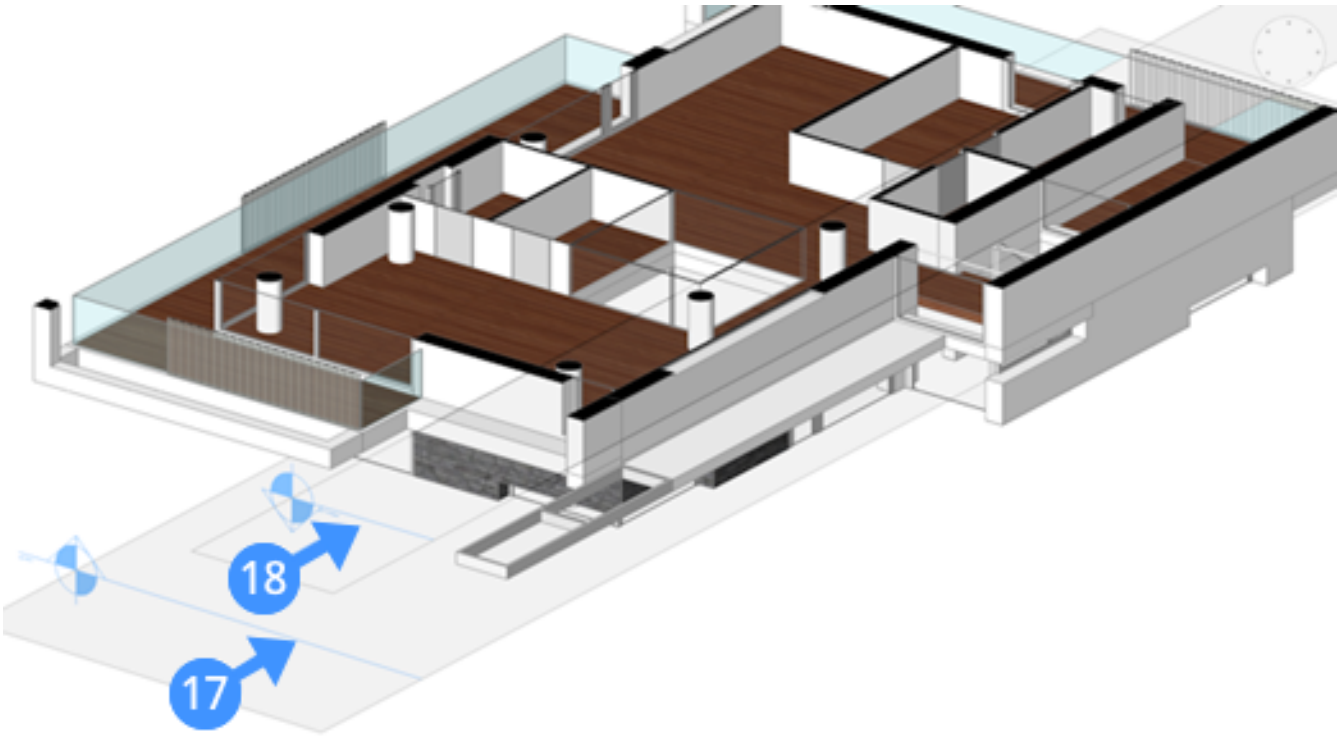

Figure 2.787

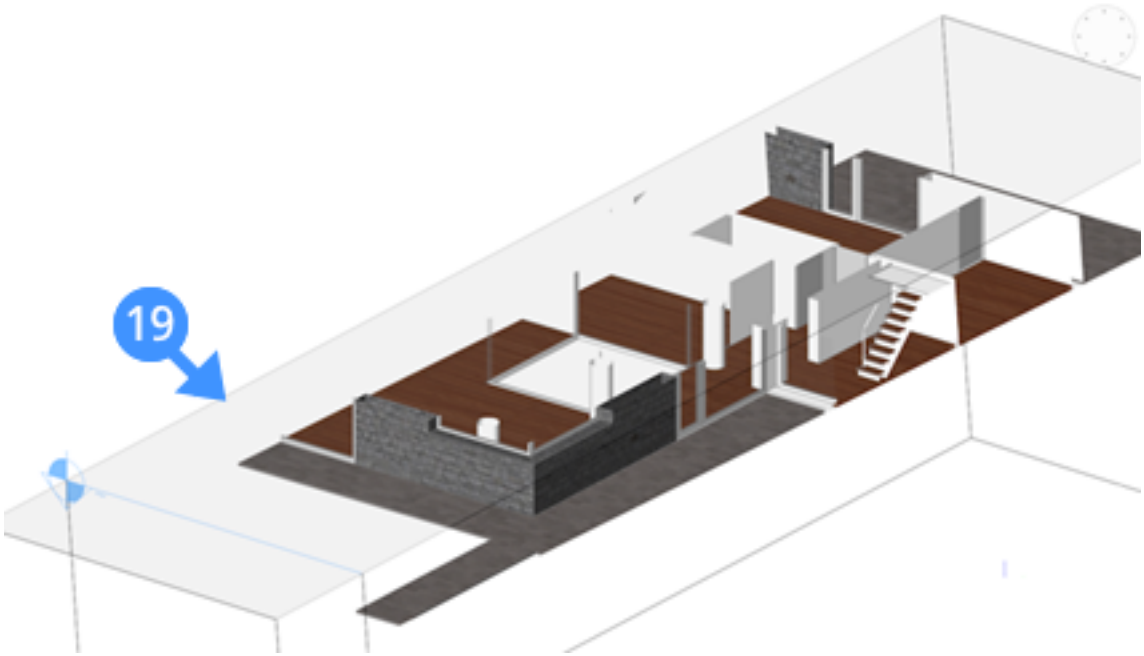

Converting a section entity to a BIM section

The BIMIFY command converts a section entity to a BIM section

1. (a) Launch the BIMIFY (6.7.23) command. You are prompted: Run Bimify on entire model or [Advanced] <Model>:
   (b) Choose the **Advanced** option. The Bimify dialog box displays.
   (c) Choose **Select entities**, then click the **Select** button. The Bimify dialog closes. You are promted: Select entities [selection options (?)]:
   (d) Select the section entity, then right click. The Bimify dialog reopens.
   (e) Click the **OK** button.

Figure 2.788

Figure 2.789

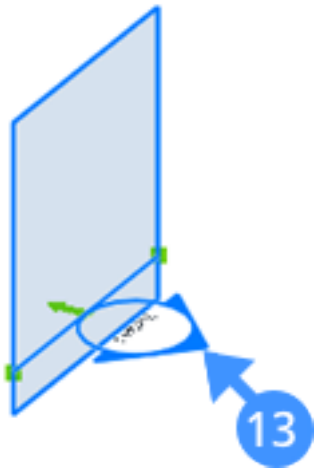

Figure 2.790

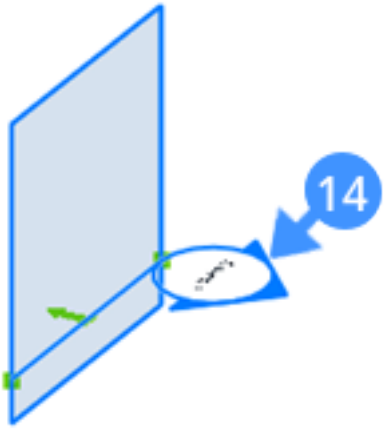

Figure 2.791

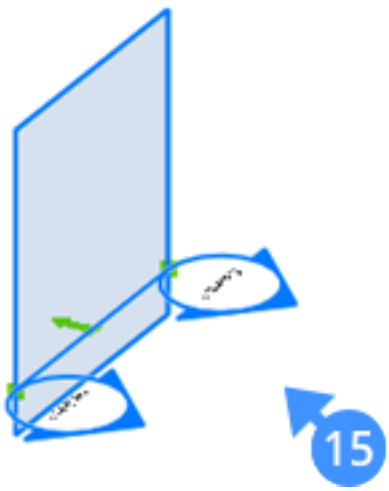

2.13.2 BIM Tags

Command: BimTag (6.7.59) **Overview:** In this lesson, you will learn how to create and annotate BIM tags. You can use one of three options to produce BIM tags in a drawing. BimTags are tags that correspond to building entities in their associative 3D BIM model. They are created as multileader (6.21.19) entities: a block containing a series of attributes. The Tag property of such attributes refers to a BIM entity property, (wall, column, window, etc.). As well as default BIM properties, a BimTag attribute any of the properties in the Properties panel (General properties, Mass quantities, Parameter values, and IFC properties). Use the BimProperties (6.7.38) command to add user-defined properties and classification system codes in a BimTag.

Source files The following source files are used to create BimTags in a generated BIM section drawing:

- **_SectionTag.dwg**: contains the tag blocks and multileader styles (6.21.24).
- **_TagTypeToStyle.xml**: links a BIM entity type to a multileader style.

Both files sit in the folder: C:\Users**<UserName>**\AppData\Roaming\Bricsys\BricsCAD\V19x64\en_US\Support\Bim\Sectio
Note: when assigning tags, BricsCAD needs to access the 3D model. For this reason it may take several seconds to place the **first** tag, **if** the 3D model is not currently opened, especially in large models. If you want to avoid this waiting time, consider having the 3D model open while placing tags.

Assign BIM tags manually

The BimTag Manual command allows you to select the BIM element that you wish to create a BIM tag for. For more information about this command, visit the Command Reference article BimTag (6.7.59). 

Manually create a BIM tag

1. Open the section drawing for which you wish to create BIM tags. **Note:** For more information about generating section drawings, please read the BIM article Generating Drawings (2.13.13) first.
2. With no selection select **Tag Assign BIM tags manually** from the Quad **or** enter **BIMTAG** followed by **m** into the commandline to choose the **manual** option. (2.792 on the next page) **You are prompted:** Pick point on a sectioned BIM element [Auto/Current mleader style/change Tag type]:
3. Select a point on a line of a BIM element to generate a tag for it. The tag will appear. If the point selected is shared between multiple BIM entities, you can use the CTRL key to cycle through the different possible tags. (2.793 on page 2372) **You are prompted: Place the tag** [Next element]:
4. Move your cursor in order to adjust the position of the tag and left-click to place it. **You are prompted:** Pick point on a sectioned BIM element [Auto/Current mleader style/change Tag type]:
5. Repeat steps 3 and 4 for all of the entities you wish to be tagged. If you do not require more tags, press the ESC or ENTER key to complete the command. If you want all elements to be tagged, you can use the **BimTag Select all entities** command which we will explore next.

The same steps above can be used to tag a floor slab or a roof. (2.794 on page 2372)

Figure 2.792

Tag
Assign BIM tags manually

Figure 2.793

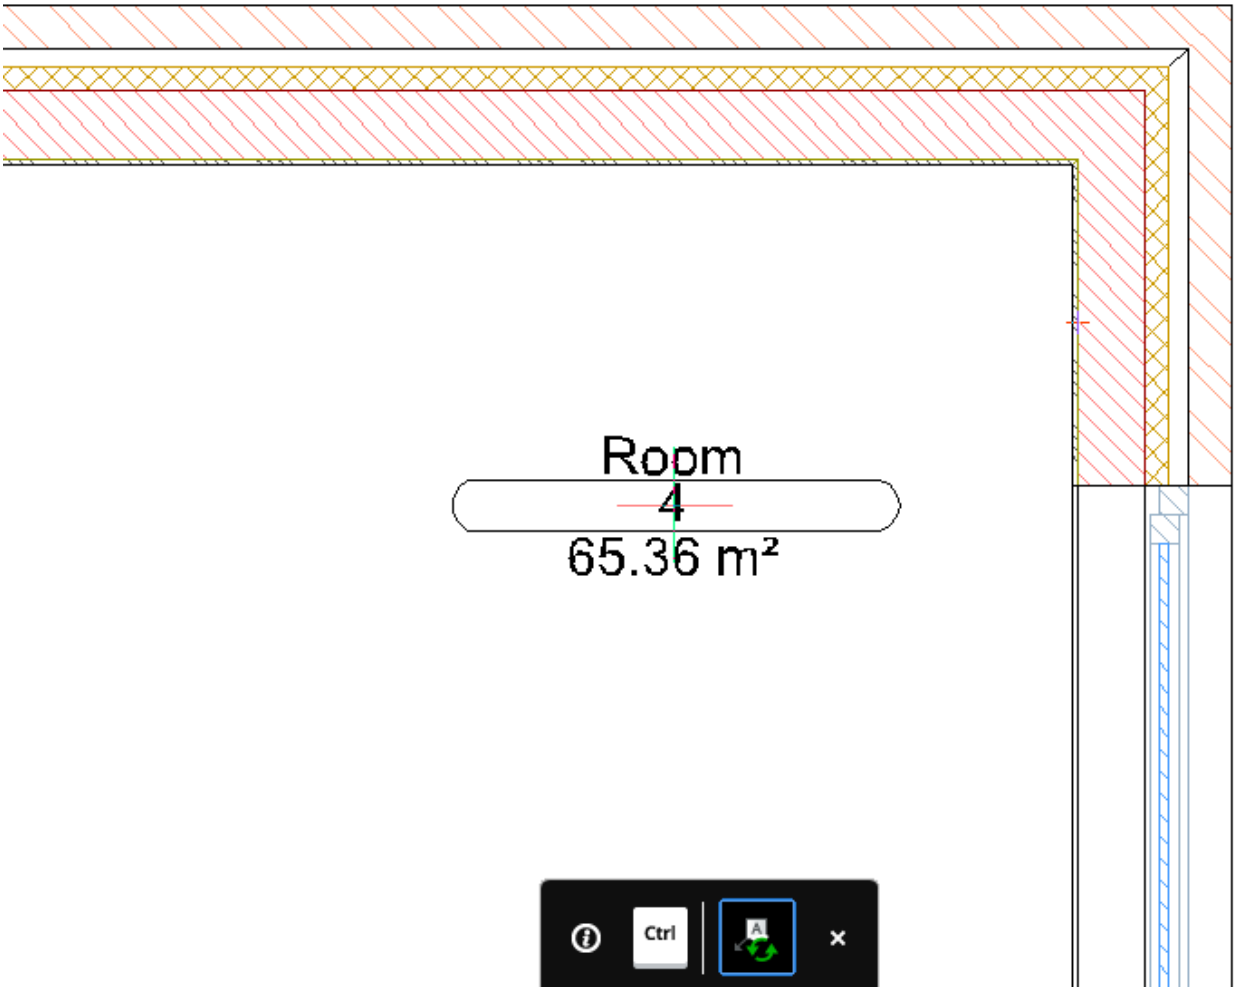

Figure 2.794

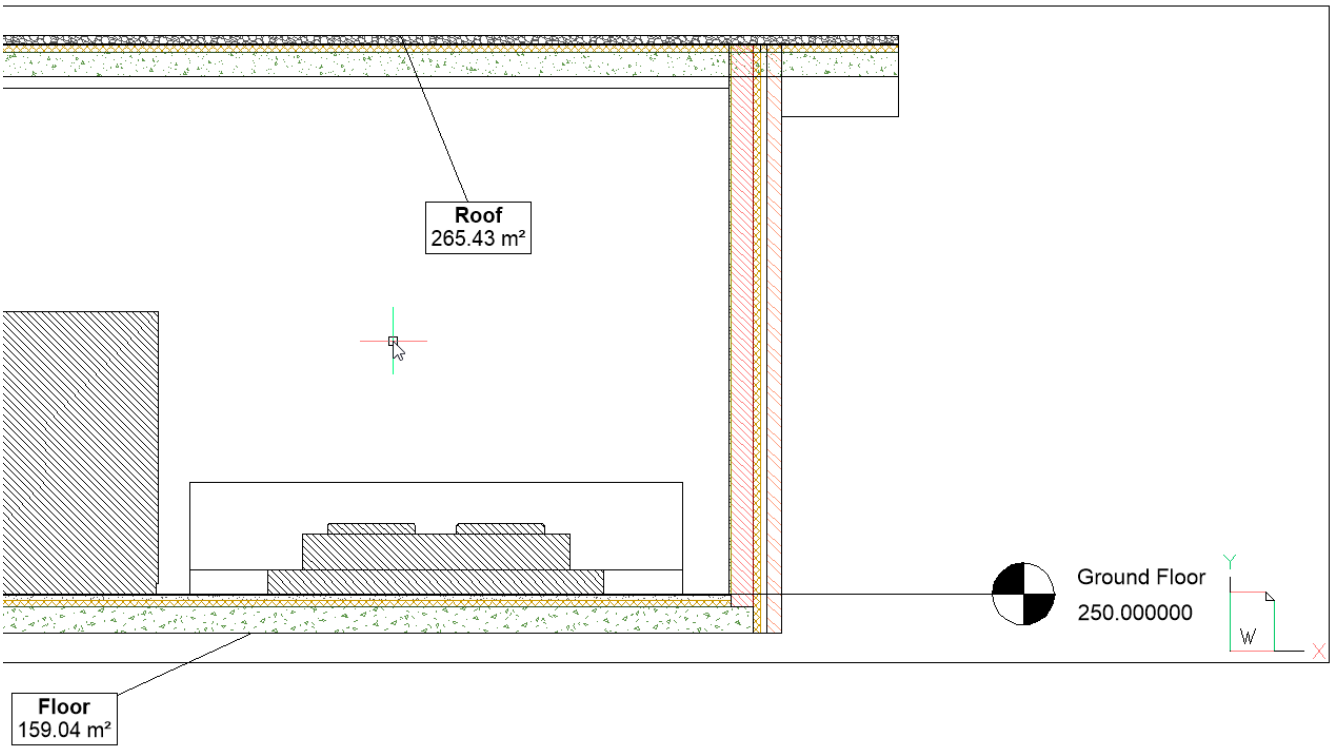

Assign BIM tags automatically

If you want all BIM elements in a section drawing to be tagged it is easiest to use the **BimTag Select all entities** command. This command automatically assigns BIM tags to all BIM entities inside a viewport. If the model is altered or new elements are added, the BIM tags can be updated and new tags added.  For more information about this command, visit the Command Reference article BimTag (6.7.59).

Automatically create BIM tags

1. Open the section drawing on which you wish to create BIM tags.
2. Select a viewport containing the section which you will add BIM tags to. (2.795 on the following page)
3. Select **Tag Assign BIM tags automatically** from the Quad **or** enter **BIMTAG** into the commandline. The BIM tags have now automatically been generated for each of the BIM entities in the viewport. (2.796 on page 2375) **You are prompted: Select BIM section viewport** [Manual]:
4. If you wish to automatically create BIM tags in another viewport on the sheet, select the viewport and these will be generated. If you do not require any further BIM tags, press Esc to complete the command.

Create the source data for a BIM entity type

By default the source data for the following BIM entity types already exist; Annotation, Beam, Column, Curtain Wall, Door, Plies, Railing, Ramp, Roof, Room, Slab, Stair, Wall, and Window. Available BIM entity types are listed in the **Classify As Bim Element** dialog box. To open this dialog box, choose the **Other** command option of the BimClassify (6.7.12) command. (6.317 on page 3643)

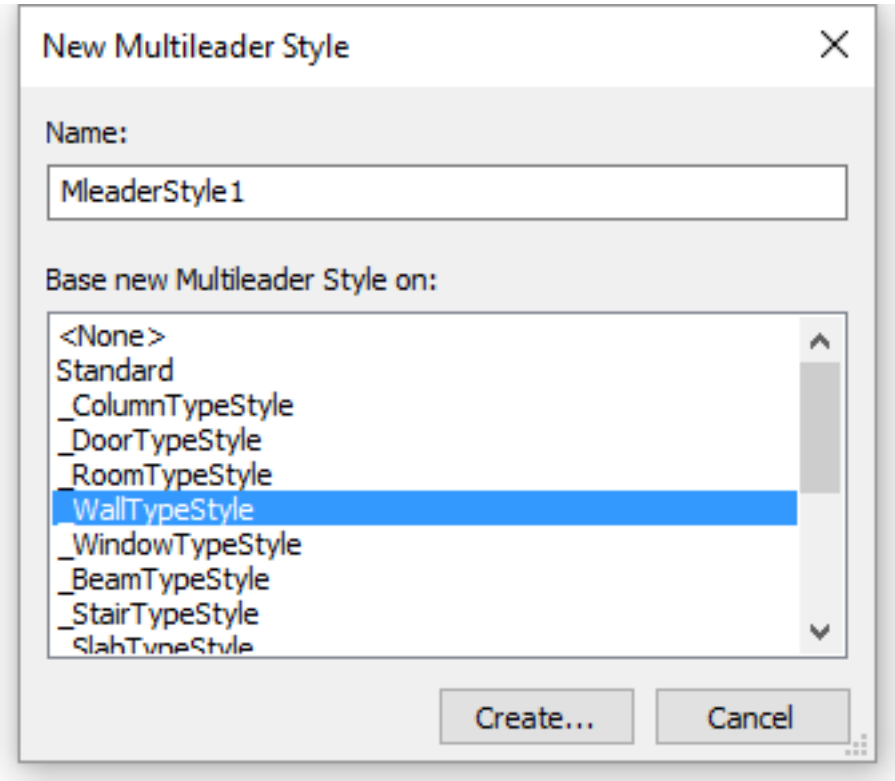
Create the tag block and multileader style To create the source data for a Bim **Member** entity type:

1. Type **Supportfolder** in the commandline and press Enter.
2. Once the folder has opened, navigate to the **.../Bim/Sections** folder and open the **_SectionTag.dwg** file.
3. Launch the ExpBlocks (6.13.11) command. The **Drawing Explorer / Blocks** dialog box will display.
4. Select the **_AnnotationTag** block (or any other existing block that you want to use as a template).
5. Right-click and choose **Copy** from the context menu.
6. Right-click and choose **Paste** from the context menu.
7. Click **Copy, but keep both** on the **Copy/Paste** dialog box.
8. Rename the copied block to **_MemberTag**.
9. Select **Multileader Styles** in the **Drawing Explorer** dialog box.
10. Click the **New** () tool button. The **New Multileader Style** dialog box will display: (2.798 on the next page)
11. In the **Name** field type '_MemberTypeStyle'.
12. Select a source style in the **Base new Multileader Style** on the list.
13. Click the **Create** button.
14. **Optional** Edit the **Leader** properties.
15. Click the **Content** tab.
16. Under **Block options**, click the **Source Block** list button and select **_MemberTag** from the list.
17. Close the **Drawing Explorer** dialog box
18. Save **_SectionTag.dwg**

Figure 2.798



Link the entity type to its multileader style

1. Type **Supportfolder** in the command line, then go to **.../Bim/Sections** folder and open **_TagTypeToStyle.xml**. Use an ASCII text editor, e.g. Notepad.
2. Add the following right before **</TagTypeToStyle>**:

```
<tag type="BIM_MEMBER"> <style  name="_MemberTypeStyle"  autoPlacement="true" autoRotation="true" o
```

3. Save the file.

Note that this style has three options:

- **autoPlacement = "true"** will make sure tags are automatically generated when using the automatic BIMTAG option. If this option is set to false, then this tag type will not be generated automatically (you can still generate these tags manually).
- **autoRotation = "true"** will rotate the tag along the main axis of the tagged entity. If set to false, the tag will be placed horizontally.
- **offset** will offset the tags perpendicular to the main axis of the tagged entity.

Customize tag blocks

The content of a Bim Tag block consists of:

- **Layout entities** Linework, fixed texts, etc.
- **Attributes** Bim entity properties.

Note	When you execute the BimTag command, BricsCAD checks whether the source data (tag blocks and their multileader styles) already exist in the Bim section drawing. If not, the source data is copied from the _SectionTag.dwg file. Otherwise, the tag block definitions and multileader styles in the section drawing are used. Therefore, editing tag blocks in the _SectionTag.dwg file only affects the creation of new Bim tags the first time BimTag is executed in a section drawing. If you edit tag blocks in a section drawing it affects Bim tags in that drawing only.

Customize tag blocks for the current drawing only

1. In the section drawing for which you wish to customize the BIM Tags, type **MLEADERSTYLE** in the command line. The drawing explorer will open in the Multileader Styles tab. (2.799 on the facing page) Each BIM tag is a multileader. The multileader style depends on the type of BIM element being tagged. All the multileader styles in the drawing are listed in the drawing explorer.
2. Select **_WallTypeStyle** from the list to see a preview of what the tag will look like. You can change the tag style from here.
3. Change the **Leader Type** from Straight to None. Now there will be no line connecting the tag to the wall element. (2.800 on page 2382)
4. In the content tab, the **Source block** is called **_WallTag**. Remember this and now close the drawing explorer. (2.801 on page 2384)

5. In the command line type **BEDIT** and select **_WallTag** from the list. Click okay.
6. Select the 'WallType' text and **Tag** value of the properties panel
7. Replace **WallType** with **Composition** and press ENTER (see the next procedure for the syntax of other property types). Now the attribute text will display **Composition.** (2.802 on the next page) (2.803 on page 2385)
8. Hover over this attribute and select **Copy** from the Quad. Select a base point to paste the copied attribute below the current one. (2.804 on page 2385)
9. Repeat steps 5 - 7 to change the new attribute **Tag** value (**Quantity/Thickness**).
10. Delete the rectangle. (2.805 on page 2386)
11. Select the Save Block icon from the Block Editor tab of the ribbon. Your section viewport will now display. (2.806 on page 2386)
12. Highlight the viewport and select **Tag Assign BIM tags automatically** from the Quad. **You are prompted: Tags already have been assigned to the section. Choose an update option** [Update existing/update existing and add New/Regenerate all] <Regenerate all>:
13. Click hit the ENTER key to accept the default option of **Regenerate all**. The wall tags will be regenerated with the new style. (2.807 on page 2386)

Figure 2.801

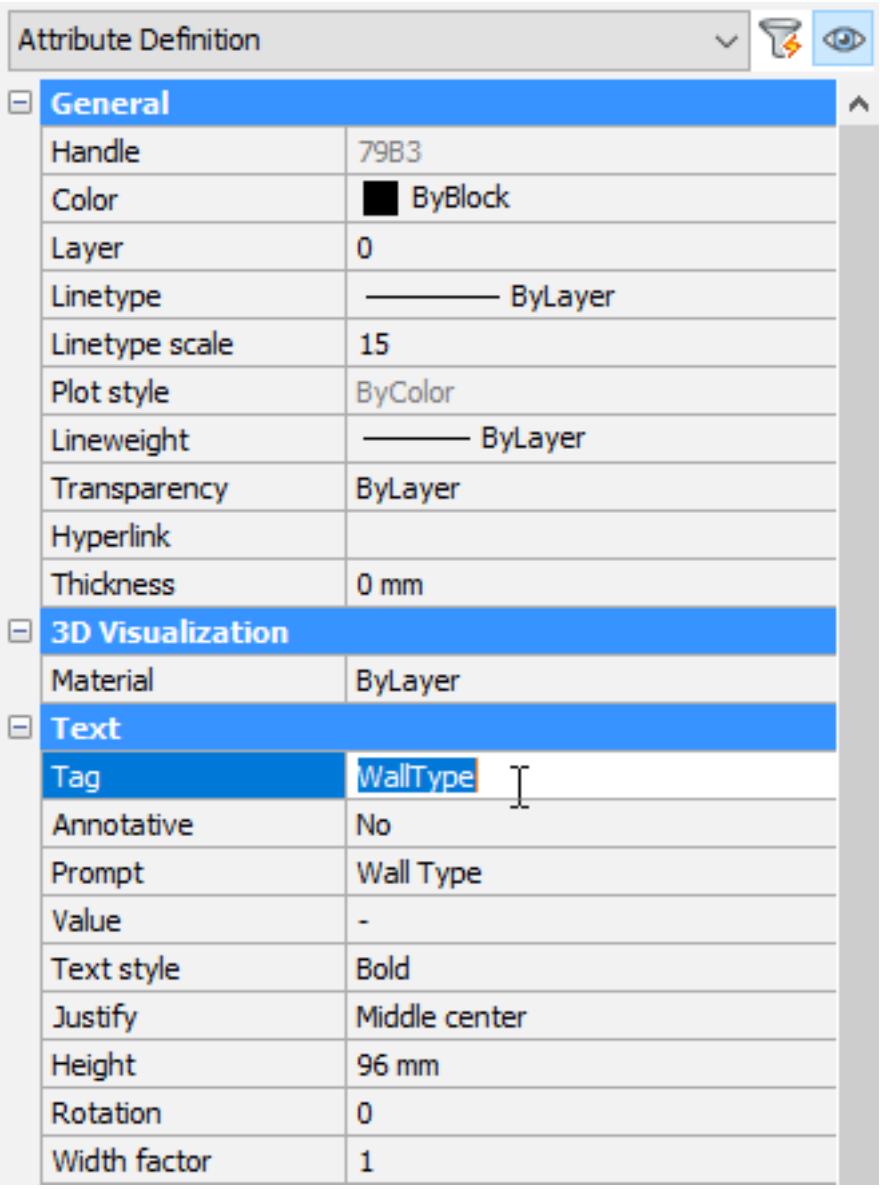

Figure 2.804

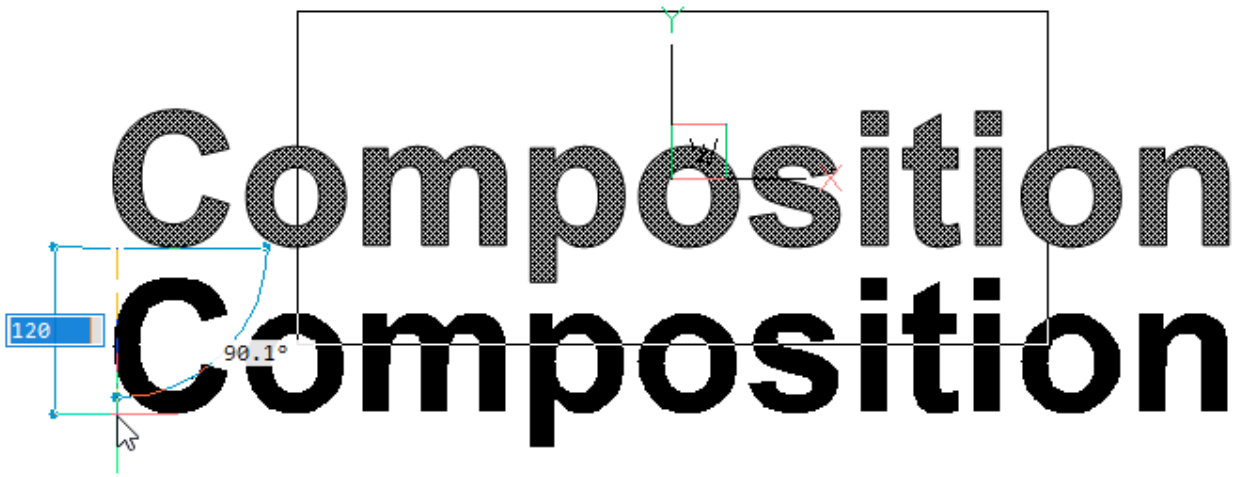

Figure 2.805

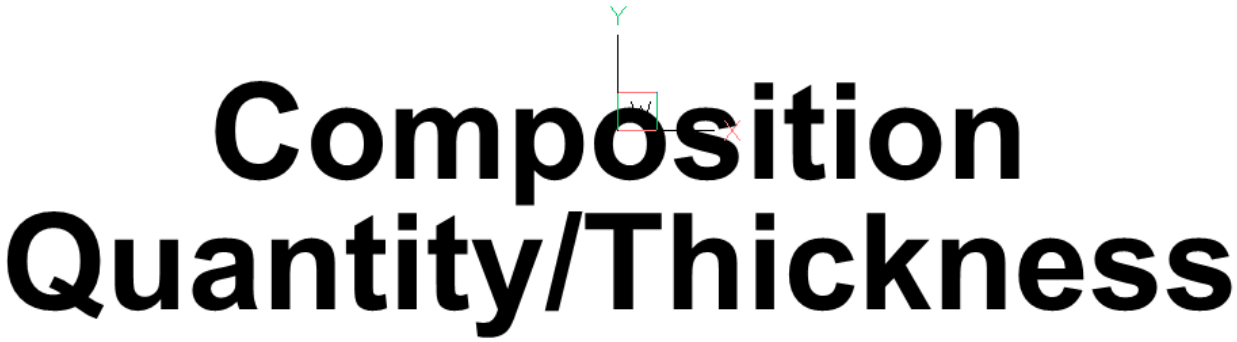

Figure 2.806

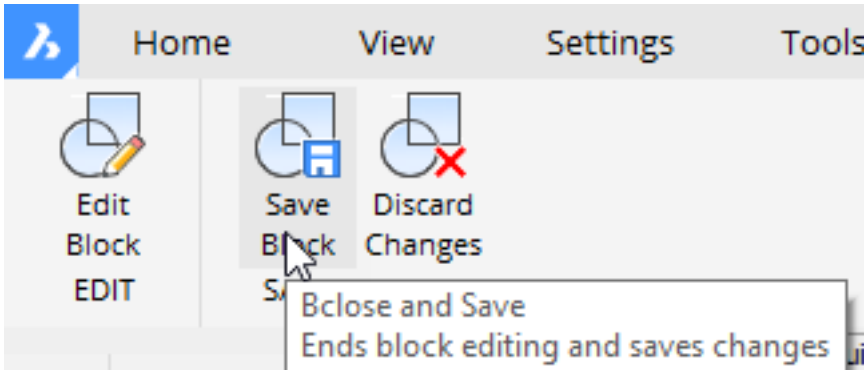

Figure 2.807

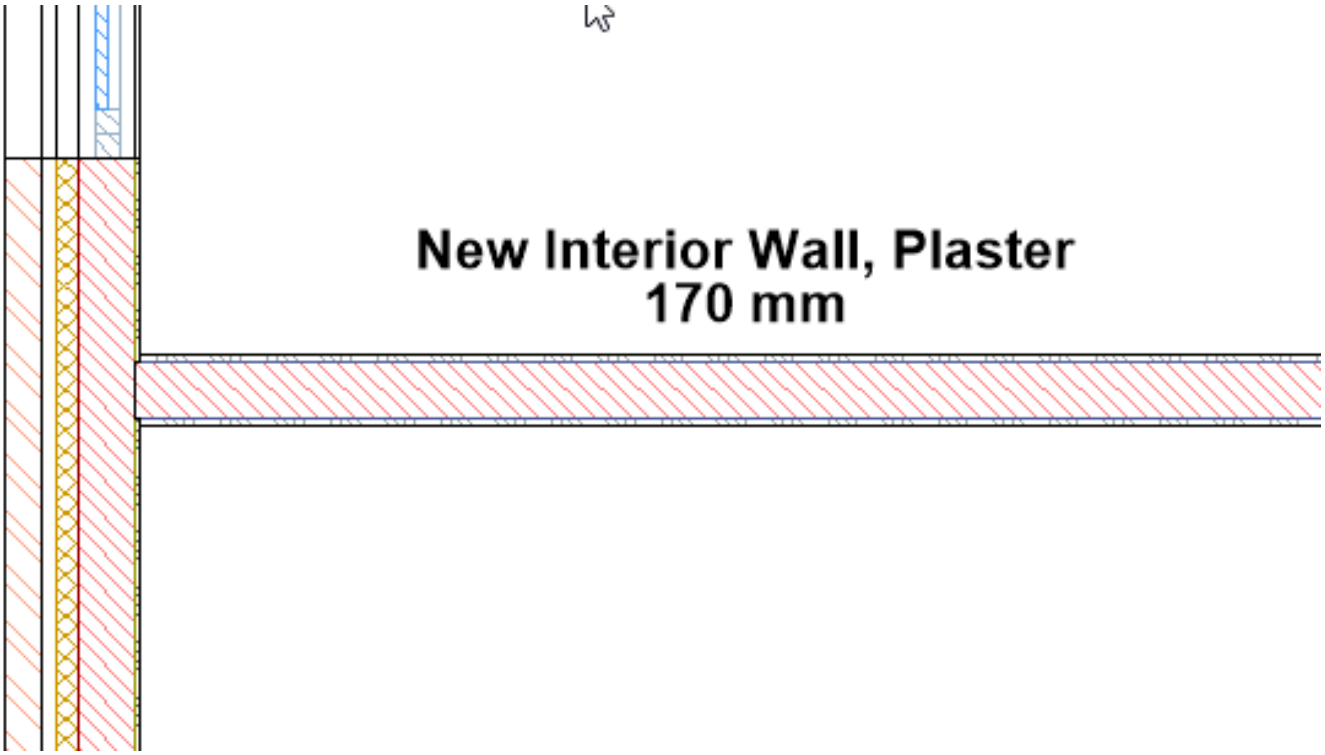

Edit the source data to customize BIM Tags for all section drawings

1. With any drawing open, type **Supportfolder** in the command line followed. Hit Enter.
2. Once open navigate to the **.../Bim/Sections** folder and open the **_SectionTag.dwg** file.
3. Launch the BEdit (6.6.7) command.
4. Select the tag block you want to edit, then click the **OK** button.
5. Add attributes using the following syntax, in the **Tag** field, in the properties panel:

Property type	Syntax	Examples
BIM	<property name>	name room bounding
Parameters	parameters/<parametername>	parameters/w parameters/framethickness
General	general/<property name>	general/layer general/linetype scale
Mass	mass/<property name> mass/<property name>:<child>	mass/surface area mass/ucs elevation:minimum
Geometry	geometry/<property name> geometry/<property name>:<child>	geometry/position geometry/ucs elevation:maximum
Quantity	quantity/<property name>	quantity/length quantity/net footprint area
IFC	<ifc property set>/<ifc property>	wall common/load bearing door window glazing type/glass layers
User Defined	<property set label>/<property label>	exterior walls/price
Classification system	<classification system label>/ <classification code label>	omniclass/omniclass classification code

Note: To know which properties are available for a specific BIM entity type, select such entity in the model, then open the Properties panel (1.15.4). In the image below the properties of a BIM Wall entity are listed. Click the + button to expand a property type node. (2.808 on the next page)

6. For each new attribute do the following:
   - Copy an existing attribute or create a new attribute (AttDef (6.4.31) command).
   - Select the new attribute. **Note** Do not double click the attribute. The Edit Attribute Definition (1.30.18) dialog box does not accept spaces in the Tag field.
   - In the Properties panel (6.24.54), type the property reference in the **Tag** field (see the syntax in the above table).
   - **Optional** Define the **Text** properties (Text Style, Justify, Height, ...) in the Properties Panel.
   - **Optional** Add linework and fixed text.
7. On the **Block Edit** toolbar: click the **Save** icon to conclude the BEdit command.

Definitions in the tag block (2.811 on page 2391)	Resulting tag (2.812 on page 2391)
_WallTag block (2.813 on page 2391)	Wall tag in a plan section (2.814 on page 2392)
WindowTag block	Window tag in a plan section

Assign composition tags

Composition tags allow you to tag a wall or a slab element in order to specify its composition. These BIM tags are a list of the ply materials which make up the element. For more information about this command, visit the Command Reference article BimTag (6.7.59). 

Create composition tags

1. Open the section drawing for which you wish to create composition tags.
2. Select **Tag Assign composition tags** from the Quad.
   (2.809 on the following page) or type **BIMTAG** in the commandline, then do one of the following:
   - type **M** +Enter for the **manual** option; then **T** + Enter for Change Tag type, followed by **O** +Enter for the **composition** option.
   - Click the options in the command line.
   - Click the options in the Prompt Menu (1.15.6)
3. **You are prompted:** Pick point on a sectioned BIM element [Auto/Current mleader style/change Tag type]: Select a point on a BIM element to generate a tag for it. The tag will appear. If the point selected is shared between multiple BIM entities, you can use the CTRL key to cycle through the different possible composition tags. (2.810 on the next page) **You are prompted: Place the tag** [Next element]:
4. To adjust the position of the tag, move your cursor and left click to place it. **You are prompted:** Pick point on a sectioned BIM element [Auto/Current mleader style/change Tag type]:
5. Repeat steps 3 and 4 for all of the entities you wish to be tagged. If you do not require any more tags, press the Esc or Enter to complete the command.

2.13.3 Annotations in 3D

Command: BimTag (6.7.59), BimClassify (6.7.12) **Overview:** In this lesson, you will learn to add annotations in a 3D model. An annotation is a graphical representation within the geometric context of a project, that adds a note or meaning to the objects of the project. Examples of annotations: additional line drawings, text, dimensioning and hatching. **Lesson Objectives** After completing this lesson, you will be able to:

- Add annotations to a 3D model
- Classify 3D solids as an annotation

BIM Classify as an annotation

1. Select a solid and select **Classify Manually** in the Quad **or** classify as **other** in the Home tab of the Ribbon: (2.815 on the following page)
2. Choose to classify as **Annotation** in the folder of Building Core Elements and click OK: (2.816 on page 2395)
3. When you open the Properties panel of the selected solid you can change the Name, Description, Building and Story. **Note:** The property GUID cannot be changed because it has a unique, automatically generated string. (2.817 on page 2396)

Show added information of a finishing material.

In this procedure, you will add design information to a concrete roof structure.

1. Use the **ExtractFaces** command under **Draw** in the quad, to extract the face of the Roof entity. A region is now created. (2.818 on the next page)
2. Classify the region as an **Annotation** as seen above (2.13.3).
3. Enter the desired text in the **Description** field (found in the Properties Panel): **Note:** By default, the BIMTag references the **Description** property. (2.819 on page 2399)
4. Make a section through the region and select **GenerateSection**() from the Quad: (2.820 on page 2400)
5. Open the generated section
6. Type **BIMTag** in the command line OR select **TagAutomatically** in the Annotate tab of the Ribbon. The text that you added is now in the 2D drawing: (2.821 on page 2400)

Show the surface area of an extracted surface

This procedure will teach you how to display other properties of an entity classified as an Annotation object. **Note:** The annotation tag pulls information from the **Description** property by default. For more information about **BIM Tags**, click here (2.13.2).

1. Select the face you want to extract the information from.
2. Select **Extract Faces** from the Quad. A region is now created. (2.822 on the next page)
3. Classify the region as an **Annotation** as above (2.13.3).
4. Make a section through the solid and select **Generate Section** () from the Quad.
5. Open the generated section
6. Type **BIMTag** in the command line OR select **Tag Automatically** in the Annotate tab of the Ribbon. **Note:** The tag appears empty because it refers to the **description** property by default.
7. Launch the BEdit (6.6.7) command.
8. Select the **_AnnotationTag** and click **OK**. (2.823 on page 2403)
9. Select the attribute definition, in the properties panel
10. Edit the **Tag** property, change it to **Geometry/Area**.
11. (optional) You can also change the **prompt** property. (2.824 on page 2404)

2.13.4 Create drawing types with Drawing Customization

Overview: In this lesson, you will learn how to make and edit various drawing types and templates with Drawing Customization. **Lesson Objectives** After completing this lesson, you will be able to:

- Use the Drawing Customization panel to create, edit, duplicate and delete a Drawing Customization template.
- Use the Entity Customizations editor to create, edit and delete a template for a specific entity.
- Use and apply the various Customization settings available to your desired entity.
- Use the Rules editor to set up and determine the filter rule parameters.
- Use the Styles editor to set up the graphic styles for the Drawing Customization template.
- Apply a Drawing Customization template onto a viewport.
- Navigate and share the Drawing Customization templates with other users.

Tutorial: In-depth Drawing Customization Click here to watch (2.826)

About Drawing Customizing

BricsCAD BIM uses drawing templates to customize your generated drawings. For a general understanding of how these templates are created and work, please visit the **Templates for generated drawings (2.13.18)** article. In V21, **Drawing Customization** allows you to create bespoke templates for drawing types based on a set filter parameter rule against an entity type's value or property within the 3D BIM model. This is especially helpful for customizing graphics of model entities independent of their assigned layers or layer states, therefore transferable and usable on other projects with similar entity properties. The Drawing Customizations tool is operated by 3 principles – **Entity Customizations**, **Filter Rules** & **Styles** – and is only accessible from the panel. **Note:** Version Control for Drawing Customization will be implemented from V21.1.06. As features and parameters are constantly improved and added in future V21 updates, using older versions of BricsCAD to open Drawing Customization templates may affect their behavior and performance. Therefore, a versioning system would help to prevent customizations from being accidentally opened or modified by BricsCAD versions that are too old to handle them properly.

Drawing Customizations Panel

1. Right-click the panel and hover to Panels. (2.827 on the following page)
2. Select **Drawing Customization** to **dock the tool icon in the panel (1.15.7)**. (2.828 on page 2409)
3. Open the panel, it allows you to create view templates to control and customize the visibility settings of your drawings on layouts. (2.829 on page 2410)

4. Click to create a new template. By default, the template is named **New Customization** with the text highlighted. (2.830 on the next page) **Note:** All the controls of Drawing Customizations are represented as

Figure 2.830

5. Rename the template whilst the text is being highlighted. Once done, press Enter to save and apply the name. (2.831 on the following page) **Note:** You can duplicate, rename or delete your customization templates.

6. Click the newly created **Drawing Customization** template tab to begin defining its customization settings. The first step into the template brings you to the **Entity Customizations**, where you will create the necessary entity customizations template and will be first described later in this article. (2.838 on page 2423) You will also notice a funnel icon and a pencil icon on the top right part of the panel. They are the **Filter Rules** and **Styles** tabs respectively. The 3 principles – **Entity Customizations**, **Filter Rules** & **Styles** – which make up the **Drawing Customization** tool as described earlier in the article, are now accessible on this main page.

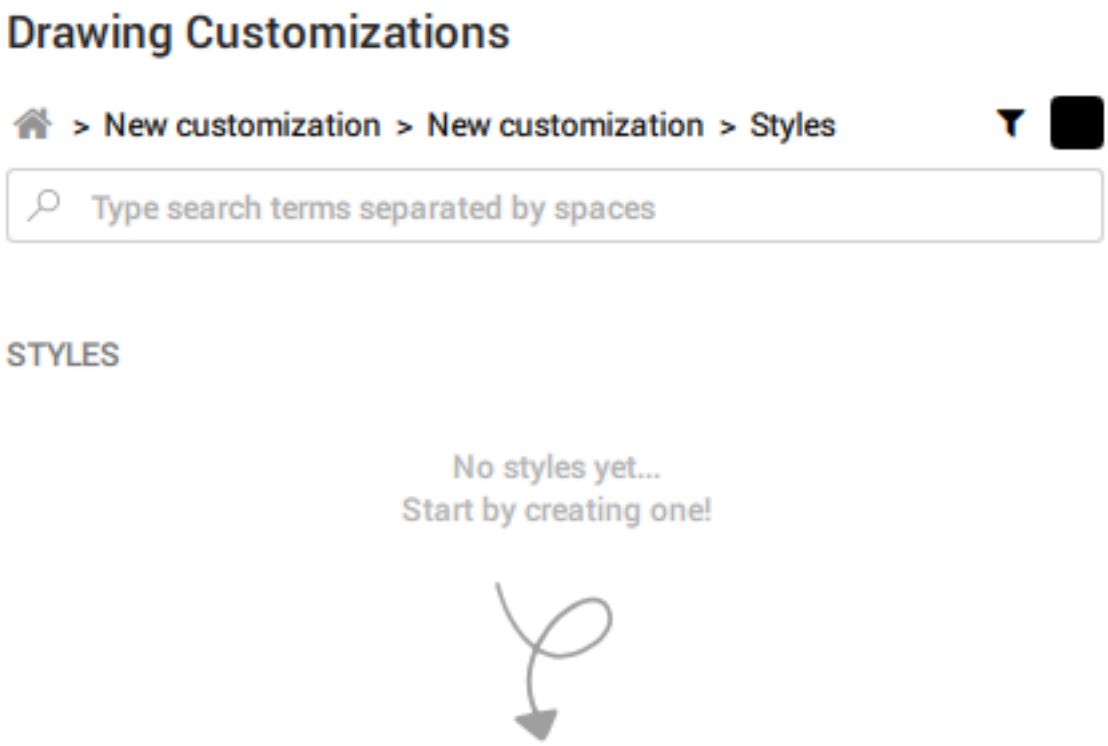
Drawing Customizations Styles

1. Click the pencil icon to access the **styles** tab. This is where your desired style options, such as line weight, line colors..., are stored and will appear as drop-down options in the Entity Customizations and Center Customizations settings as shown in the previous section above. (2.833 on the facing page)

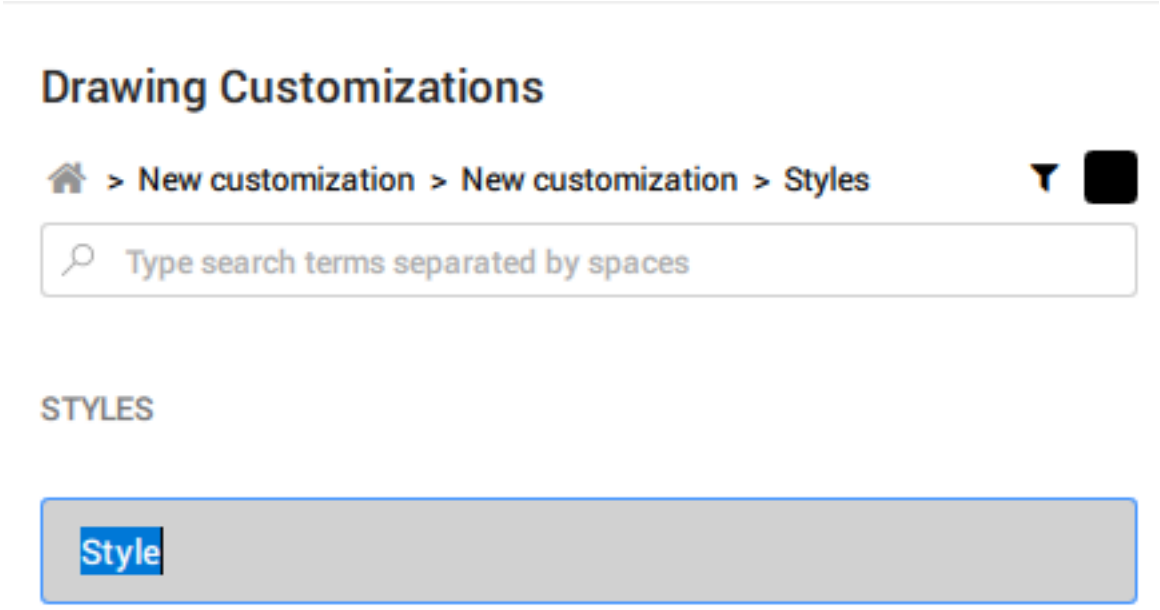
Figure 2.833



Drawing Customizations
> New customization > New customization > Styles
Type search terms separated by spaces
STYLES
No styles yet...
Start by creating one!

2. To create a new **style**, click at the bottom right of the panel and a new **Style** template tab will appear. (2.834 on the next page)

Figure 2.834



3. By default, the tab is named **Style**. Rename it whilst the text is being highlighted as shown. After you are done, hit Enter to save and apply.
4. Create a list of desired styles that you wish to use in this **Drawing Customization** template. Each tab contains its individual styles settings, such as the style's color, line type, line weight and line type scale. An example of the style pages a list of templates: (2.835 on the following page)
5. To edit any of the styles template available, click on its relevant tab to access its settings. **Note:** Similar to the Drawing Customization template tabs, hover over the styles template tabs to reveal the function icons to duplicate, rename or delete. Style settings include the options to define **Color (6.9.19)**, **Line Type (6.20.32)**, **Line Weight (1.25.7)** in their respective drop-down dialogs. Once done, click OK to save and apply the changes. (2.836 on page 2421)
6. To leave the **styles** page, click **Back** at the bottom left side of the panel to return to your previous page. From there, you can navigate to modify the **Entity Customizations** or **Rules** templates. **Or** Click on your desired branch in the tree structure map above the search bar to navigate to your desired page.
(**2.837 on page 2422**) **Note:** The tree structure map is helpful to keep yourself orientated within the Drawing Customization tool. Similarly, the search bar allows you to narrow to a specific template if you have a long list of values to navigate through.

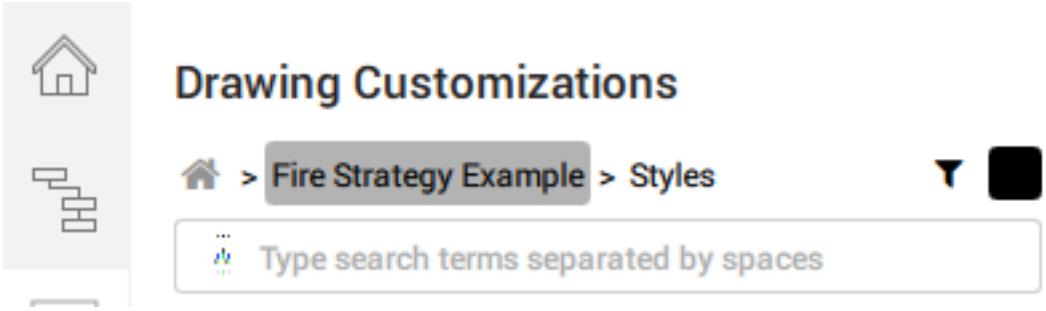
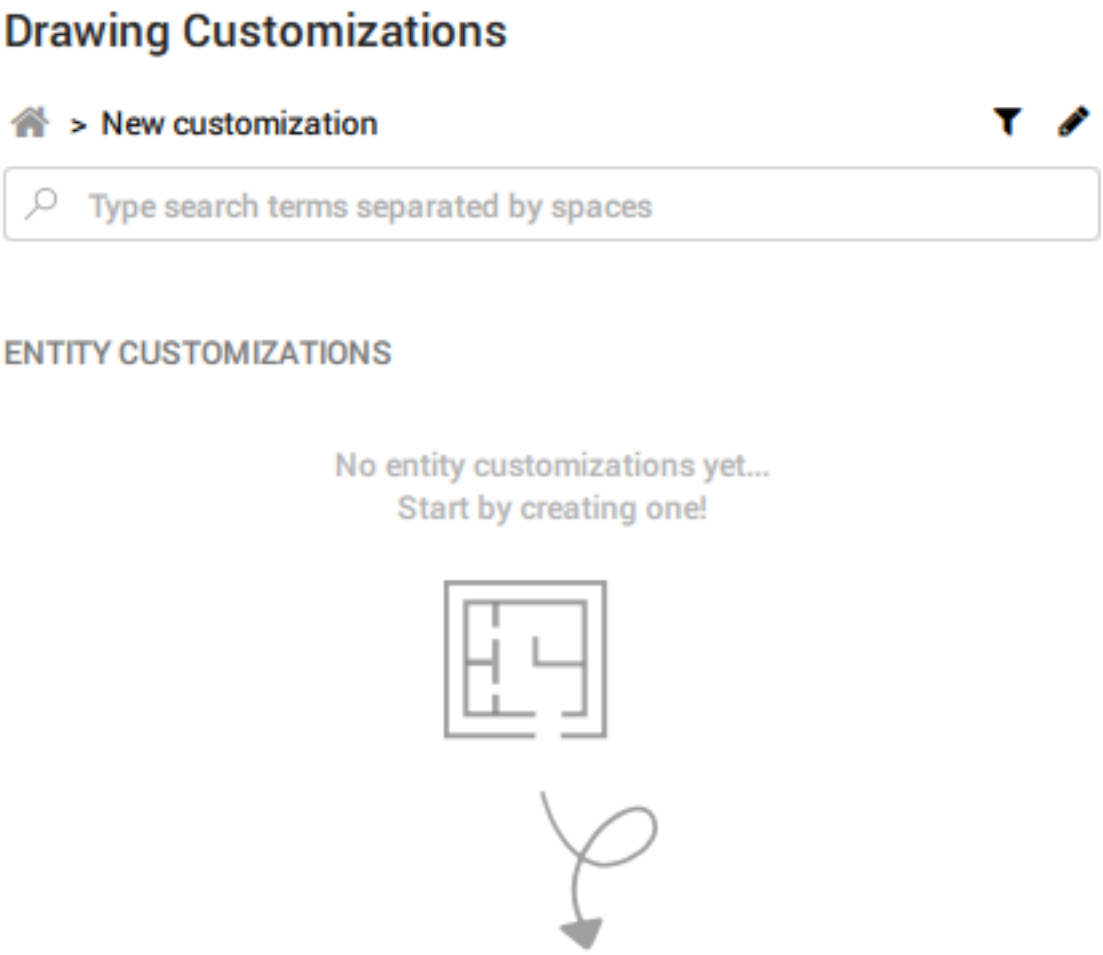
Figure 2.837



Entity Customizations

Entity Customizations refer to the visibility settings of how you would like to have your elements in your model drawing to look like. (2.838 on the next page)

Figure 2.838



Drawing Customizations
> New customization
Type search terms separated by spaces
ENTITY CUSTOMIZATIONS
No entity customizations yet...
Start by creating one!

1. Click

Figure 2.839

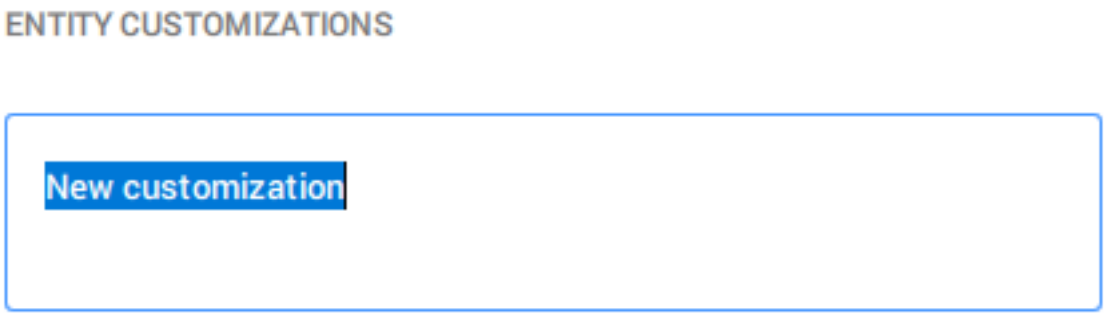


Figure 2.840

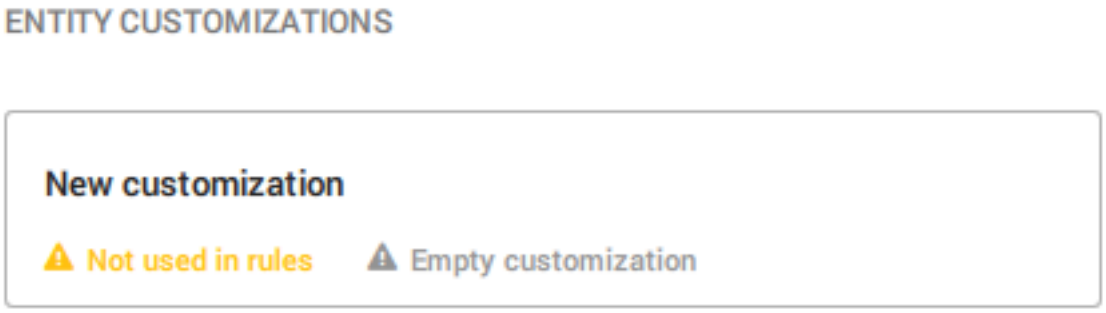

2. to create a new **entity customization** template. By default, the template is named **New Customization** with the text highlighted. (2.839)

3. Rename it whilst the text is being highlighted as shown. After you are done, hit Enter to save and apply. (2.840) As the **entity customization** was newly created and not fully set up, you will find the relevant notices at the bottom of the **entity customization** tab. This is a helpful mechanism to remind you if any customization settings have not been defined yet, saving you the need to check the settings manually.

4. Create a list of templates for the entities you wish to customize. A list of **Entity Customizations** templates could look like this: (2.841 on the facing page)

5. After creating your desired **entity customization** templates, click onto the individual tabs to modify their respective settings. You can choose how the element should look like as a section result, or how a centerline type representation should appear, or how an external symbol representation should replace the original entity. (2.842 on page 2428) You can further modify and customize a specific ply layer of your desired entity composition, but only if appropriate, i.e. a **wall (2.5.7)**, **slab (2.5.8)** or **roof (2.5.6)** entity.

6. The **section result customization** displays a series of controls with drop-down values from the Styles tab for more specific control of the section result graphics. You can override the entities' hatches via the **Appearance Override** with pre-set or custom **Physical Materials (6.21.10)** available in your project. (2.843 on page 2429) The diagram above illustrates how you could control the visibility and customization settings of an entity with the **Drawing Customization** tool. Notice that the **section plane (6.27.18)** is aligned with the Blue square with Red outline.

   - Green outline represents **Background**, which is essentially the elevation outline of the cut object.
   - Red outline represents **Intersection Boundary**, which traces over the cut area.
   - Blue hatch represents **Intersection Fill**, as it shows the area of being cut by the section plane.
   - Orange hexagons hatch represents **Elevation Fill**, which refers to the area bound by the elevation outline (see **Background**).
   - Pink outline represents **Hidden Lines**, as it is below the blue hatch
   - Yellow outline represents **Cut away geometry**, as it is above the section plane.

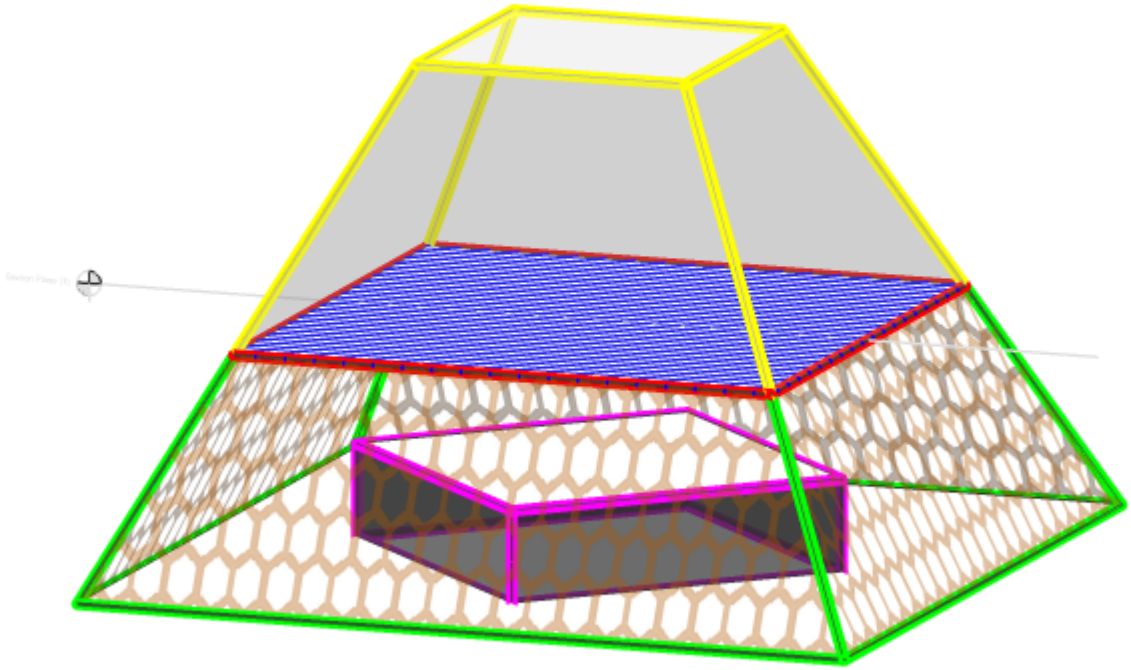
Figure 2.843



Appearance Override allows you to specify how an entity's hatch appearances (section and elevation) would appear, in place of the default hatch patterns already defined within the **Physical Materials** library. When you create any new **Physical Material** entry in the "In Project" category as part of the **Drawing Customization** template, your desired configurations are independent of the drawing project and stored in the template instead. You can later apply this template to other project models as you wish. You can further ensure the customization applies to the plies within the entity composition, if appropriate, by checking the **Inherit for plies** box. (2.844 on the next page) (2.845 on page 2432)

7. A similar setup can be found in the **Center Customization** settings, where your values in the **Styles** section of the customization template determines the drop-down selections. (2.846 on page 2433) Center customization is particularly useful in scenarios where you would like to display the center elements of various planar and/or linear entities. For example, if you were to apply the center customization settings against a planar entity, i.e. a wall, you would be referring to the display behavior of its center plane. However, if you were to apply the same settings against a linear entity, i.e. a beam, you would be adjusting how the beam's center line appears on the sheet. (2.847 on page 2434) The diagram above illustrates an example of how the center elements differ between planar (wall center plane highlighted in green; slab center plane highlighted in blue) and linear entities (both column and beam center lines in dashed red lines) There is no default setting to adjust the visibility of these center elements, and they are not normally displayed in section results.

8. For the **Symbol Customization** settings, you can find an input dialog to specify your desired external symbol drawing in .dwg format. If you would like to make any further changes to the 2D geometry itself, you can use the **Edit** button once the dialog is referring to your desired symbol drawing. Alternatively, you can begin creating one on a default symbol template by hitting the **Create New** button below the dialog. You can further apply your saved **Styles** to specific layers within your external symbol source, thereby allowing you to retain a general symbol drawing across several customization templates with different output results. (2.848 on page 2435) You could also choose not to specify any External Source Symbol, if you already have your desired 2D layers inside the model, usually as a 2D graphical representation that comes alongside the 3D geometry of a **Component.** In this instance, simply add a new **symbol layer customization** value containing part of the desired layer name. If they are part of the default **BRX_2D** layers, adding "BRX" as a name value will suffice. **Drawing Customization** will now search within the component entity that the customization template is applied to. This method, however, will not allow any exchanging or sharing of 2D symbols across entities, i.e. replacing a **Column** with a symbol derived from a BRX layer stored within a (table) **Furnishing Element.** (2.849 on page 2436) For more information on how BRX layers operate, please visit the chapter **Procedure: Understanding the BRX_2D layers (2.13.18) in the Templates for generated drawings article**.

Filter Rules

To be able to apply the right customization styles to specific entities, you have to set the appropriate filter rules to target those entities correctly in the **Filter Rules** tab located as a funnel icon  on the top right-hand part of the panel next to the **Styles** icon. **Note:** Nested Property Search function has been introduced from V21.1.06 onwards, allowing you to specify how nested objects within an assembly are filtered by and displayed. 2. Adding and editing a filter parameter will lead you to a prompt, where the options of filter property are determined by the **BIMPROPERTIES (6.7.38)** imported in the **namespace** settings. (2.852 on the next page)

3. The **Filter Operation** values are also available as a drop-down. **Note:** You can also start typing a certain keyword to search a specific property that you want to filter on.

(2.859 on page 2451) (2.860 on page 2452)

4. You can specify a string manually in your check value if your **Check Type** is a **Literal**. If you have selected a **Property (2.7.11)** value for **Check Type**, your **Check Property** value will refer to the same values found in the **Filter Property** drop-down.

(2.861 on page 2453) (2.862 on page 2454)

5. To end and legitimize a **filter rule**, the **entity customization** value must be added and filled in. The options available in the drop-down selection reflects the existing customizations tab available in the **Entity Customization** page. (2.853 on page 2444)

Applying templates to Viewports on sheets

With your **entity customizations**, **filter rules** and **styles** all set, your **Drawing Customization** template is now ready.

1. To apply the template, navigate to your sheet drawing with your desired viewport (1.23.16).
2. Open the Properties Panel (1.15.4) and select the viewport to view its properties. (2.854 on the next page)
3. Navigate to the **Drawing Customization** property and click on the drop-down selection to the right. (2.855 on page 2448)

Accessing Customization Templates

By default settings, these templates are stored in the Customizations folder within your **Support folder (6.27.59)** in the following path, under Bim folder and then Sections subfolder: **C:\Users\<user_name>\AppData\Roaming\Bricsys\BricsCA** The AppData folder is hidden by default, so you may have to unhide it first. This path can also be accessed by entering **SupportFolder** in the command line. You can specify a different path if your Customization files are stored elsewhere in an accessible folder. Simply redefine the path in the **Section settings search path** in the **Settings dialog box (1.17.10)** or typing **SRCHPATH** in the command-line: (2.857 on the following page) New customizations created with the panel will be stored in a Customizations subfolder in the specified path. Each customization template is saved as an individual folder which contains in its basic form Settings.dwg, a Filter.json and a New customization.json files. The folder will also contain any external symbol sources which you have created new using the **Create New** buttons. Settings.dwg contains the values created in the **Style** tab in the form of layers and if you have created any custom properties that you wish to use as a **Filter** parameter, you have to ensure they are also reflected in the Settings.dwg. (2.858 on the next page) **Note:** As these Customization folders are stored locally in the machine you have created it with, you need to ensure the folders and their contents within are copied and pasted into the same location on other machines, should you wish to share it with other users on other machines. This is the current, temporary procedure to do so, as a dedicated function to streamline the sharing process within the Drawing Customization tool will be released shortly in an update.

2.13.5 Customizing Sections

Overview: In this lesson, you will learn how to customize your sections. **Lesson Objectives** After completing this lesson, you will be able to:

- Customize sections using the SectionPlaneSettings
- Save the customizations of sections into a template

About

In the SectionPlaneSettings (6.27.12) you can control per section plane how certain types of lines are plotted, and on which layer they are created. This, together with your templates, should give you full control over which layers are created and what your generated 2D drawings will look like. See the article 'Templates for generated drawings (2.13.18)' for more info on how to set your templates.

Understanding the section plane settings

Customizing the section plane settings

Saving the section plane settings

2.13.6 Define Detailed Section

Command: BimSection (6.7.54) **Overview:** In this lesson, you will learn how to use the Detail option of BimSection in order to produce detailed sections.

About

The detailed sections are section planes that have the volume state applied automatically. These sections only contain the details inside of the volume and so they are used to focus on a part of the project. Detailed sections can be defined from scratch or based on an existing section.  For more information about this command, visit the Command Reference article BimSection (6.7.54).

Define a detailed section from scratch

1. Select **Detail Section** from the ribbon **or** use the command line by entering **BimSection** followed by **D** to choose the detail option. **You are prompted:** Select the first corner of the section box or [Based on an existing section/Scale]:
2. Select the first corner of the area you wish to be contained within the detailed section. **You are prompted:** Select the opposite corner of section box:
3. Select the opposite corner snap to a point or enter the distances. Use the TAB key to switch between dynamic dimension fields. **You are prompted:** Select the height of volume box <4000>: In this case, the default height is 4000mm.
4. To complete the volume, do one of the following:

- Press Enter to accept the default height.
- Specify a point.
- Type a value in the dynamic dimension field (1).

(2.863 on the facing page) To view the detailed section which has just been defined, hover over the section and select **Clipdisplay (6.9.22)** (2) from the Quad **Or** double-click the selected section. Now only the detailed section will be visible (3). (2.864 on page 2458) (2.865 on page 2459)

Figure 2.863

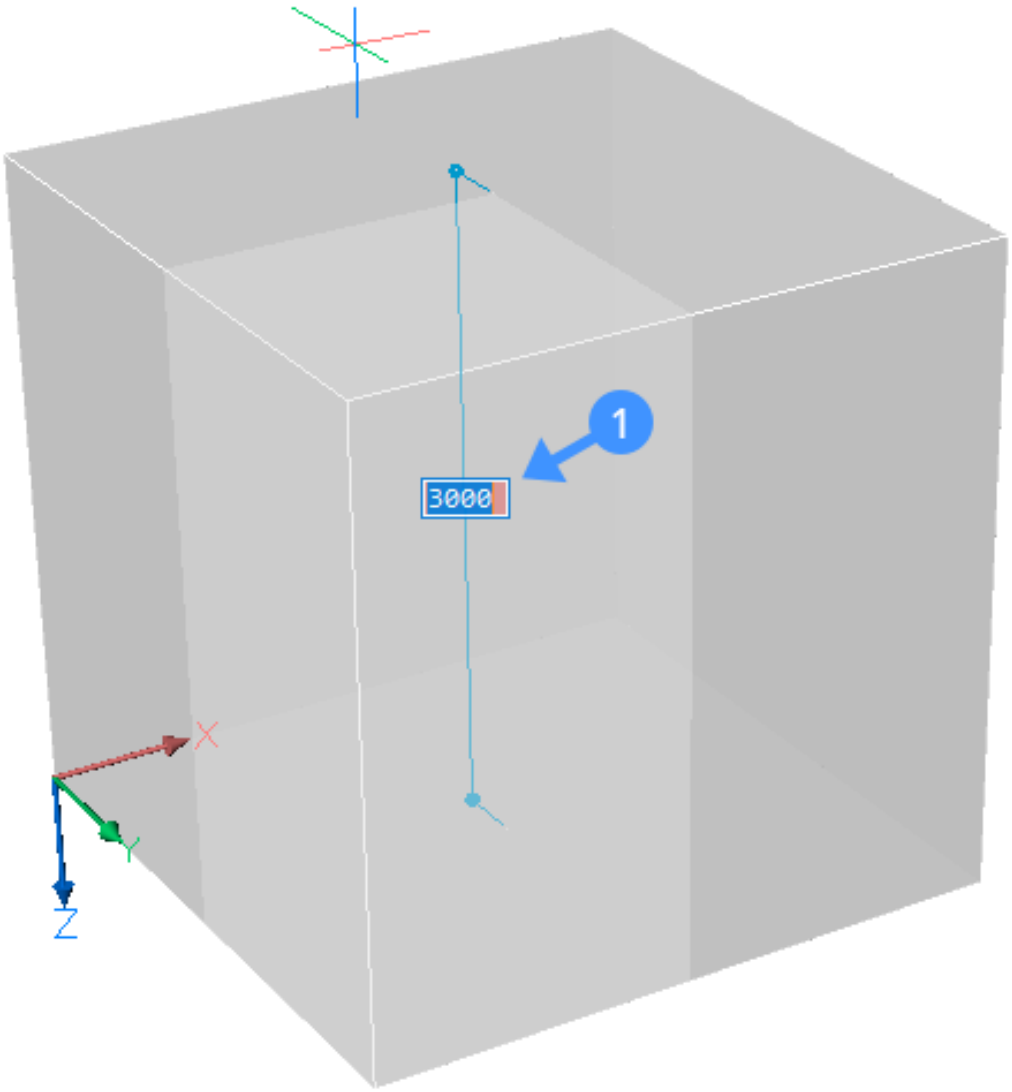

Figure 2.864

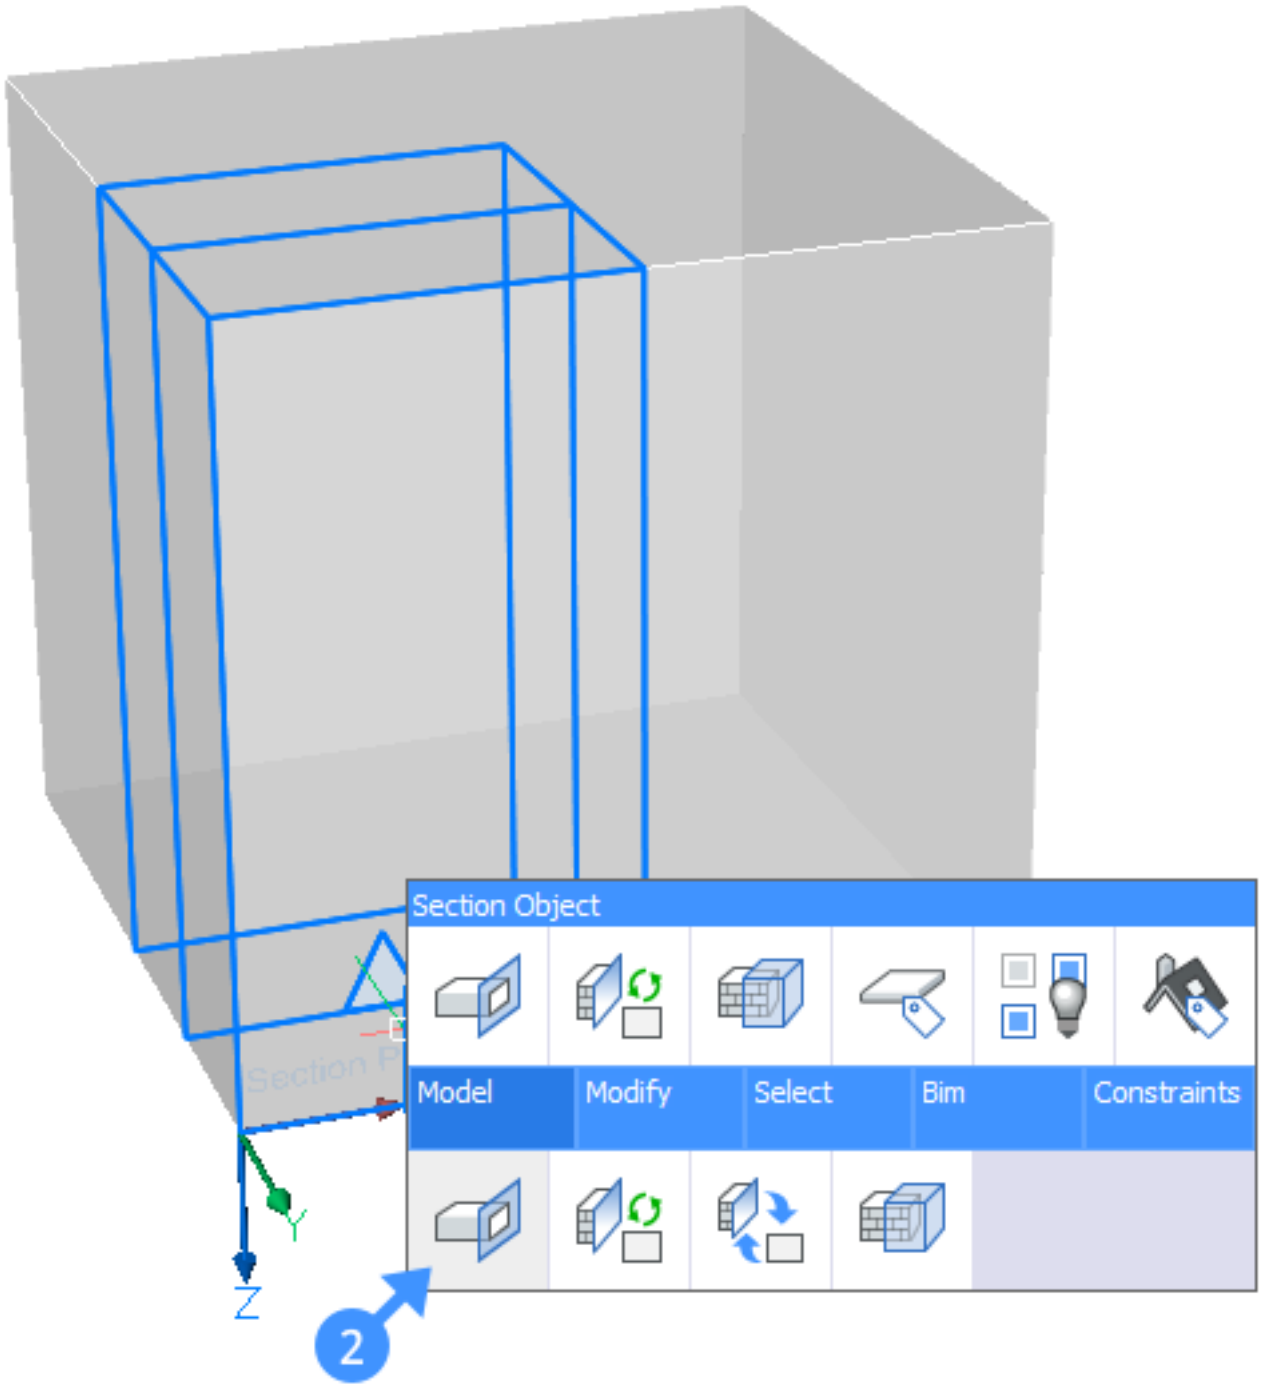

Figure 2.865

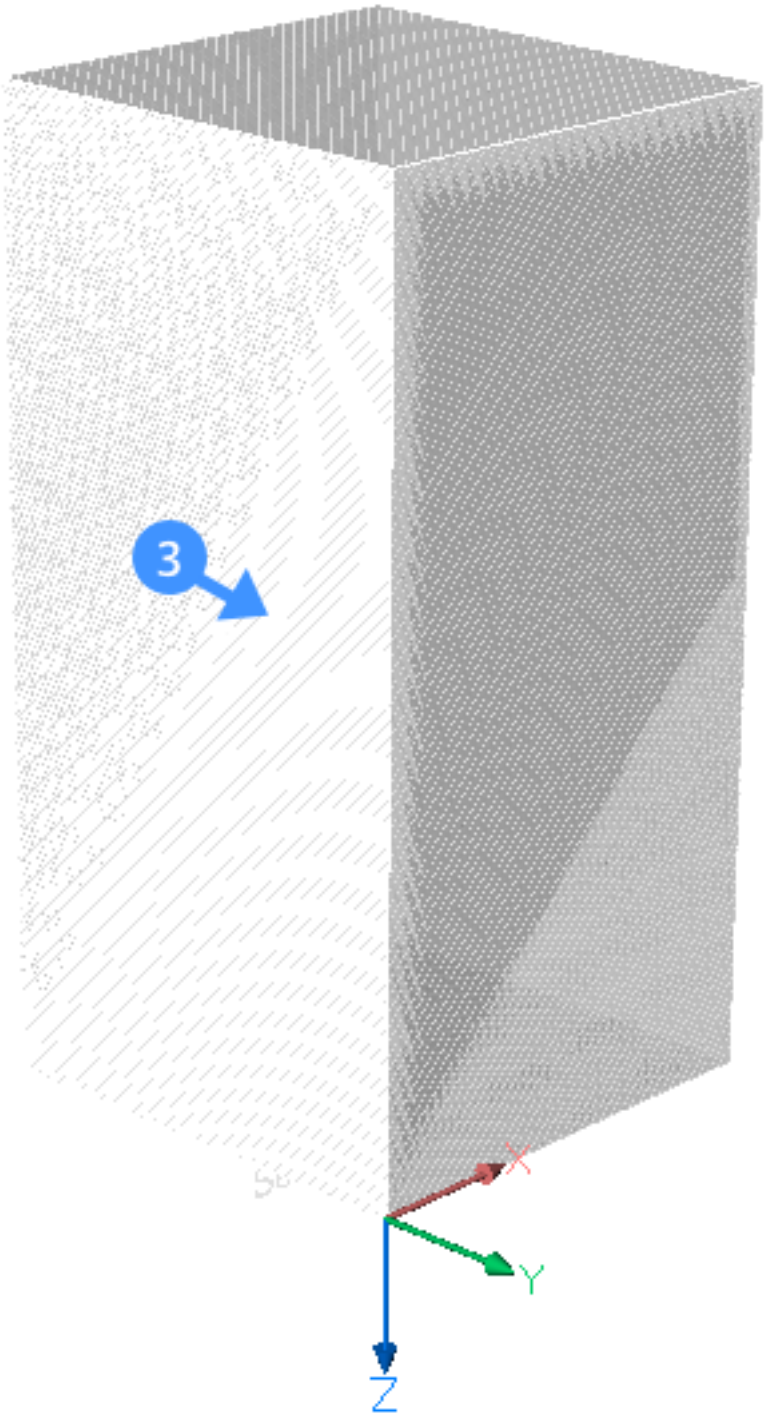

Define a detailed section based on an existing section

Here you will be shown how to position the base of your detailed section on an already existing section.

1. Highlight the existing section that you want the detailed section base to be positioned on and select **Detail Section** from the Quad. (2.866 on the next page) **You are prompted:** Select first corner of volume box base rectangle:
2. Draw a rectangle around the desired area by typing the values in the dynamic dimension fields. Hit the TAB key to go back and forth between the dynamic dimension fields (4, 5). Your selection will be aligned with the plane of the existing section.
3. Press Enter to confirm the values. The volume section box displays dynamically. (2.867 on the facing page) **You are prompted:** Select the height of the volume section box.
4. Press Enter to accept the default height.
5. Specify a point.
6. Type a value in the dynamic dimension field.
7. The detailed section has now been defined and can be found in the structure browser. Hover over the section and select **Clipdisplay** from the Quad **Or** double-click the selected section to view it.
8. To generate the detailed section on a sheet, select the detailed section and select **Generate Section** from the Quad.
9. You can open the section results by clicking **Open Model.** When the section plane(s) are selected. The sheet is saved to the same folder containing the model drawing. (2.868 on page 2462) (2.869 on page 2463)

If you need more help with how to generate drawings, visit the Generating Drawings page (2.13.13). If you want to annotate your drawings, see how to add tags (2.12.1) and linear dimensions (1.29.7).

Figure 2.866

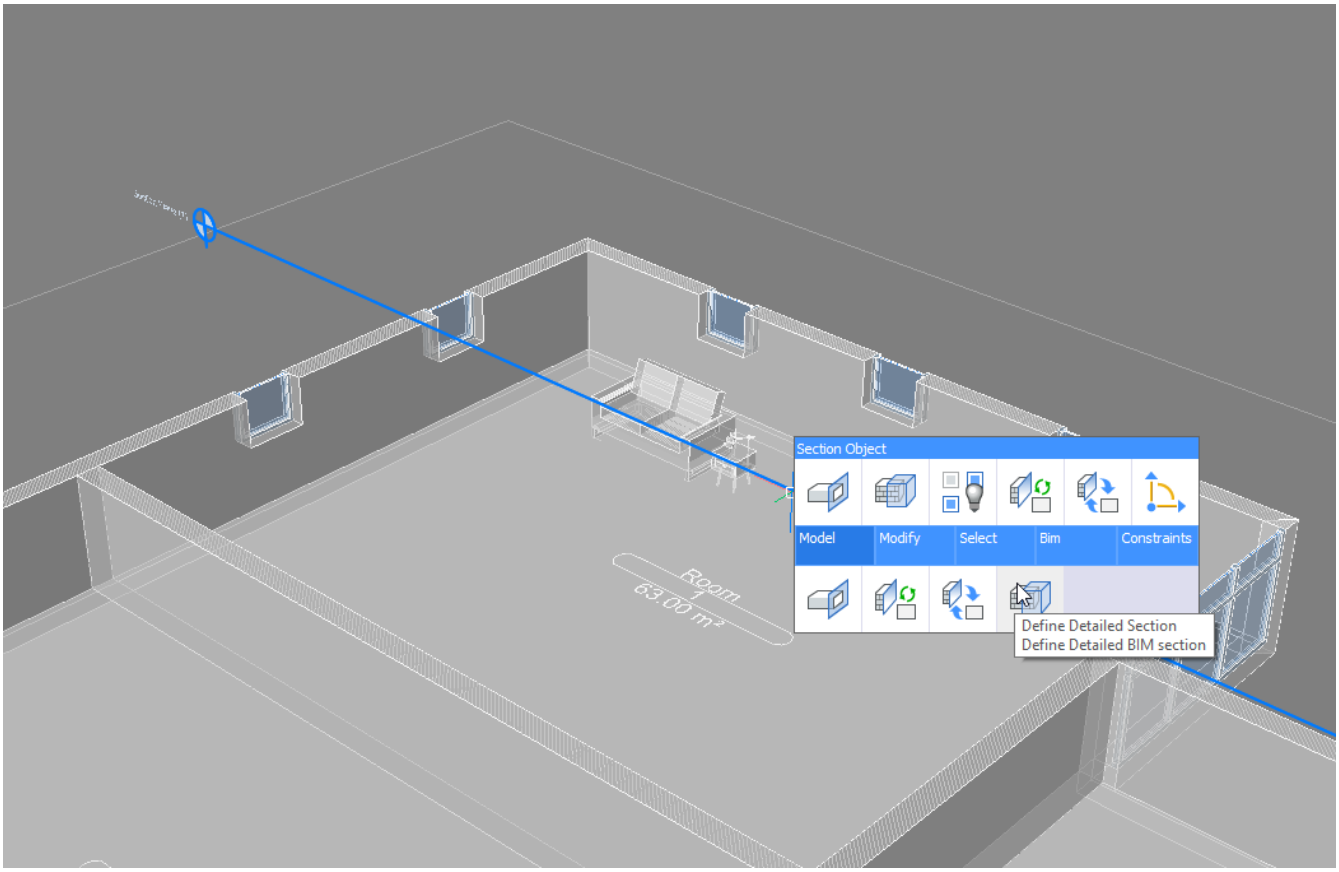

Figure 2.867

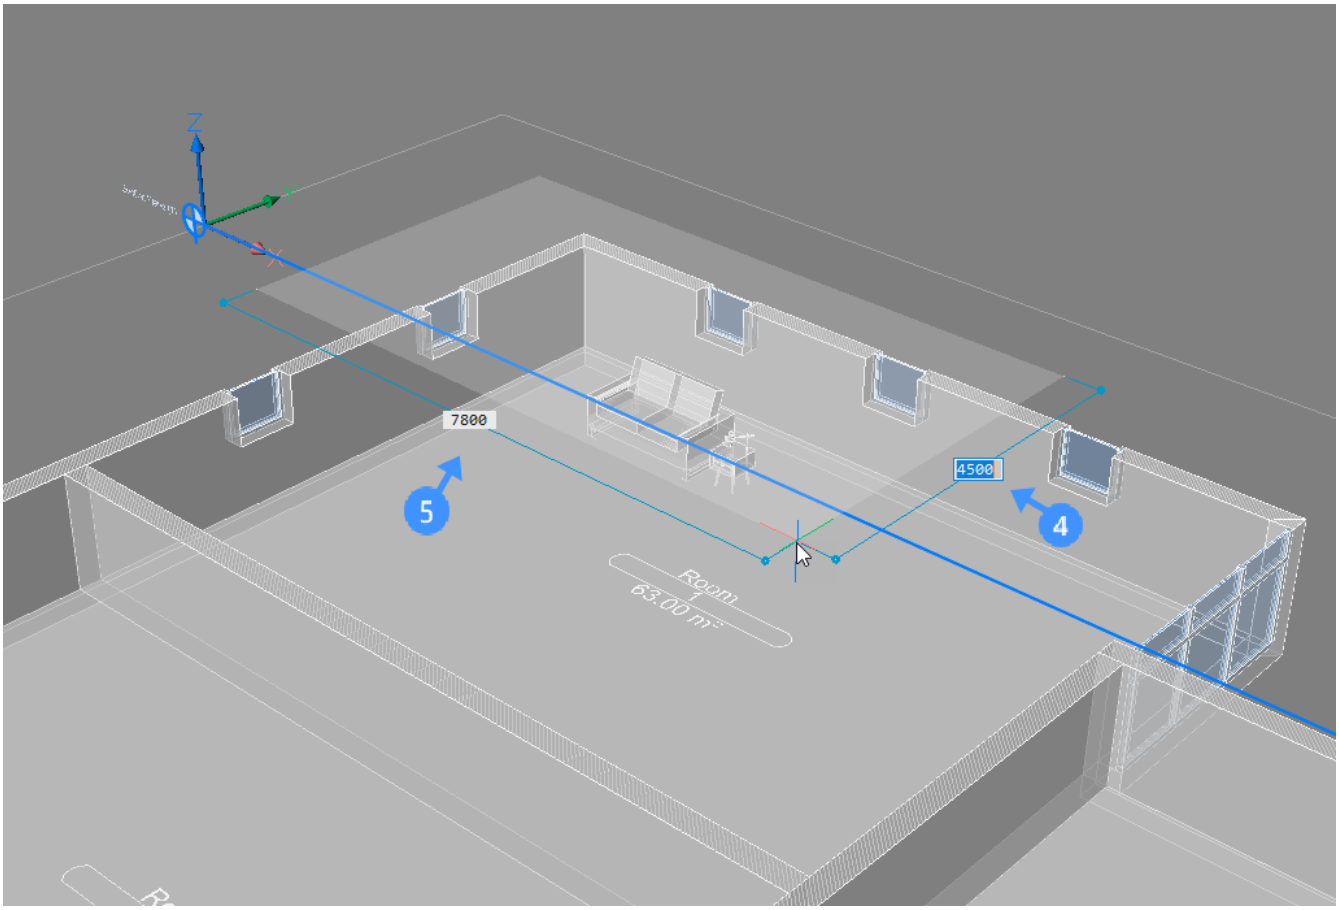

Figure 2.868

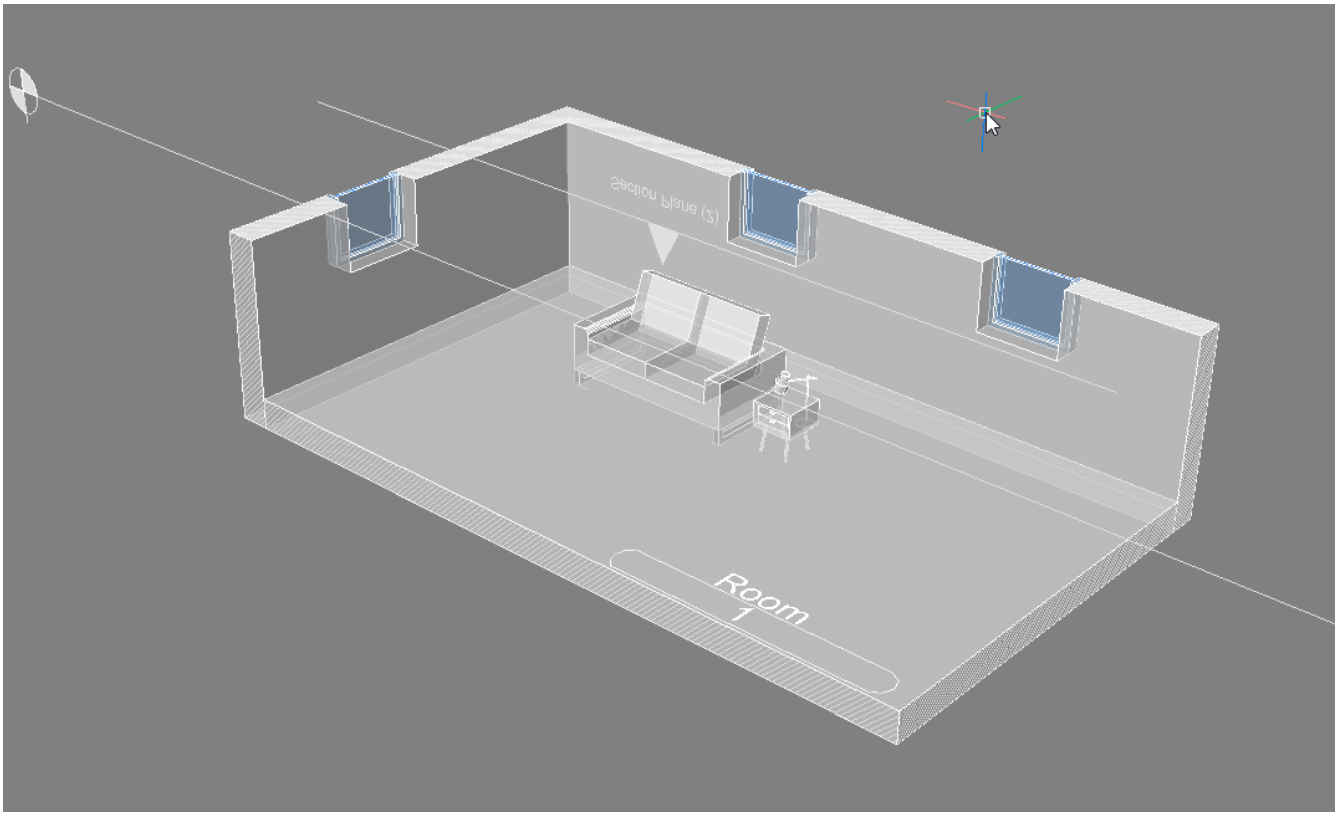

Figure 2.869

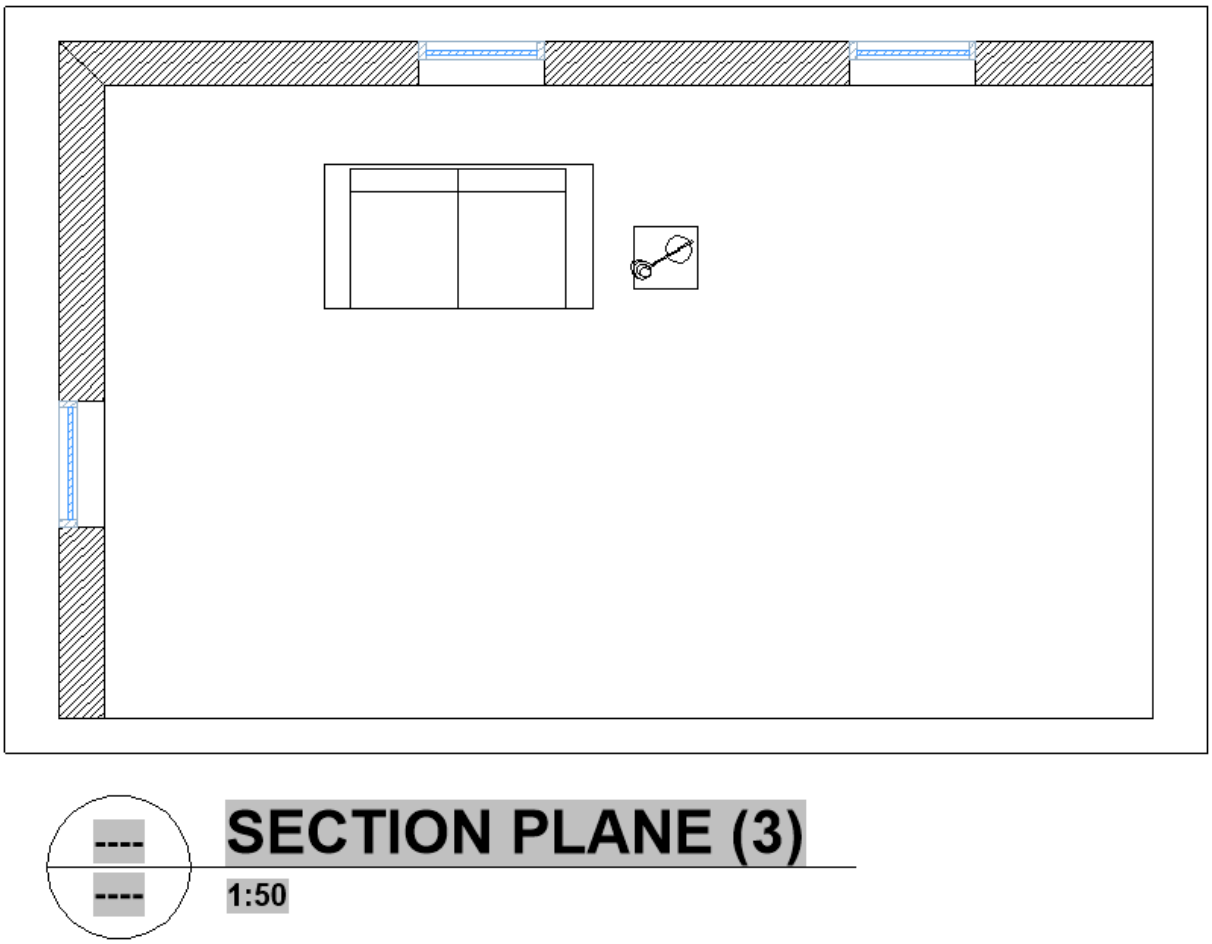

2.13.7 Define Reflected Ceiling Plan

Command: BimSection (6.7.54) **Overview:** In this lesson you will learn how to use the Reflected ceiling option of BimSection in order to produce reflected ceiling plans.

About

Reflected ceiling plans show a mirror image of the ceiling. These are useful to show the layout of lights and other installations in the ceiling. To produce the reflected ceiling plan a section is created. This section displays the part of the building above the section boundary.  For more information about this command, visit the Command Reference article BimSection (6.7.54).

Create a reflected ceiling plan

1. Select **Reflected Ceiling Plan** from the ribbon **or** enter BimSection (6.7.54) into the commandline followed by **R** to choose the Reflected ceiling option. **You are prompted:** Select a point to place section:
2. Select the ceiling or a face with a plane parallel to that of the ceiling. (2.870 on the next page) **You are prompted:** Specify distance:
3. Do one of the following:
   - Type a value in the dynamic dimension field to offset the section from the initial position.
   - Left-click when the section plane is at the location you want.
4. The reflected ceiling section has now been defined. To view hover over the section and select **Clipdisplay (6.9.22)** from the Quad. (2.871 on the facing page)
5. To generate the reflected ceiling plan on a sheet, hover over the section in the model and select **Generate Section** from the Quad.
6. To open the section result click **Open Model**. The sheet is saved to the same folder that contains the model drawing.

(2.872 on page 2466) If you need more help with how to generate drawings, visit the Generating Drawings page (2.13.13). If you want to annotate your drawings: see how to add tags (2.12.1) and linear dimensions (1.29.7).

Figure 2.870

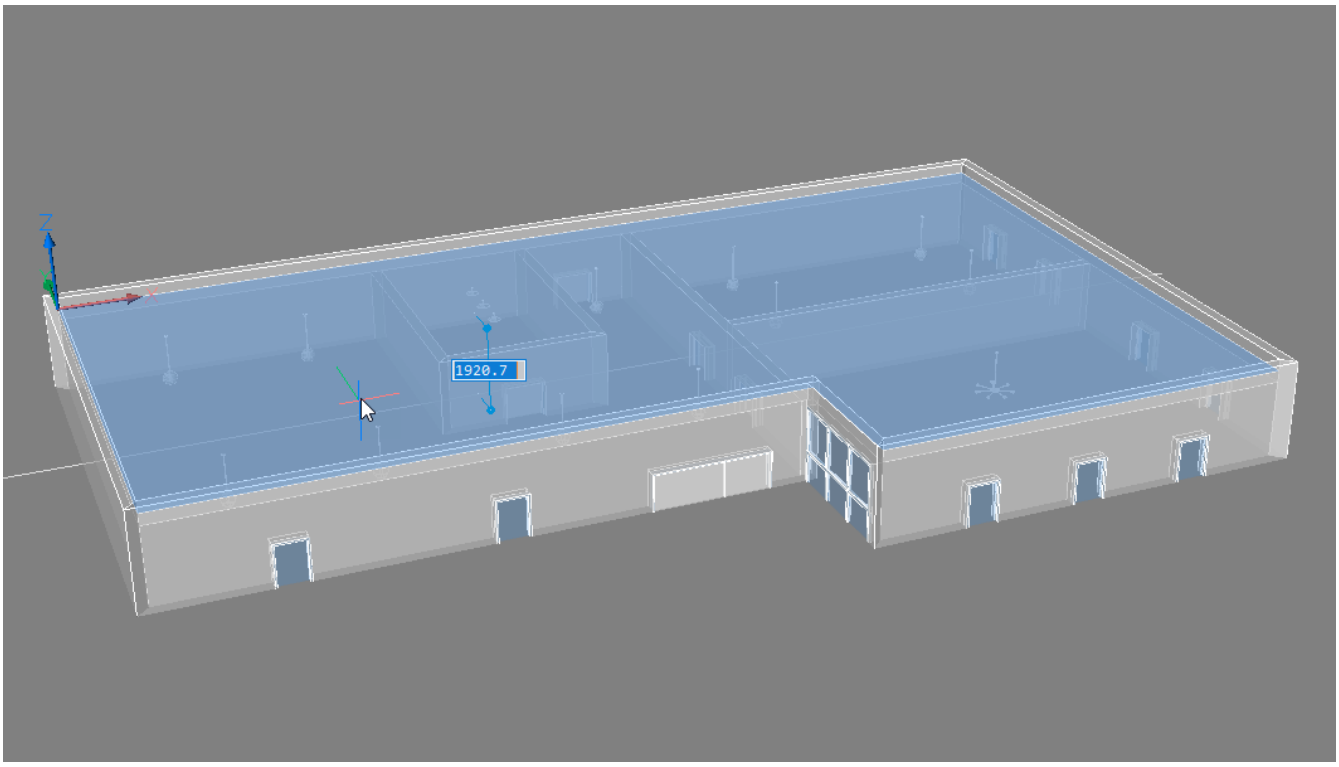

Figure 2.871

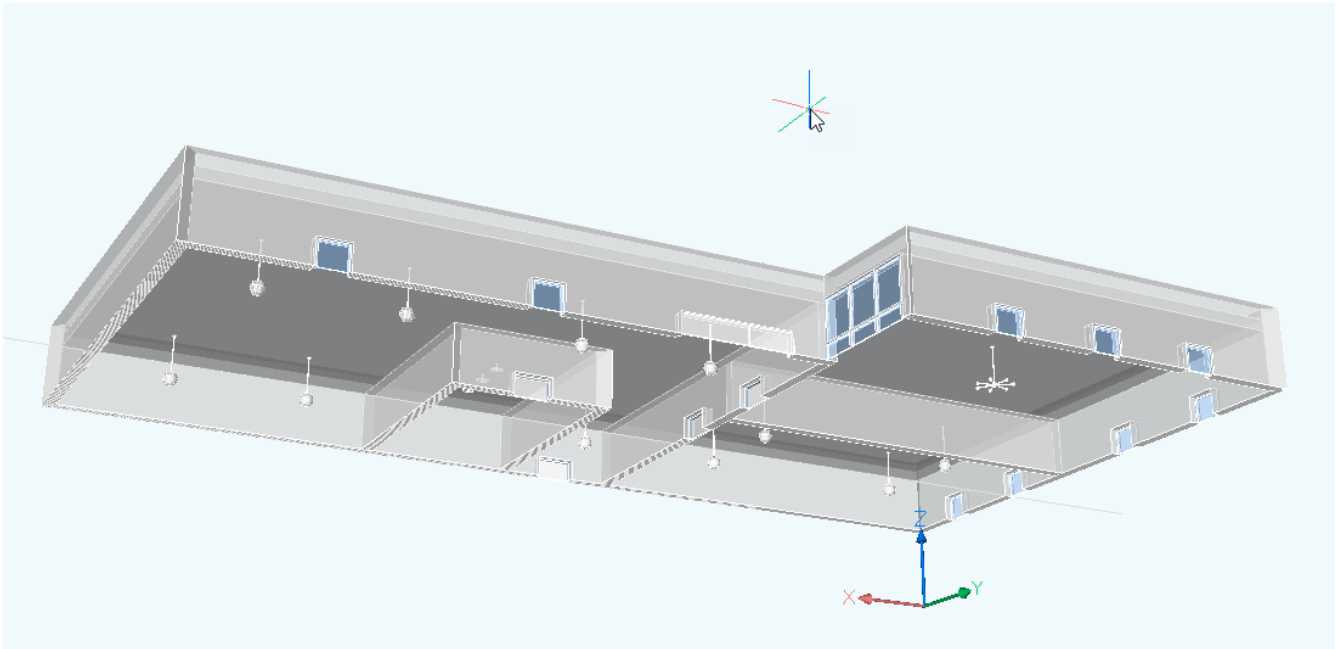

Figure 2.872

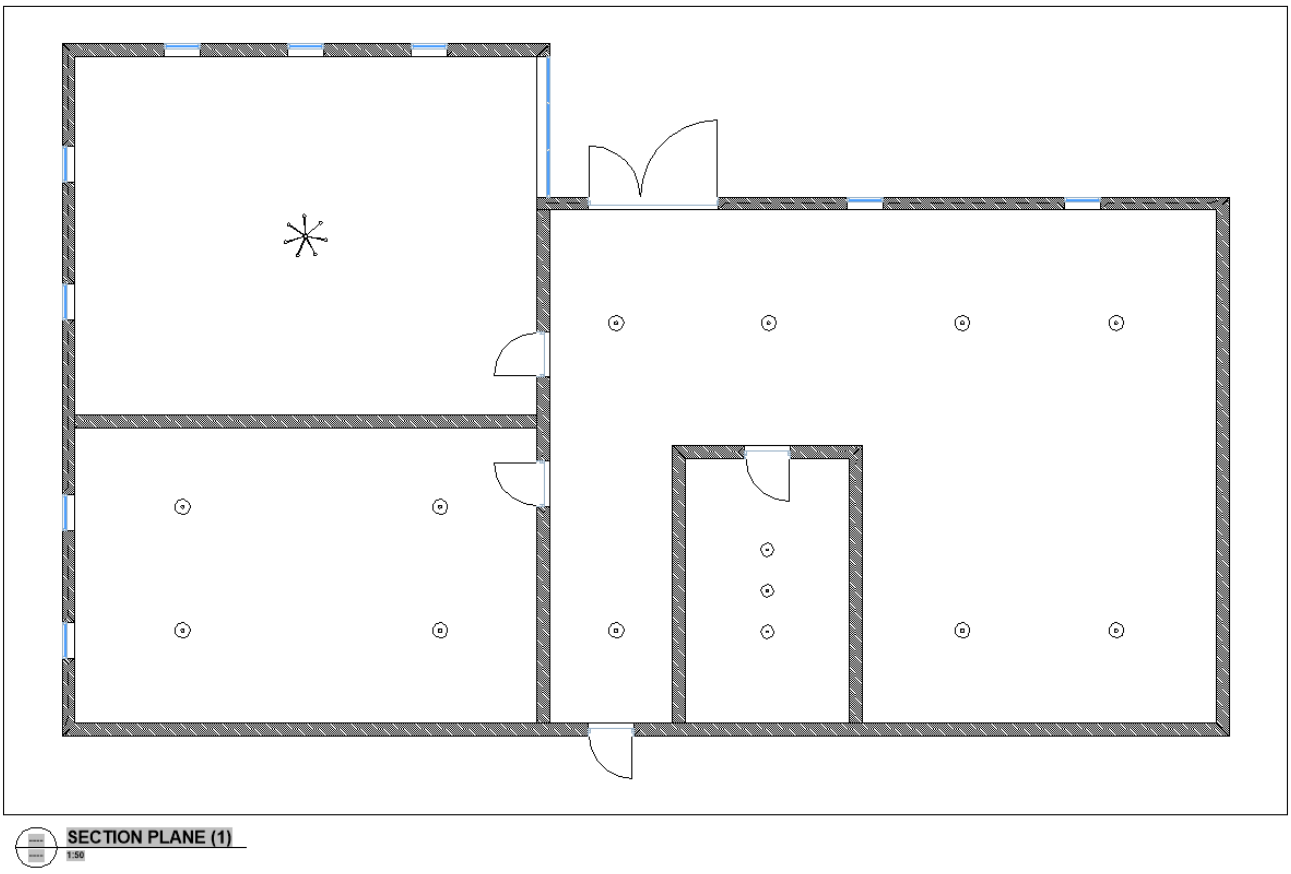

2.13.8 Detailing with BimPatch

Note: BIMPATCH cuts out part of geometry and replaces it by a block reference. In this cutting process, entity data linked to the 3D model are lost. Therefore, starting from V21.2, this command is no longer available. **Command**: BimPatch (6.7.27) **Overview:** In BricsCAD BIM sections are generated from the 3D model into 2D line drawings, which come in the form of a section result block. **BimPatch** allows you to detail a certain area of this result block by overlaying a 2D patch that you can edit with **RefEdit**. **Lesson objectives:** In this lesson, you learn how to use **BimPatch** to edit a generated section.

About

The **BimPatch** command allows you to specify a rectangular area on a block that you previously generated. When you use **BimSectionUpdate** again to update the section, BricsCAD checks if the geometry bounded by the patch has changed. If it is unchanged, then the patch is preserved; if changes occurred, then BricsCAD outlines the patch boundary in red. The Patch enables you to replace/edit a part of a generated section.

Procedure: Detailing a window connection

In this procedure, we will add fixtures and a vapor barrier to our window-wall connection. We will detail this window-wall connection. (2.873 on the following page)

1. Open the section. For more information about creating sections, click here (2.12.5).
2. Go to the model space by double-clicking in the viewport **or** toggle the viewport mode in the Status Bar. (2.874 on the next page)
3. Launch the **BimPatch** command in the model space.
4. Draw the rectangle over the detail and hit enter. (2.875 on page 2469)
5. Hover over the section object and launch **RefEdit** from the quad. (2.876 on page 2470)
6. A menu appears, select the patch (1) and click ok (2). (2.877 on page 2471)
7. Draw the required detail for the window-wall joint. We will add a vapor barrier. (2.878 on page 2472)
8. Save the changes made in the **RefEdit** session with the **Save** option of the **RefClose** command.
9. Go back to the paper space. The detailing of the window connection is done. If we now move the window to the left in the 3D model, you will see that the detail you made a patch of moves along. (2.879 on page 2473) **Note**: If you would have added the vapor barrier in the model space of the section without making a patch of it, the vapor barrier wouldn't be seen as a part of the detail. If you would move your window, the vapor barrier would stay in the same position as you drew it before. (2.880 on page 2473)

2.13.9 Editing Data Extraction Definition (.dxd) files.

DXD (Data Extraction Definition) files are plain text files. You can edit DXD files created by the DataExtraction (6.10.4) command using a text editor such as MS Notepad and use them in the Creating Schedules (2.7.15) procedure in the Project Browser (2.7.15). Lines starting with semicolon (;) are comments and ignored on parsing. Empty lines are ignored as well. The file can contain 4 sections, each section name is written between square brackets;, section names are English case-insensitive (ECI) strings. The sections are:

- Settings
- Entity Types
- Properties
- Filter

The [Settings] section

The section contains values of the following parameters which control the behavior:

- **ExtractFromBlocks** - whether to take entities from blocks into account, considering all nesting levels.
- **ExtractFromXrefs** - whether to take entities from external reference blocks into account.
- **CountXrefs** - whether xrefs are taken into account at all.
- **CombineEqualRows** - whether to group equal rows in the output table; if yes, then the 'Count' column is added, which indicates how many equal data rows are included.
- **IncludeNameColumn** - whether the output includes the 'Name' column. The 'Name' column indicates the source entity type: 3D Solid, 3D Solid Ply, ...

Parameter names are ECI strings. The format is: ParameterName=value, The value is either 1 or 0. No spaces should be written around the equal (=) character.

The [Entity Types] section

This section contains list of entity types which will be processed. The format of each line can be one of the following types:

EntityType|DisplayEntityType

- **EntityType** is the ECI entity type name, such as Circle or AttributeDefinition . This is the mandatory part of the line. .
- **DisplayEntityType** is optional and can be any character string including spaces in any language. If present, this string appears in the DATAEXTRACTION dialog and in the output table.

Block|BlockName|DisplayBlockName

- **Block** is the predefined ECI word, and **BlockName** is case-insensitive name of the block to be processed, including xrefs and minserts.
- **DisplayBlockName** is optional and has the same meaning and format as DisplayEntityType.

Block|* This is a variant of the previous format meaning that all blocks will be taken into account; if present, then all other lines regarding blocks in this section are ignored. You can use the **Filter** section to filter the content to be processed.

* All entity types and blocks will be taken into account, all other lines in this section are ignored then. You can use the **Filter** section to filter the content to be processed.

The [Properties] section

This section contains a list of all properties to be included in the data extraction output. The format of each line can be one of the following types: Entity Property, Attribute, Drawing, Formula or Block View.

EntityPropertyName|DisplayEntityPropertyName|ValueOutputFormat

- **EntityPropertyName** is the ECI name of entity property, e.g. Lineweight, Color, Center Y and so on. Note, all names do not contain spaces except those which represent coordinates of 2D or 3D points or vectors. In the last case, coordinate letters X, Y and Z should be separated by single space from the general property name. EntityPropertyName is the mandatory part of the line, the remaining part is optional.
- **DisplayEntityPropertyName** is user-defined and can be in any string including spaces in any language. By default it is equal to EntityPropertyName.
- **ValueOutputFormat** is a string which is used to format the output. The syntax of the string is the same as in fields formatting (1.29.23).

Attribute|AttributeTagName|DisplayAttributeTagName|ValueOutputFormat

- **Attribute** is the predefined ECI word.
- **AttributeTagName** is the ECI attribute tag name as it is stored in the drawing.
- **DisplayAttributeTagName** and has the same meaning as for **EntityPropertyName** (see above).
- **ValueOutputFormat** is a string which is used to format the output. The syntax of the string is the same as in fields formatting (1.29.23).

Drawing|DrawingPropertyName|DisplayPropertyName|ValueOutputFormat

- **Drawing** is a predefined ECI word.
- **DrawingPropertyName** is an ECI name, which can be one of the following:
  - Comments
  - DrawingRevisionNumber
  - FileAccessed
  - FileCreated
  - FileLastSavedBy
  - FileLocation
  - FileModified
  - FileName
  - FileSize
  - HyperlinkBase
  - Keywords
  - Subject
  - Title
  - TotalEditingTime
- **DisplayPropertyName** has the same meaning for **EntityPropertyName** (see above).
- **ValueOutputFormat** is a string which is used to format the output. The syntax of the string is the same as in fields formatting (1.29.23).

Formula|EntityPropertyName|DisplayEntityPropertyName=FormulaExpression|ValueOutputFormat,

- **Formula** is predefined ECI word.
- **EntityPropertyName** is an unique name for this formula item.
- **DisplayEntityPropertyName** is an optional output name of the property, if it is omitted, then **EntityPropertyName** is used as the table column title.
- **=** is a mandatory sign, which must exist even if **DisplayEntityPropertyName** is omitted.
- **FormulaExpression** is the expression in format as in **\AcExpr** formula fields, which can contain constants such as PI or functions such as SIN (see Using Expressions (1.21.7)). An operand in an expression can be a DisplayPropertyName enclosed in arrow brackets (<>). For instance: =2 * PI * <Radius> calculates the circumference of a circle.
- **ValueOutputFormat** is a string which is used to format the output. The syntax of the string is the same as in fields formatting (1.29.23).

BlockView|BlockViewPropertyName|DisplayBlockViewPropertyName|BlockViewOptions

- **BlockView** is a predefined ECI word
- **BlockViewPropertyName** is an unique name for this block view item
- **DisplayEntityPropertyName** is the output name of the property; cannot be omitted
- **BlockViewOptions** is a string in the following format: ViewType;DwgPath;SectionName
  - **ViewType** is one of the following: **Front**, **Top**, **Left** or **Right**; cannot be ommited

- **DwgPath** is path to dwg file, may be relative with respect to the dxd file; can be ommited
- **SectionName** is the name of the section to extract the section settings from for the block view construction,;can be ommited

If **DwgPath** or **SectionName** are ommited or not found, default settings will be applied. An example: BlockView|BlockViewProperty1|Elevation symbol|Front;../Sections/_SectionSettings.dwg;_BlockViewSettingsSection

*** If present all entity properties are taken into account; all other lines in this section, except Drawing and Formula lines, are ignored.**

The [Filter] section

Syntax description:

Operator	Meaning
==	equal to
!=	not equal to
<	less than
>	greater than
<=	less than or equal to
>=	greater than or equal to

Relational operators:

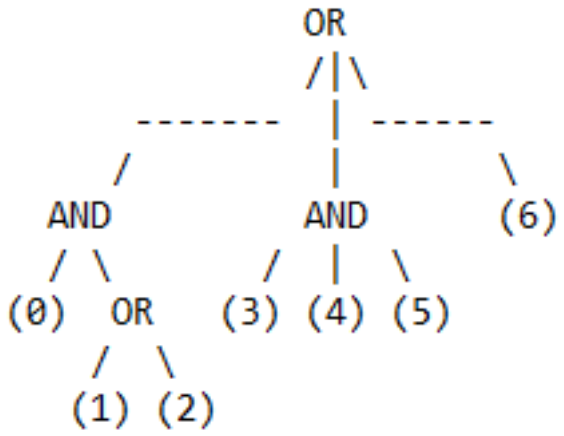
- Relational expressions are enclosed in '()' brackets
- Logical operators AND and OR are case-insensitive and enclosed in '<>' brackets.
- Logical expressions use a prefix notation.
- No spaces are allowed between '<' and a logical operator ('<OR', '<AND')
- Tokens can be separated by zero or any number of spaces, except logical expression begin, example: <AND (Layer == "MyLayer")(Thickness<=3) >
- Expressions can be split into any number of lines; tokens are not broken.
- Use the **EntityPropertyName** to refer to properties (not the **DisplayEntityPropertyName**).
- Lines can be commented with ';' .
- String values are enclosed in double quotation marks ""

<OR (Type == Window)(Type == Door)> The result of the filter in the above example is that only BIM entities classified as windows or doors are included in the data extraction. See the BimClassify (6.7.12) command to learn more about BIM entity types.

The filter expression is either a single relational one or several ones grouped by logical operations.

Example: <OR <AND (0) <OR (1) (2)» <AND (3) (4) (5)> (6)> where (0),...,(6) are relational expressions such as (Radius >= 3). (2.881 on the facing page)

Figure 2.881



2.13.10 Editing Generated Drawings

When a BIM Section is generated, a block containing the drawing generation result is added to the model space of the target drawing, as well as a paper space viewport looking onto this block. The block and the viewport initially are placed so they do not overlap with existing geometry contained in the drawing. You can move this block or viewport to a new location, which will be preserved on subsequent updates. In the default template drawing which is used to create the generated drawings a **Viewlabel** and **NumberBubble** blocks exist. You can place them associated to the selected sheet view. The **Title** block in this drawing contains attributes that will be filled in automatically when the associated Sheet Set properties are defined. A sheet list table can be placed on any sheet of the sheet set. In the current implementation, the table content is not associative yet.

Inserting the Title block

1. Open the Drawing Explorer - Blocks (1.30.11) dialog.
2. Double click the **Title** block. The Drawing Explorer dialog closes and the block is attached to the cursor. In a metric units project the size of the **Title** block fits the A1 paper size (594 x 841 mm) In an imperial units project the size of the **Title** block fits the Arch D paper size (24 x 36 inches)
3. Click at the lower left corner of the paper sheet in the layout.
4. Define the Project and custom properties in the Sheet Sets panel.
5. Select the **Title** block, then click the **Update Fields** tool button () in the **Redraw/Regen** toolbar. (2.882 on the next page)

Inserting a view label for a sheet view

1. Select the sheet view In the Sheet Sets panel.
2. Right-click the sheet view you want the view label block to insert for. (2.883 on the facing page)
3. Choose **Place View Label Block** in the context menu. **You are prompted:** VIEWLABEL Units: Millimeters Conversion: 1 Insertion point for block:
4. Specify the insertion point. **You are prompted:** Scale factor for block <1.0>:
5. Specify the scale factor or right-click to accept the current scale. **You are prompted:** Rotation angle for block <0>:
6. Specify the rotation angle or right-click to accept the current angle. The **View Label** block is inserted. The Sheet Number (1), Sheet View Number (2), Sheet View Title (3) and Viewport Scale (4) of the selected sheet view are filled in automatically. (2.884 on the next page)

Figure 2.883

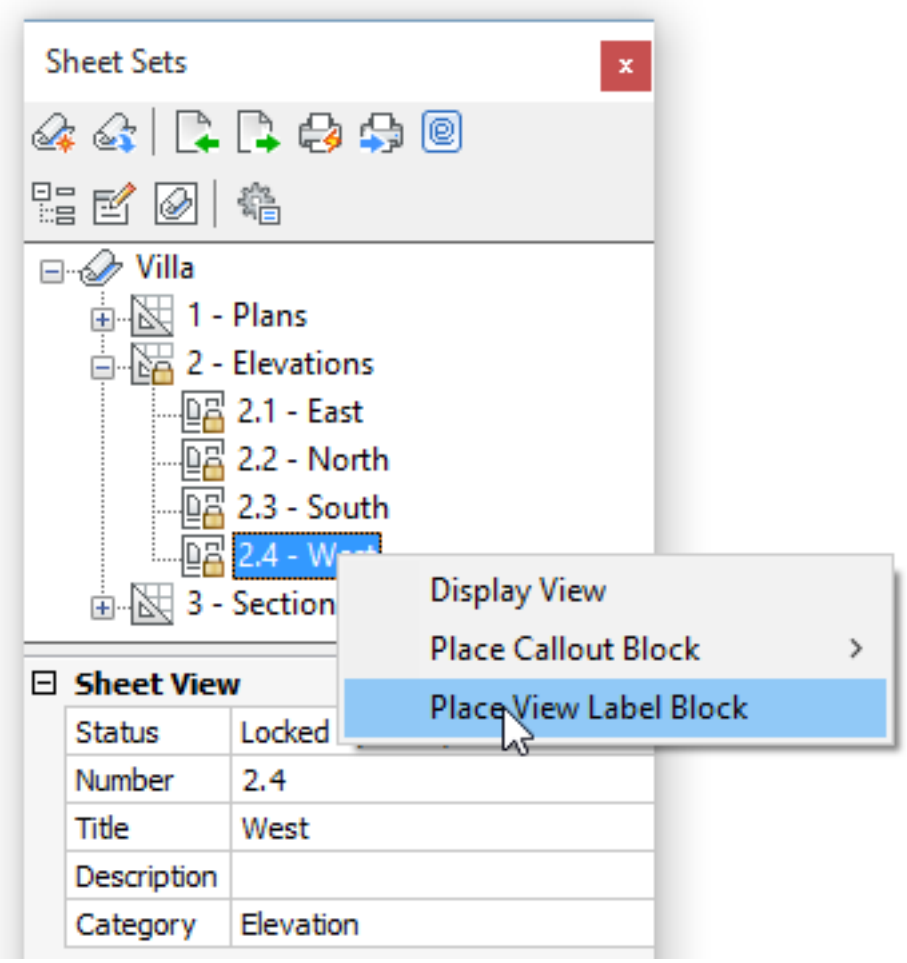

Figure 2.884

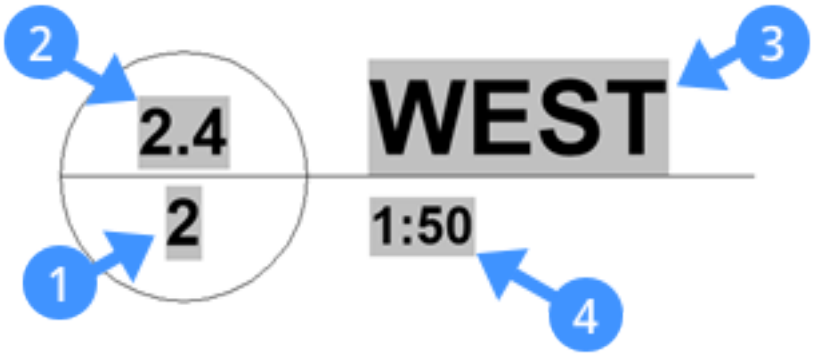

Inserting a number bubble block for a sheet view

1. Select the sheet view In the Sheet Sets panel.
2. Right-click the sheet view you want the number bubble block to insert for. (2.885 on the facing page)
3. Choose **Place Callout Block > Number Bubble** in the context menu. **You are prompted:** ._CALLOUT Units: Millimeters Conversion: 1 Insertion point for block:
4. Scale factor for block <1.0>:
5. Rotation angle for block <0>:
6. Specify the insertion point. **You are prompted:** Scale factor for block <1.0>:
7. Specify the scale factor or right-click to accept the current scale. **You are prompted:** Rotation angle for block <0>:
8. Specify the rotation angle or right-click to accept the current angle. The **Number Bubble** block is inserted. The Sheet Number (5) and Sheet View Number (6) of the selected sheet view are filled in automatically. (2.886 on the next page)

Figure 2.885

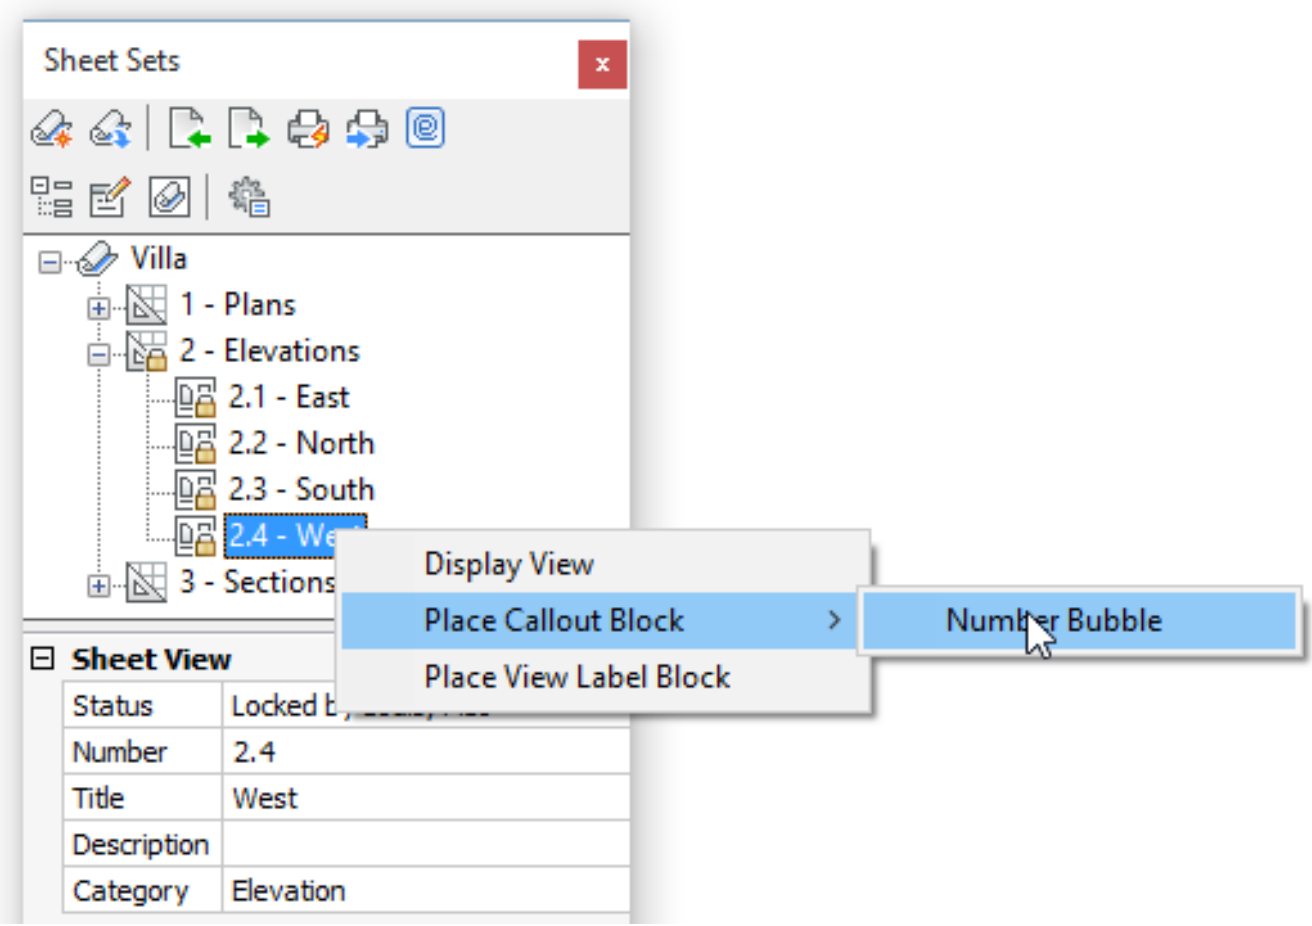

Figure 2.886

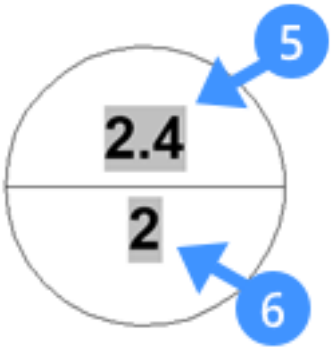

Inserting a sheet list table

A **Sheet List** table can be inserted on any sheet of the sheetset. In the current implementation, the table content is not yet associative and therefore will not be updated automatically when sheets are added, removed or renamed.

1. Right-click the sheetset name in the **Sheet Sets** panel and choose **Insert Sheet List Table** in the context menu. **You are prompted:** Select insertion point.
2. Specify a point in the drawing.

2.13.11 Elevation Hatch

Overview: In this lesson, you will learn how to generate textures or solid fills in a 2D elevation. **Lesson objectives:** After completing this lesson, you will be able to:

- Make elevations
- Generate textures or solids fills on a 2D elevation
- Change the hatch, scale, angle, line type, line weight or color of the textures or fills

About Elevation Hatch

'Generate elevation fill' is a property of a section plane that can display the texture or solid hatch of a composition when a 2D elevation is generated. Hatches can also be generated for other types of sections when activated in the properties panel. The hatch is generated for every visible boundary on the 2D elevation including boundaries that are not perpendicular to the section. Hatches are generated without perspective corrections. The union of elevation lines can be changed independently from the 'union section' settings in the physical material dialog.

Make elevations

Note: 'Elevation' here refers to a **Section Plane** in a 3D model that has its **Type** property set to **Elevation**. This can then be used to generate 2D drawings that represent the elevations of your model.

1. Create BIM elevations by using Bimify (6.7.23).
2. Select the BIM elevation and choose Generate Section in the Model command tab in the Quad.
3. Select the BIM elevation and choose Open BIM Section in the Model command tab in the Quad. The section result displays in the layout viewport of the destination drawing.
4. Select the paper space viewport. The viewport properties display in the Properties panel.
5. Under BIM, set the Generate Elevation Fill property to On.
6. Select the viewport and choose Generate Section in the Model command tab in the Quad.
7. (option) Copy the viewport, then set the Generate Elevation Fill property to Off to create two versions of the section result, one with and one without elevation hatch.

Tutorial: How to generate sections? Click here (2.12.5) to watch

Configure the hatch

1. Go to physical materials dialog by typing BLMaterials (2.7.17) **or** BLCompositions (6.7.57) (1) into the command line.
2. Click on the composition and double click on the pattern of the composition to open the physical material dialog (2). **(2.887 on the following page)**
3. To configure the texture or solid fill, go to the appearance tab page (3). The elevation hatch is set by default to 'None'. Click the elevation hatch type button and select the type of hatch: **None, Solid, Linear, Predefined** or **Custom** (4). **(2.888 on page 2487)**
4. Configure the hatch. Define the scale, angle, color and/or layer of the pattern. (5) **Note:** type a name in the layer field or click the arrow button and select a layer in the list. (2.889 on page 2487)
5. To remove connection lines in the elevation between different solids of the material go to the properties tab (6) and set Union of elevations to 'Yes' (7). **Note:** Union elevation works independently from the union section setting. (2.890 on page 2488)
6. After regeneration, the hatch will appear on the elevation. (2.891 on page 2488)

2.13.12 Enscape Integration

Command: StartEnscape, CloseEnscape, EnscapeExportSettings, EnscapeImportSettings, EnscapeBatchScreenshot, EnscapeLoadVideoPath, EnscapePanorama, EnscapeSaveVideoPath, EnscapeScreenshot, EnscapeSettings, EnscapeStartVideo, EnscapeStopVideo, EnscapeToggleLiveUpdate, EnscapeCreateStandalone **Overview:** In BricsCAD BIM, you can use the Enscape plug-in to render realistic images and videos of your 3D model.

About

Enscape is a real-time rendering plugin for BricsCAD. With a single click, you can start Enscape in seconds and walk through your fully rendered 3D model. There is no need to export to other programs. All changes in BricsCAD are immediately available for display and evaluation in Enscape. You can quickly explore different materials and design options to present to clients. With the option to create output renders, videos, and panoramas of your project, you can send the output files to your clients or colleagues, which allows for quick demonstrations. You can edit the changes in BricsCAD, and Enscape will immediately show the changes you have made to the project, even in VR.
(2.892 on the next page)

Figure 2.892

Enscape System Requirements

The minimum requirements to run Enscape:

- Windows 7 64 Bit or higher
- Intel i5 CPU or higher
- NVIDIA or AMD GPU with 2GB VRAM Supports OpenGL 4.3 NVIDIA GeForce GTX 660/Quadro K2000 and newer AMD Radeon R9 260/FirePro W5100 and newer
- 4 GB RAM (8 GB recommended)
- 2 GB Video-RAM (4 GB recommended)

For more information about Enscape system requirements, visit https://enscape3d.com/knowledgebase/system-requirem
For more information about Enscape specific features, you can visit their knowledge-base on their website.

How to install/uninstall Enscape

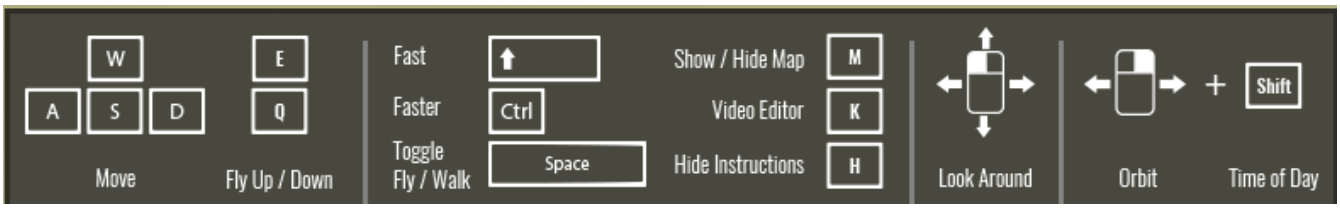
1. Download the Enscape-BricsCAD Connection from the Application Store,
2. The installer copies the necessary files to the 'Program Files\Bricsys\Enscape'-folder.
3. Restart BricsCAD.
4. You now have a new tab in the ribbon. Use this to launch Enscape. **Note:** The first time you will start the Enscape-plugin, you will be asked to provide a license key. If you don't have a license key yet, you can start by choosing the trial option.

How to uninstall Enscape Uninstall the connector from 'Add or Remove Programs' in Windows, by searching on 'Enscape' and click 'Uninstall'.

Navigate your model in Enscape

1. Click on **Start Enscape** in the ribbon **or** type in STARTENSCAPE in the commandline. Changes made in BricsCAD (e.g. deleted furniture, new material, a new section, etc.) can be seen instantly in Enscape.
2. Follow the instructions to navigate through your model. You can switch between Walk mode and Fly mode by pressing the Space bar. Type H to hide the instructions. (2.893 on the facing page)

Figure 2.893



Settings in Enscape

Open the Enscape Settings dialog by clicking **Settings** in the ribbon **or** type in ENSCAPESETTINGS in the commandline. When you change the settings, they will be automatically saved for the user, not in the drawing. There is also an option to create and import presets for the Enscape settings. You can find more information about saving and importing presets in the following link: https://enscape3d.com/community/blog/knowledgebase/settings-presets/ The Enscape Settings consists of 7 tabs:

- **General:** general Rendering style options, Depth of field and Exposure settings. You can find a more in-depth explanation in the following tutorial link: https://youtu.be/0PqtiBoDxEY
- **Image:** Contrast and Color settings. You can find a more in-depth explanation in the following tutorial link: https://youtu.be/mbZ7wKBF0zE
- **Atmosphere:** Horizon/background options, Fog, Clouds and Sky orbs. You can find a more in-depth explanation in the following tutorial link: https://youtu.be/PkcHJeV3lMM
- **Input:** Mouse navigation settings.
- **Advanced:** Spectator options. You can find a more in-depth explanation in the following tutorial link: https://youtu.be/bZtQfkCVdP4
- **Capture:** Image, Video and Panorama options. You can find a more in-depth explanation in the following tutorial link: https://youtu.be/MrY8DuNx3v0
- **Customization:** Interface options.

Render materials in BricsCAD

In BricsCAD BIM, there are two methods to add render materials to your model.

- Directly apply to render materials (without compositions) to the solids/surfaces in your model, using the Render materials Panel.
- Apply render materials via compositions, using the Compositions Panel.

Note: When Render materials are attached to an entity both applied directly with the Render materials Panel and compositions attached, the composition materials will be shown (when Level of detail = 2). Thus, if an entity already has a composition and you want to change the render material, don't try to 'overrule' it with the Render materials Panel, but change the composition plies instead.

Render materials with the Render materials Panel

To assign a material to a single entity

1. Select the material in the Render Materials (6.21.6) panel.
2. Click on the entity **or** press and hold the left mouse button, then drag the material onto the entity

To assign a material to multiple entities

1. Select the entities.
2. Search the material in the Render Materials (6.21.6) panel.
3. Click on the material.

For more information about render materials, click here (1.34.4).

Figure 2.894

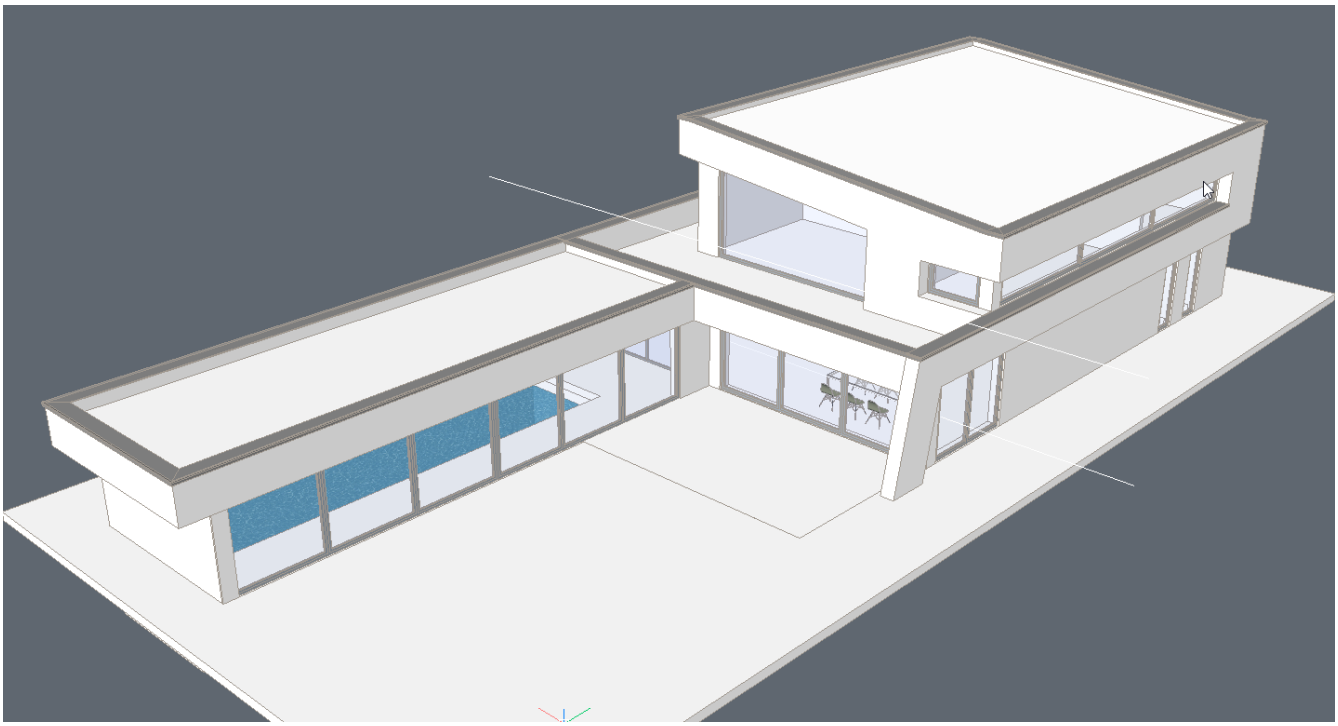


Figure 2.895

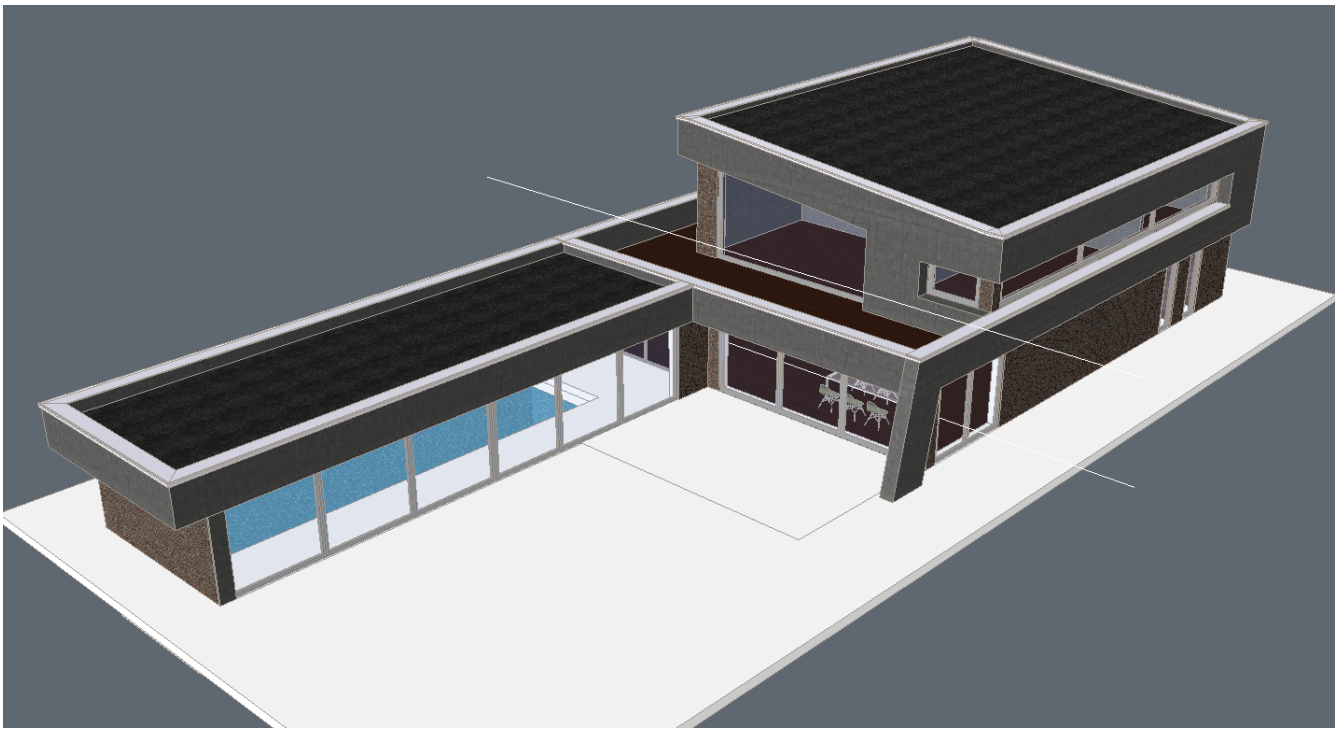


Render materials with Compositions

1. Click on Level of detail (2.7.8). The materials of the composition plies will display. (2.894 on the preceding page) (2.895 on the facing page) **Figure 1: Level of detail = 0** , **Figure 2: Level of detail = 2**
2. Open the Composition panel. For more information about compositions, click here (2.7.4).
3. Double-click on the composition **Cavity Wall, Brick**. The Composition dialog (6.7.57) will display.
4. Double-click the material **Facing Bricks, Hand-formed** to edit the ply material. The window for Physical Materials (2.7.17) display.
5. Click on the material image under tab **Appearance>3D** to change render material for the ply.

Editing render materials in BricsCAD

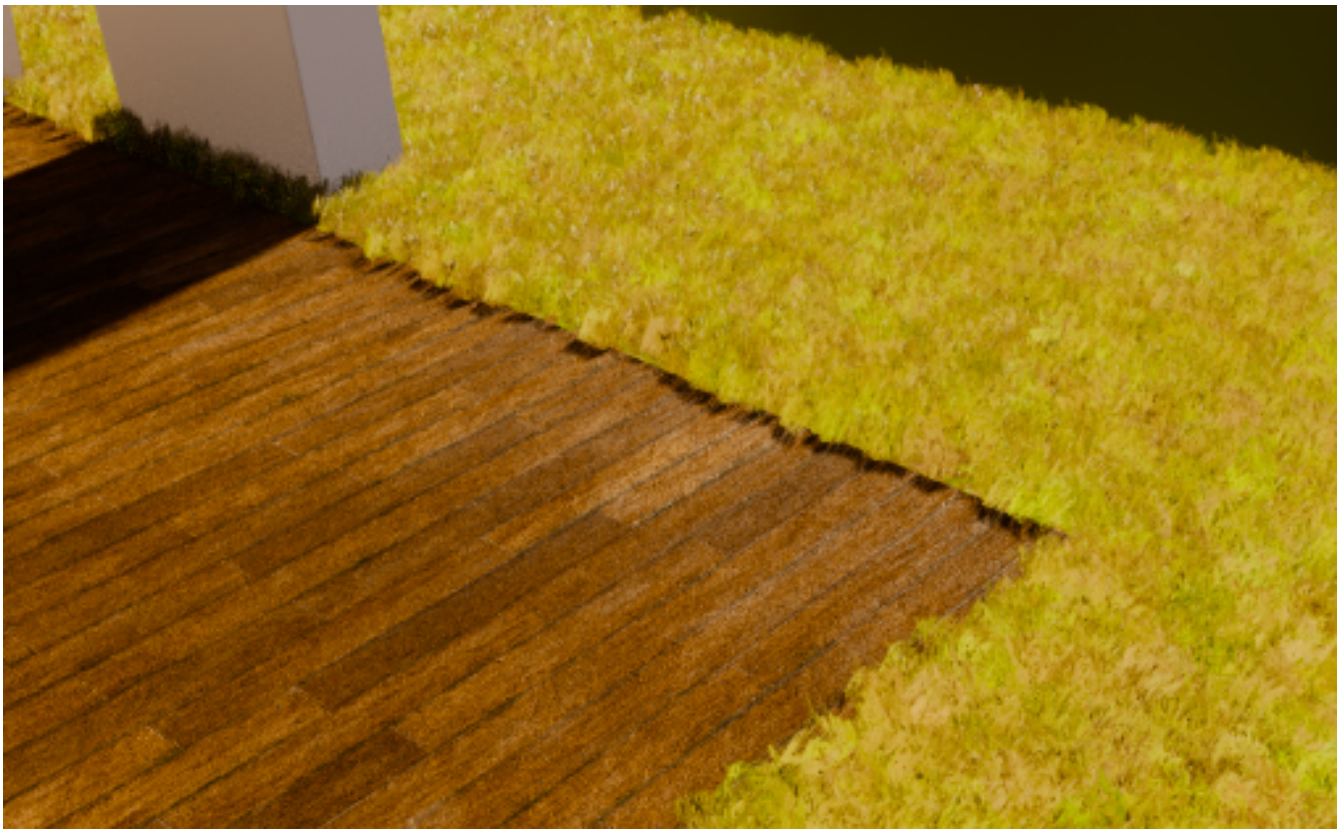
1. To edit all the render materials used in your drawing, type in MATERIALS (6.21.10) in the commandline.

Keywords in Enscape

Grass Any time the word 'Grass' is used in a material name, grass will be rendered in Enscape. You can use diffuse colors to choose options of green, but also texture maps can be used as well.

1. Go to the Materials dialog (6.21.10).
2. Click to **Add New Material**.
3. Give the new material a name that includes the name **'Grass'**, for example, 'Grass_ground'.
4. Close the Materials dialog.
5. Select the solid that you want to render in grass.
6. Open the Properties Panel
7. Change the property **3D Visualization>Material** from 'ByLayer' to 'Grass_ground'. (2.896 on the next page)

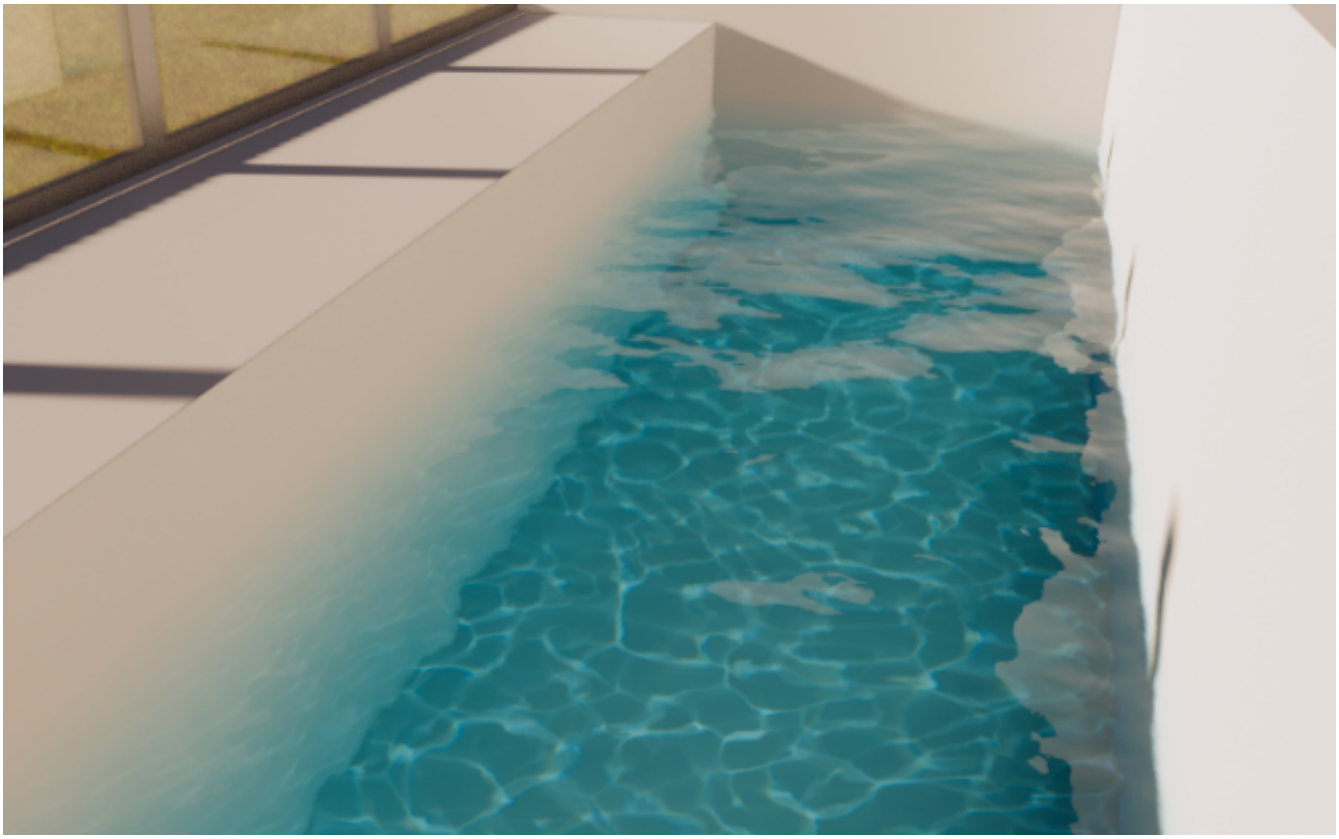
Figure 2.896



Water Any time the word 'Water' is used in a material name, water will be rendered in Enscape. You can also create your own water material by including the word 'Water' in the material name and give it a diffuse color in a shade of blue.

1. Select the solid that you want to render in water.
2. Open the Render materials Panel and choose the folder named 'Water'.
3. Drag and drop material **'Water Blue Two'** into the drawing. (2.897 on the facing page)

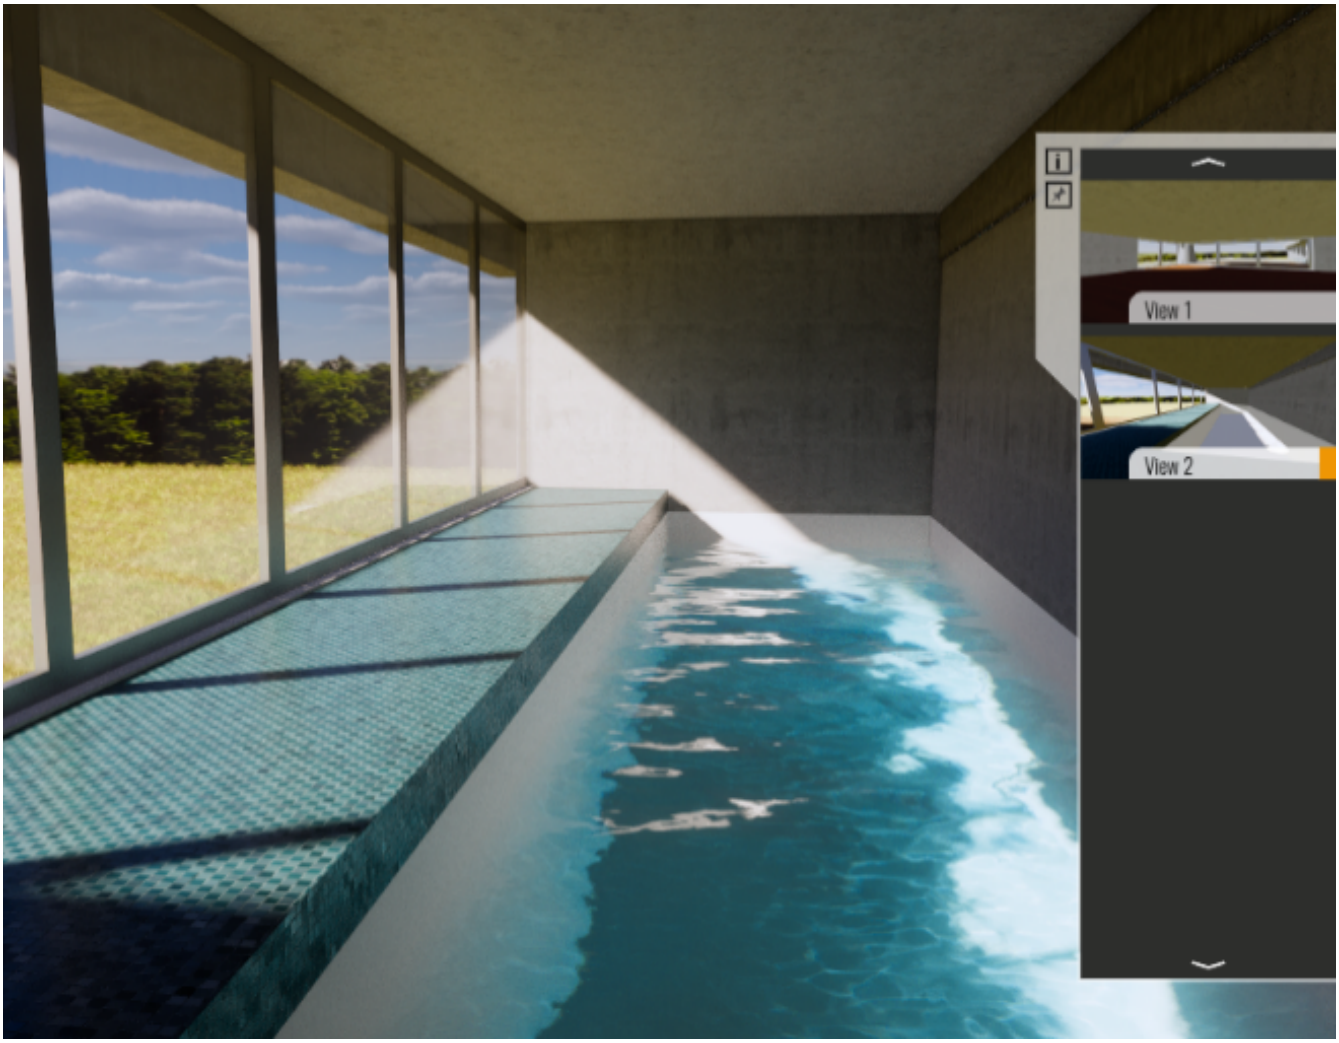
Figure 2.897



Saved Views in Enscape

1. Navigate in the BricsCAD drawing until you get a view that you want to safe. **Note:** Make sure your viewing style is in **Perspective** to have a more accurate saved view in Enscape. You can check this in the **Properties Panel>View>Perspective>ON**. And close the Properties Panel afterward.
2. Click on **Create View** in the ribbon. **You are prompted:** View [? to list/Delete/Orthographic/Restore/Save/Window]:
3. Type S and press Enter to save the view. **You are prompted:** Save view as:
4. Name the view and press Enter to confirm.
5. You can delete or adjust existing views by clicking **View** in the ribbon or type in VIEW (6.31.2) in the commandline.
6. In the Enscape window: On the right-hand side of the window, you can find all the saved views in the drawing.
7. Click on the view wanted to switch between views. (2.898 on the next page)

Figure 2.898



Render images with Enscape

1. Navigate through the Enscape window.
2. **Or** you can choose a Saved View on the right side of the Enscape window, click a saved. The saved view will display.
3. Go back to BricsCAD and select **Render Image** in the ribbon to render the current view **or** type in ENSCAPESCREENSHOT in the commandline.
4. Select **Batch Rendering** in the ribbon, or type in ENSCAPEBATCHSCREENSHOT in the commandline, to render all the saved views to a folder.
5. Specify a destination file to save the rendered image and click **Save**. The rendered image is now created.

Render a video with Enscape

1. Click on **Start Enscape** in the ribbon or type in STARTENSCAPE in the commandline. (2.899 on the following page)
2. In the Enscape window: type K to open the video editor.
3. Click **Add Keyframe** (2) to add the first keyframe.
4. Click on the triangle to open the keyframe settings (3). (2.900 on the next page)
5. Change the parameters as required.
6. Click **Apply** (4). (2.901 on page 2500)

Figure 2.899

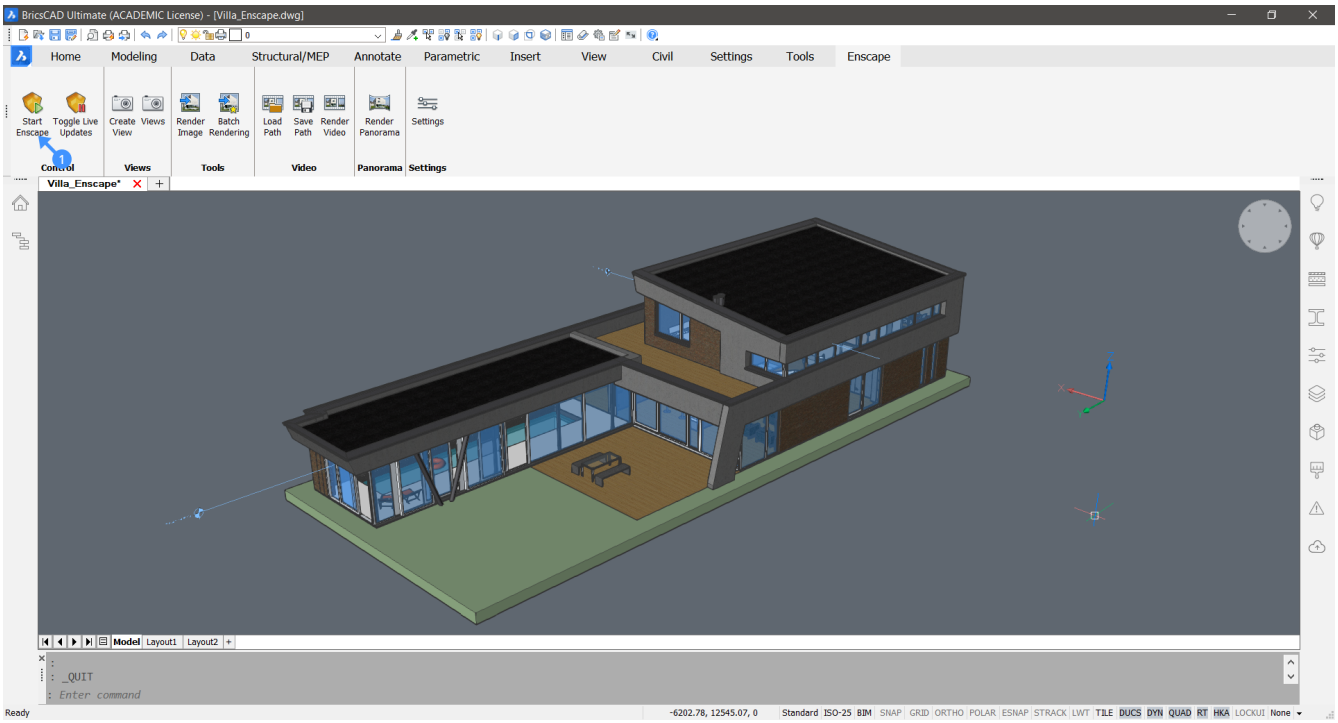


Figure 2.900

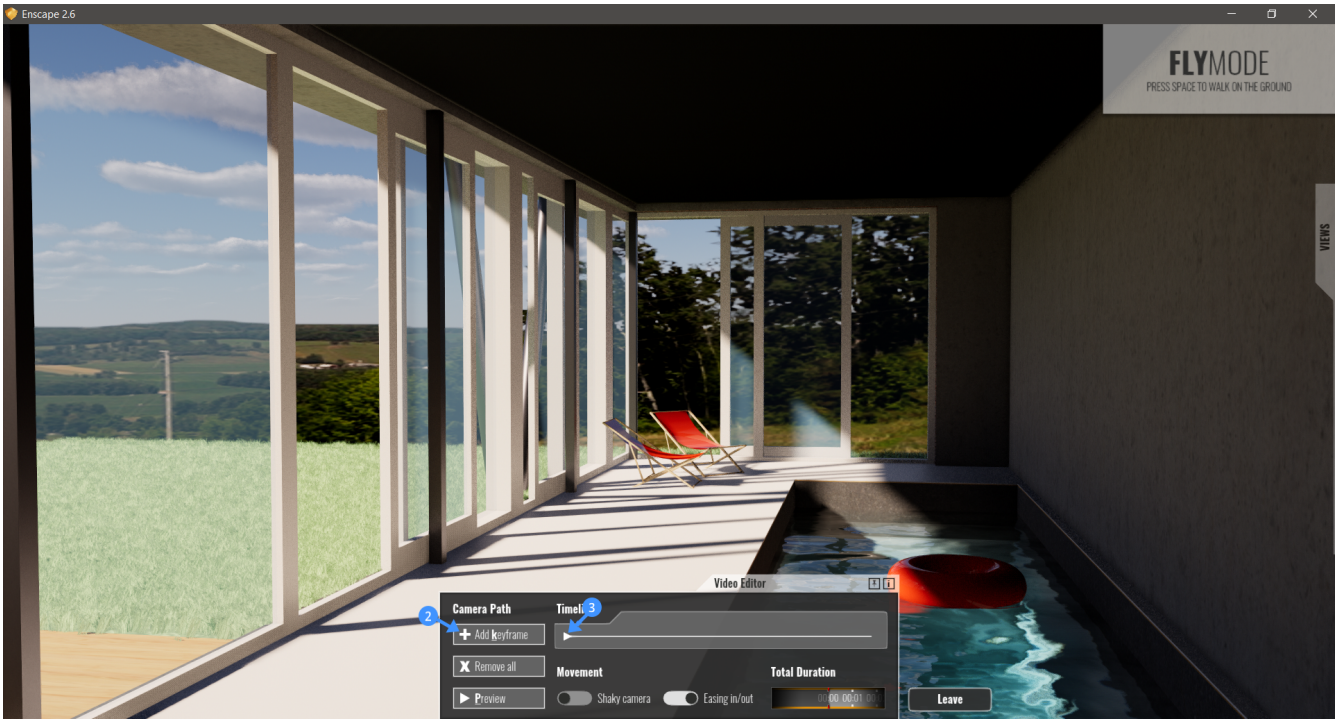

7. Click **Insert** (5) to add a second keyframe.
8. Change the time of day to 7 pm (6) and the timestamp to 8 seconds (7). (2.902 on the next page)
9. Click **Confirm** (8).
10. Click **Back** (9). **Note:** Before you click Leave to exit the Video Editor, your video path will not be automatically saved. So. Before you exit your Video Editor, you should save your video path using the command EnscapeSaveVideoPath.
11. Go back to BricsCAD and click on **Render Video** (10). Specify a destination file and click **Save** (11). The video is now rendered and saved. (2.903 on page 2501)

Figure 2.901

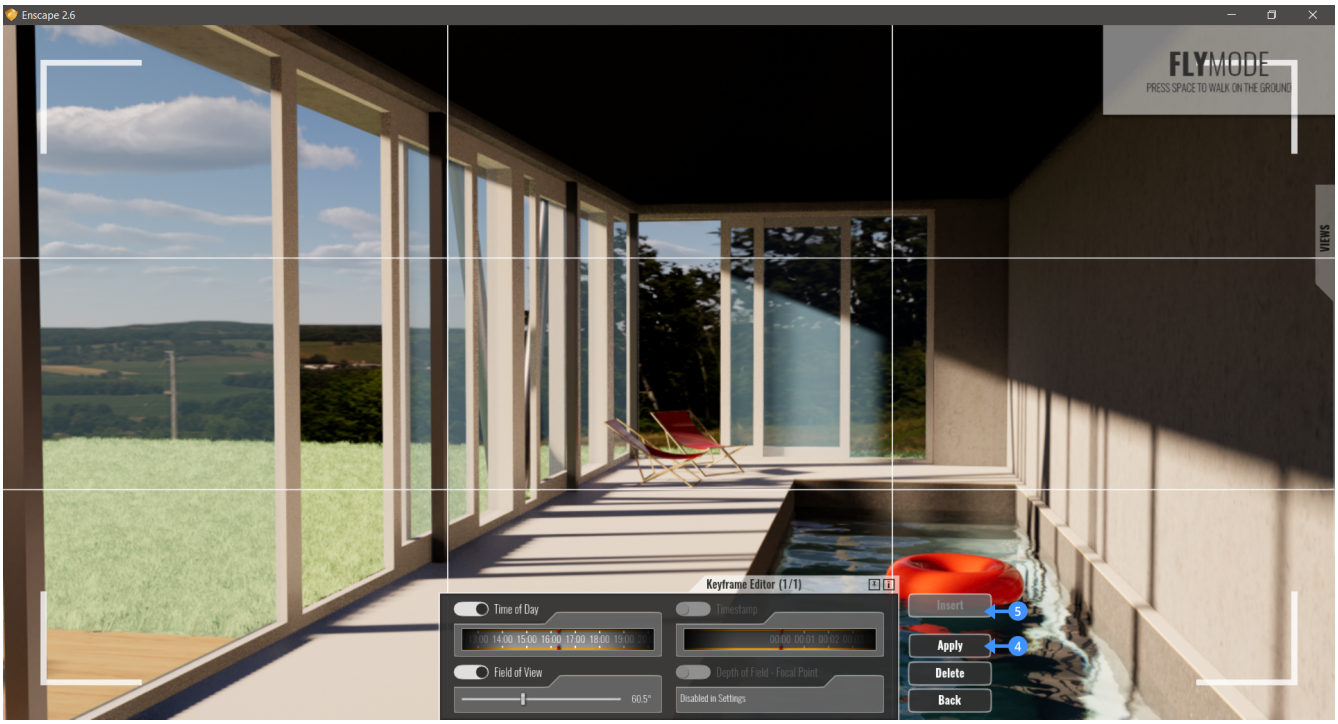

Figure 2.902

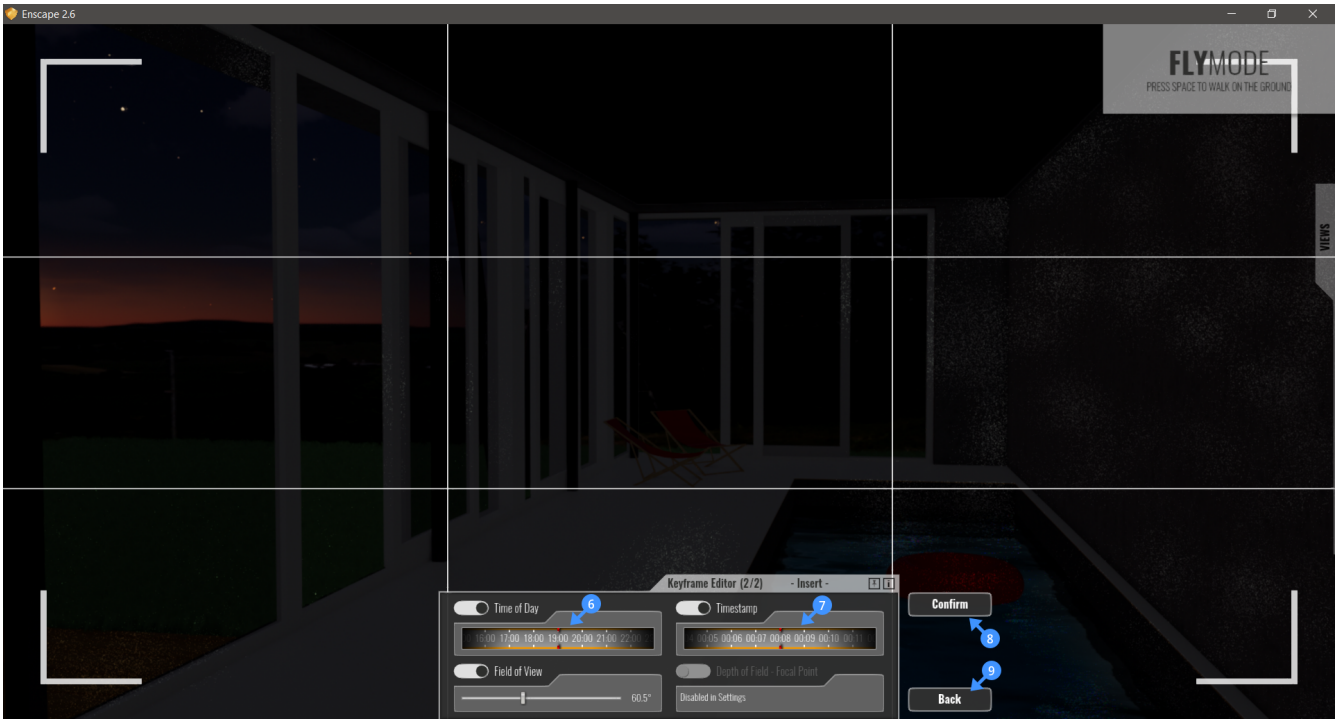

Figure 2.903

Export a standalone .exe

The Executable export function provides the same experience and quality that Enscape does, but does not require Enscape and BricsCAD to run.

1. Click **Export Standalone** in the ribbon **or** type in ENSCAPECREATESTANDALONE in the commandline.
2. A new dialog will pop up asking you where to save your standalone file. Choose your destination file, name your standalone and click **Save**.

2.13.13 Generating Drawings

Commands: BimSection (6.7.54), BimSectionUpdate (6.7.43), BimSectionOpen (6.7.49) **Overview:** In BricsCAD BIM, it is possible to automatically generate 2D documentation as new .dwg files from a 3D model. **Lesson objectives:** In this lesson, you will learn to:

- Generate 2D sections of your 3D model automatically as new drawing files.
- Open the generated files.
- Update existing sections.
- Work with section indicators.

Tutorial: How to generate sections Click here (2.12.5) to watch

About BimSectionUpdate

BimSectionUpdate generates section drawings from BIM Section (6.7.54) entities. The command can be used either by selecting a BIM Section entity in the 3D model or by selecting an existing section in a generated drawing. The result is placed in a new drawing, saved to the same folder as the model drawing unless a different folder is specified in the Destination File property of the BIM Section entity.  For more information about this command, visit the Command Reference article BimSectionUpdate (6.7.43).

Procedure: Generating BIM Sections.

BIM Sections can be generated in 2 ways:

- In the model space
- Using the BIM Project Browser (2.7.15)

Model Space

1. Select one or more BIM section entities.
2. (Optional) Edit the section properties (e.g. Scale, Name, Destination File).
3. Choose **Generate section** in the **Model** command tab of the Quad.

BricsCAD reports the number of generated sections and their name(s) in the Command Line (1.15.2) e.g.: 8 section(s) were generated: D:\Bricsys Reports\V16\Villa\Elevations.dwg D:\Bricsys Reports\V16\Villa\Plans.dwg D:\Bricsys Reports\V16\Villa\Sections.dwg In the example above 2 plans, 4 elevations, and 2 cross-sections were generated and exported to 3 drawings.

Project Browser

1. In the **Sections** segment of the project browser, right-click the section.
2. (Optional) Choose 'Select Section Entity'. to change its properties in the properties panel.
3. Choose Update (1). (2.904)
4. Choose **Refresh** in the project browser menu. (2). (2.905 on the facing page)

A new section is generated in the Sheets segment of the Project Browser.

Figure 2.904

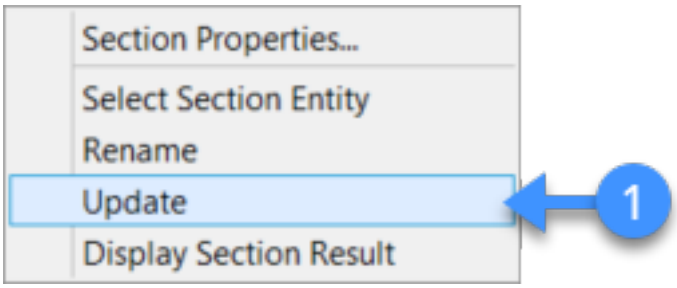

Figure 2.905

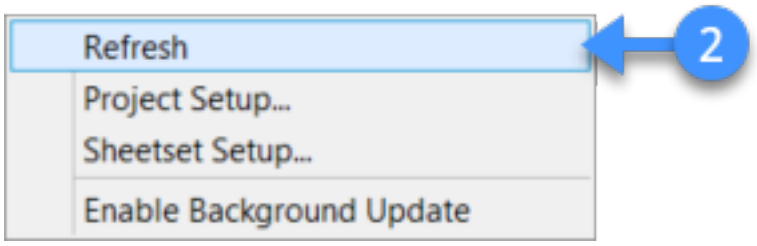

Notes

- BIM_SECTIONS_PREVIOUS layer: the result of the previous section generation is stored on the dedicated BIM_SECTIONS_PREVIOUS layer. This is frozen by default.
- BIM_VIEWPORTS layer: generated viewports are placed on the dedicated BIM_VIEWPORTS layer if desired.
- The SheetSet manager automatically and silently adjusts the file paths after the project folder has been relocated if the same folder is used for all files.

Open BIM sections

BimSectionOpen navigates between the model drawing containing a BIM Section entity and the corresponding generated drawing. The command works bi-directionally.  For more information about this command, visit the Command Reference article BimSectionOpen (6.7.49). BIM Sections can be opened in different ways:

- From the 3D Model.
- Using the BIM Project Browser (2.7.15)

3D Model To open a 2D document from the 3D model:

1. Select one or more BIM sections.
2. Choose **Open Model** in the **Model** command group of the Quad.
3. The 2D section drawing(s) open(s).

Project Browser To open the 2D section drawings from the Project Browser, do one of the following:

- Double click the sheet view in the **Sheets** segment of the Project Browser (3). The 2D section drawing opens with the selected sheet view. (2.906 on the next page)
- In the **Sections** segment of the project browser, right-click the section and choose **Display Section Result** in the context menu

(2.913 on page 2509)

Figure 2.906

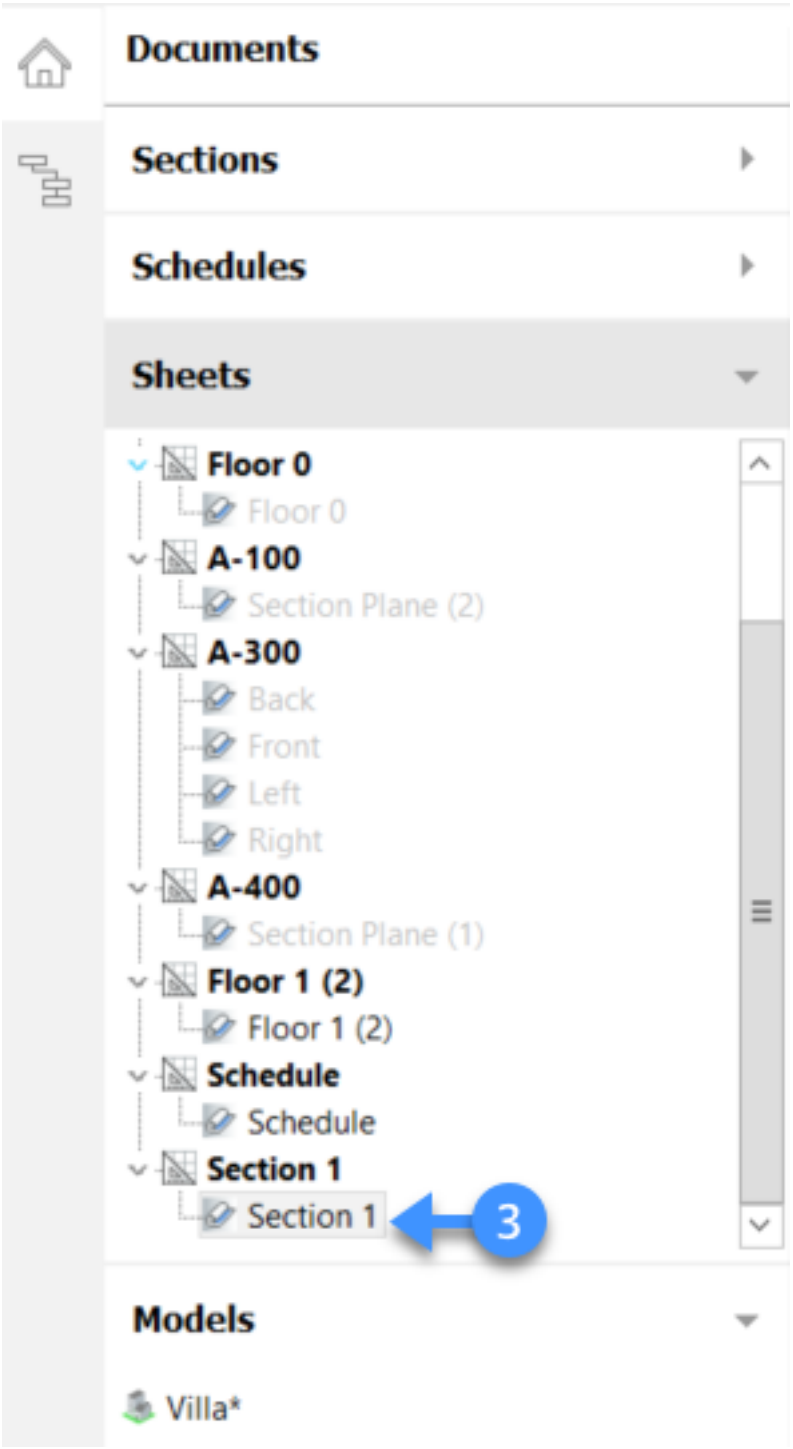

Figure 2.907

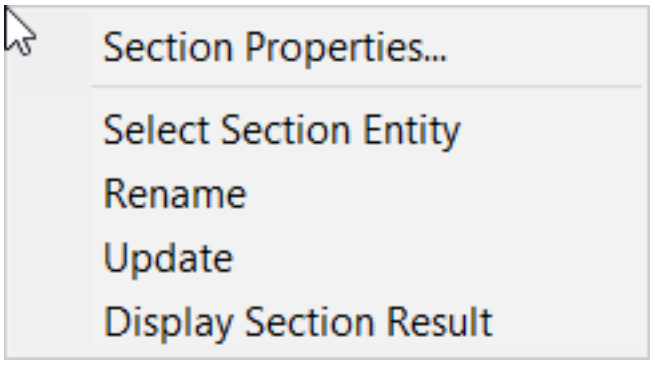

Update BIM Sections

BIM Sections can be updated in different ways:

- In the 3D model
- In the generated 2D documentation file
- In the BIM Project Browser (2.7.15)

When the 2D documentation is no longer in sync with the 3D model, the corresponding sheet views display in red in the **Sheets** segment of the Project Browser. (2.908 on the next page)

Update BIM Sections in your 3D model To update BIM Sections via your 3D model using the same process as used to generate views.

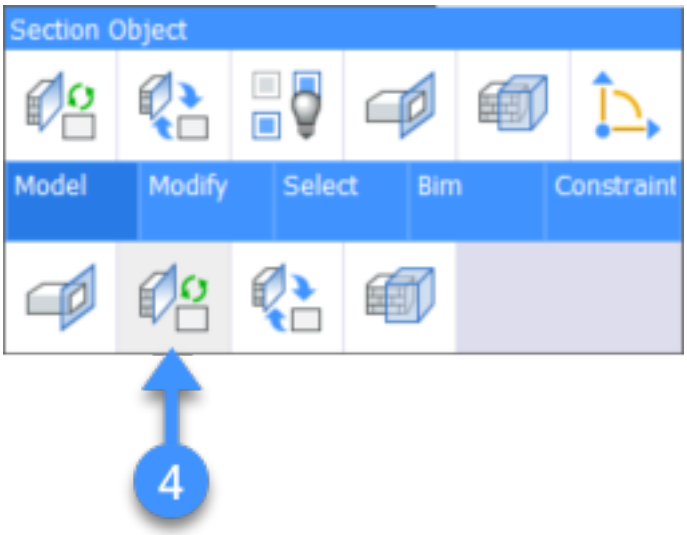
Update BIM Sections in the 2D documentation file A red frame around the section result indicates that the BIM Section generated block is no longer in sync with the 3D model and needs to be updated. This can be done in **Model Space** or in the **Layout.**

Update a BIM section in Model Space

1. Place the cursor over the section block to update.
2. Choose **Update Section** in the **Model** command group in the Quad (4).

(2.909 on the following page)

Figure 2.909



Update a BIM Section in a layout

1. Click the **Layout** tab.
2. Place the cursor over the viewport of the BIM Section to update.
3. Choose **Update Section** in the **Model** command group of the Quad (5). (2.910)

The result of the previous section generation is stored on the dedicated BIM_SECTIONS_PREVIOUS layer. Thaw the layer (6) to check the modifications. (2.911 on the facing page) The content of the BIM_SECTIONS_PREVIOUS layer displays in magenta. (2.912 on the next page)

Figure 2.910

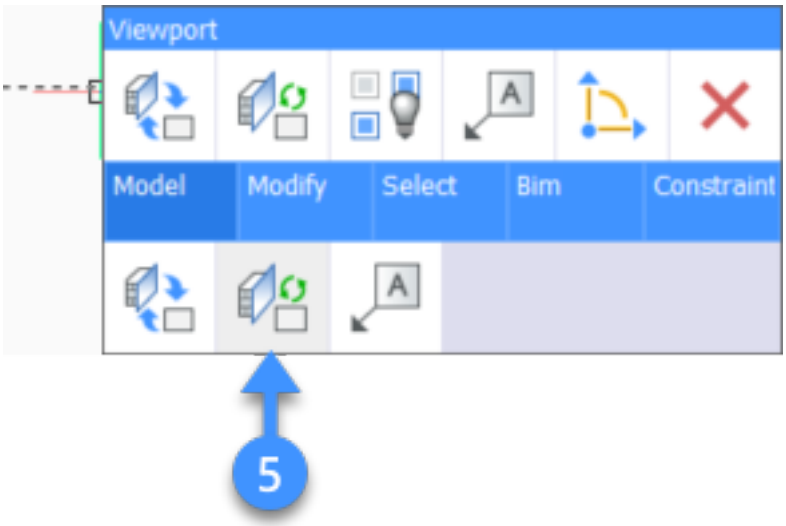


Figure 2.911

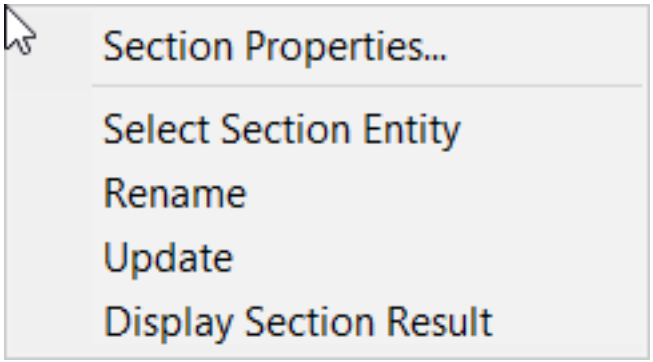
Figure 2.912

Update BIM Sections in the Project Browser

1. Right-click on a section in the Project Browser.
2. Select **Update** in the context menu. (2.913)

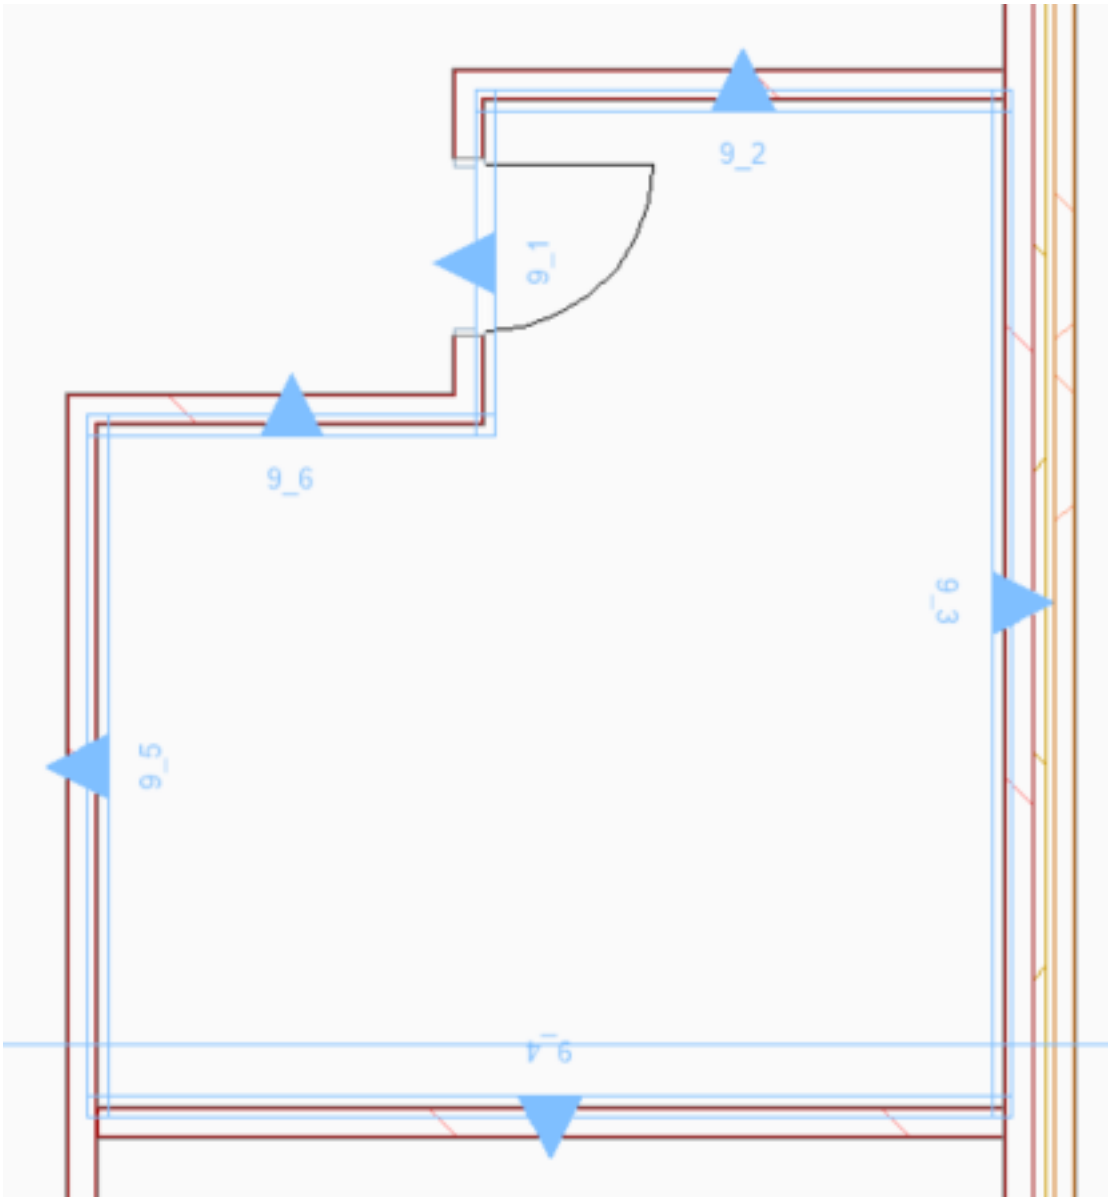
Figure 2.913



Section Indicators

A generated plan and reflected ceiling plan provide section indicators for interior elevations and detail sections if they intersect with the section plane. The section indicators are stored on the dedicated BIM_SECTIONS layer. To change the visibility of indicators, turn the layer ON or OFF. (2.914 on the next page)

Figure 2.914



2.13.14 Interior Elevations

Command: BimSection (6.7.54) **Overview:** In this lesson, you will learn how to use the Interior option of BimSection in order to produce interior elevations.

About

Interior elevations show wall elevations and floor plans for individual Spaces. They provide the details and dimensions of building elements. This can be particularly useful for interior designers or to make a layout of power sockets and light switches. In BricsCAD they can be automatically defined by a BIM Space (6.7.45).  For more information about this command, please read BimSection (6.7.54).

Create interior elevations from a BIM Space

1. Hover the cursor over a Space Tag and select **Define Interior Elevations** from the BIM Tab in the Quad **Or** type BimSection (2.13.1) in the commandline, followed by **i** and Enter to choose the interior option. **You are prompted:** Select BIM Spaces (6.7.45) to generate Interior Elevations or [**Attach section**]: (2.915 on the facing page)

1. (Skip if you used the Quad) Select the BIM Space for which you want to create the interior elevations and hit Enter. The interior elevations for each wall and the interior floor plan are now defined. They can be found in the Structure Browser (2.7.18). (2.916 on page 2514) (2.917 on page 2514)
   Six interior elevations and one interior floor plan have been created and will appear in the structure browser.
   Note: if there already are interior sections for a Space, running BimSection again on that Space will have no effect. To regenerate the interior elevations, you must delete the existing interior elevations in that Space and run BimSection again.
2. To show or hide the interior elevations you can use the Hide/Isolate/Unisolate objects commands **Or** you can go to the properties of the Space and switch the interior elevations on and off in the BIM tab. (2.918 on page 2515)
3. Select all elevations, as illustrated above and select **Generate Section** from the Quad to generate the interior elevations on a sheet. (2.919 on page 2516)
4. To open the section results click **Open Model** whilst the section planes are selected.

The sheet is automatically saved in the same folder as the model drawing. The following elevations have been produced and can be edited for the selected Space in the model above: (2.920 on page 2516) **Note:** the section drawings are stored in the file InteriorElevations by default. If you generate sections of a second Space, the sections will be added to the same file as the previous ones. If you need more information on how to generate drawings, visit the Generating Drawings (2.13.13) page. If you want to annotate your drawings: learn to add tags (2.12.1) and linear dimensions (1.29.7).

Edit the size of the interior elevations

It's possible to edit the size of these sections to include furniture for example. If you create interior elevations for a BIM Space, the offset value is 50mm by default. To include furniture in a section, you have to change this value.

1. To change this setting type **InteriorElevationOffset** in the commandline and hit Enter. Type a new value and press Enter **Or** click on two points in your drawing and the distance between them will be selected. You can also change the offset by typing **Settings** in the commandline, search for elevation and adapt the Interior Elevation Offset Value. (2.921 on the following page)
2. If you make new Interior Elevations, the offset distance will be the chosen value. This is also visible when you select the interior elevations in your drawing: (2.922 on page 2519)
3. This results in more detailed section sheets with the furniture included. (2.923 on page 2519) (2.924 on page 2521)

2.13.15 Working with Point Clouds in BIM

Commands: PointCloudDetectFloors (6.7.4), PointCloudFitPlanar (6.7.2), PointCloudProjectSection (6.7.1). **Overview:** In BricsCAD, it is possible to automatically generate 2D documentation as new .dwg files from a point cloud. **Lesson objectives** In this lesson you will learn to:

- Automatically make a section box around a building.
- Convert a detail section into a 2D drawing.
- Make a BIM model from a point cloud.

About PointcloudDetectFloors

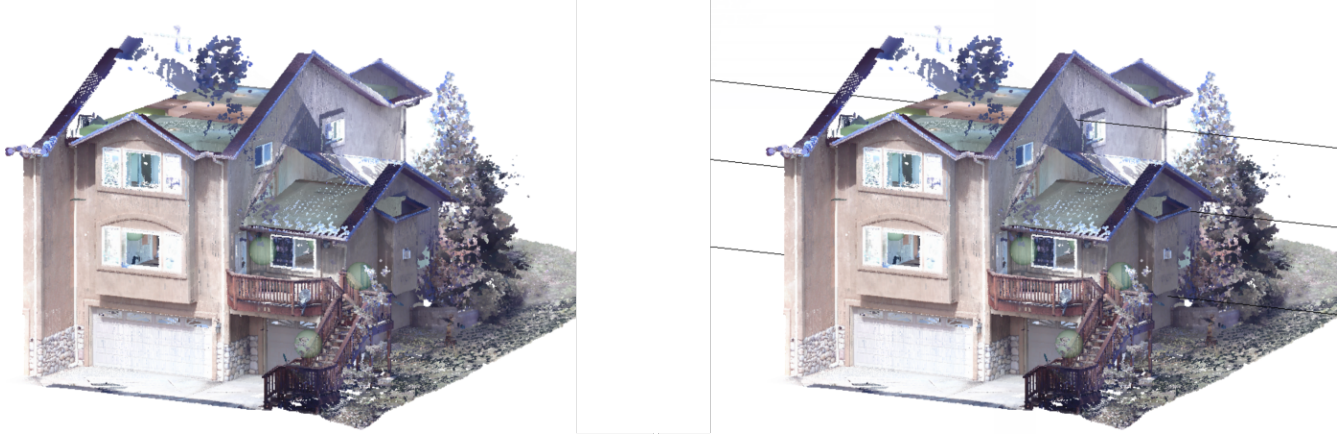
The new PointCloudDetectFloors command generates volume sections for each floor found in a point cloud representing a building. The detection is based on regions of points with similar Z-coordinates. The generated volume sections can help in navigating point clouds of buildings. Section planes work on point clouds as well, they can be used to show parts of point clouds. The difference between point cloud crops and section planes is that point cloud crop only clips the point cloud while section planes will clip all geometry in your drawing. If the point cloud building has multiple floors, there will be multiple section volumes.  For more information about this command, visit the Command Reference article PointCloudDetectFloors (6.7.4).

Detecting floors from Pointclouds

1. Type **PointCloudDetectFloors** in the commandline.
2. **You are prompted:** Operate on full point cloud or a selection? [Full/Selection]
   - Full: The command will search the entire point cloud for floors and generates a section for each of them.
   - Selection: The command only runs on the selected area.
3. Press Enter.

(2.927) **Note:** This volume selection is a detail section of the selected building. You can manipulate the section box (1.26.4) if you want to include more or fewer points from the point cloud using the green grips.

Figure 2.927



About PointCloudFitPlanar

PointCloudFitPlanar is used to semi-automatically make 3D geometry based on a point cloud scan. It will create a planar surface or solid after a selection of one point in a point cloud. The points that seem to be in a plane are never exactly in one plane, therefore a threshold value is set as a property of the point cloud entity. This also works in bubble view. Select planes in the point cloud to generate 3D solids based on the given geometries. These 3D solids can be further used in the process of creating a full BIM model.  For more information about this command, visit the Command Reference article PointCloudFitPlanar (6.7.2).

Creating 3D solids from the Bubble View If the bubble viewer is open before launching the command, BricsCAD expects you to select in the bubble viewer. The cursor will give you a preview of the direction of the plane. When you click you get a preview in both bubble view and model view. You can toggle between 2 shape representations using the CTRL-key.

1. Double click a green point cloud bubble to open the bubble view.
2. Type **PointCloudFitPlanar** in the commandline.
3. Select the desired wall. (2.928 on the next page) (2.929 on the facing page)
4. Press A to accept the selection. **(Optional)** Select more walls. (2.930 on page 2526) (2.931 on page 2526)
5. Close the bubble view. The surfaces are created and you can edit them to closed spaces with LConnect (6.20.19) or other connecting tools. (2.932 on page 2527) (2.933 on page 2527)

Figure 2.928

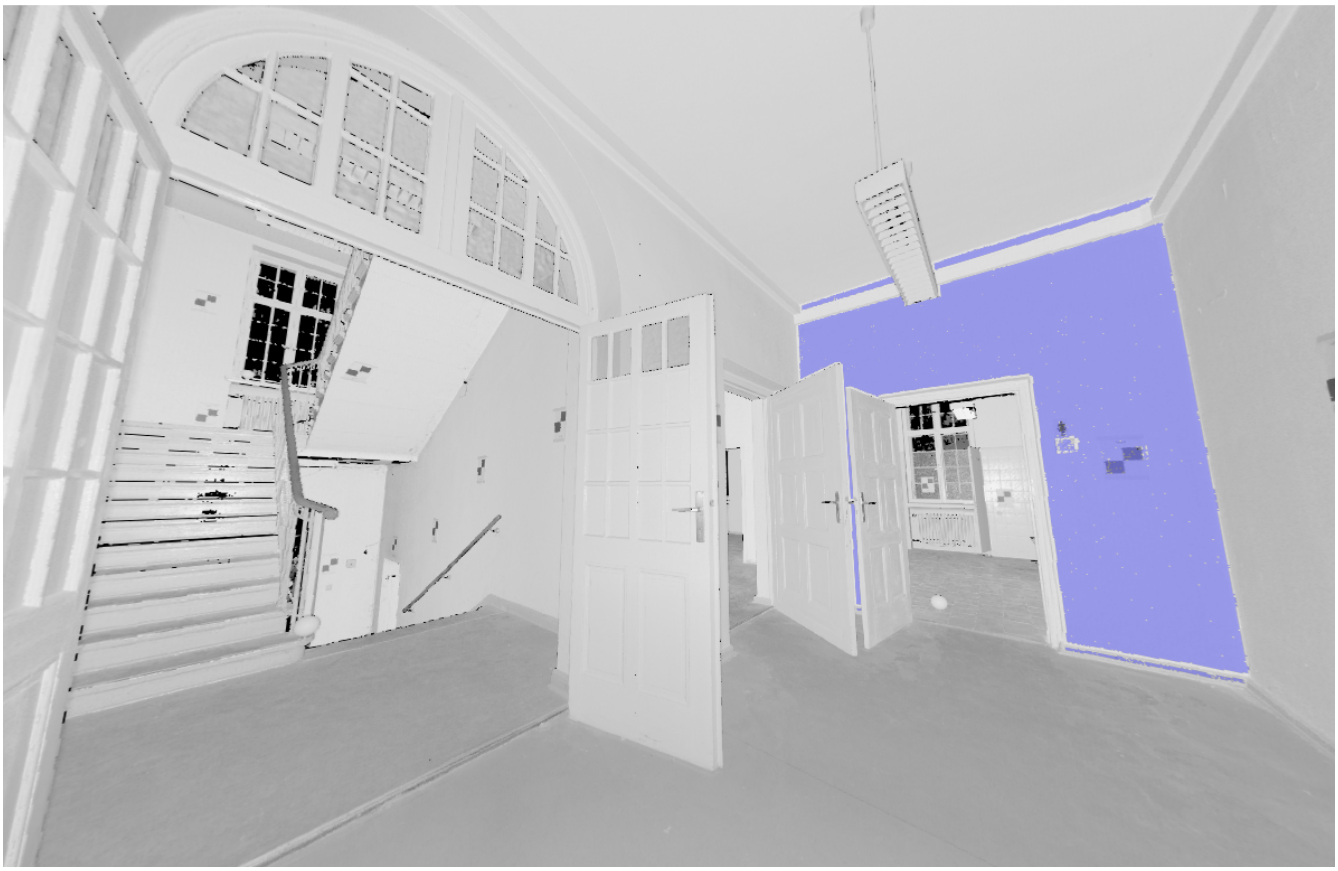


Figure 2.929

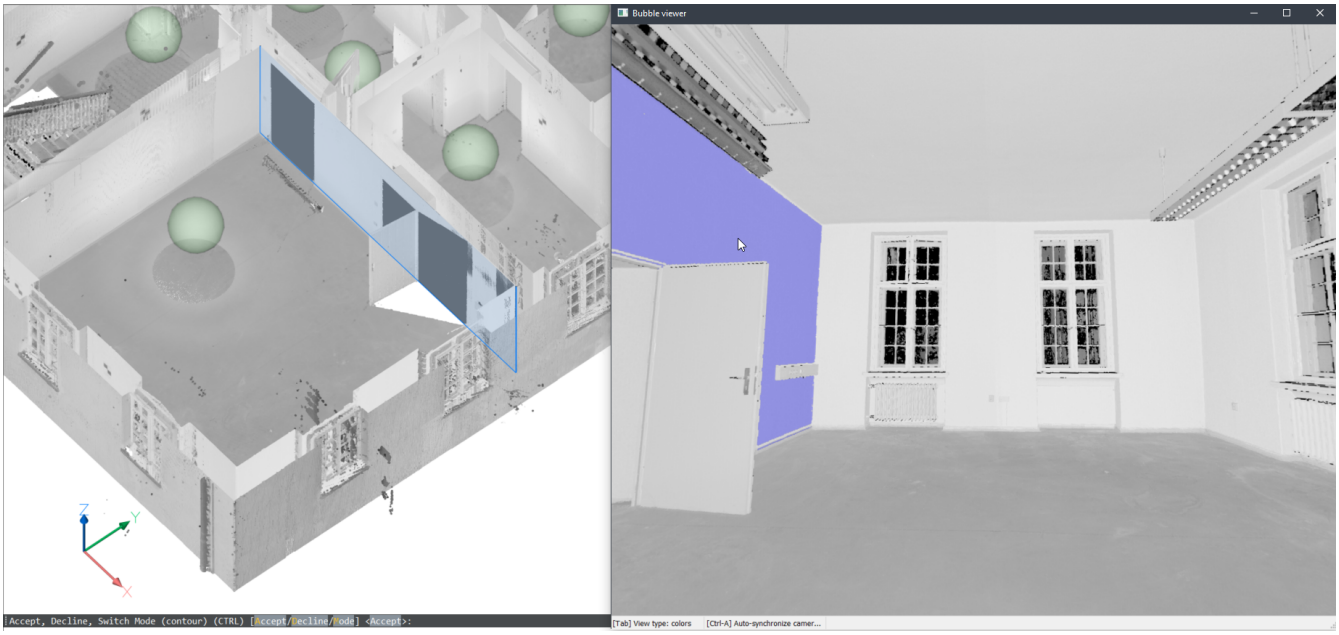

Figure 2.930

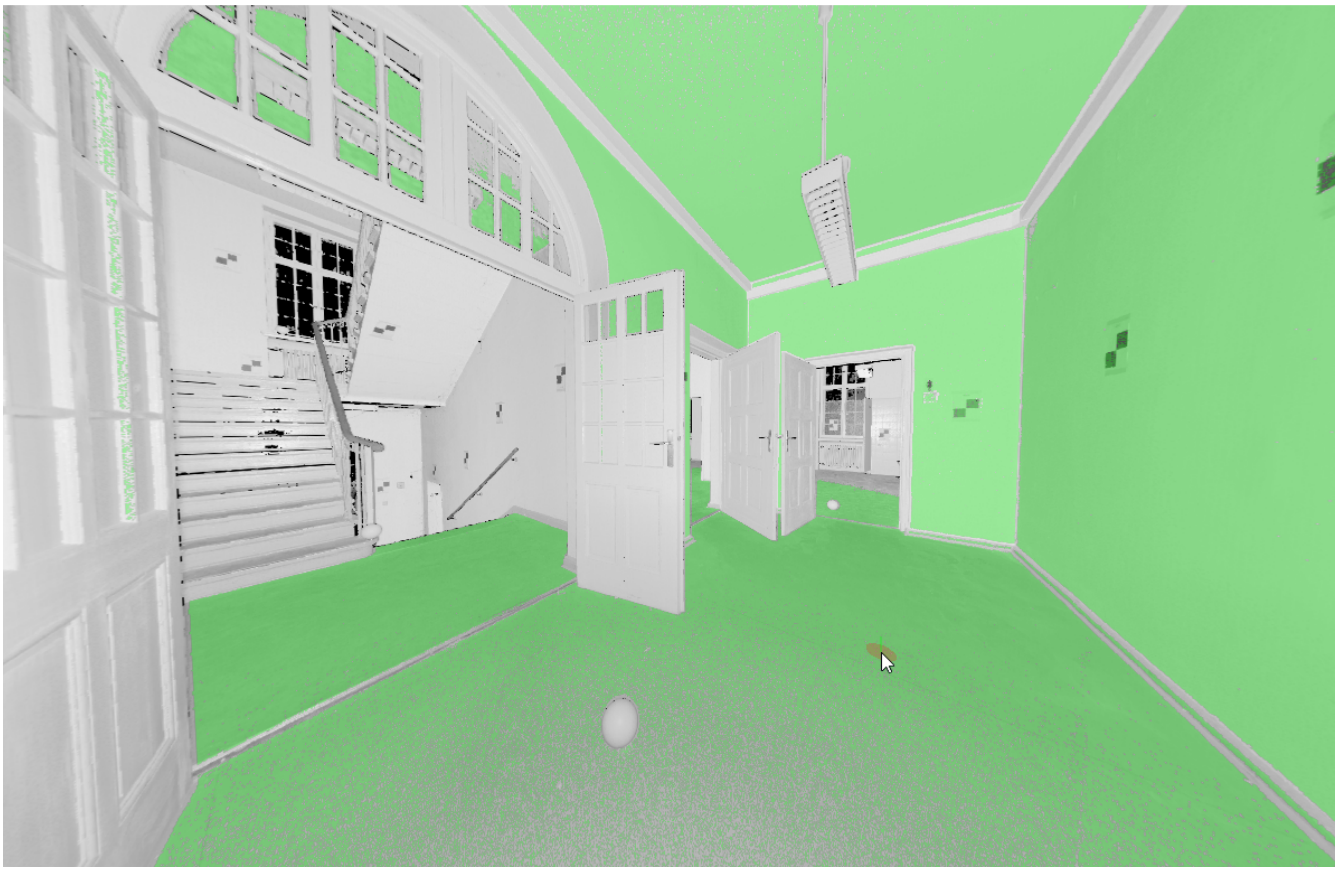

Figure 2.931

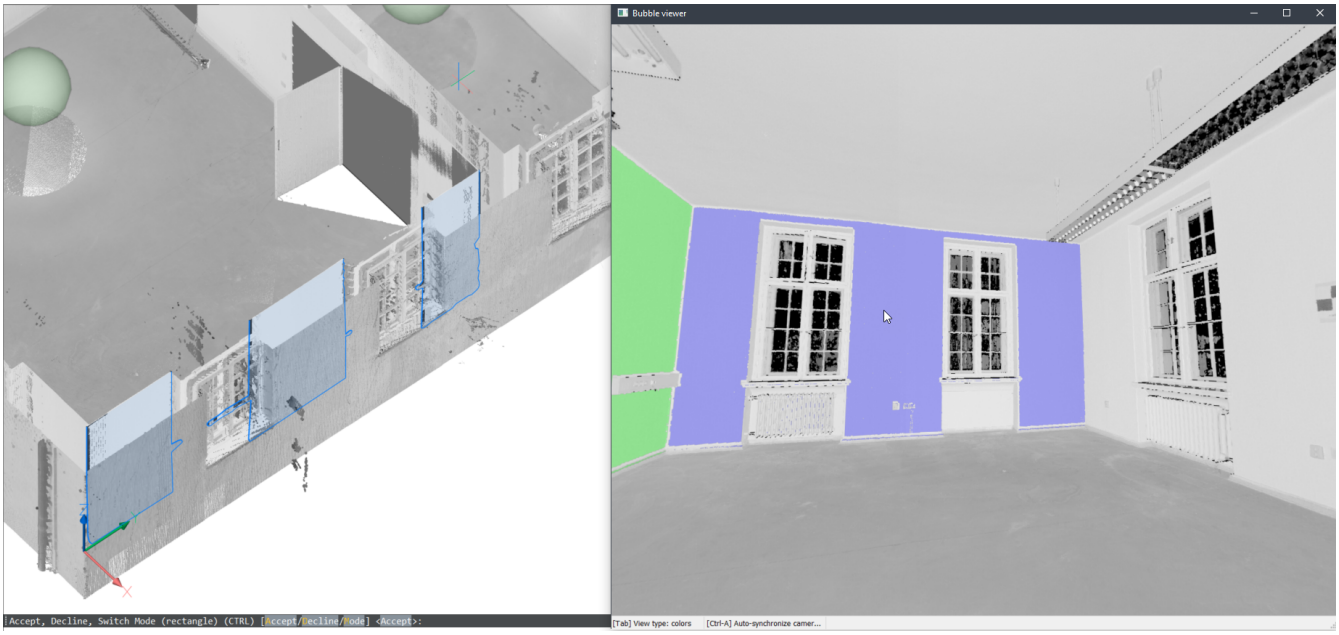

Figure 2.932

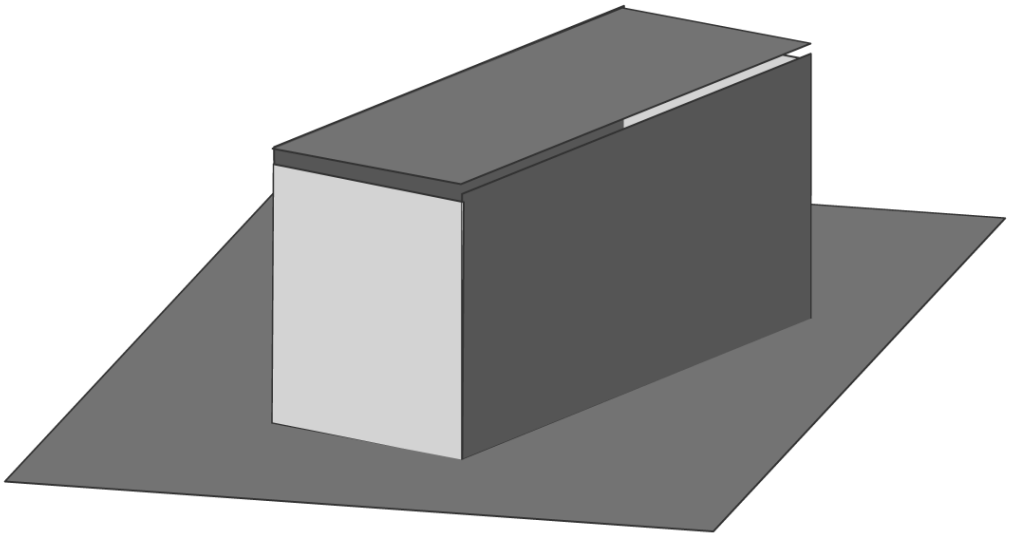

Figure 2.933

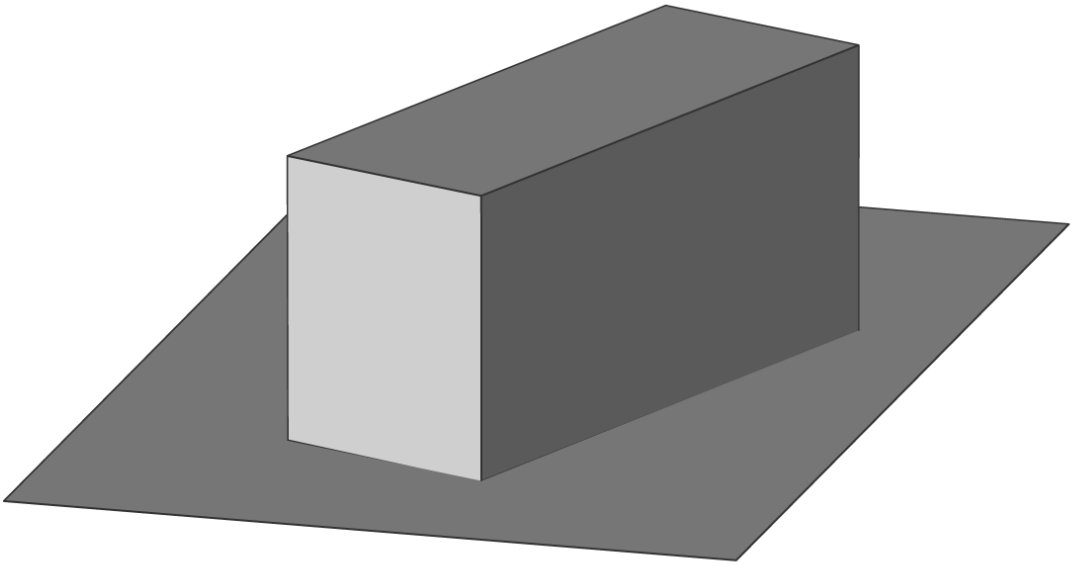

Create 3D entities from the Model Space You can also use this command in the model space when the bubble viewer is not open. BricsCAD will ask you to select a point of the point cloud in model space. Depending on the size of the cropped point cloud, it takes more time but it has 2 advantages by searching multiple scan positions:

- It can create larger surfaces where only parts are visible in each scan position
- It can detect wall and slab thickness since it can take the opposite surface into account.

1. Type **PointCloudFitPlanar** in the commandline.
2. Select a wall where you want to create a plane or solid.
3. **You are prompted**: Accept, Decline, Switch Mode (contour) (CTRL) [**Accept/Decline/Mode**]:
   - Press A to create the wall.
   - Press D to decline.
   - Press M or CTRL repeatedly to switch between different modes. Contour mode will create the best fitting plane. (2.934 on the next page) Rectangular mode will create a rectangular plane around region of planar points. (2.935 on the facing page) Solid mode will create a solid from two parallel point cloud planes.
     (2.936 on page 2531)

Figure 2.934

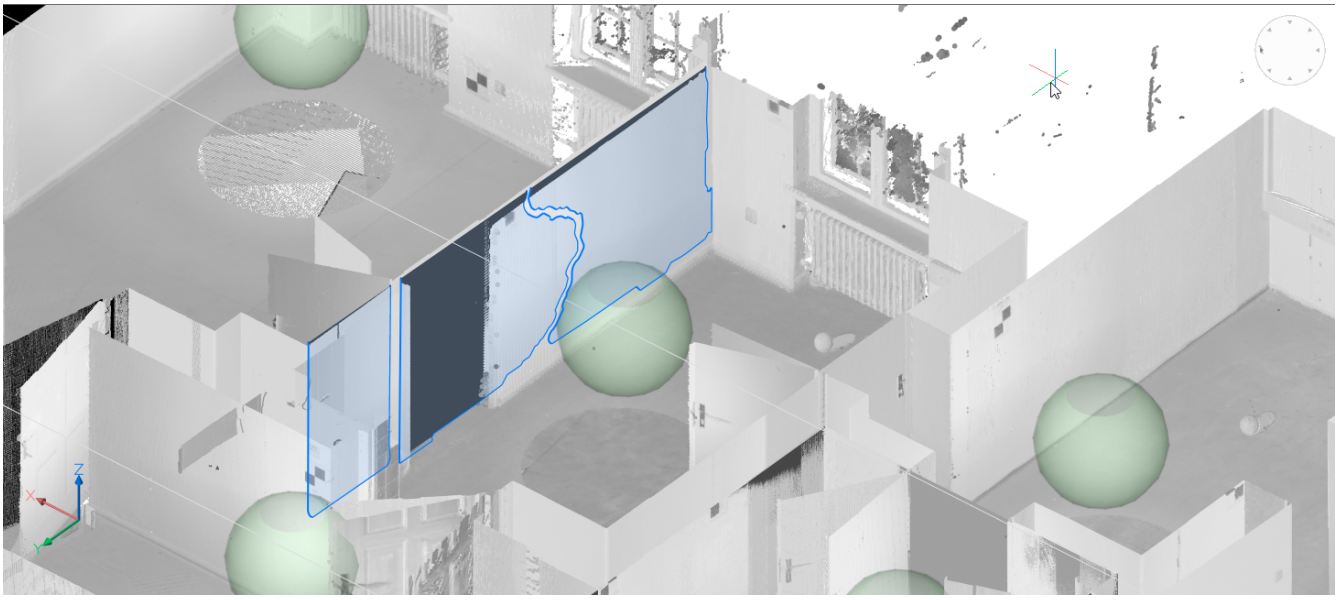

Figure 2.935

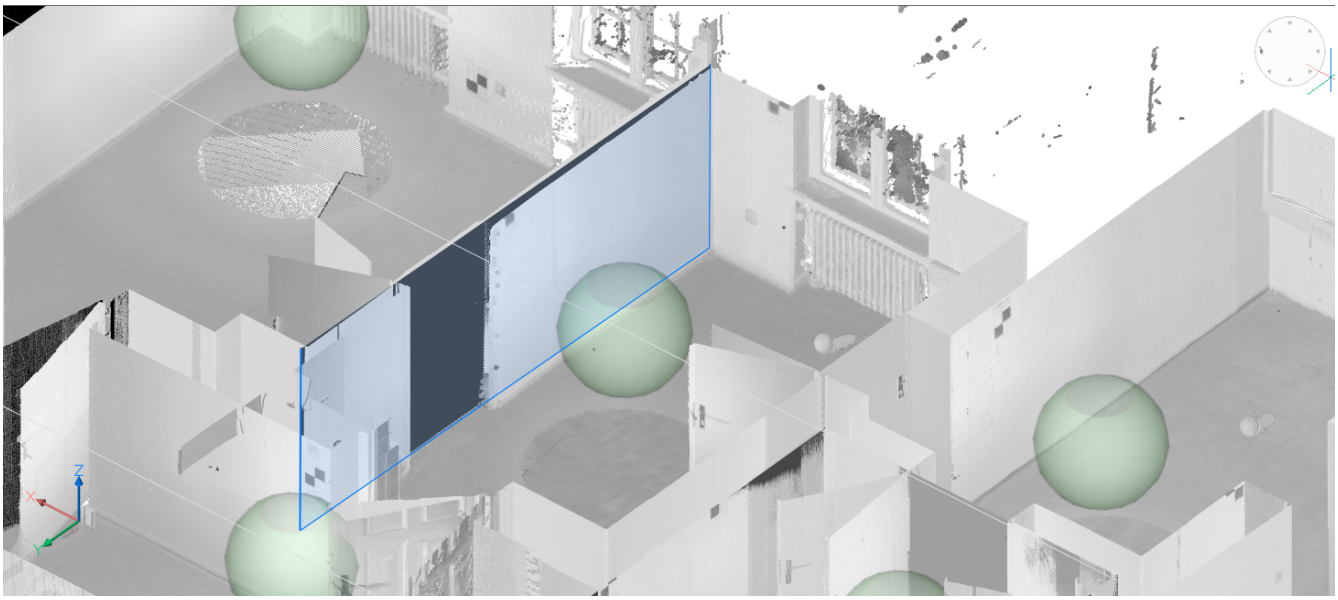
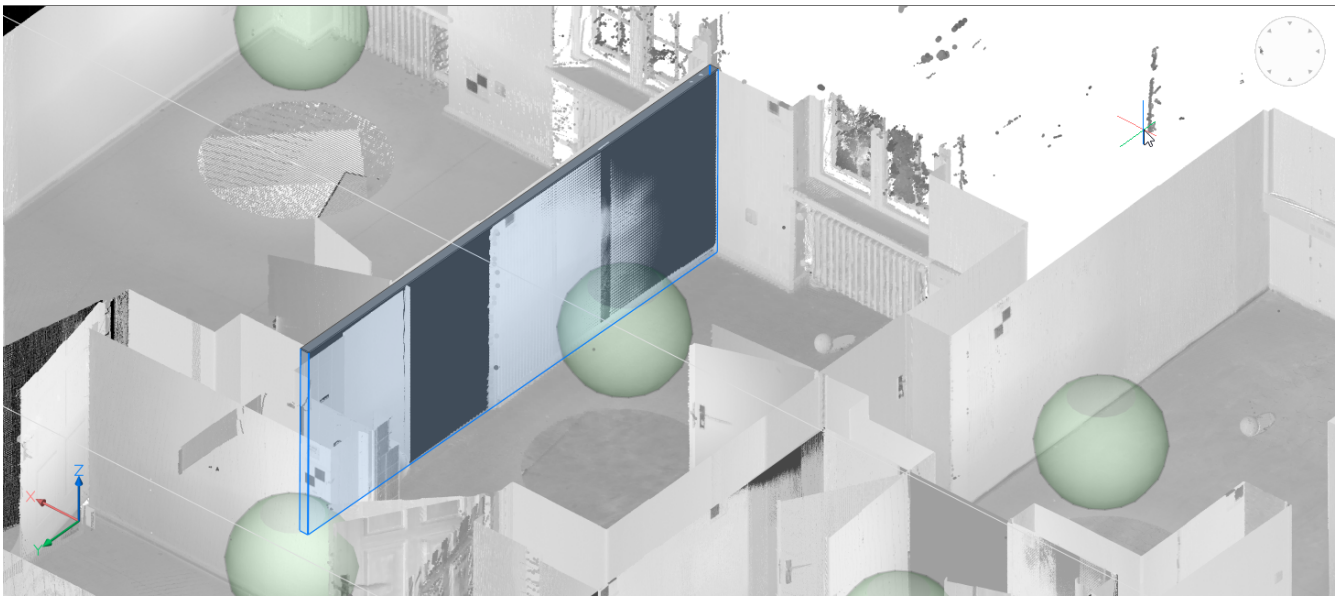


Note: If the point cloud exists out of multiple rooms, you can use the solid mode to automatically create solid walls.

4. Press A to create the wall.

These solids can be the base for a more complex BIM Model. Use modeling commands to complete the building and add BIM data with Bimify, Automatch and Propagate to quickly transform your point cloud into a complete BIM Building. It may be helpful to turn on the **Point Cloud Closest Point** Esnap setting. This snap setting significantly improves your ability to select relevant point cloud points.

Figure 2.936



About PointcloudProjectSection

PointcloudProjectSection automatically generates a raster image with optional contour lines out of a defined section box. These lines can be easily manipulated into a detailed 2D drawing. The command enables you to detect walls from the volume section of a point cloud based on a variety of wall detection options. You can create volume sections automatically for each floor in a building with PointCloudDetectFloors. You can use these sections to generate 2d lines to create a 2d floorplan or a vertical section. This is a background process and multiple sections can be processed in a queue. This way it is possible to run this command in full resolution on all sections. For more information about this command, visit the Command Reference article PointCloudProjectSection (6.7.1).

Procedure: Creating a raster image from a point cloud

1. Type **PointCloudProjectSection** in the commandline.
2. Select a section volume and press Enter.
3. The Wall detection options dialog appears. Edit the options to customize your projected section. Turn **OFF** "Detect Walls" (2.937 on the following page) **Note:** link to command reference for the descriptions of the options dialog.
4. Click OK to generate raster image. (2.938 on the next page) **Point Cloud scan by RealVisuals.**

Figure 2.937

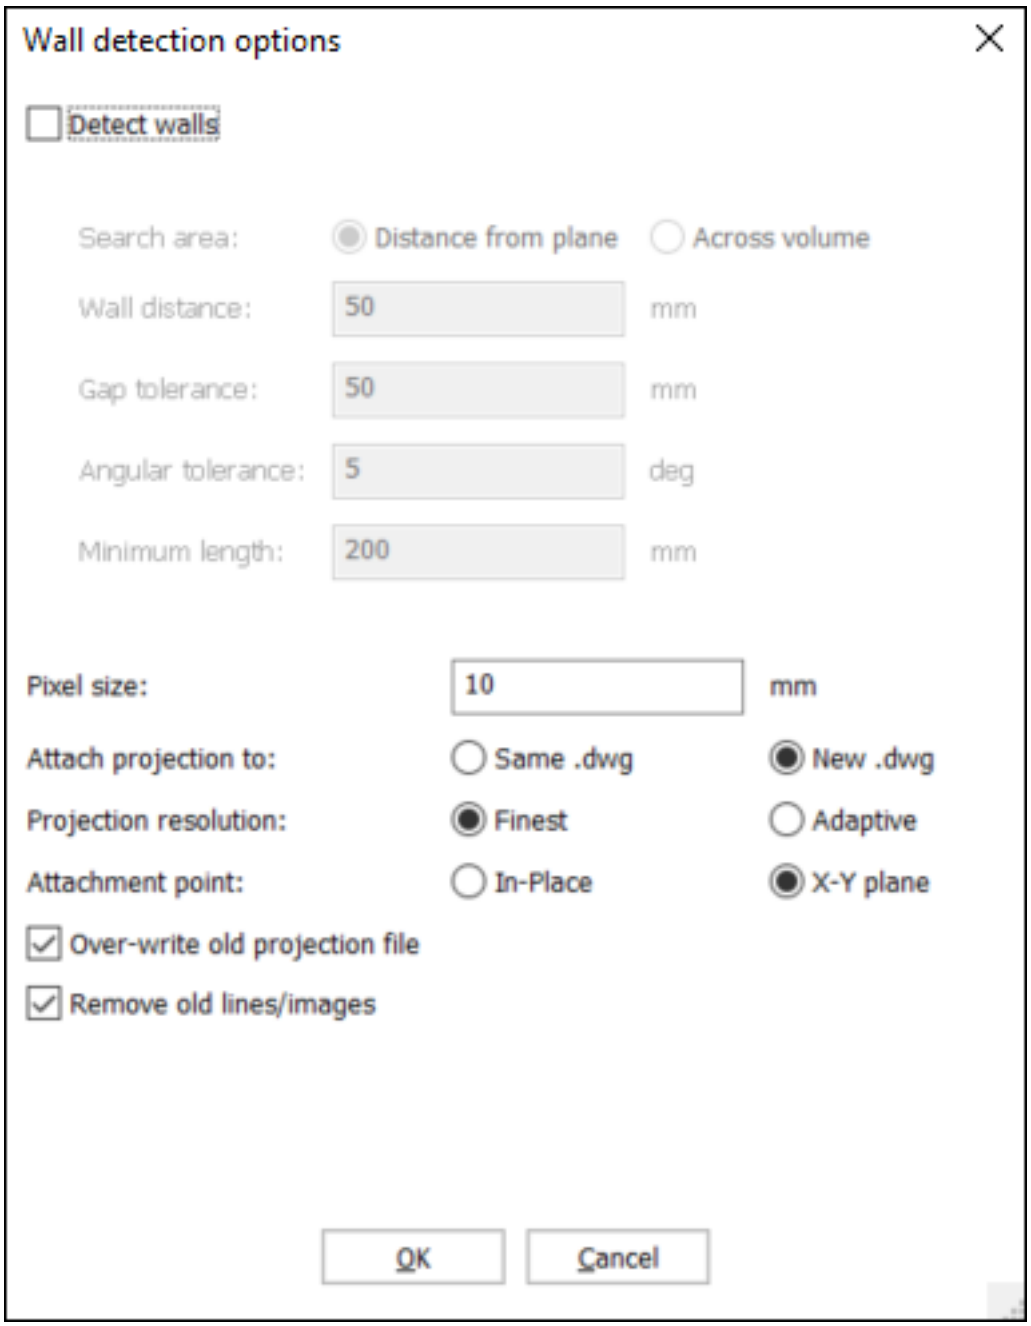


Figure 2.938

Procedure: Detecting walls from a point cloud and generate in 2D

Making horizontal sections from Point clouds

1. Type **PointCloudProjectSection** in the commandline.
2. Select a section volume and press Enter.
3. The Wall detection options dialog appears. Edit the options to customize your projected section. **Note:** See the command reference page for more information about the customization options. **Note:** Turn on “Detect Walls" to generate the green lines as seen in the image below. (2.939 on the following page)
4. Press Enter to create the projection. **Note**: If there are some missing lines, you can draw them yourself by tracing the background image. (2.940 on page 2535)

Making vertical sections from Point clouds

1. Make a vertical section box on the place you want the vertical projection. Make sure that the blue round arrow aims to the side you want your projection.

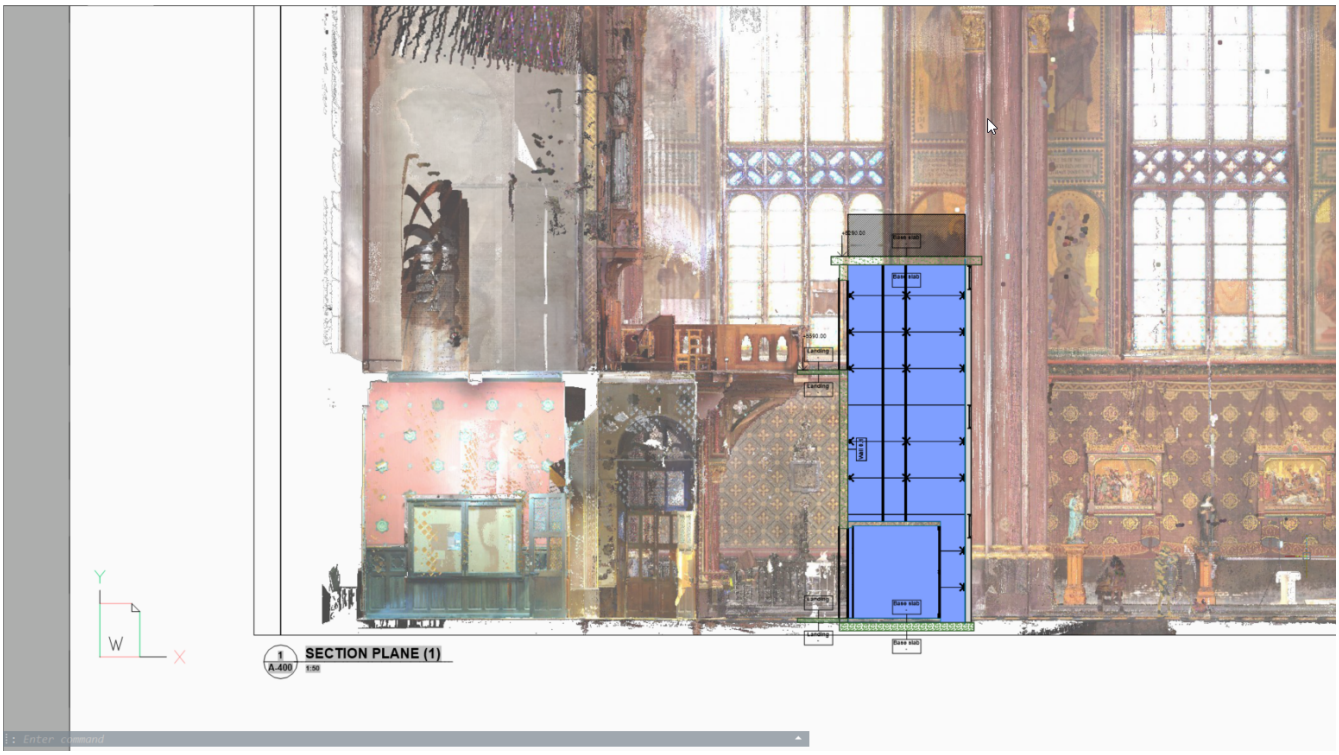
(2.941 on the following page)

Figure 2.941

Generating BIM sections with point clouds

In some cases it is not necessary to recreate the existing building. Background images can give so much more context to the design documents. These can be used to verify the created 2d geometry, in high quality scans these images can also be used as graphical material. For example, as a background image for a BIM model in renovation projects where modern intervention are made in historical buildings. **(2.942 on the next page) Point Cloud scan by RealVisuals.**

Figure 2.942



2.13.16 Schedules

Open the BIM Project Browser panel

1. Move the cursor over a toolbar, ribbon item or a dockable panel (1.15.7).
2. Right-click.
3. Choose **BIM Project Browser** in the context menu.

Click here (2.7.15) for more information about the **BIM Project Browser**.

How to create Schedules

Schedules are; exports, entity properties, block attributes and drawing information to tables on sheets, tables.

Tutorial: How to create Schedules. Click here (2.12.3) to watch

Step 1: Create a project For more information about creating a project, click here (2.7.15) When the project is created, right-click in the Schedules section. Click **Add Schedule (Wizard)...** to open the wizard.

Step 2: The schedule wizard A wizard of 3 pages displays, this will help you to create a schedule.

Page 1 (2.943 on the facing page) **(1) Create data extraction definition** creates a new .dxd (data extraction definition) file:

1. Turn the option on.
2. Click the **Browse** button*.
3. In the file dialog box, select a folder
4. Enter a name in the **File name** field.
5. Click the **Select Folder** button.

Note: By default, the .dxd file will be placed in the project folder. To change this path click the 'Browse' button. **(2) Based on an existing data extraction definition** uses an existing .dxd file as the template for the new one:

1. Turn the option on.
2. Click the **Browse** button*. **Note:** the dxd files are stored in ..\bim\schedules serve as templates.

1. In the file dialog box, select a .dxd file.
2. Click the **Open** button.

Note: By default .dxd files are saved in the **...\Bim\Schedules** subfolder of the **Support (6.27.59)** folder. You can use newly created custom .dxd files to. You can create .dxd files yourself too in a text editor. Please scroll down to the procedure in this article. You can either choose a new name for your schedule or keep the default name. **(3) Model file path**: The model path links to the model. This is filled in automatically if the wizard is started in the model file. If the wizard is started in another file from the project, link the model file:

1. Click the **Browse** button (===ERROR WITH DOWNLOADED IMAGE===).
2. In the file dialog box, select the model file.
3. Click the **Open** button.

(4) Result file path: The result file path determines where the schedule is created. When left blank the Schedule is created as a new sheet:

1. In the file dialog box, select the sheet file.
2. Click the **Open** button.

Click **Next** for the next page. Page 2 (2.944 on the previous page) **(5) Edit Filter:** The filter selects which BIM entity types are included in the Schedule. Use an existing data extraction definition to automatically define the filter. See the Editing Data Extraction Definition (.dxd) files (2.13.9) to learn more about the filter syntax. (2.945) **(6) Include current drawing** - adds the current drawing for data extraction. **(7) Extract entities from blocks**: Adds entities in blocks which will also be processed in the schedule. **(8) Extract entities from xrefs:** Adds all entities in xrefs which will also be processed in the schedule **(9) Add xrefs to block counts:** Counts selected xrefs as blocks. **(10) Include all blocks:** Includes all blocks into the schedule. **(11) Extract from layouts:** When toggled on, all entities layouts will also be processed in the schedule. **Note:** The Wizard automatically selects all entities in the drawing

Figure 2.943

Update and display Schedules

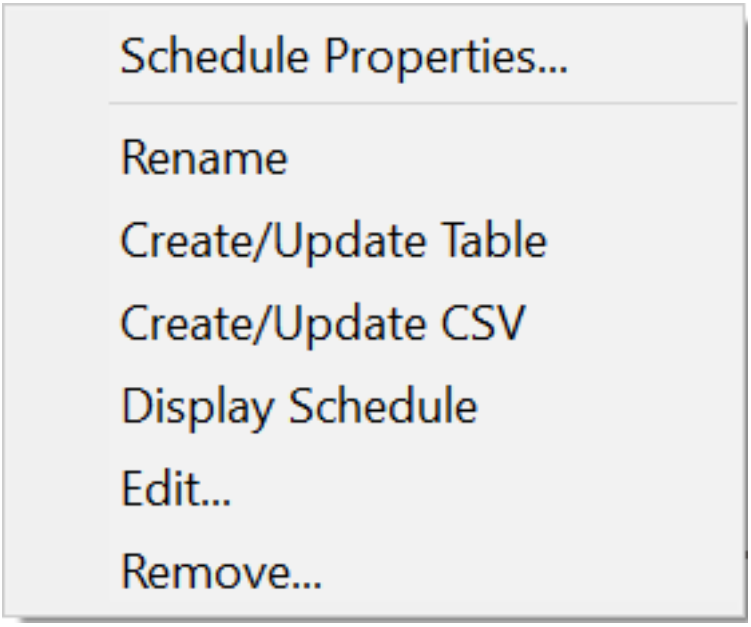
1. Right-click on the new schedule (created in the **BIM Project Browser**). A context menu appears:

   (a) (2.961 on page 2561)

Schedule Properties	**Name**: Renames the schedule **Model**: Displays the link to the model file **DWG Handle**: Displays the DWG Handle. **Data Extraction File**: Displays the link to the Data Extraction Definition **Result Path**: Displays the resulting path
Rename	Renames the schedule
Create/Update Table	Creates a sheet with the schedule or updates the sheet.
Create/update CSV	Creates a CSV file with the schedule information and saves it in the folder where de model file is located or updates the CSV file if it already exists.
Display Schedule	Displays the schedule in the resulting drawing. (If not already open, the drawing is opened.
Edit...	Opens the Wizard Page dialog box where you can edit your schedule. More information about this setup can be found in the procedure in this article.
Remove...	Removes the schedule

2. Click on **Update**.
3. Once the schedule is updated, click on **Display Schedule**. The schedule is shown in the desired sheet. **Or** Double click on the schedule's name to display the schedule.

Figure 2.949



Procedure: Create a window schedule

In this example, you will learn how to make a window schedule from scratch. You can create a door schedule in the same way.

Step 1: Open Schedule Wizard

1. Open the **BIM Project Browser**.

2. Right-click on **Schedules** A context menu appears.
3. Click on **Add Schedule (wizard)...** to open the wizard.

(2.950 on the next page)

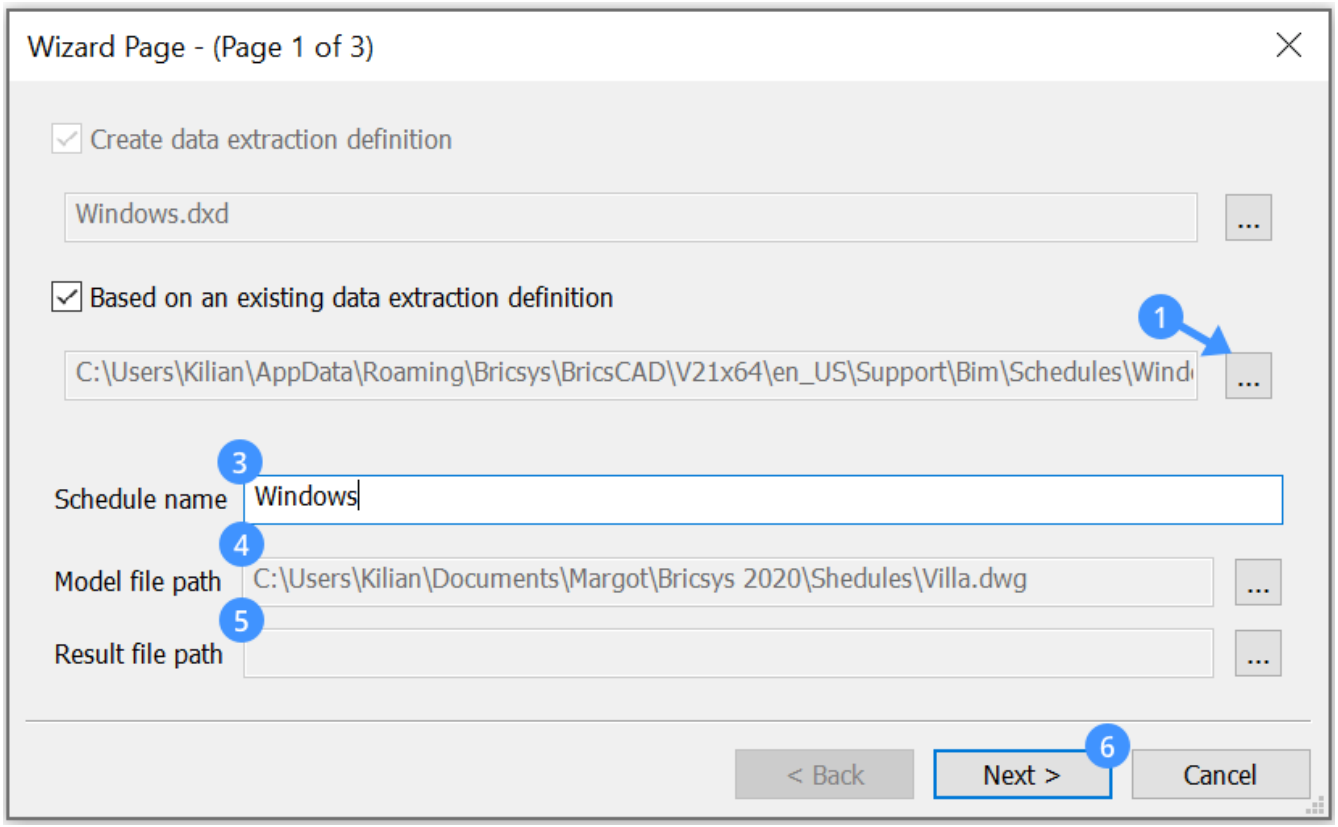
Step 2: The schedule wizard

Page 1 (2.951 on the following page)

For this example, use an existing data extraction definition. **(1)** Click on the **browse** button. A folder pops up. This contains the predetermined data extraction definitions. **(2)** In the folder, select '**Windows.dxd**'. **(3)** Change the schedule name, in this case, "windows". **(4)** The **Model file path** is correct because it was taken from the model file. To create the schedule on a separate sheet keep the **Result file path** empty. **(5)** Click **next**.

Page 2 (2.952 on page 2549)

Figure 2.951



(6) The wizard automatically selects all the entities in the model. **(7)** Click **next.**

Page 3 (2.953 on page 2550)

8. Because you use an existing .dxd, the properties are already pre-selected. Views such as Front and Top are also pre-set.
9. Click on their **Category**, the '**Edit Block View**' window appears.
10. Choose the view. (2.954 on page 2551)
11. Click **Finish**.

Procedure: How to create and edit your own Data Extraction file: Furnishing Elements

You can also create a Data Extraction File yourself and use it to make new schedules. The **DATAEXTRACTION** command will, just like the Schedules wizard, make a new .dxd file with your settings, but it will also make a .csv file with your data in it.

1. Open your model file.
2. In the Structure Browser, select all Furnishing Elements.
3. Type in **DATAEXTRACTION** in the command line. A wizard of 5 pages appears: (2.956 on the next page)
4. Check the **Create Data Extraction Definition** box, and choose a file: name it **"FurnishingElements.dxd"** and save it in your project folder. **Note:** you can base you dxd file on an existing Data Extraction Definition file by checking **Based on an existing data extraction definition.** And choose the file you want to base on.
6. Click **Next.**
7. Select all entities you want to include in your schedule. (2.957 on page 2556)
8. Click **Next.**
9. Select all entities you want to have a data extraction of. (2.958 on page 2557)
10. Click **Next.**
11. Check the all properties you want in the **Furniture Information** (2.959 on page 2558)
12. Click **Next**. The next page appears: (2.960 on page 2559)
13. Click on the three dots next to the **Output to CSV** Give in a new name for your .csv file and click **Save**. You can choose between different options for the delimiter, but It's best to use a semicolon.
14. You can create a Data table as well. When checking this, you will have the option to place the table any where inside your drawing either model space or paper space.
15. Click **Finish**.
16. This should have created 2 files: a .csv file containing the results of the data extraction (basically the same as a schedule, but in an external file), and a .dxd file. This .dxd file can now be re-used for creating a schedule. (See procedures above)
17. Open the .dxd file in a text editor. We can see 5 sections: **Settings**, **Entity Types, Properties, TableFormatOptions** and **SELECTION SET.**
18. Leave the **Settings** as they are.
19. The **Entity Types** are chosen because of the selection set you had active when using data extraction. However, instead of explicitly choosing which types (and handles, see later) you want to extract data from, you can replace the explicit entity types by an asterisk (*), to define that we want to extract information from **all** entity types.
20. Leave the **Properties** as they are.
21. Leave the **TableFormatOptions** as they are.
22. You can delete the entire **SELECTION SET** section, if you don't want to explicitly define which entities you'll be extracting data from.
23. You can add a filter by adding a new section: The section title is called **[Filter]** The section content is (Type == Furnishing Element) (cfr. the .dxd files that are given as example in the support folder, there a Filter on Door and Window type is used).
24. Thus, the contents of the .dxd file should be as follows:

```
 [Settings] ExtractFromBlocks=0 ExtractFromXrefs=1 CountXrefs=0 CombineEqualRows=1 IncludeNameColumn=1 Fo
[Entity Types] *
[Properties] Furniture Information:Article Number|Article Number| Furniture Information:Cost|Cost|%1u2%pr
[TableFormatOptions] TableStyle=Standard TitleCellStyle-TITLE HeaderCellStyle-HEADER DataCellStyle-DATA
[Filter] (Type==Furnishing Element)
```

25. Save this .dxd file in your project folder.

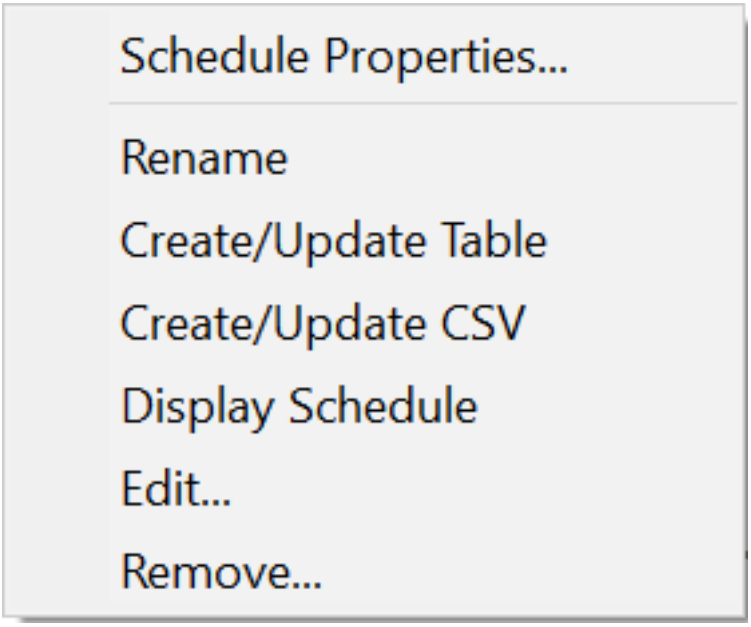
Procedure: How to edit a schedule

1. Go to the Schedules tab in the Project Browser
2. Right-click the selected schedule. A context menu appears: **(2.961 on the facing page)**
3. Click **Edit…** A Wizard of 2 pages appears: (2.962 on page 2562)

Figure 2.961



4. Check or uncheck the options you want.
5. Click **Next**.
6. Check all properties you want to be in the schedule or uncheck all properties you want to leave out.
7. Click **Finish.**
8. Right-click on the schedule again and choose **Create/Update Table**
9. Repeat this action but choose **Create/Update CSV.**
10. The table and CSV file are now updated. You can update and open your sheet with the schedule again and see the changes.

2.13.17 Spot Elevation Level

Command: BimTag (6.7.59) **Overview:** In this lesson, you will learn how to use the Spot Elevation tag. **Lesson objectives** After completing this lesson, you will be able to:

- Use the spot elevation tag to display the height of any point of a 2D drawing representation on paper space.
- Edit the layout of the text of the spot elevation level tag.
- Edit the layout of the Multileader of the spot elevation level tag.

About

The Spot Elevation tag displays the absolute elevation of a selected point of a BIM object displayed in a section view, based on the **World Coordinate System (WCS) (1.21.21)**. As the Spot Elevation tag is an associative tag type, it can only be used in the **paper space (1.23.12)** of a drawing sheet. For more information on how to set up Sheets and create Projects, please visit the **Project Browser (2.7.15)** article.

Procedure: how to place a Spot Elevation tag on a Section Sheet

1. Open a section sheet of the model. Right-click on the section in the Project Browser and select Display View.
2. Type **Bimtag** in the command line **or** click on **tag** in the Draw menu of the Quad.
3. **You are prompted: [Manual/selection options (?)]** Type **M** to choose Manual and press Enter.
4. **You are prompted: [Auto/Current mleader style/change Tag type]** Type **T** to change the Tag type and press Enter.
5. **You are prompted: [Tag/cOmposition/Load-bearing directions/Spot-elevation]** Type **S** to choose Spot-elevation and press Enter.
6. Click on a point on the edge of a BIM object to display the elevation height. the displayed value is the elevation level measured relative to level 0 of the model. **Note:** you can select any point of the edge of a BIM object. Turn off ESNAP if you don't only want to select snapping points.
7. When there are several tags possible on the location where you place the tag, hit CTRL to scroll through the different options while the Hotkey Assistant appears at the bottom of the screen.
8. Move your cursor in order to adjust the position of the tag and Left-click to place the tag. (2.963 on the following page) **Note:** the spot elevation level is a non-dynamic value. When you move the tag, the value does not always change along. The moment you move a tag that will not be updated, you can see the tag value becomes dissociated in the command line. (2.964 on the next page)
9. Update the section to make sure the right values are displayed. Select the section, open the Quad and click on **Update Section** in the model tab. **Note:** If the tag has been displaced, it may behave irrationally or haphazardly by either turning red or omitting its value, as illustrated below: (2.965 on page 2565) **Tag turned red after displacing the arrowhead of the leader and updating the section.** (2.966 on page 2565) **Tag turned red after displacing the entire tag and updating the section.** (2.967 on page 2566) **Tag value disappeared after displacing the tag and updating the section.**

Figure 2.963

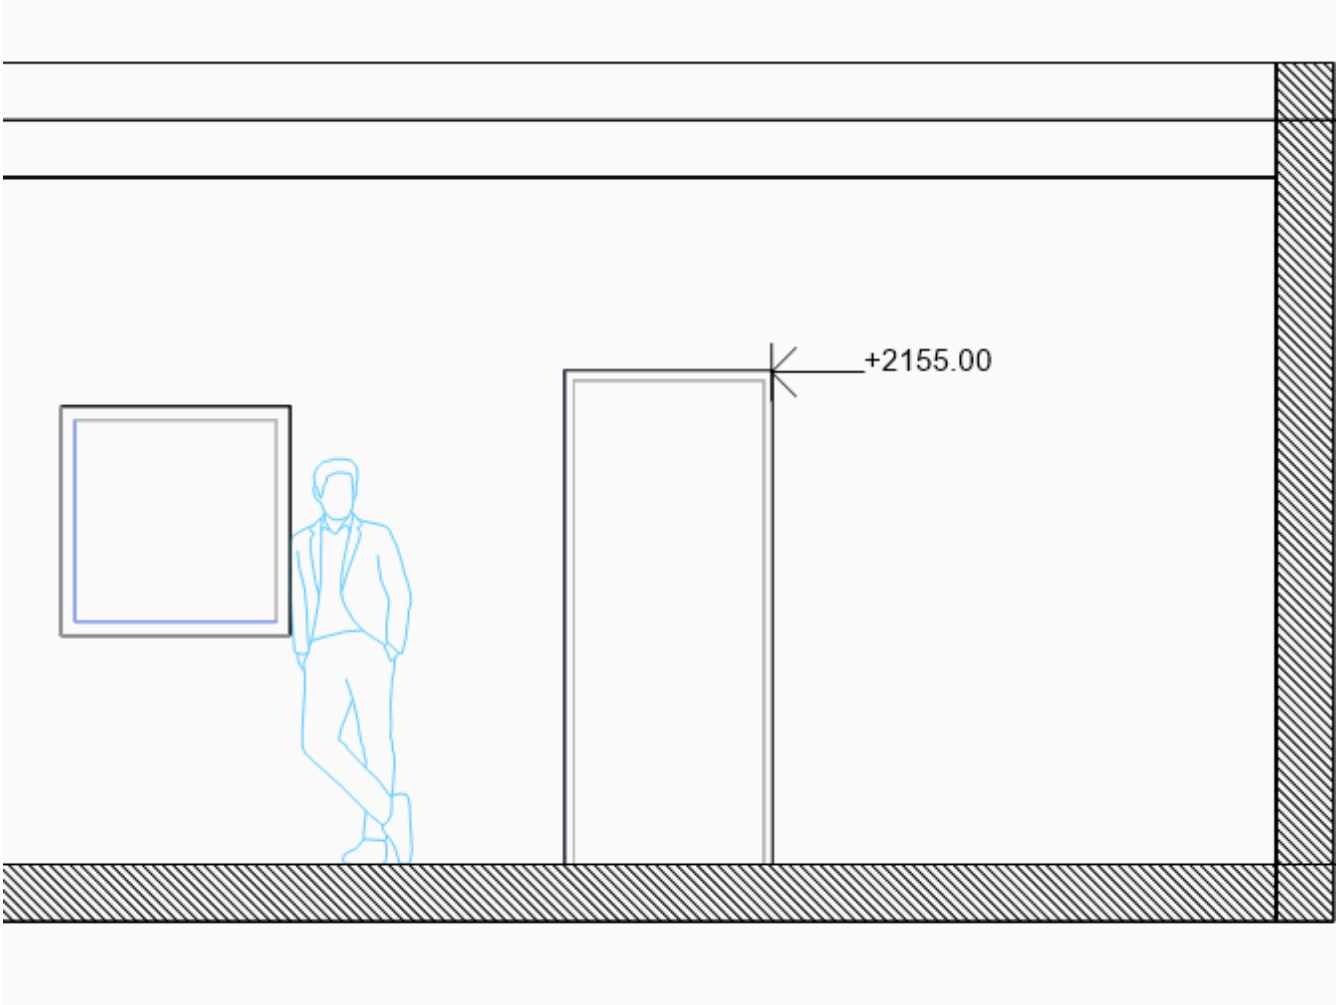

Figure 2.964

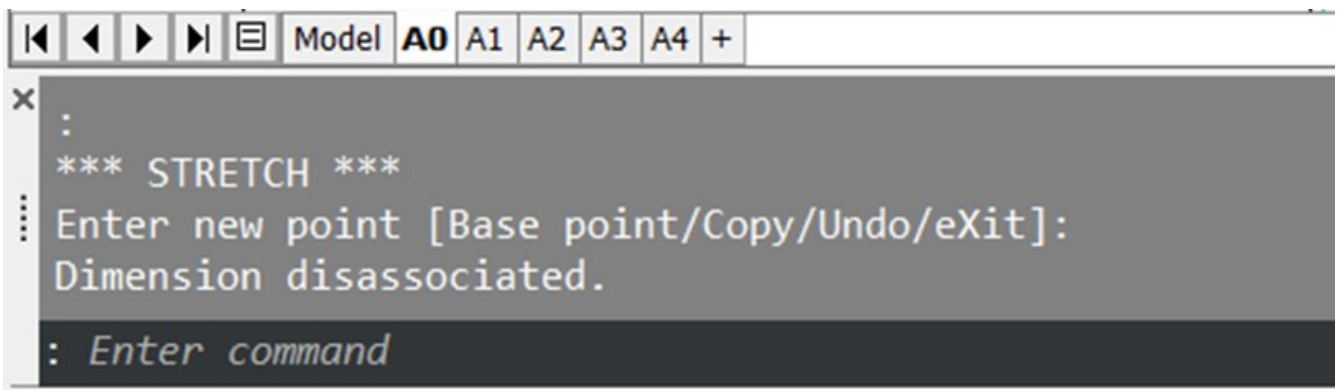

Figure 2.965

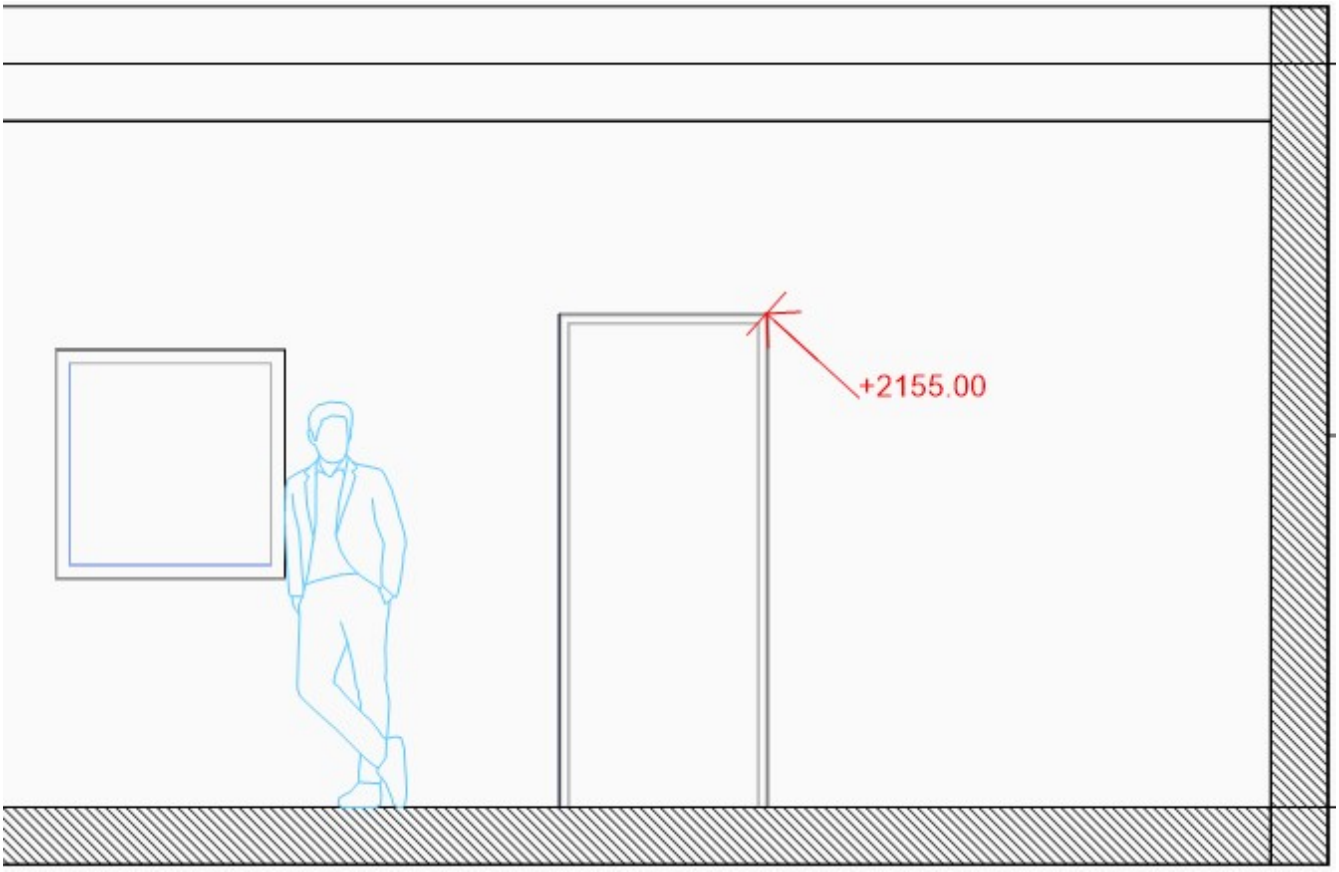

Figure 2.966

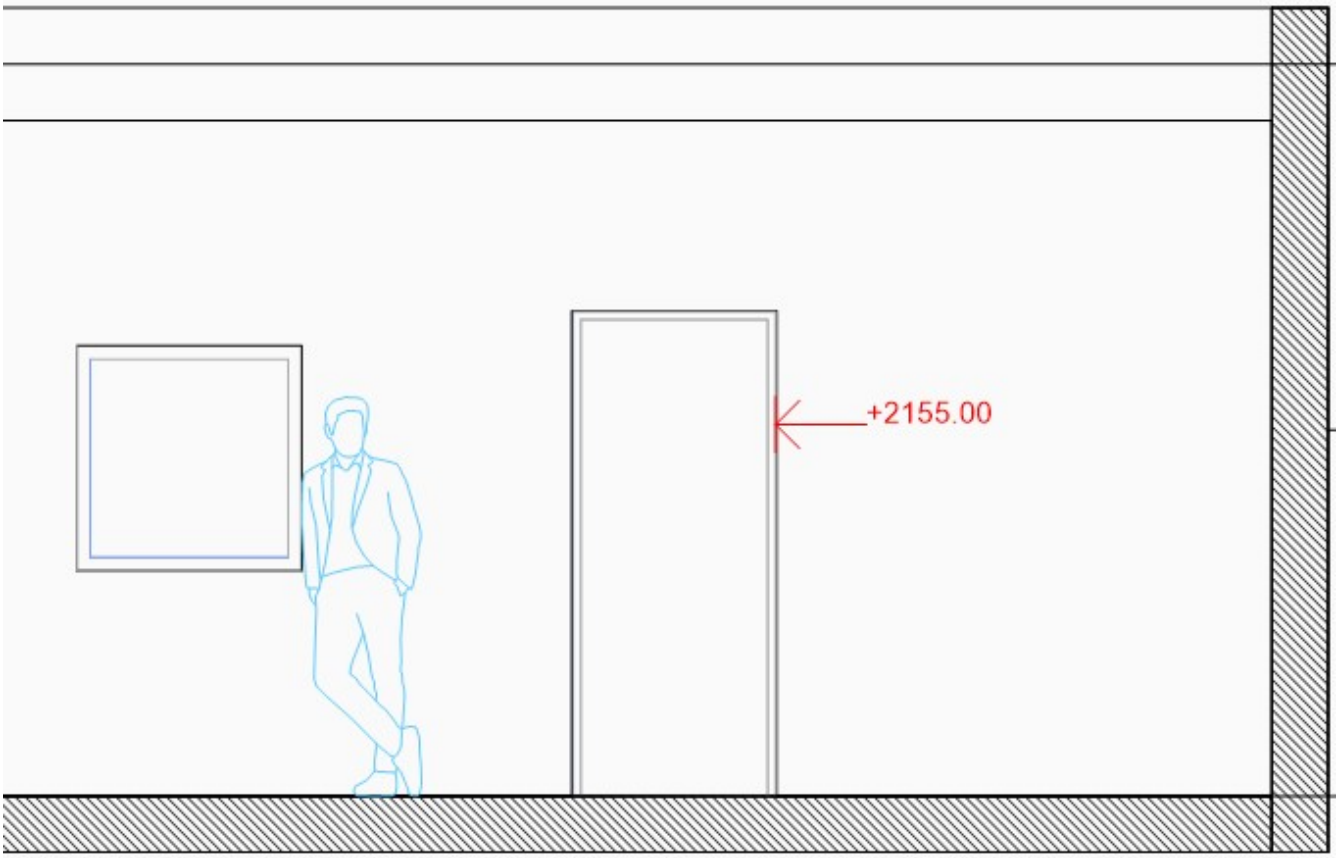

Figure 2.967

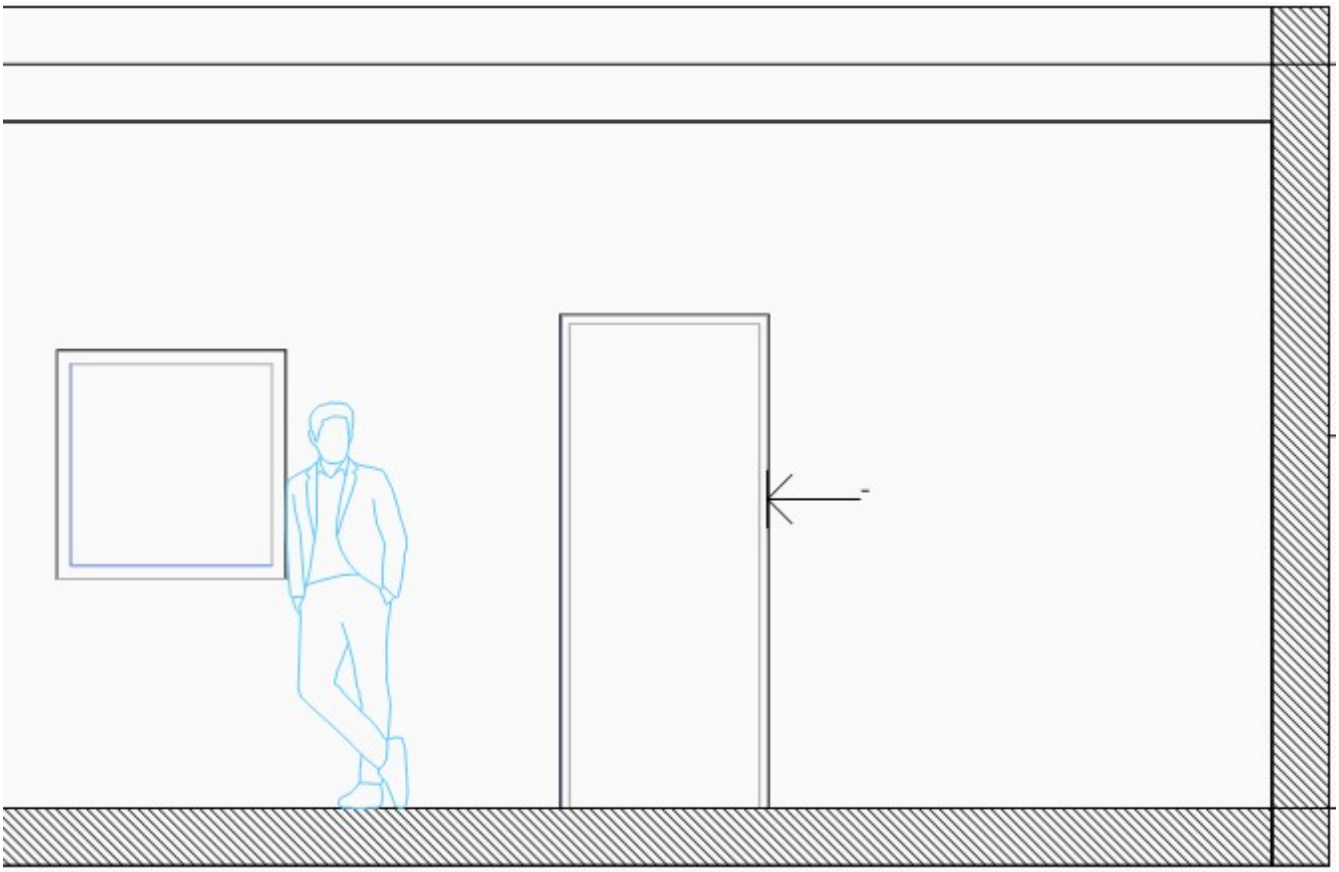

Procedure: how to place a Spot Elevation tag on an Elevation Sheet

1. Open an elevation sheet of the model. Right-click on the elevation sheet in the Project Browser and select Display View.
2. Type **Bimtag** in the commandline **Or** Click on **Tag** in the Model menu of the **Quad**. (2.968 on the next page)
3. **You will be prompted: [Manual/selection options (?)]** Type **M** to choose Manual and press Enter.
4. **Later, you will be prompted: [Auto/Current mleader style/change Tag type]** Type **T** to change the Tag type and press Enter.
5. **Finally, you will be prompted: [Tag/cOmposition/Load-bearing directions/Spot-elevation]** Type **S** to choose Spot-elevation and press Enter.
6. Click on a point on the edge of a BIM object to display the elevation height. The displayed value is the absolute elevation level measured relative to Floor 0 of the model. **Note:** you can select any point of the edge of a BIM object. Turn off ESNAP if you don't only want to select snapping points.
7. When there are several tags possible on the location where you place the tag, hit CTRL to scroll through the different options while the HotKey Assistant (HKA) appears at the bottom of the screen.
8. Move your cursor in order to adjust the position of the tag and Left-click to place the tag. (2.969 on the facing page) **Note:** the spot elevation level is a non-dynamic value. When you move the tag, the value does not always change along. The moment you move a tag that will not be updated, you can see the tag value is dissociated in the command line. (2.970 on page 2568)
9. Update the section to make sure the right values are displayed. Select the section, open the Quad and click on **Update Section** in the model tab. The tag should not behave irrationally or haphazardly by either turning red or omitting its value when it's displaced. (2.971 on page 2568) **Tag turned red after displacing the arrowhead of the leader and updating the section.** (2.972 on page 2570)

Figure 2.968

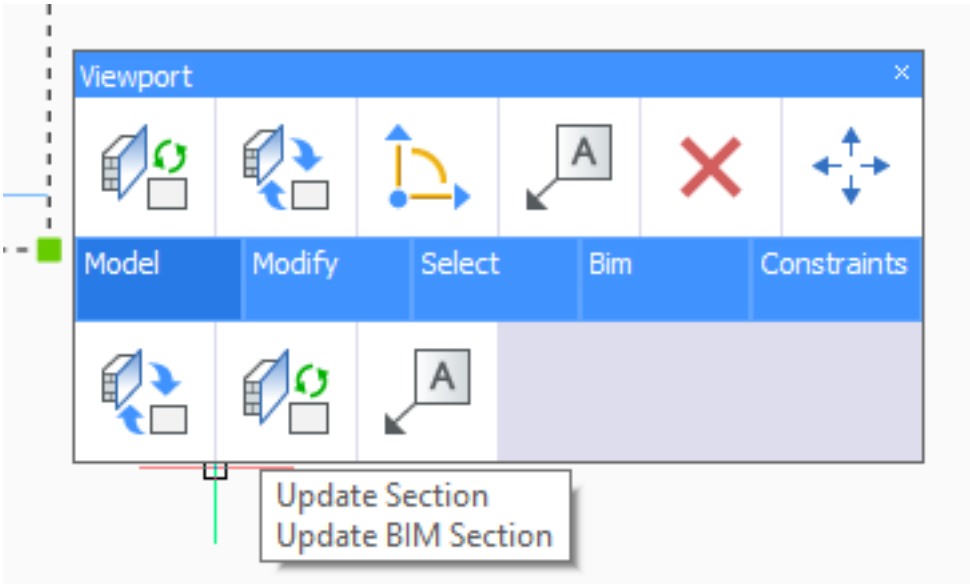

Figure 2.969

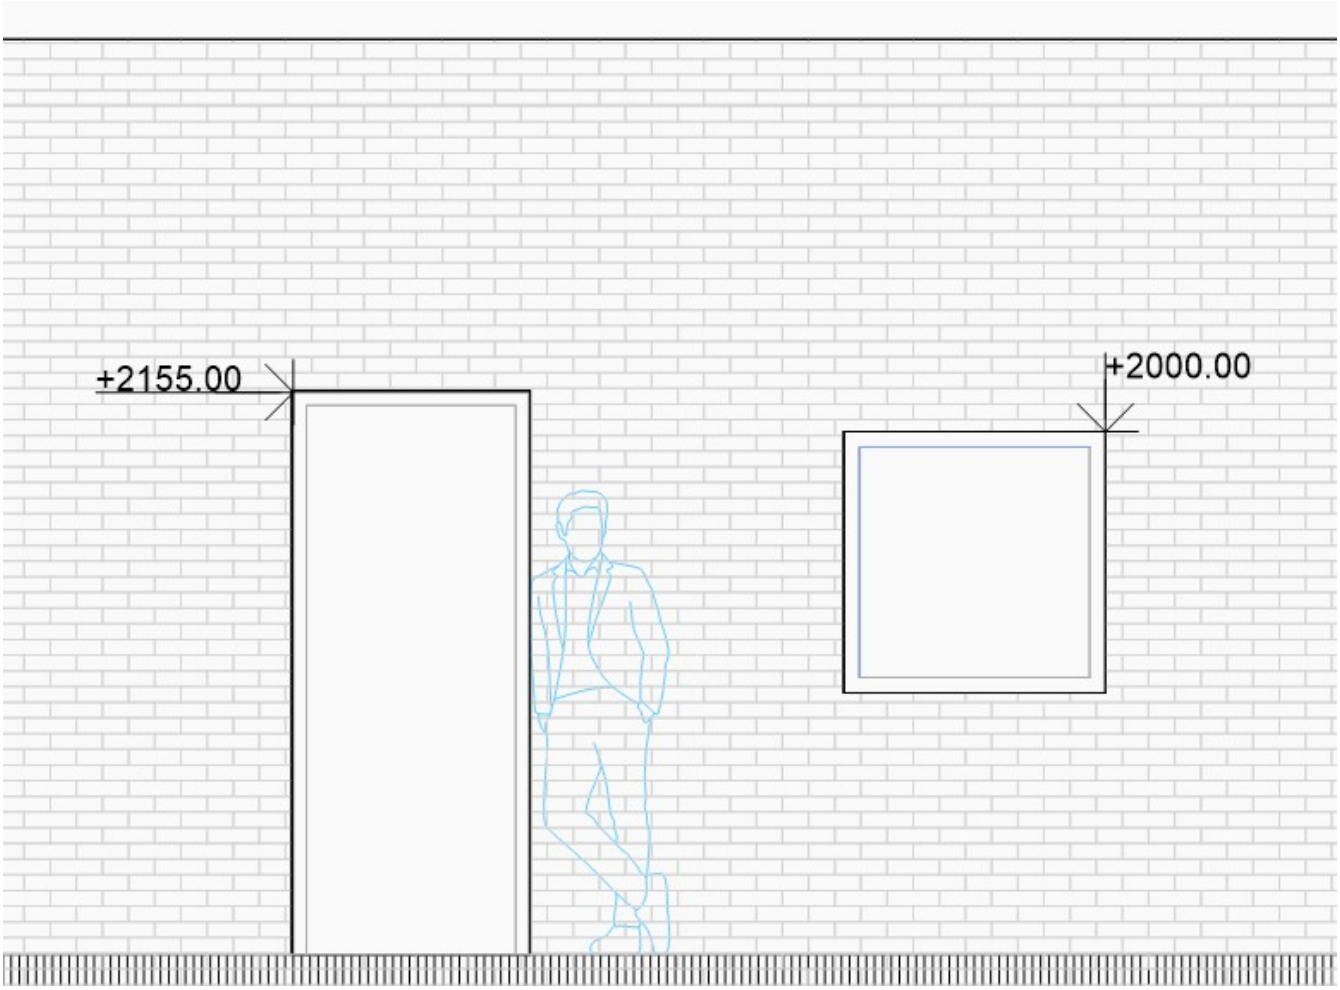

Figure 2.970

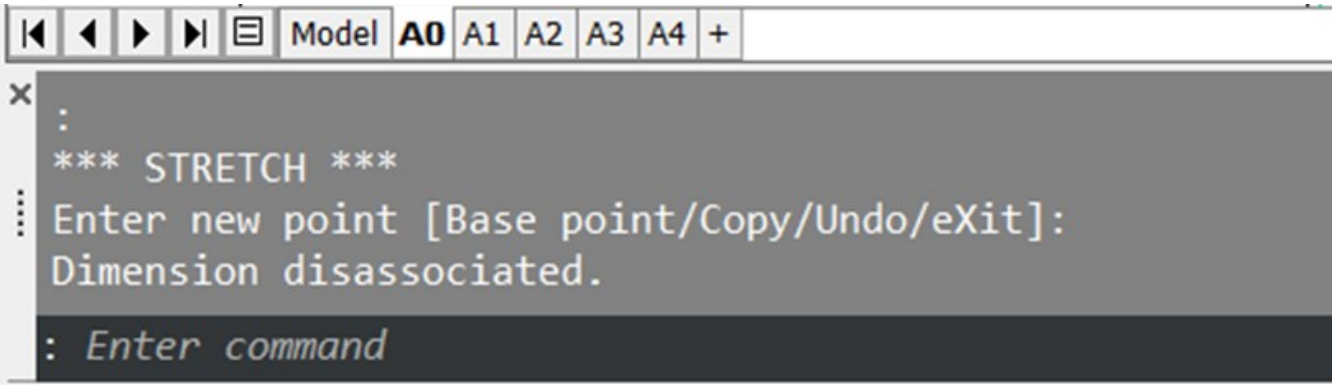

Figure 2.971

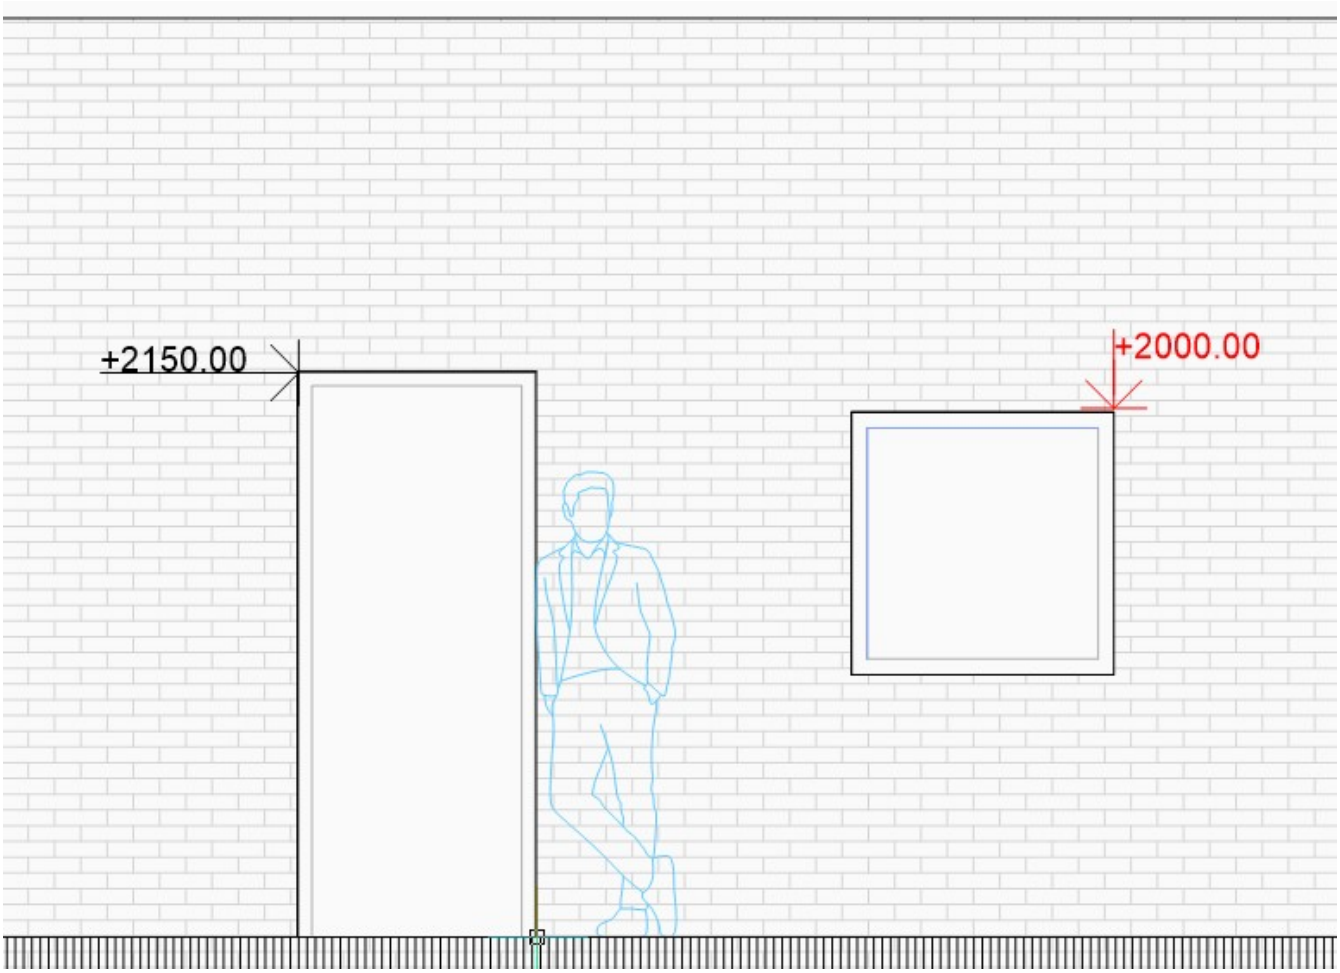

Tag turned red after displacing the entire tag and updating the section. (2.973 on page 2571) **Tag value disappeared after displacing the tag and updating the section.**

Figure 2.972

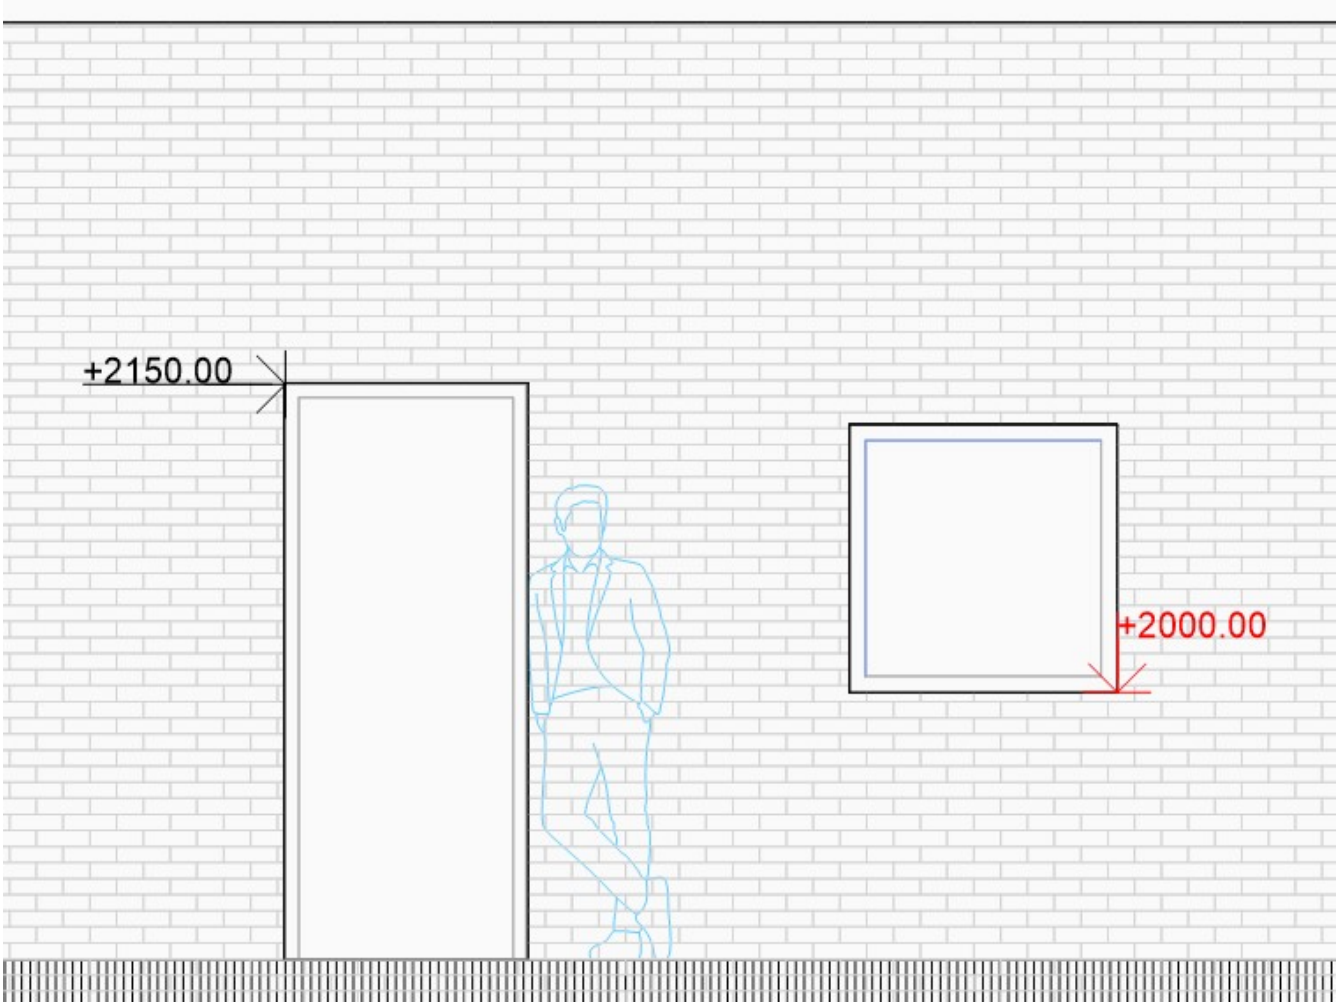

Figure 2.973

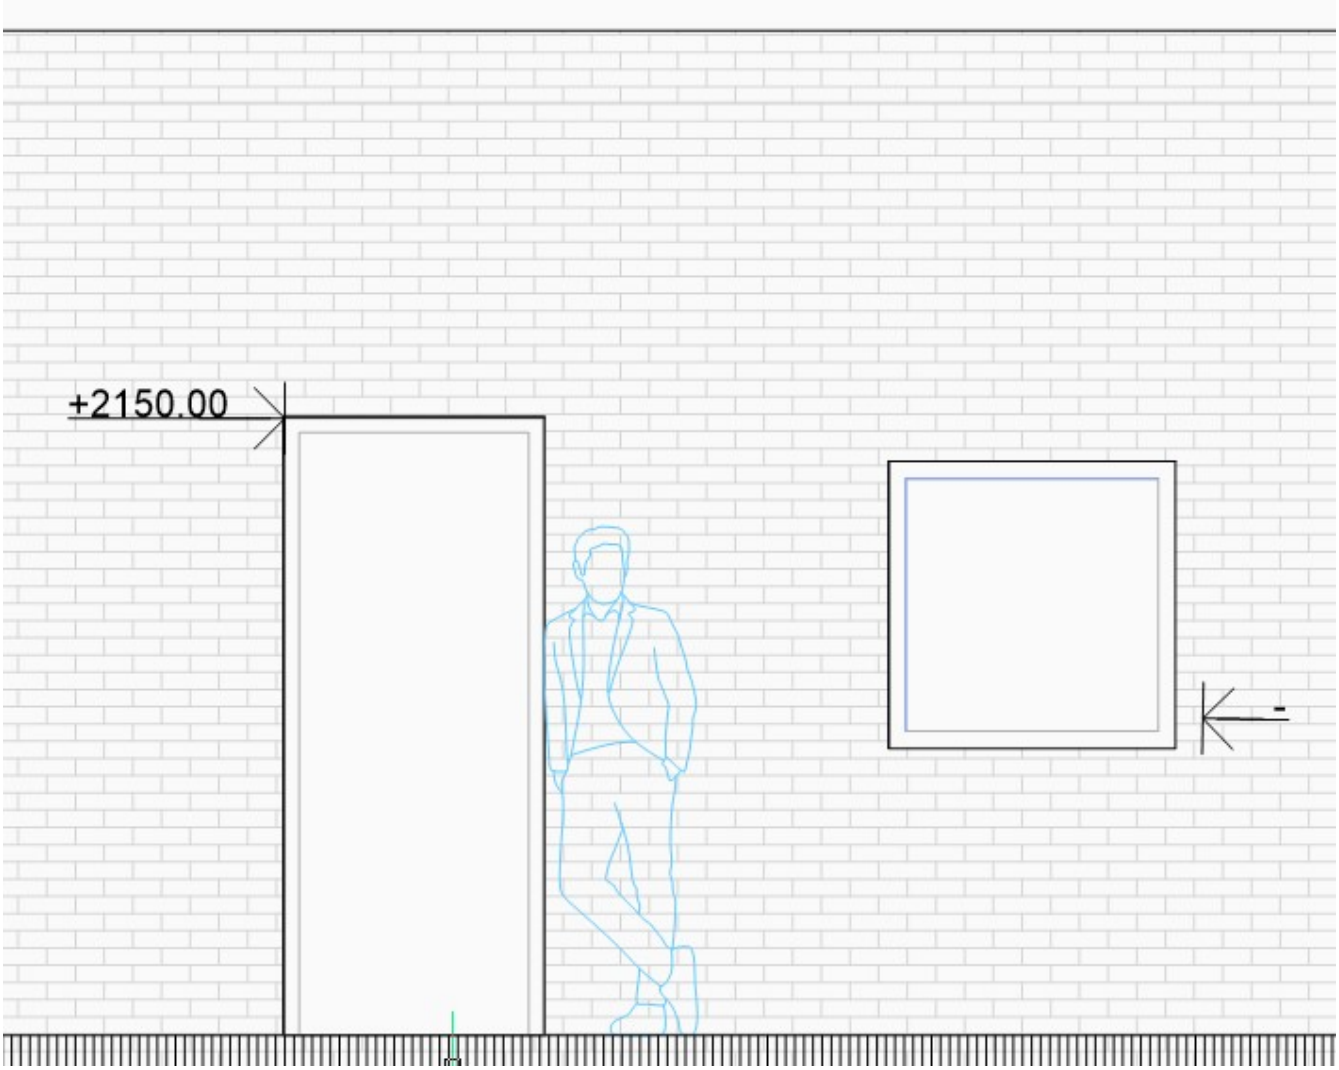

Procedure: Placing Spot Elevation Level tags on a Floor Plans or Reflected Ceiling Plans

1. Open a floor plan or a reflected ceiling plan from the Project Browser.
2. Go through step 2-7 of how to place Spot Elevation Level tag in a Section Sheet.
3. In a floor or ceiling plan, there are 2 different tags possible.
   - **With MLeader** This annotation tag type, which illustrates with a leader line, is also normally used in the section or elevation sheets. You can use this tag on entities that do not reach or aligned to the floor/ceiling level, such as a window sill in the picture below. (2.974 on the next page) (2.975 on the facing page) **Spot elevation level tag on window sill level which is not on floor level.**
   - **Without MLeader** This tag has a different layout to the tags found in the elevation or section sheets. This tag appears when you place a spot elevation tag on entities that reaches the floor/ceiling plane, thereby displaying the elevation level of the floor plane. (2.976 on page 2574) (2.977 on page 2574) **Spot elevation level tag on wall that reaches till the floor slab.**
4. When placing a tag on a wall in plan view, you may encounter different results for different plies of the wall. This is due to how elevation levels are measured In BricsCAD. When placing a spot elevation tag on an entity in plan view, it refers to the elevation value of the lower level of the entity's ply, if applicable. Similarly, when you place a tag on a ceiling plan, the upper level of the ply is measured. Since plies of a wall may differ in their lengths based on how they are designed at detail junctions, the spot elevation tag value may differ according to the ply you have selected.
   - **Construction detail with unedited plies** The interior and exterior plies have the same length. All the spot elevation tags you place on this wall in plan view will therefore display the same value. (2.985 on page 2581) (2.979 on page 2576) **Note:** The value is -250 instead of 0 because Floor 0 is defined as the level of the upper side of the ground floor in this model.
   - **Edited construction detail** If you have adjusted how the wall would connect to a floor slab based how it would be constructed, the plies of the wall will therefore have different lengths. Depending on which ply you select to place the spot elevation level tag, a different value will be displayed. (2.980 on page 2577) (2.981 on page 2578) **Elevation level of interior ply is higher because ply does not reach till the base level of the floor.**

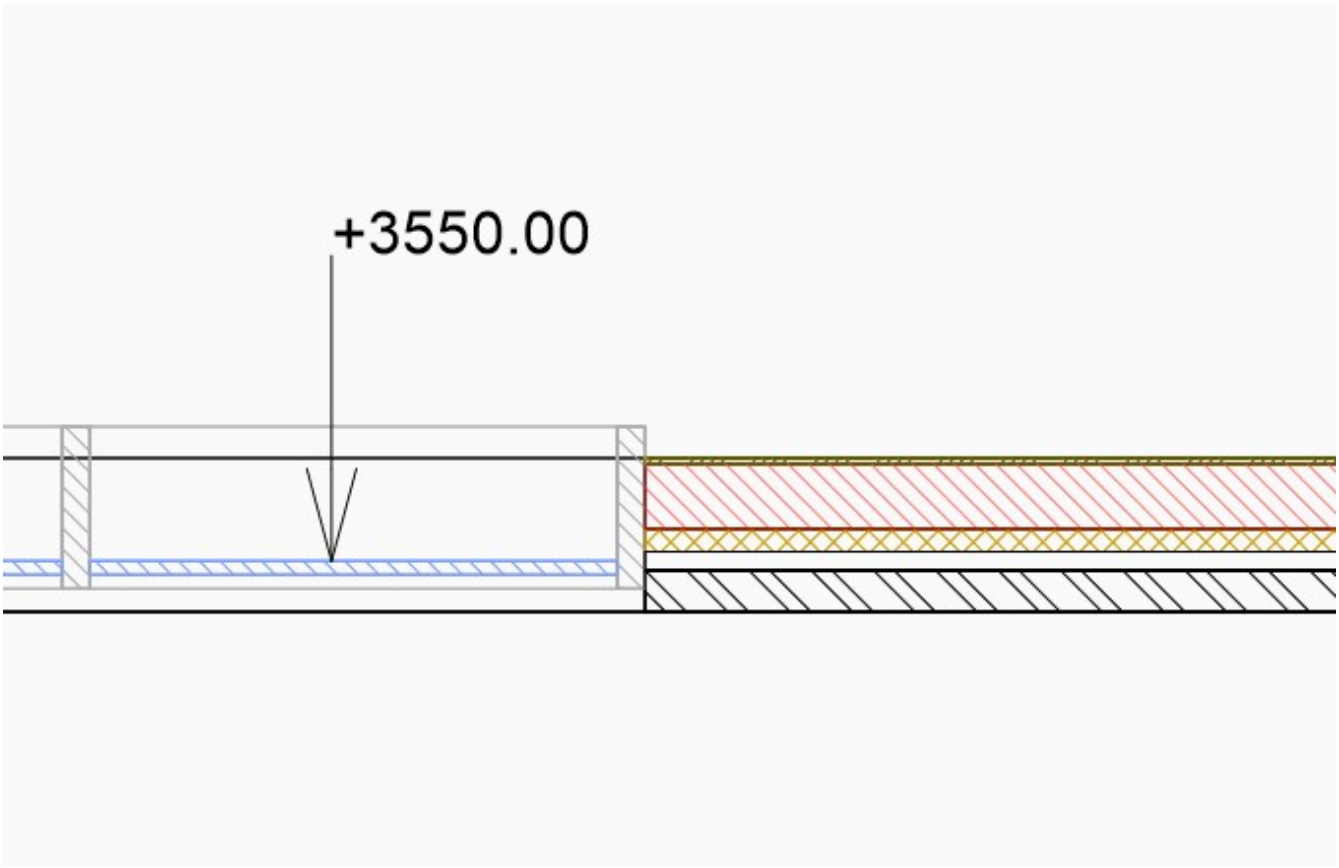

Figure 2.975

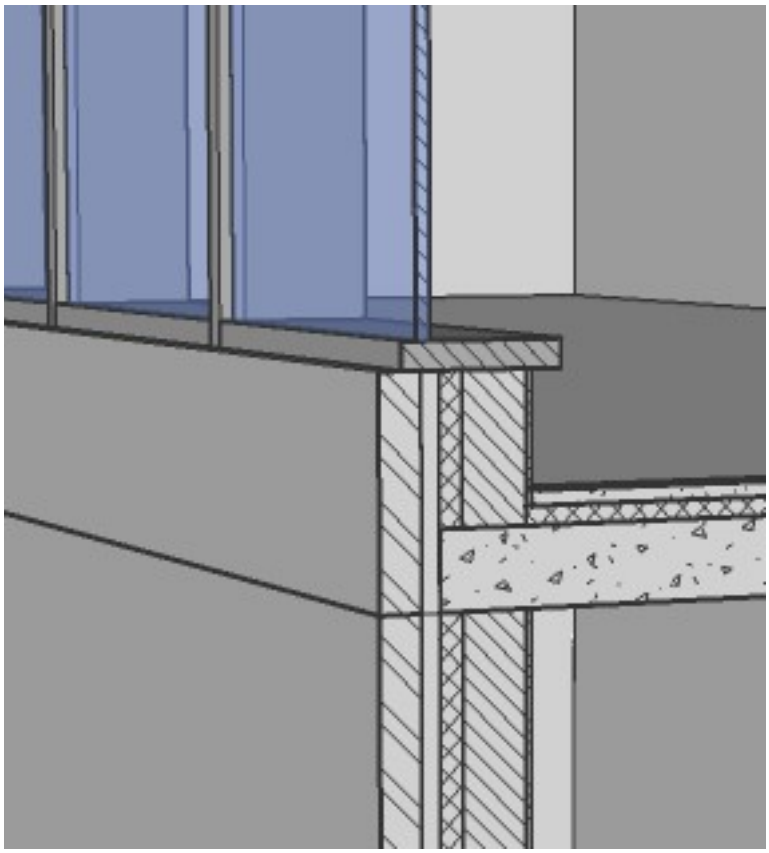

Figure 2.976

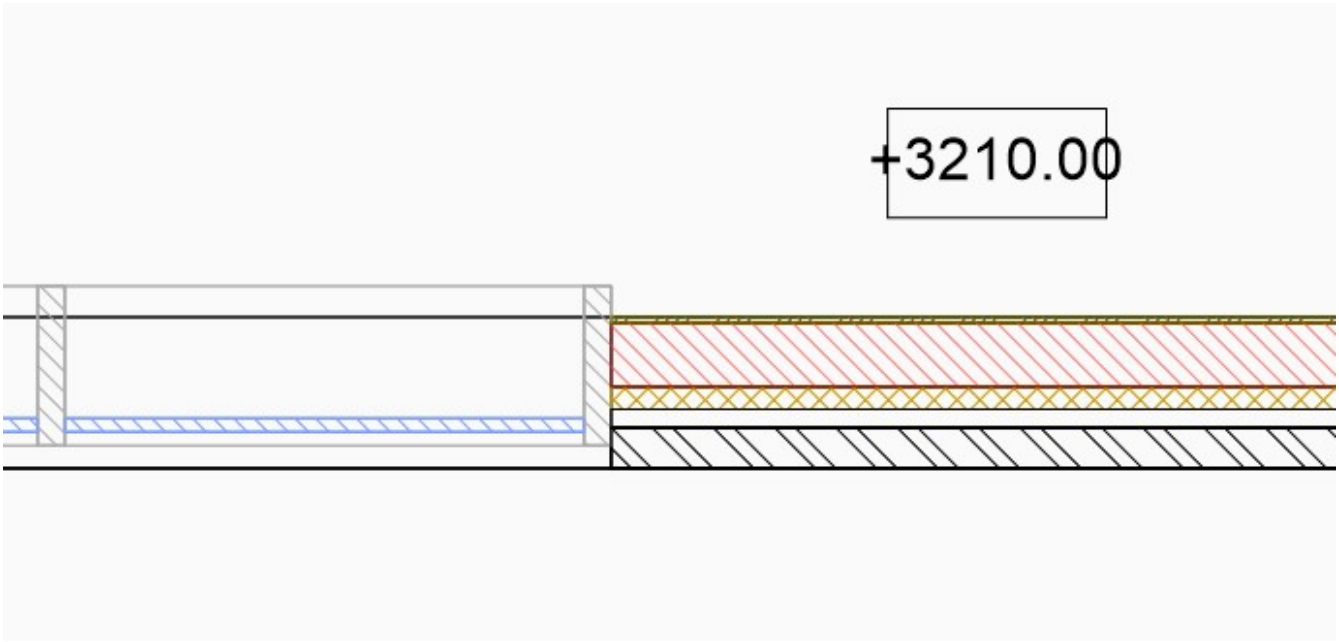

Figure 2.977

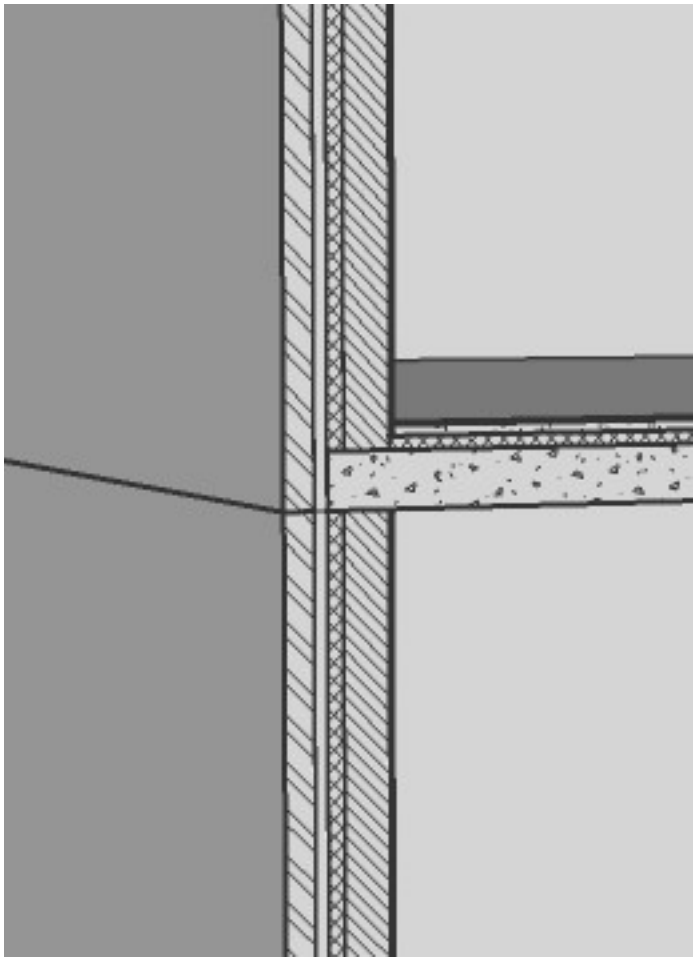

Figure 2.978

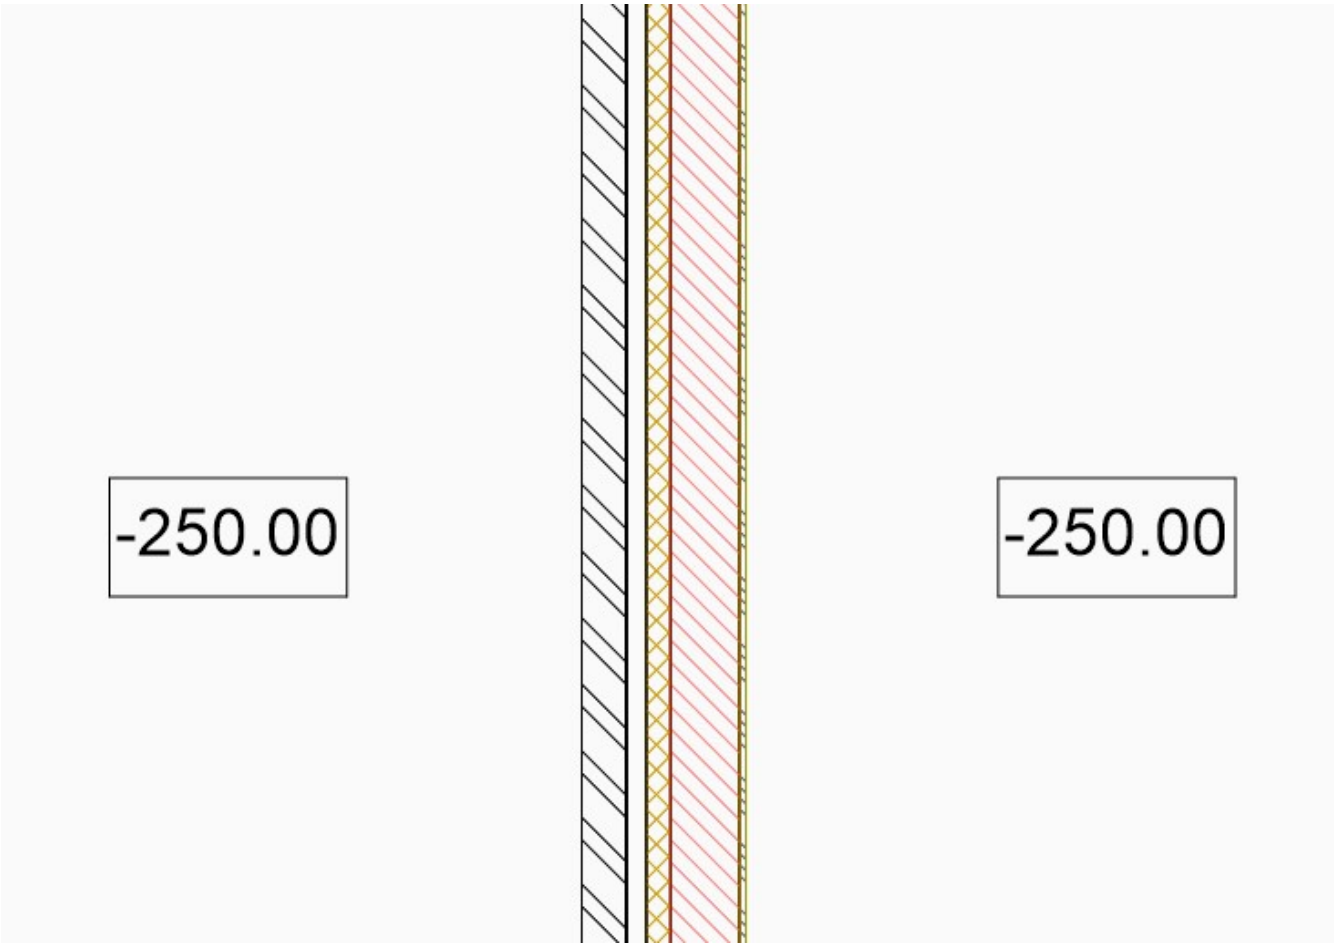

Figure 2.979

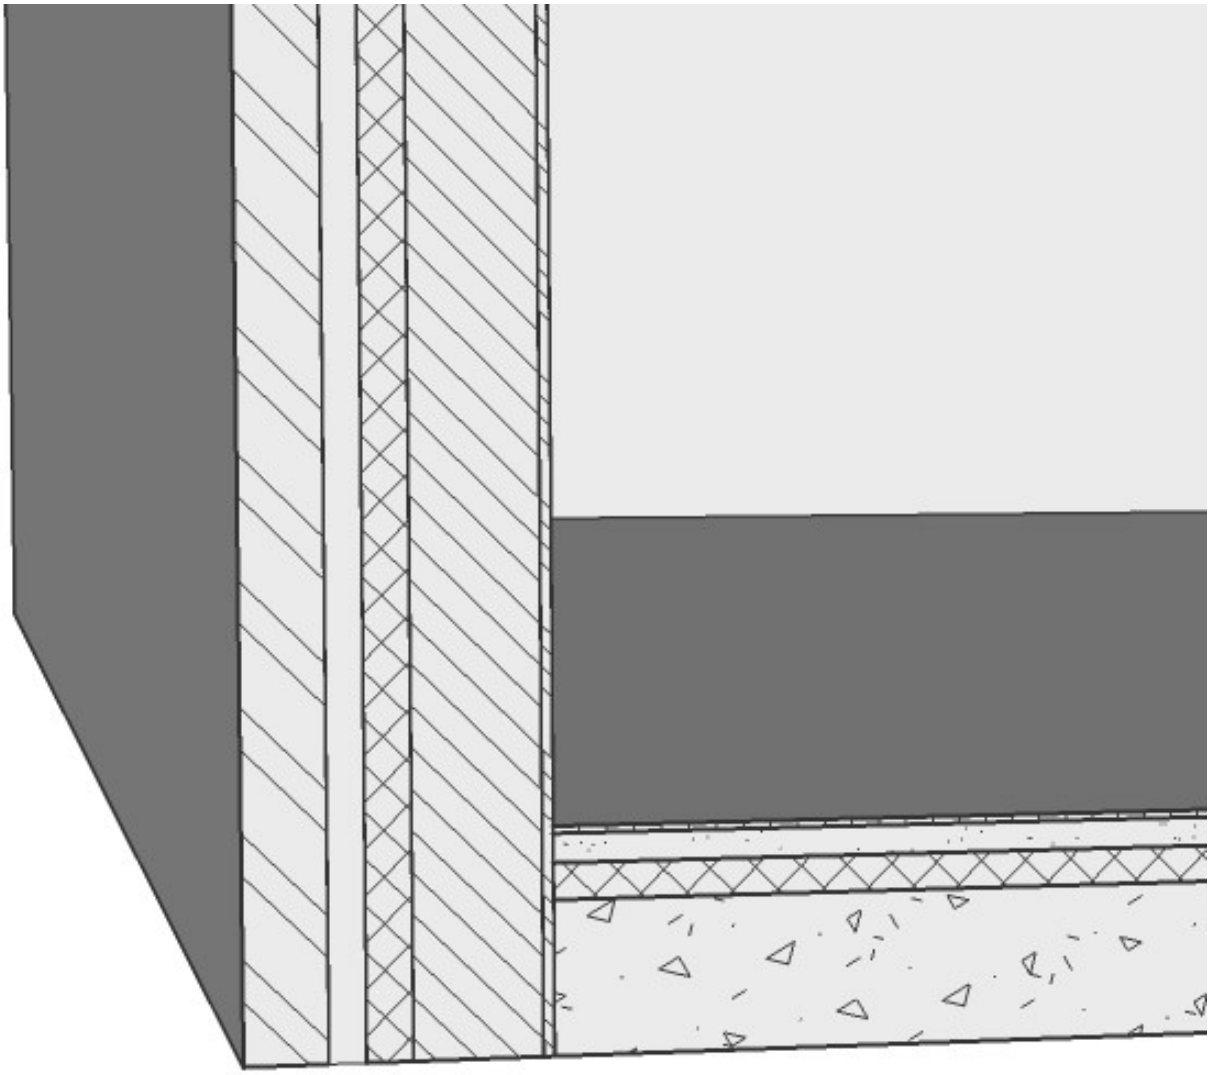

Figure 2.980

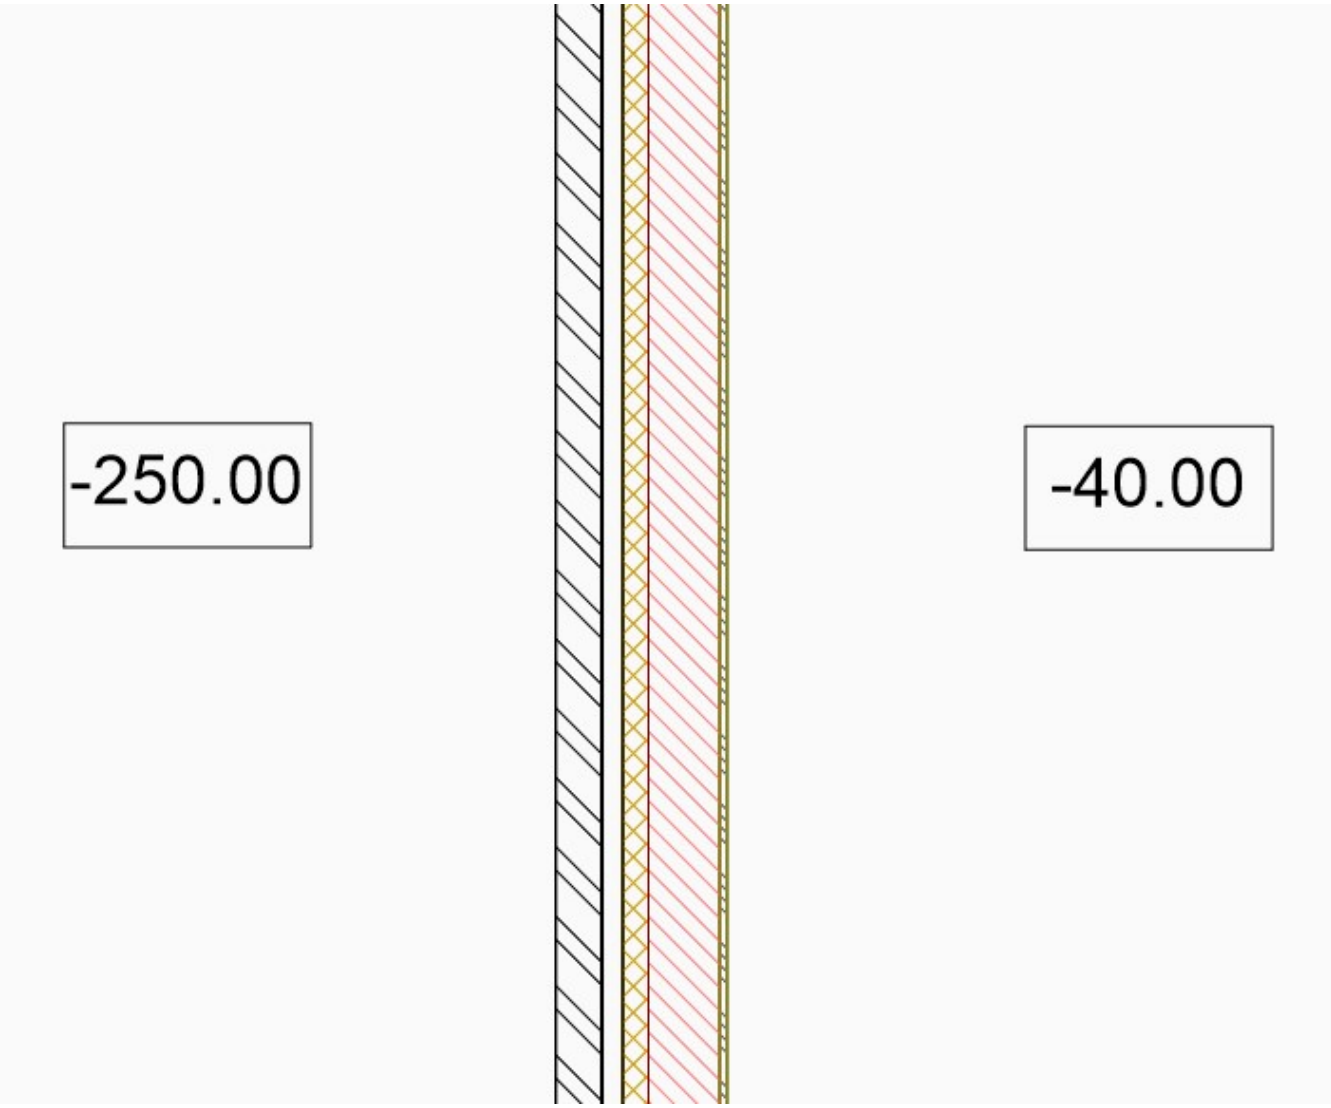

Figure 2.981

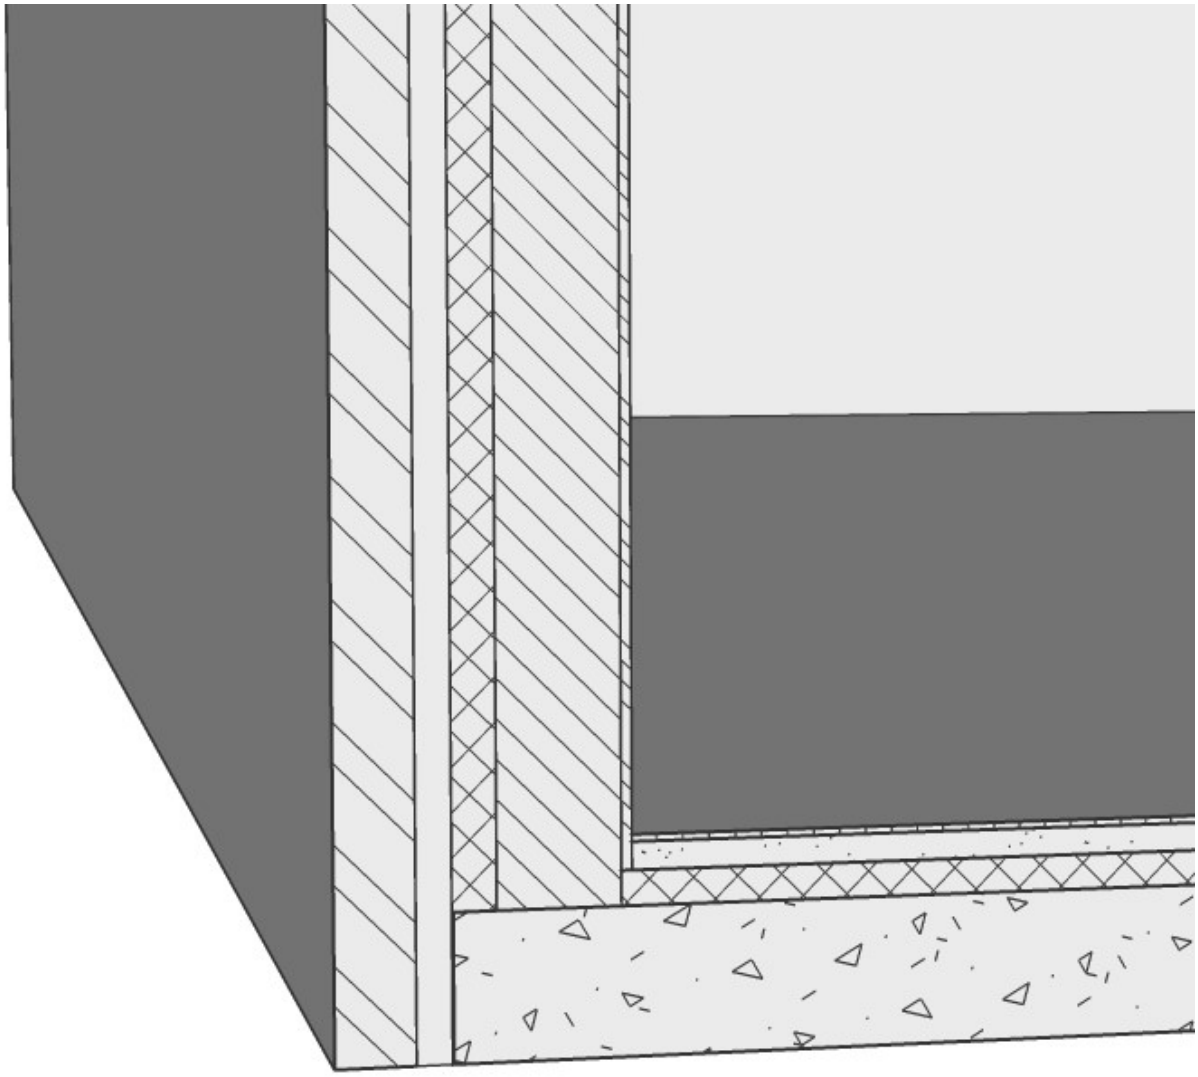

Procedure: Adjusting the layout of the tag

1. Double-click on the value of the spot elevation tag to adjust the layout. A dialog box will pop-up where you can edit the attributes. (2.982 on the next page)
2. Click on the three dots to open the Text Formatting dialog box. (2.983 on the following page)
3. Here you can edit the attributes of the displayed value of the spot elevation level tag. You can put prefixes and/or suffixes to the values, ie. FFL, SSL, to better illustrate the levels you are referring to. (2.984 on page 2581) (2.985 on page 2581)
4. If the prefixes and/or suffixes are commonly used, you can create or edit the tag blocks so you do not have to repeat Step 3. For more info, visit the command article BEdit (6.6.8).
5. For a detailed explanation about attributes, visit the command article MText (6.21.38).

Figure 2.982

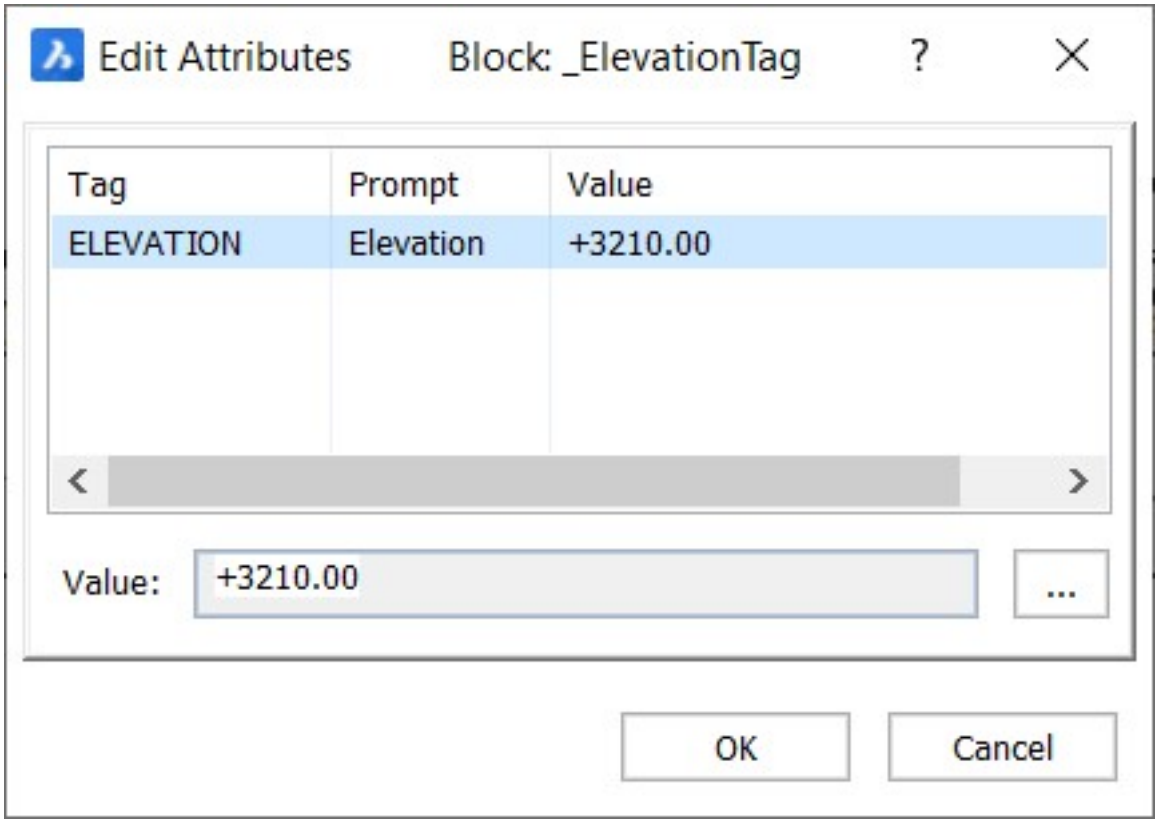

Figure 2.983

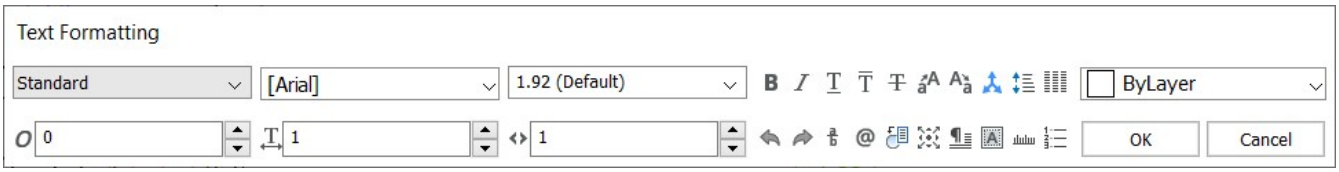

Figure 2.984

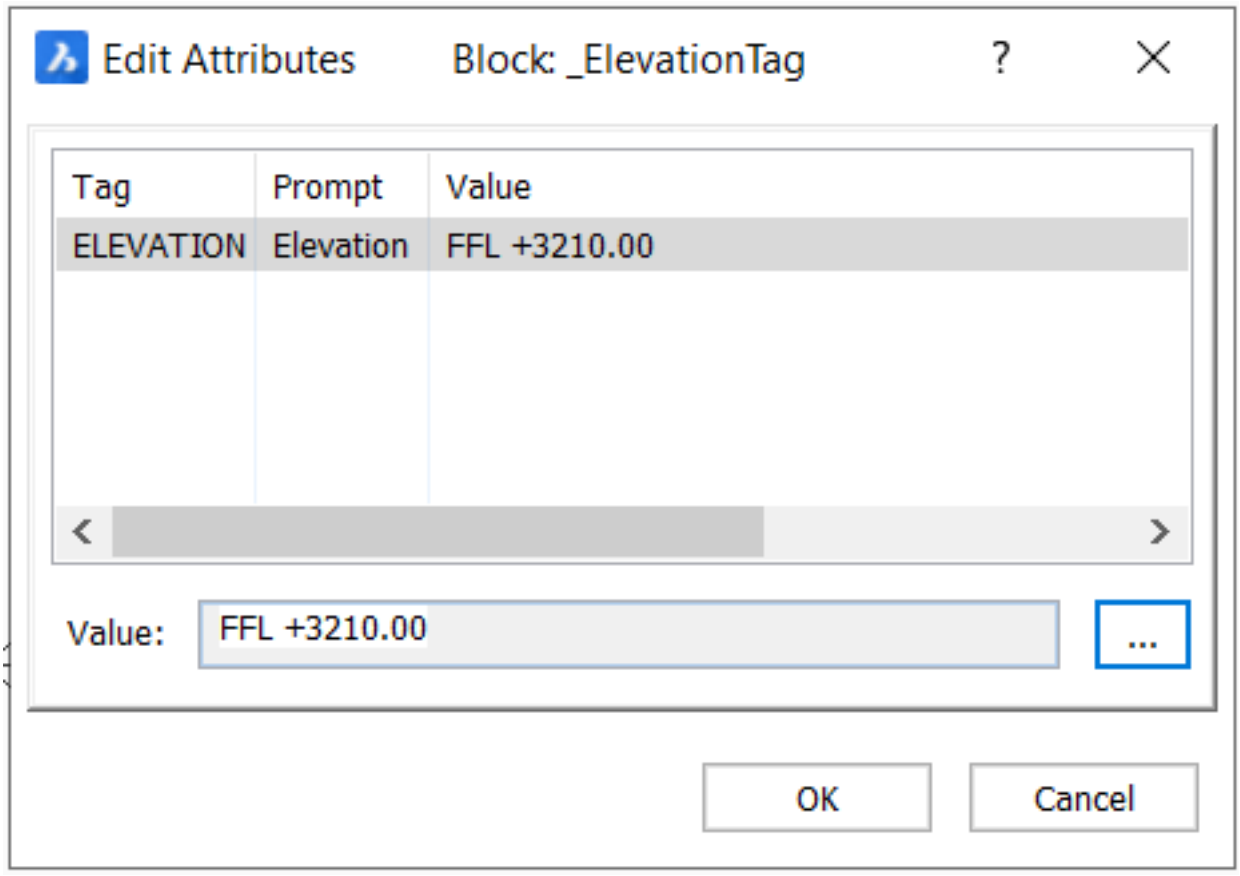

Figure 2.985

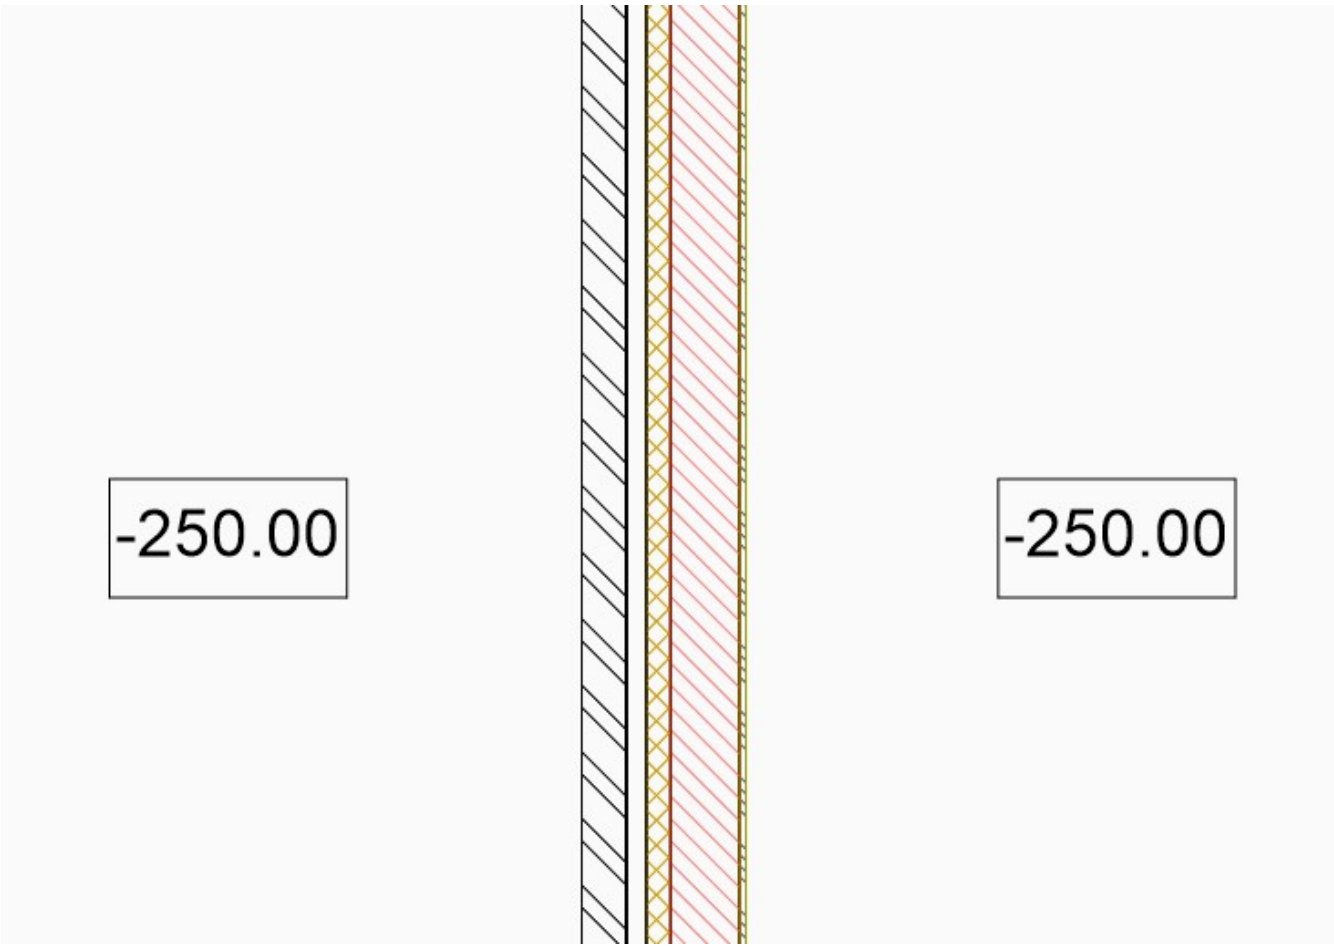

Procedure: Adjusting the layout of the leader

1. Type **MLeaderStyle** in the commandline and press Enter. The Drawing Explorer dialog box will pop-up where you can adjust the layout of the leader.
2. Click on SpotElevationSectionTypeStyle in the Multileader Styles dialog box. (2.986 on the next page)
3. You can edit the settings of the leader in the Edit MLeader Style dialog box. For more info about the MLeader style settings, visit the article MLeaderStyle (6.21.24) (2.987 on page 2584)
4. After adjusting the settings, click on regen, close the Drawing Explorer and update the section to load the new settings. **Note:** if the new settings don't load, type **BIMTAG** in the commandline, select the viewport, click **R** to select Regenerate All and press Enter to load the new settings. (2.988 on page 2585) **New Settings** (2.989 on page 2586) **Resulting BimTag**

2.13.18 Templates for generated drawings

Overview: In this lesson, you will learn how to use templates to customize your future generated drawings. **Lesson Objectives** After completing this lesson, you will be able to:

- Understand the created layers in your generated drawings.
- Understand and use the BRX_2D layers for symbolic representations in your sections.
- Customize the colors and line weights of your hatch patterns and generated lines.
- Customize the types of hatch patterns that are used to represent certain materials.
- Customize your tags per entity type.
- Customize call-out blocks.
- Customize your sheet set template.

About

BricsCAD BIM has a series of templates to customize your generated drawings. These templates are stored in your **Support folder** in the following path: C:\Users**<user_name>**\AppData\Roaming\Bricsys\BricsCAD\V20x64\en_US\Support\
The Appdata-folder is a hidden folder by default, you may have to unhide folders first. This path can also be accessed by the SupportFolder (6.27.59) command. To understand how it works, we must know how BricsCAD creates layers, hatches, tags, and call-out blocks. Then, for each template, we will discuss how to customize them.

Procedure: Understanding the created layers

1. Open a millimeter template **BIM-mm.dwt**.
2. Draw two boxes of 500x500x400, one being a bit behind the other.
3. Put the first box on the layer **Layer1** (with layer color green) and the second box on the layer **Layer2** (with layer color red).
4. Create a BIM section (6.7.54), aligned with the front face of the first, green box and cutting through it in the middle, but not cutting through the second, red box. (2.990)
5. Generate (6.7.43) and open (6.7.49) the section. (2.991 on the following page)
6. Take a look at the Layers (6.13.17) panel: three groups of layers have been created: **Background, Boundary,** and **Fill. (2.992 on the next page)**
7. The generated layers for the green solid are:
   - **Boundary_Layer1**: the boundary of the section through the box.
   - **Fill_Layer1**: the hatching of the section.
   - **Background_Layer1:** shows subentities (e.g., vertices of solids) that are **not** sectioned.
8. The layers all inherit the color of the **Layer1** layer.
9. Since the red solid is not sectioned, only the **Background_Layer2** layer is created. It inherits the color of the **Layer2** layer.
10. Drag the **Cavity Wall, Brick** composition from the Compositions Panel (2.7.5) onto the green box. **Note**: turn on the Level of detail (2.3.6) to display the ply materials.

Figure 2.990

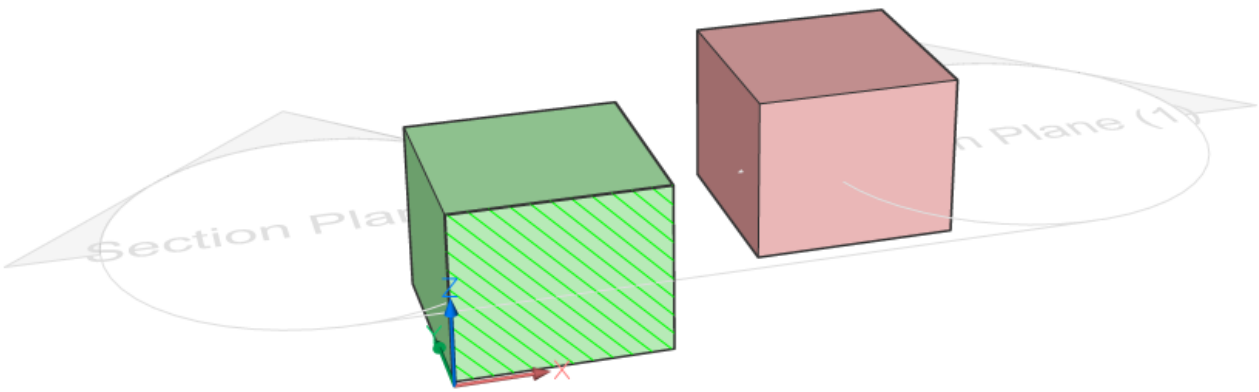

Figure 2.991

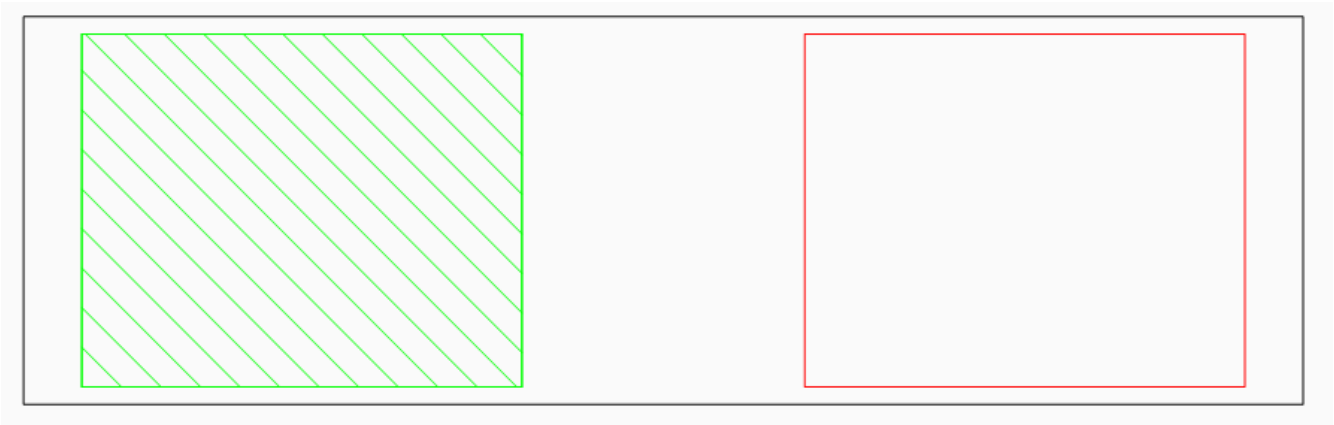

Figure 2.992

	Current	Name	D..	On/Off	Freeze	Locked	Color
1		0					White
2		Background_Layer1					Green
3		Background_Layer2					Red
4		BIM_SECTIONS_PREVIOUS					Magenta
5		BIM_VIEWPORTS					White
6		Boundary_Layer1					Green
7		Defpoints					White
8		Fill_Layer1					Green
9		Title Block Frame					175
10		Title Block Labels					157
11		Title Block Text					251

Figure 2.993

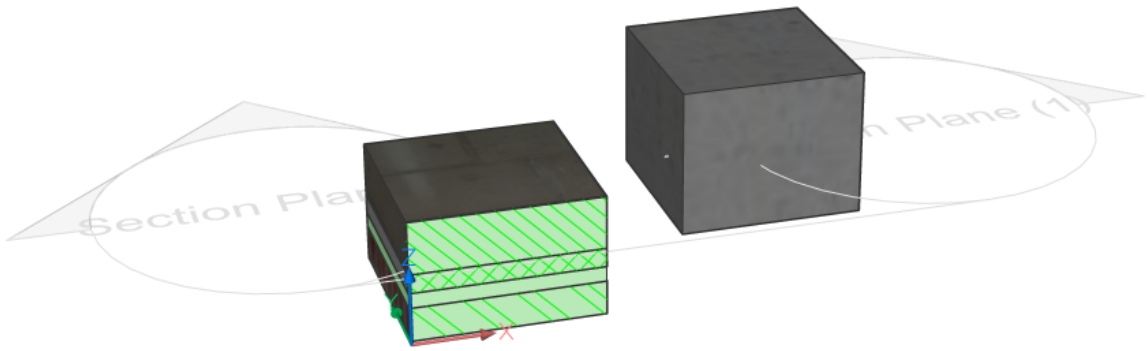

Figure 2.994

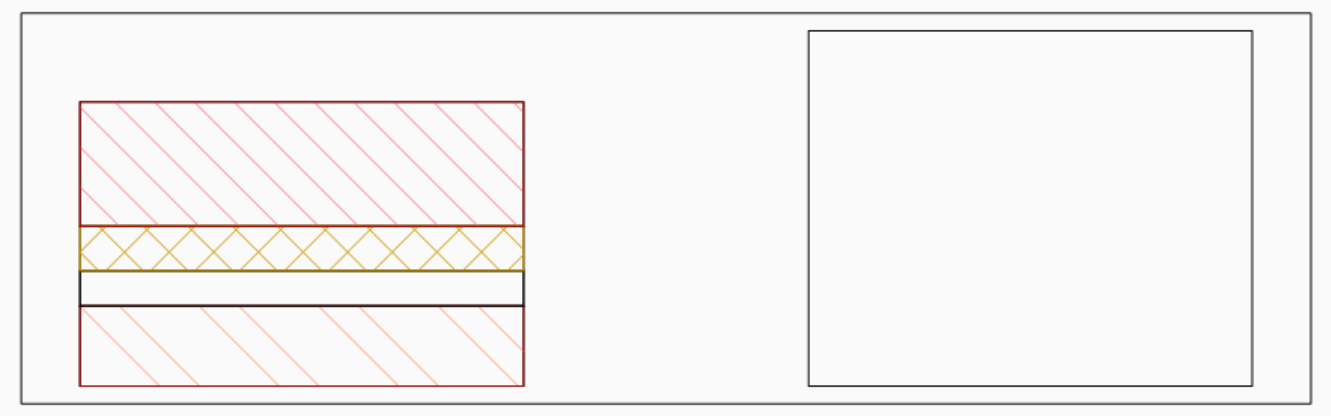

11. Double-click the **Cavity Wall, Brick** composition in the Compositions Panel. This composition consists of 4 plies, each with its own material. A physical material (2.7.17) is associated with a hatch pattern, used for floor plans and sections. Another pattern is specified for elevations.
12. Assign the **Concrete, Reinforced** composition to the red box. (2.993)
13. Update and open the section. (2.994)
14. Go to your layers and execute the Purge (6.24.60) command to remove the unused layers. (2.995 on the following page) You see the three categories (**Background**, **Boundary,** and **Fill**) again. Now the second part of the layer name is the name of the physical material used in the solid, instead of the layer name of the box:
    - **Background_**Facing Bricks_Hand-formed, **Background_**Insulation_Polyurethane Foam, and **Background_**Supportir Wall_Brick
    - **Boundary_**Facing Bricks_Hand-formed, **Boundary_**Insulation_Polyurethane Foam, and **Boundary_**Supporting Wall_Brick
    - **Fill_**Facing Bricks_Hand-formed, **Fill_**Insulation_Polyurethane Foam, and **Fill_**Supporting Wall_Brick
15. Set the **Generate elevation fill** property of the section ON to add an elevation hatch (2.13.11).
16. Update the section.
17. The outline of the second box is now hatched and the layer **Elevation_Concrete_Reinforced** is added.

Figure 2.995

	Current	Name	D..	On/Off	Freeze	Locked	Color

6		Background_Layer1					Green
7		Background_Layer2					Red
8		Background_Supporting Wall_ Brick					White
9		BIM_SECTIONS_PREVIOUS					Magenta
10		BIM_VIEWPORTS					White
11		Boundary_Air					White
12		Boundary_Cavity Wall_ Brick					White
13		Boundary_Facing Bricks_ Hand-formed					14
14		Boundary_Insulation_ Polyurethane Fc					42
15		Boundary_Layer1					Green
16		Boundary_Supporting Wall_ Brick					14
17		Fill_Facing Bricks_ Hand-formed					21
18		Fill_Insulation_ Polyurethane Foam					42
19		Fill_Layer1					Green
20		Fill_Supporting Wall_ Brick					11
21		Title Block Frame					175
22		Title Block Labels					157
23		Title Block Text					251

Procedure: Understanding the BRX_2D layers

1. Open a millimeter template **BIM-mm.dwt** and save the drawing.
2. Drag the component **Furniture Bookshelf** into the drawing, You can find the component in the **Furnishing Elements** category in the Components panel (2.5.3). (2.996 on the next page)
3. If you now show and isolate (6.17.22) the **BRX_2D_Symbols** layer, you will see a symbol drawn at the insertion point of the bookshelf. (2.997 on the facing page)
4. Now show (6.30.7) all layers again and make a section (1.26.4) through the bookshelf. (2.998 on page 2592)

5. Generate (6.7.43) and open (6.7.49) the section. (2.999 on page 2592)

Figure 2.996

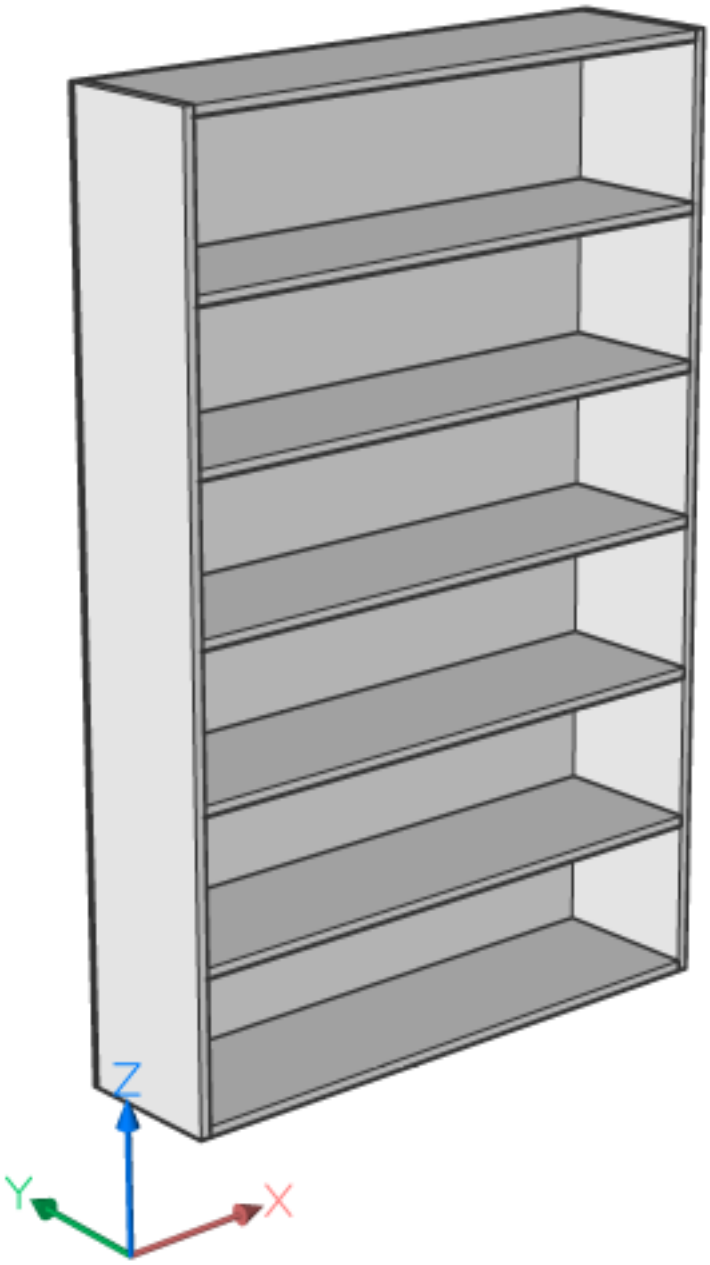

Figure 2.997

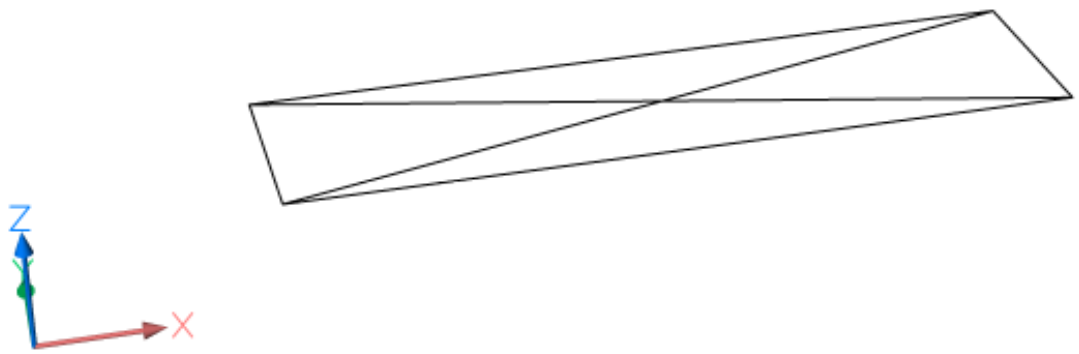

Figure 2.998

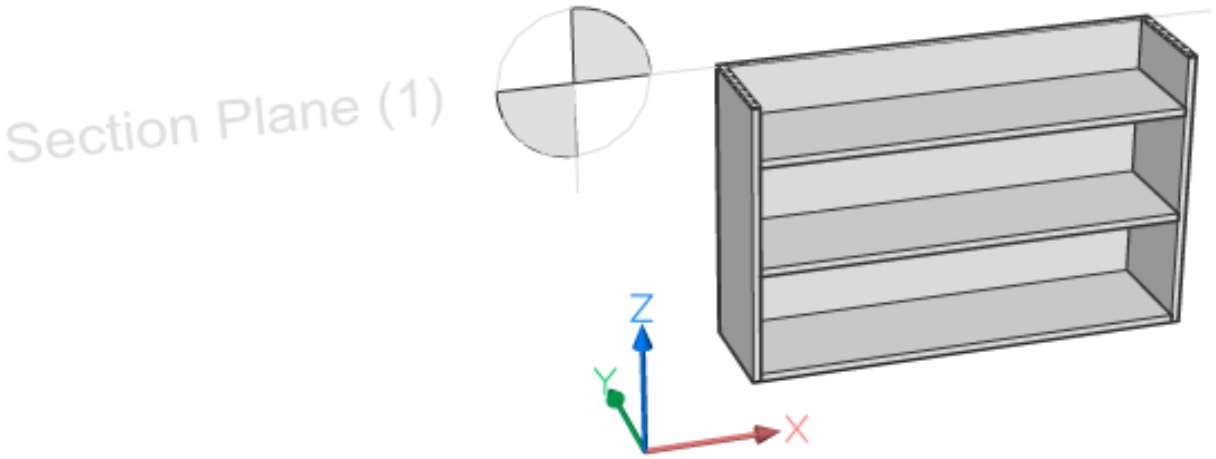

6. You will see (if the **Boundary_BRX_2D_Symbols** layer is on) that only the symbol is drawn onto the plan, and not the real section. It happens because this component had a 2D symbol on the BRX_2D layer attached to it.
7. Now return to your 3D model and Open a copy (6.8.22) of the bookshelf.
8. Hide the bookshelf itself and make sure the **BRX_2D_Symbols** layer is on.
9. Delete one of the lines (of the cross).
10. (Optional) Draw extra 2D lines on the **BRX_2D_Symbols** layer.
11. Save the drawing.
12. Go back to the original 3D model and type in BMInsert (6.8.16) and go to the file path where you just saved the new bookshelf. Click OK and choose a point to insert the bookshelf.
13. Regenerate the section and open it. Widen the viewport if necessary by dragging the existing viewport. (2.1000 on the next page)
14. You will now see that the second bookshelf has the adapted symbol displayed.
15. Draw a wall in your 3D model and insert the door **Door Ext Plain** into this wall. (2.1001 on the facing page)
16. Repeat steps 3 to 5 but now use the **BRX_2D+_Swing** layer instead of the **BRX_2D_Symbols** layer.
17. The generated plan displays the symbol of the door swing as well as the door section itself. The BRX_2D+ layer of a component makes sure you can show the real section together with a symbol.
    - Symbols on a layer with prefix **BRX_2D_**will be used to replace the geometry resulting from the actual section.
    - Symbols on a layer with prefix **BRX_2D+_**will be added to the section result. Only those 2D entities in a plane parallel to the section plane are. (2.1002 on page 2594)

Figure 2.999

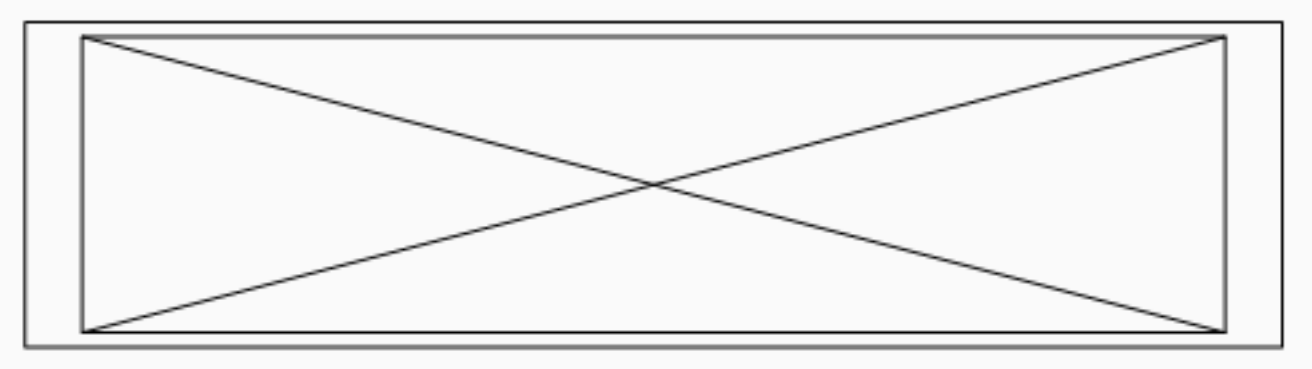

Figure 2.1000

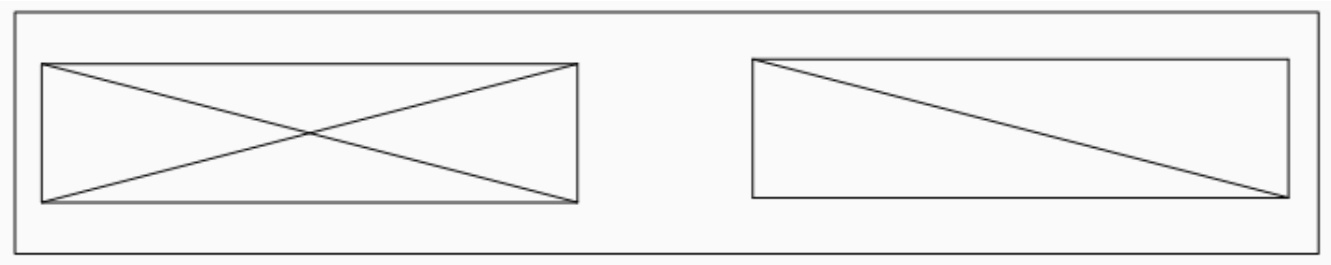

Figure 2.1001

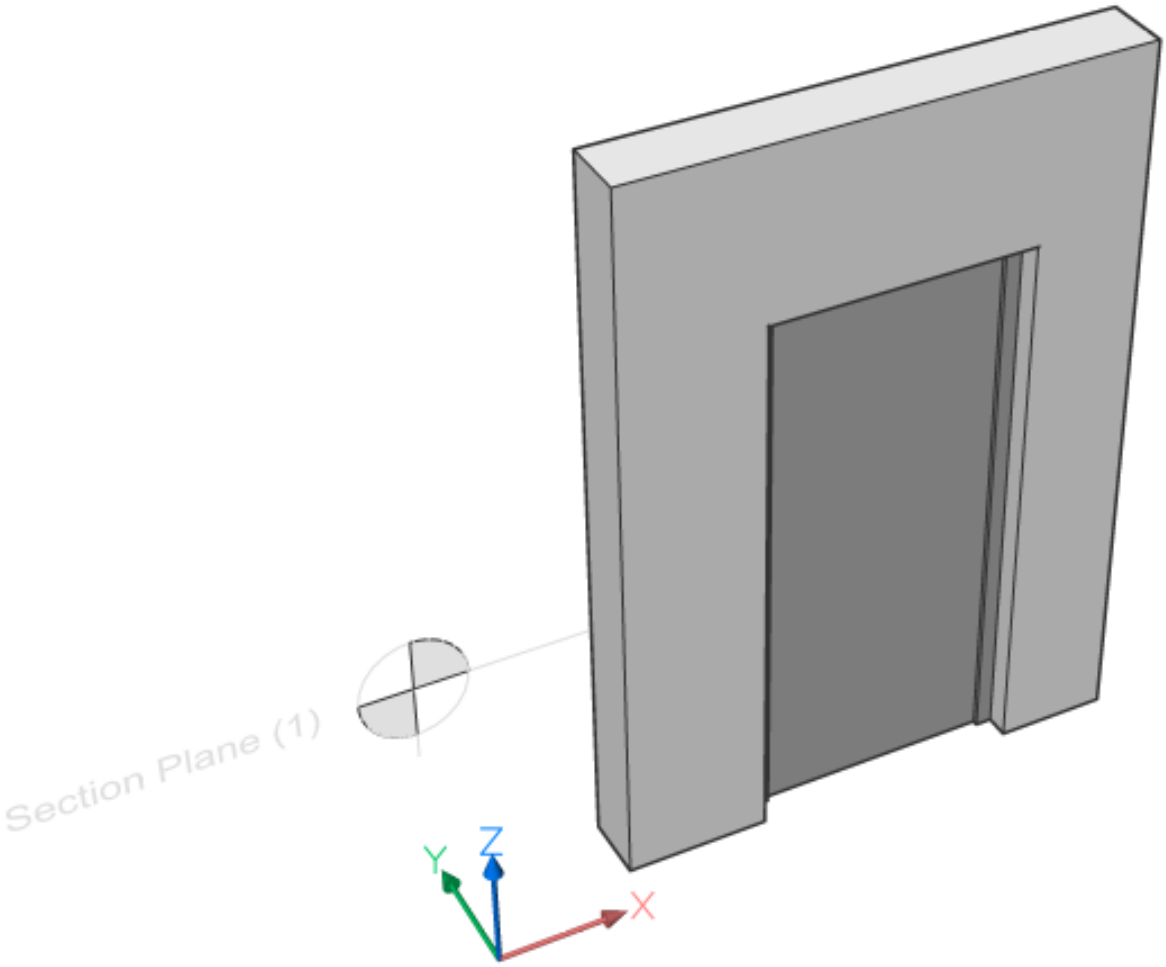

Figure 2.1002

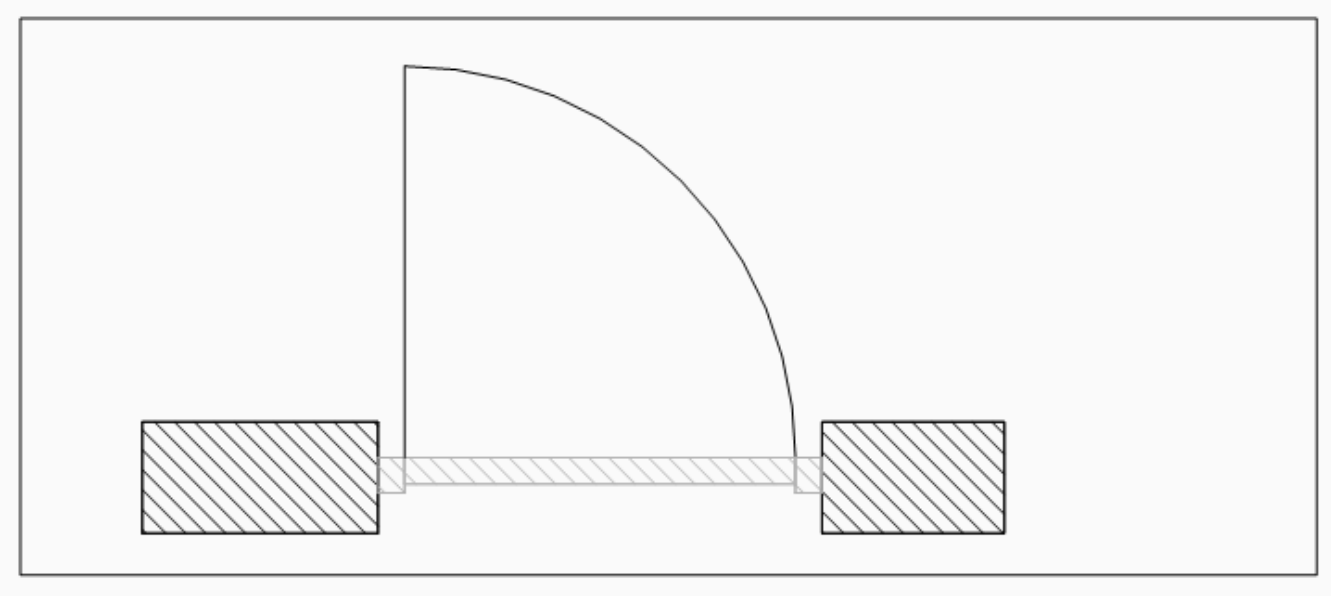

Procedure: Customizing the colors and line weights of hatch patterns and lines

1. Firstly in the procedure 'Understanding the created layers', you saw that for objects **without** a composition, the colors and line weights of the **Fill_, Background_,** and **Boundary_** layers are copied from the layer properties in the 3D model.
2. However, for objects **with** a composition, the default colors are set by a template found by typing in Supportfolder (6.27.59) and browsing to **Bim/Sections/_SectionSettings.dwg.**
3. Open this drawing.
4. Go to the Layers panel, you will find a list of all the possible layers that can be created for every material present in the material library. They all have a color and line weight. Changing the color or line weight and saving the file will change the default color/line weight for this layer in your future generated drawings. You can fully customize how your drawing will look for every type of line (**Fill, Background, Boundary**, or **Elevation**) per material. (2.1003 on the facing page)

221		Fill_Insulation_ Rock Wool					42
222		Fill_Iron					251
223		Fill_Lead					151
224		Fill_Marble					43

Procedure: Customizing the hatch patterns

1. Open the drawing made in the procedure 'Understanding the created layers'.
2. Open the Compositions Panel (2.7.4).
3. Double-click the composition **Cavity Wall, Brick.**
4. In the procedure 'Understanding the created layers', you can change the hatch patterns of the materials here. How you need to do this will follow in the next steps. (2.1004 on the next page)
5. Double-click on the row of **Facing Bricks, Hand-formed.** The Physical Materials dialog will pop-up on the material **Facing Bricks, Hand-formed**. You could have entered this dialog box by typing in the command BLMaterials (6.7.58), after which you could have selected the **Facing Bricks, Hand-formed** material. (2.1005 on page 2598)
6. Go to the tab **Appearance**.
7. Under the title **Section,** double-click on the hatch pattern.
8. You can now choose your new standard section hatch representation for this particular material. In every composition with this material, the same hatch representation will be used. (2.1006 on page 2599)
9. If you want to change the appearance of an elevation hatch, you can do so by double-clicking the hatch pattern under the **Elevation (2.13.11)** title. The outer most visible material of a composition will be used to determine the elevation hatch.
10. **Note** that the representation of these hatches will not be copied into new drawings as the Materials dialog is not a template, but rather a way to define the representation in a specific drawing. If you would like to store this information, it is recommended to start a library of compositions. The best way to do so is to make a drawing where you attach the compositions you would like to store to little cubes. Make sure each composition has the hatch appearance you want by going through the process described above.
11. Once this is finished, type in BIMProjectInfo (6.7.32) in the command line. You will enter the BIM Project Info dialog.
12. In the **Project DB** tab, switch the value for the database from **Embedded** to **External.** You will be asked to save the database on your computer and give it a name, for example, 'CompositionsTemplate.bsyslib'. (2.1007 on page 2600)
13. If you now want to use this database in a new drawing, switch the value for the database from **Embedded** to **External**. You can find this under the BIMProjectInfo (6.7.32) button. This time select the .bsyslib file you created.

Figure 2.1004

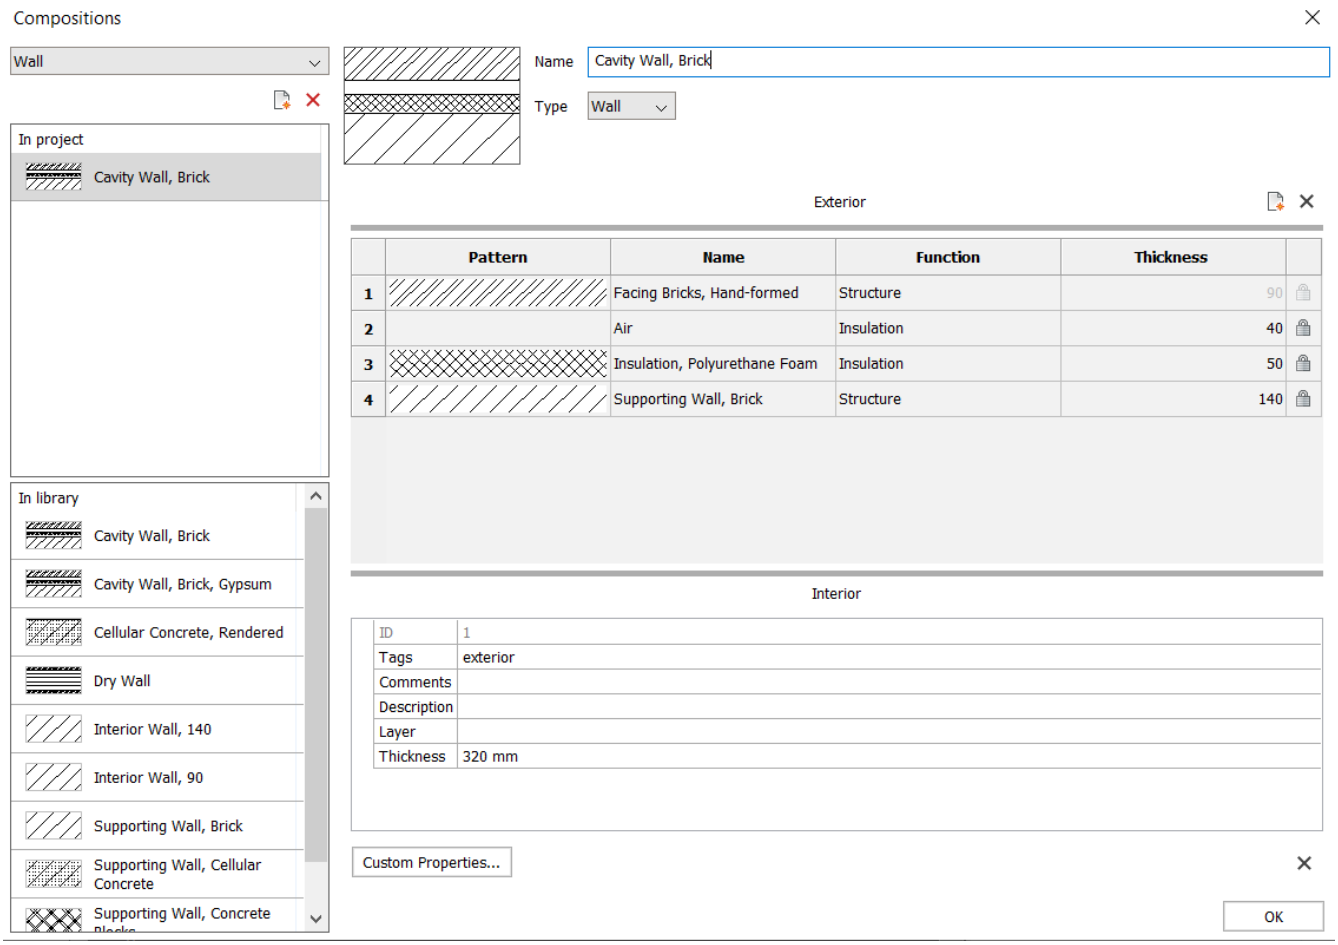

Figure 2.1005

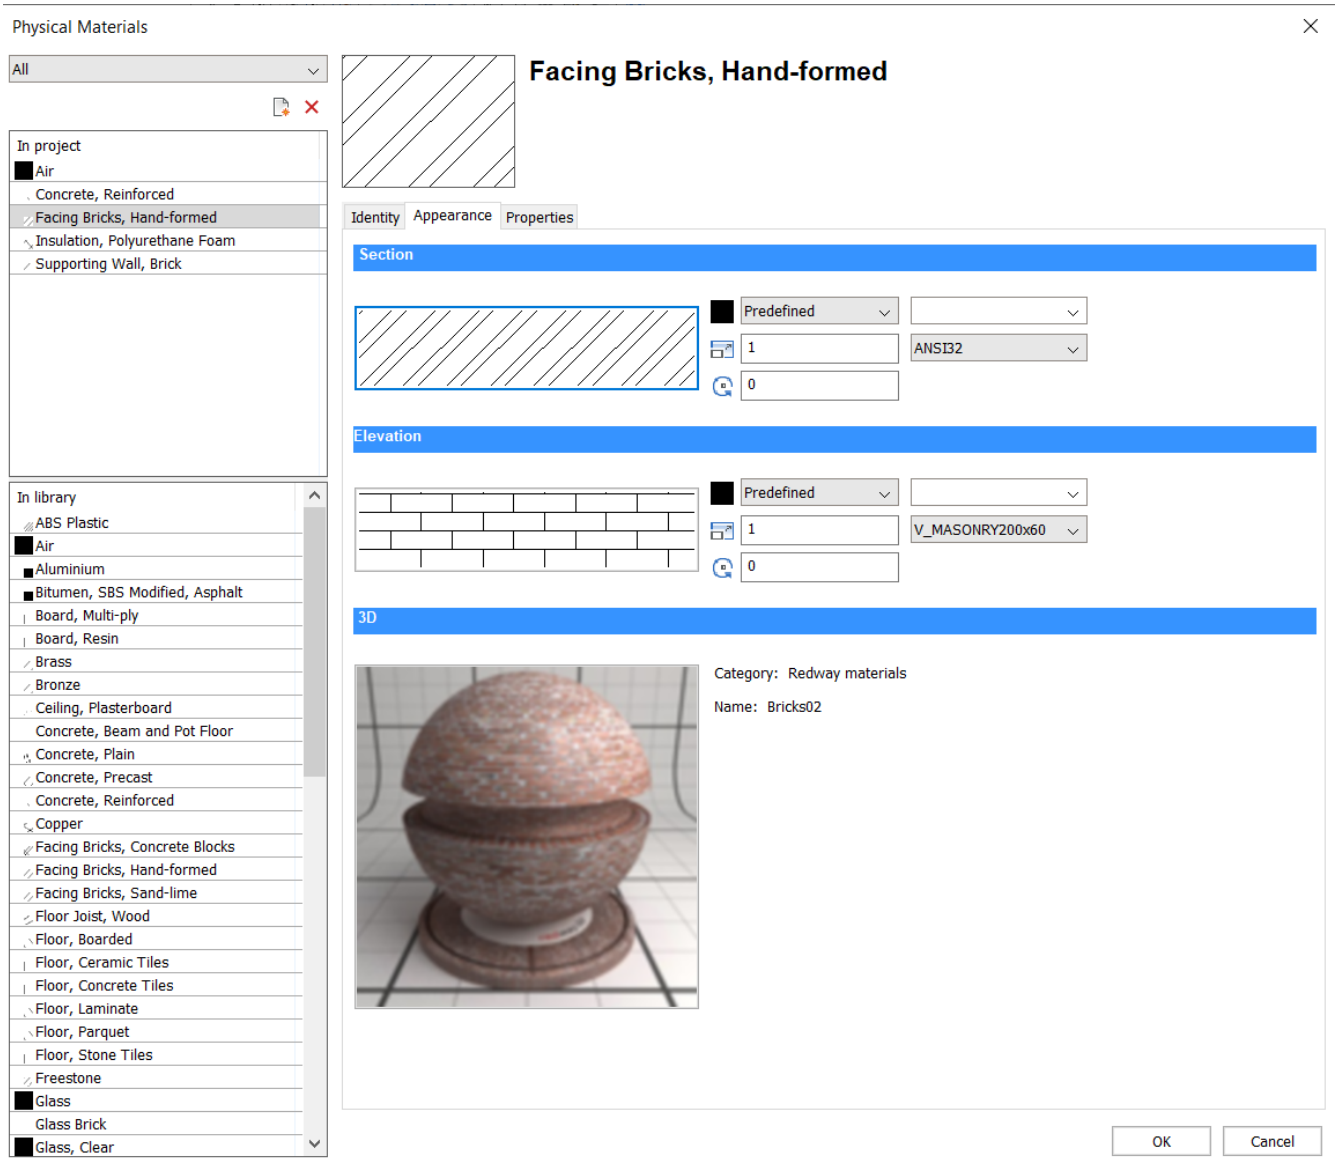

Figure 2.1006

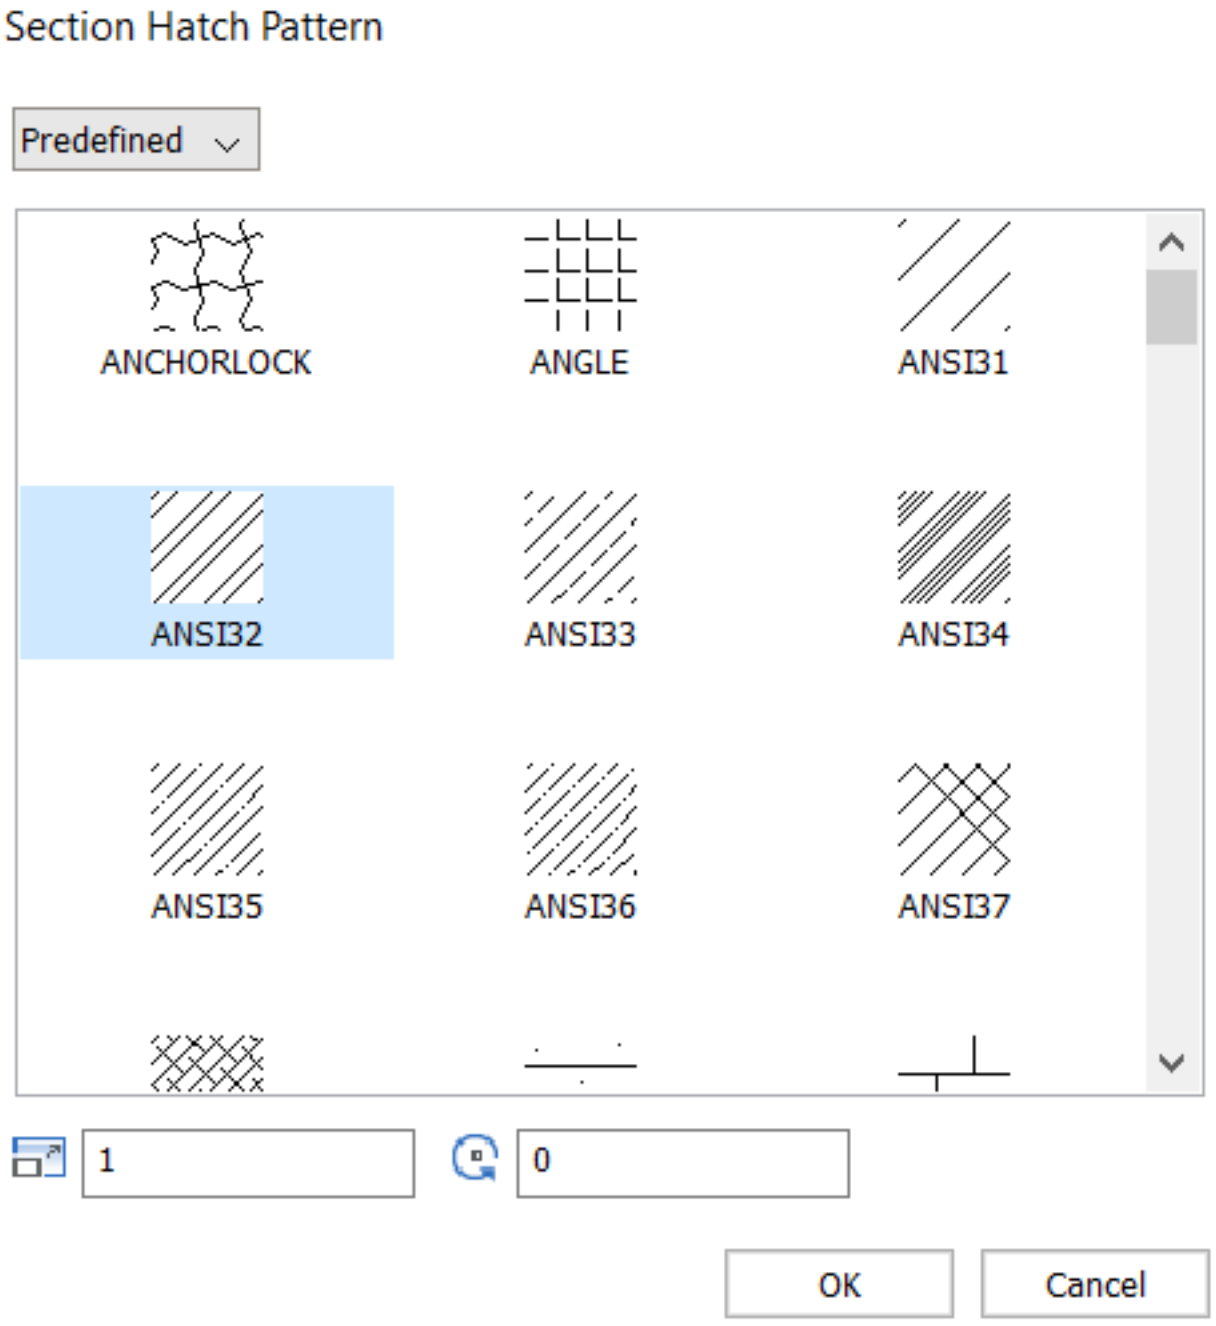

Figure 2.1007

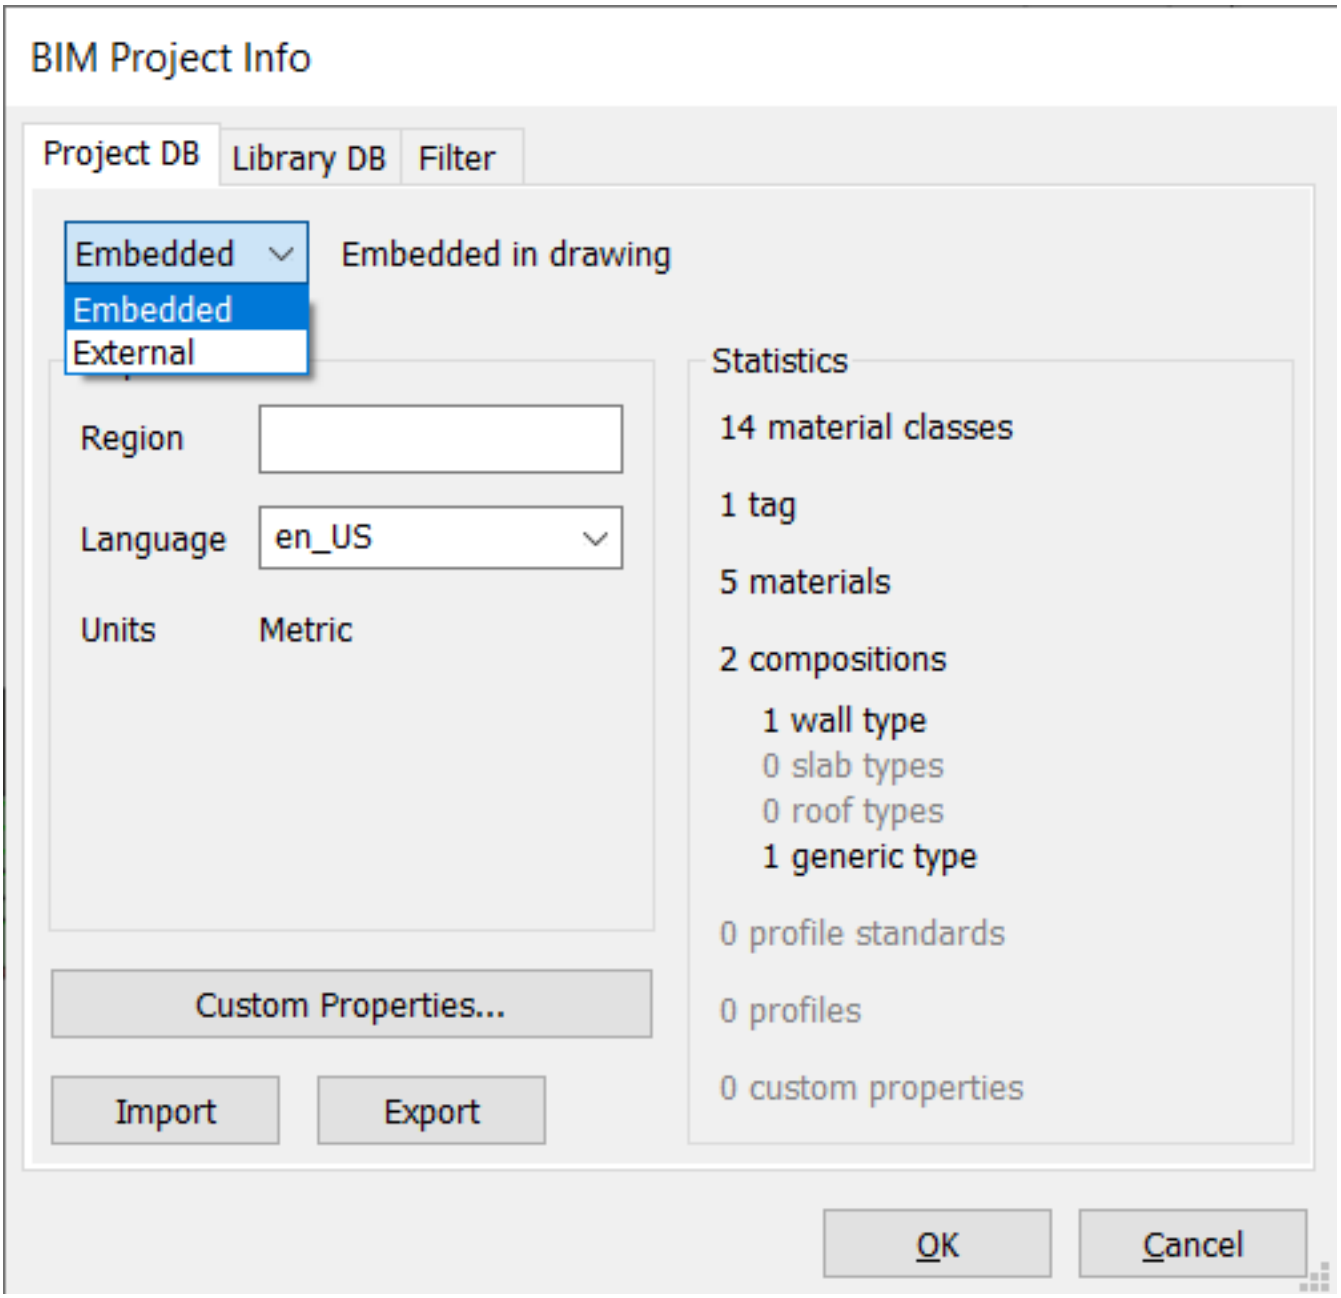


Procedure: Customizing tags per entity type for all section drawings

For this procedure, please visit the following procedures from the BIM Tags page (2.13.2):

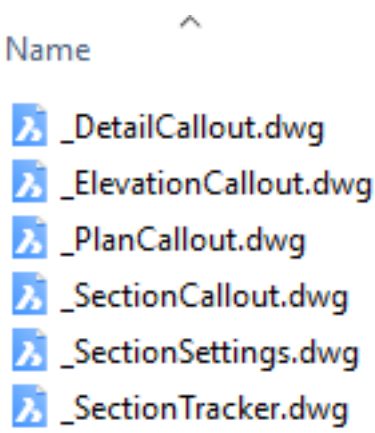
- Create the source data for a BIM entity type (2.13.2)
- Customize tag blocks (2.13.2)
- Edit the source data to customize BIM Tags for all section drawings (2.13.2)

To change the tags in the current drawing, visit the procedure Customize tag blocks for the current drawing only (2.13.2).

Procedure: Customizing call-out blocks

1. Source files of the various call-out blocks and the section tracker exist in the **..\Support\Bim\Sections** sub-folder of the **Roamable Root** folder. By default this is: **C:\Users\<user_name>\AppData\Roaming\Bricsys\BricsCAD\Vxx** You can easily access this file by typing in Supportfolder (6.27.59) and browsing to **Bim/Sections.** (2.1008)
2. You can edit these files to customize the layout of the call-outs and the section tracker blocks.
3. When a drawing is generated, the needed call-out blocks are created from the call-out blocks source file(s). When a BIM section is updated, the existing call-out blocks in the target drawing are used (type BEDIT (6.6.7) to choose one to edit).

Figure 2.1008



Procedure: Customizing the sheet set template

1. The sheet set templates are stored in the **C:\Users\<user_name>\AppData\Local\Bricsys\BricsCAD\Vxx\en_US\Templa** folder.
2. If you want to edit an existing template, you have two options. Either you edit it directly, or you make a copy.
   - To edit it directly, you can go to **Open** under the BricsCAD icon, choose **.dwt** in the 'Files of type' drop-down and choose the file you want to edit. You can then make the modifications and save the file.
   - To make a copy, double-click on the .dwt file you want to copy. A new .dwg with this template will open. Make your modifications and **save your file as .dwt**. Save it in the templates folder to easily use the copied template in a new drawing.
3. If you want to start from scratch, using a wizard, follow the procedure 'To create a drawing using a wizard (1.19.1)'. After the creation and modification of the dwg, save it as a .dwt file in your sheet set templates folder.
4. If you have saved the template .dwt to the sheet set templates folder, you will see it appear when you use the New Wizard (6.22.6) to open a new drawing. You will be able to select it as the template for the creation of generated drawings in the sheet set set-up of the Project Browser (2.7.15).
5. What can you store into a template? You can make a title block for your template, with sheet set properties, by following the procedure 'Using sheet set properties in a title block (1.30.13)'. Do this for every layout in your template. You can also store the following things by using them in your .dwt file:
   - Layers
   - Colors
   - Line types
   - Hatch patterns
   - Blocks
   - Text styles
   - Dimension styles
   - Page set-ups

Chapter 3

BricsCAD Mechanical

3.1 What's new in BricsCAD V21 Mechanical

3.1.1 Overview

BricsCAD Mechanical V21 offers all the new and improved tools available in BricsCAD V21 plus additional enhancements specifically for mechanical workflows. This section gives an overview of all the new features and improvements in **BricsCAD V21 Mechanical tools**: BOM Manager (3.1.2) Parts Libraries (3.1.3) Parameters and Constraints (3.1.5) Standard parts (3.1.4) Sheet Metal (3.1.6) For information about the new features and improvements in **BricsCAD V21 Core and Civil tools**, go to the What's new in BricsCAD V21 section. It contains the following articles: Overview (1.1.1) User interface (1.1.2) Productivity (1.1.3) Drafting (1.1.4) Modeling (1.1.5) Civil Tools (1.1.6) Performance and compatibility (1.1.7) For information about the new features and improvements in **BricsCAD V21 BIM**, go to the What's new in BricsCAD BIM V21 section. It contains the following articles: Overview (2.1.1) Modeling Techniques (2.1.2) Building Data (2.1.3) Project Collaboration (2.1.4) Design Documentation (2.1.5) Point clouds (2.1.6)

Release notes

Click here for an overview of the release notes.

Diagnostics and Usage Data Collection

Many of the improvements were inspired by requests and suggestions from you, BricsCAD users. At Bricsys, we continue to expand our methods of gathering user feedback with new data collection tools. When you launch BricsCAD for the second time, a dialog box displays, inviting you to participate in the Diagnostics and Usage Data Collection program (1.35.1). The data collection process enables you to share anonymous diagnostic and usage data with Bricsys to help improve BricsCAD. You can withdraw your consent and have your data removed from our databases at any time.

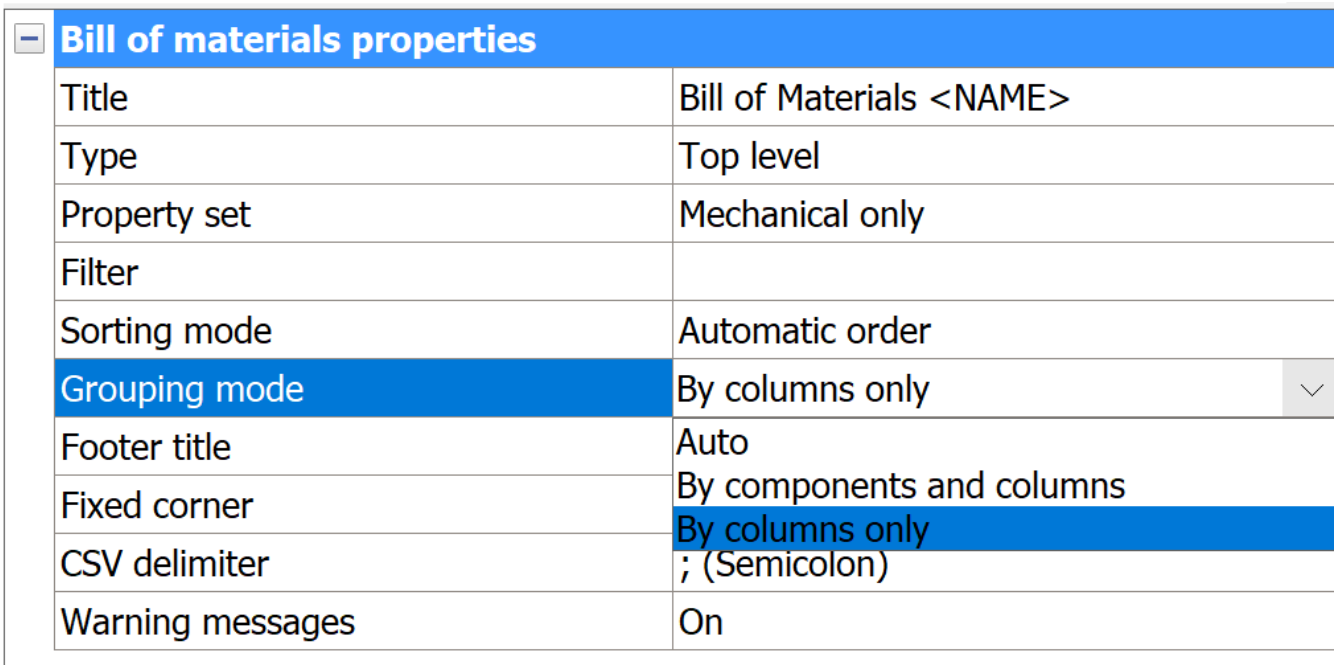
3.1.2 BOM Manager

Creating and editing bills of materials is easier than ever.

Grouping

With the addition of the grouping property, you can now quickly group the contents of your BOM table into condensed rows by common properties of the existing columns. (3.1 on the facing page)

Figure 3.1



Columns

It is now possible to set one of several predefined column filters, for any column in a BOM. (3.2) Aggregated columns are now supported in top-level and bottom-level BOM tables created with the BMBOM command. They allow you to calculate the sum, minimal, maximal or average values of a given property with respect to the current grouping. (3.3 on the following page) An option in the main menu of the BOM Manager opens the new Filter Configurator dialog box. In the Filter Configurator you can screen the contents of your BOM table; and wildcard expressions are supported for string properties in a BOM filter. (3.4 on the next page) Template Columns are a new type of evaluated column, which allow you to combine values of several properties into a single BOM column, as text, using DIESEL expressions. (3.5 on the following page) You can configure and preview formula or template column expressions using the expression editor dialog. (3.6 on page 2607) With the addition of the Format dialog box, you may now customize the expression of your data in BOM tables with prefix, suffix, and delimiters. (3.7 on page 2607) The new Column Role option allows you to specify which column should be the source of balloons for drawing views. (3.8 on page 2608) It is now possible to select a unit for material density, both in the Physical Materials dialog and in BOM tables under the column properties section. Supported units are: kg/m³, kg/dm³, g/cm³, lbs/ft³ and lbs/in³. (3.9 on page 2608) An option has been introduced to limit the reported level of a hierarchical BOM. (3.10 on page 2609)

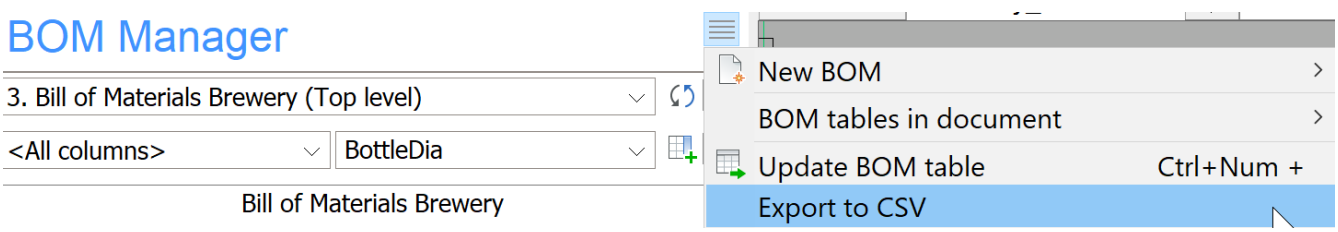
Exporting

You may now export your BOM table to a CSV file. (3.11)

Figure 3.11



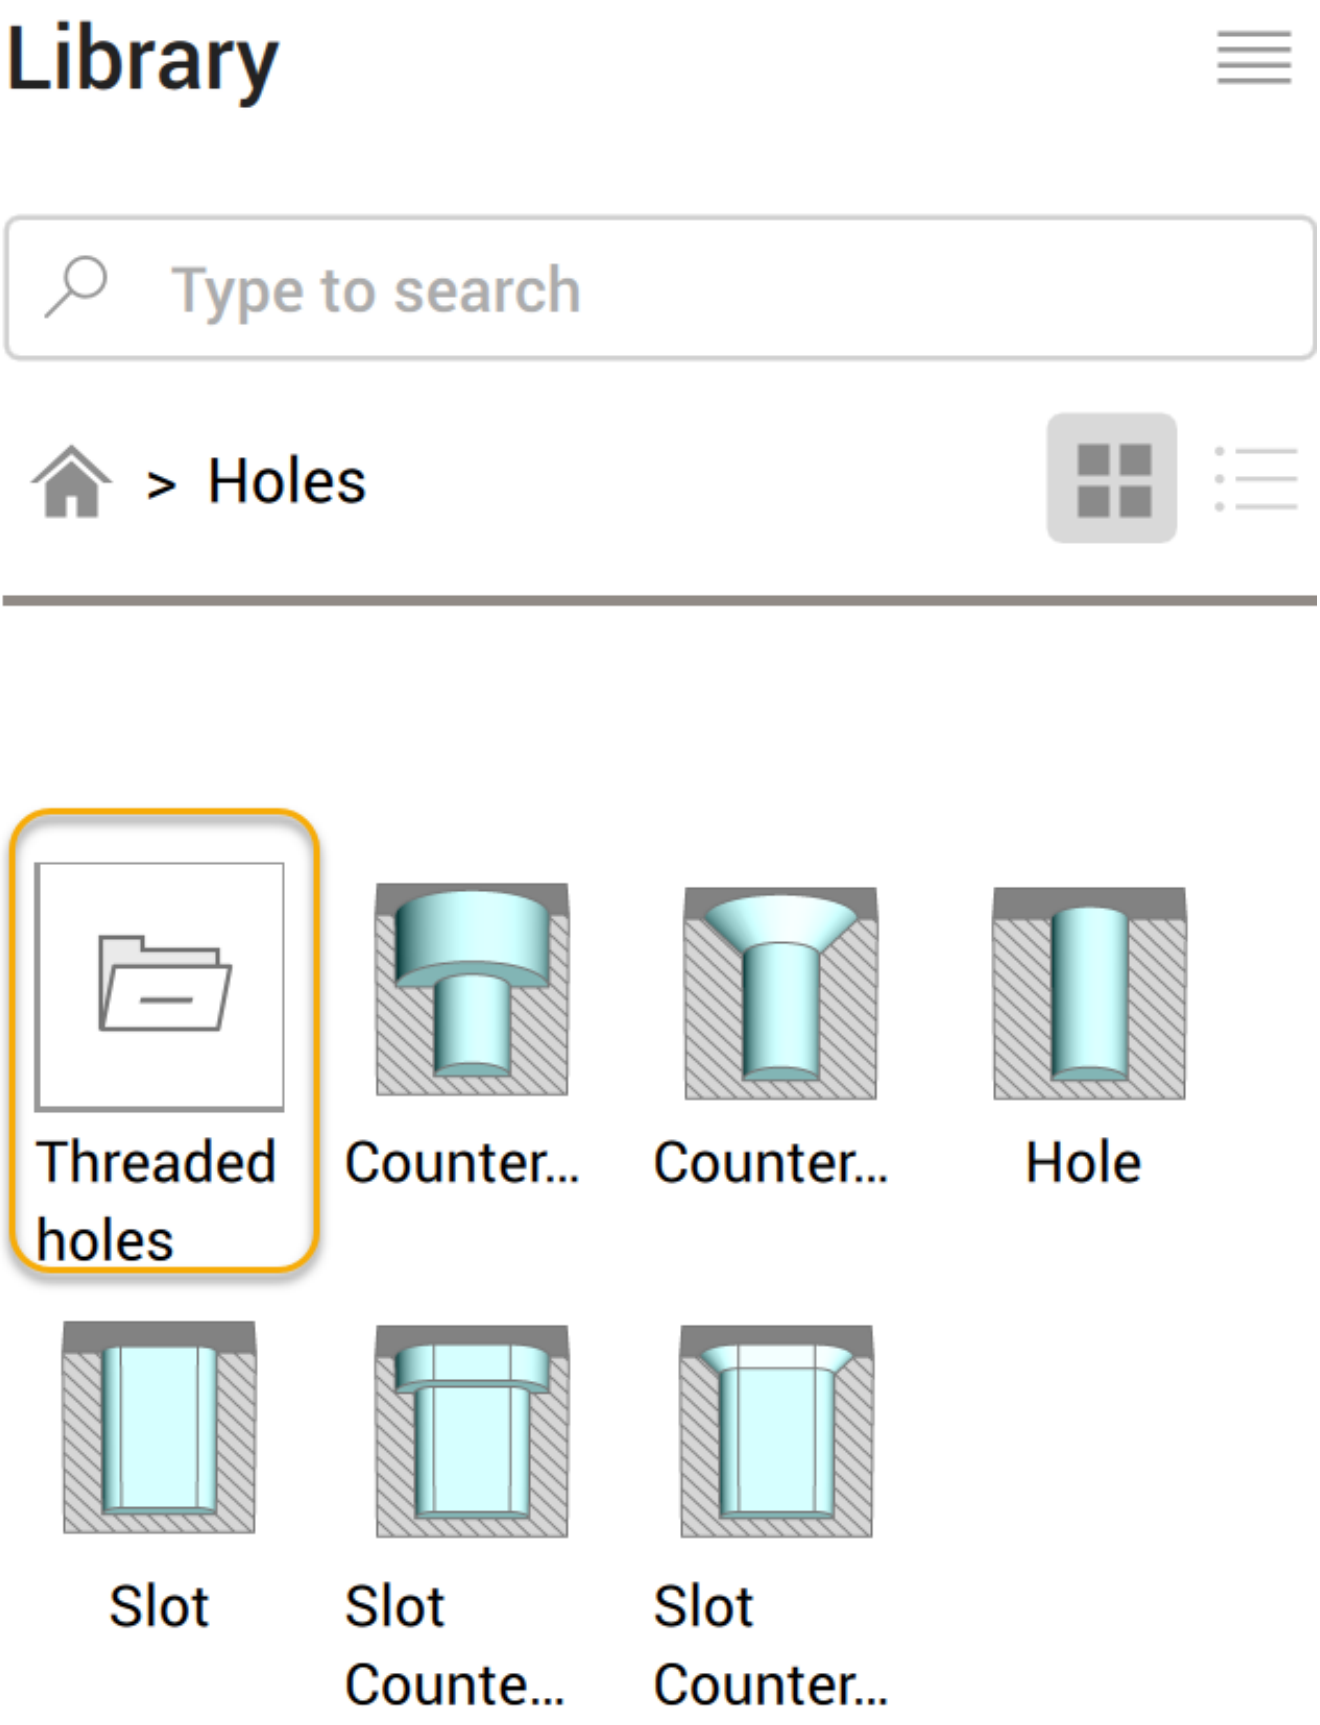
3.1.3 Parts Libraries

The launch of BricsCAD v21 has seen a significant increase in the number of standardized parts available to you.

Holes

A library of threaded hole components has been added. (3.12 on the next page)

Figure 3.12



Library
Type to search
> Holes
Threaded holes
Counter...
Counter...

Elbows
Flanges
Gaskets
Pipe Plug
Pipes
Reducers
Tees

3.1.4 Standard parts

Constraints are now automatically restored after changing the parameters of a standard part.

3.1.5 Parameters and Constraints

Piping

Along with the release of the piping standardized parts, a new BMCONNECT command will automatically constrain the selected pieces based on their proximity to each other.

3.1.6 Sheet Metal

Sheet metal tools in BricsCAD Mechanical v21 offer more flexibility and faster workflows. For example, a specific bend table can be assigned to each solid and arts with a different thickness can exist in the same block.

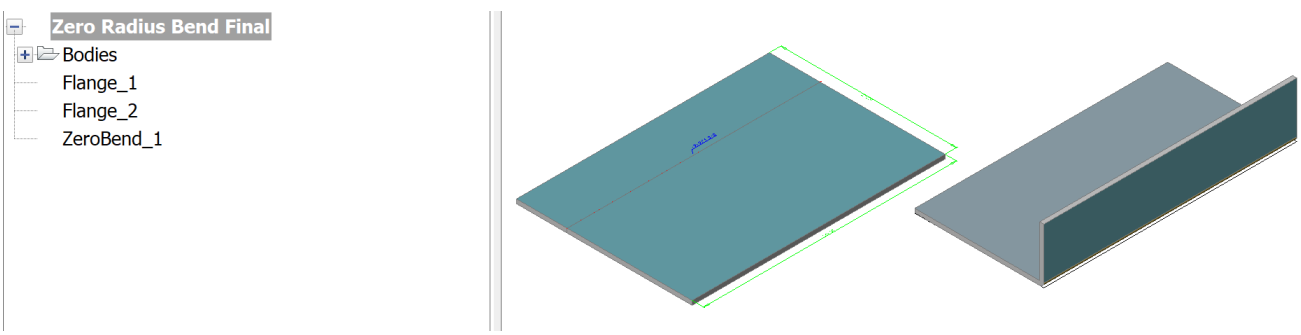
Bevels

The newly added Bevel feature is supported in the SMCONVERT, SMREPAIR and SMUNFOLD commands.

Zero Radius Bends

A new feature ZeroBend allows for the creation of a bend with no internal radius for sheet metal components. (3.14)

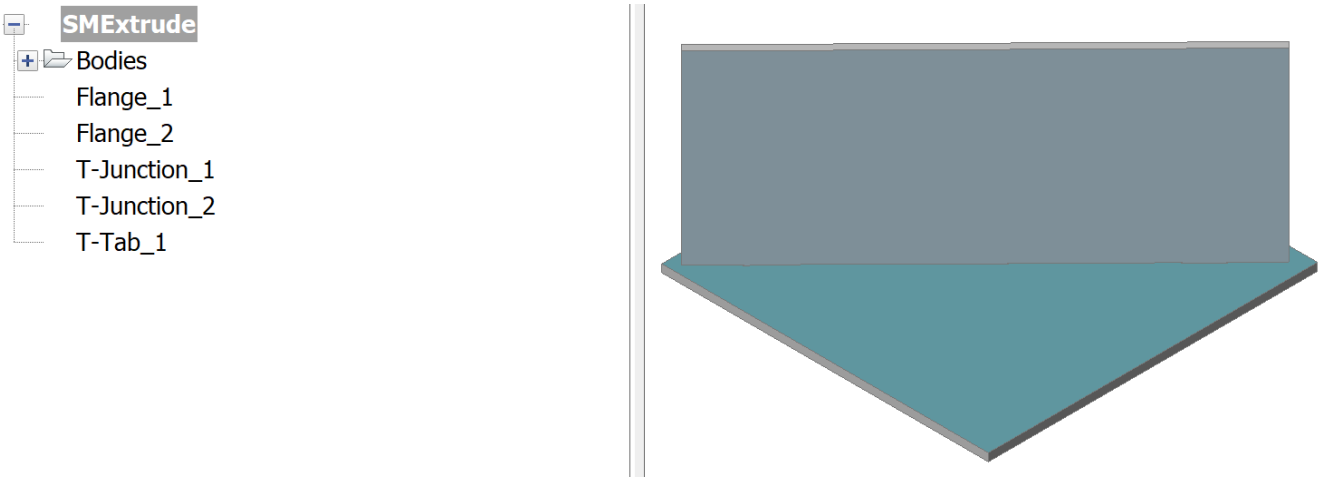
Figure 3.14



T-Junction

A new feature T-Junction can be created using SMEXTRUDE on a single segment poly line lying on a flange to create a new flange orthogonal to the existing. Using the T-Junction feature we can then convert it to a T-Tab which will automatically add tabs to the orthogonal flange and remove the necessary material from the original. (3.15)

Figure 3.15



Updated Smart Features

You may now create sheet metal drawings even faster by utilizing the upgraded SMSMARTFEATURE command which allows you to automatically create junctions when utilizing the bend tool. (3.16) (3.17 on the following page)

Tabs

The SMTABCREATE command now has an option to create a curved tab on a curved hard edge, connecting a flange and a bend, including lofted bends. (3.18 on the next page) The SMUNFOLD command offers improved behavior for conical lofted bends. They can now be unfolded analytically, to avoid splitting them into a specified number of bends and flanges. (3.19 on the following page)

Figure 3.18

Assembly Export

The SMASSEMBLYEXPORTMODE system variable allows you to keep recognized features for sheet metal and poorly modeled sheet metal parts when using the SMASSEMBLYEXPORT command. (3.20 on the next page)

3.2 Part Design - Workflows

3.2.1 Shaft support editing

https://www.youtube-nocookie.com/embed/jpQf9RN_YZg You need a **BricsCAD Platinum** license for this tutorial.

3.2.2 Step 1. Resize

1. Open the **Shaft_support.dwg** file from Shaft_support_files.zip.
2. Select **Bearing_support** in the Mechanical Browser (3.3.2).
3. Click **Open (6.23.8)** () on the right-click menu.
4. Click the **Same Radius fillets (6.12.28)** () button on the **Solid | Select** panel in the Ribbon (1.17.6) and click any fillet face. (3.21 on the following page)
5. Delete all fillets with the **Erase (6.13.8)** () button on the **Solid | Edit** panel in the Ribbon (1.17.6) or the **Modify** section of the Quad (2.3.3).
6. Delete the chamfer on the front cylindrical edge with the **Erase (6.13.8)** () button in the **Solid | Edit** panel in the Ribbon (1.17.6) or the **Modify** section of the Quad (2.3.3). (3.22 on the next page)
7. Select the two inclined faces. Select **Push/Pull (2.5.11)** () from the **Model** section of the Quad (2.3.3).
8. Enter a distance of **10** and hit **Enter.** (3.23 on page 2627)
9. Select the outer top cylindrical face. Select **Push/Pull (2.5.11)** () from the **Model** section of the Quad (2.3.3).
10. Enter a distance of **70** and hit **Enter**. (3.24 on page 2627)
11. Select the larger of the two internal cylindrical faces. (3.25 on page 2628)
12. Select **Push/Pull (2.5.11)** () from the **Model** section of the Quad (2.3.3).
13. Enter a distance of **55** and hit **Enter**.
14. Select the smaller of the two internal cylindrical faces. (3.26 on page 2628)
15. Select **Push/Pull (2.5.11)** () from the **Model** section of the Quad (2.3.3).
16. Enter a distance of **50** and hit **Enter**.
17. Increase the Overall Depth: select the front and back vertical faces. (3.27 on page 2629)
18. Select **Push/Pull (2.5.11)** () from the **Model** section of the Quad (2.3.3).
19. Enter a distance of **3.5** and hit **Enter**.
20. Increase the place for the bearing: select the inner vertical circular face. Select **Push/Pull (2.5.11)** () from the **Model** section of the Quad (2.3.3).
21. Enter a distance of **3.5** and hit **Enter**. (3.28 on page 2629)

Figure 3.21

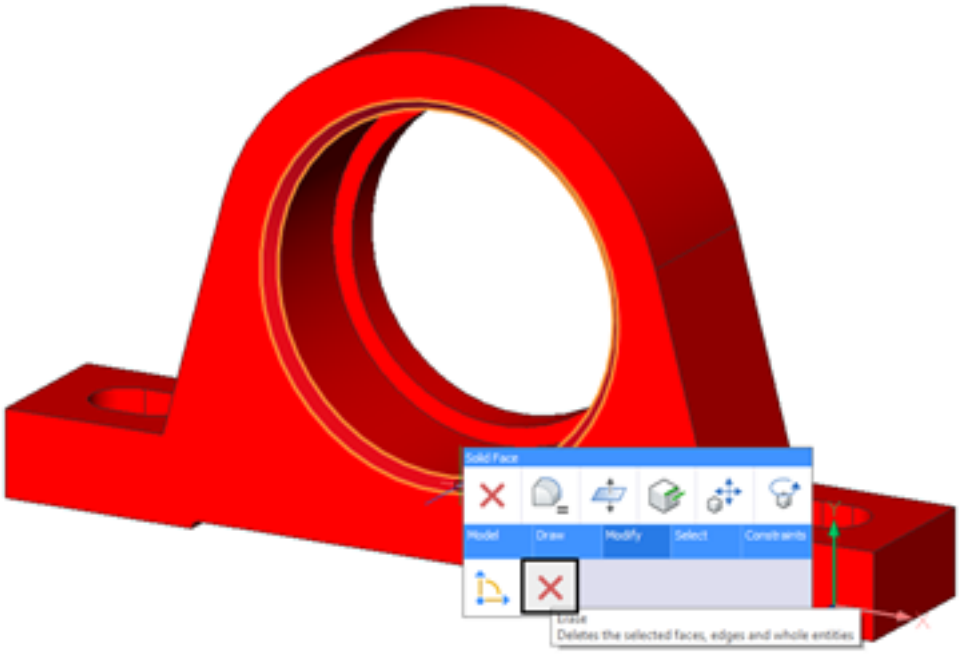

Figure 3.23

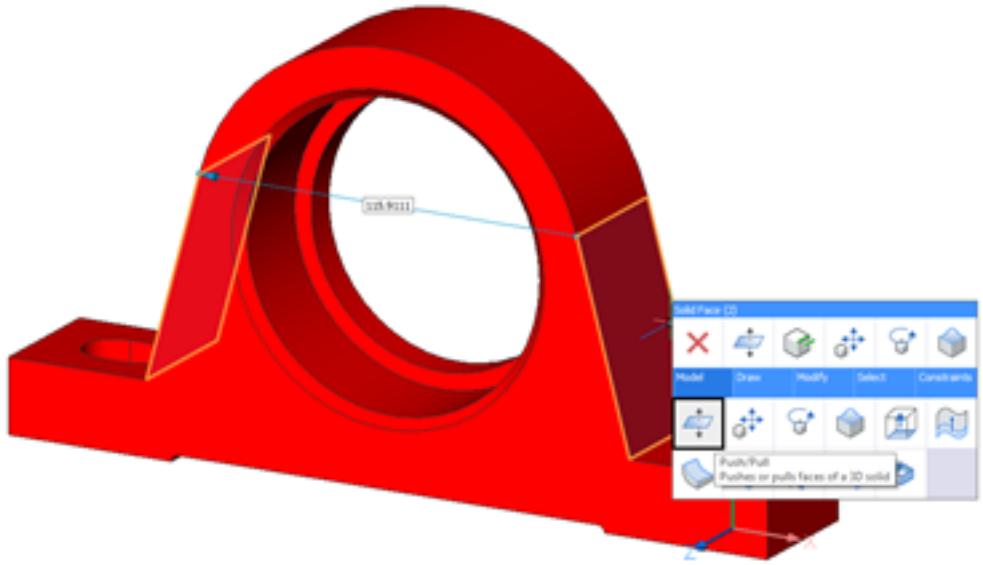

Figure 3.24

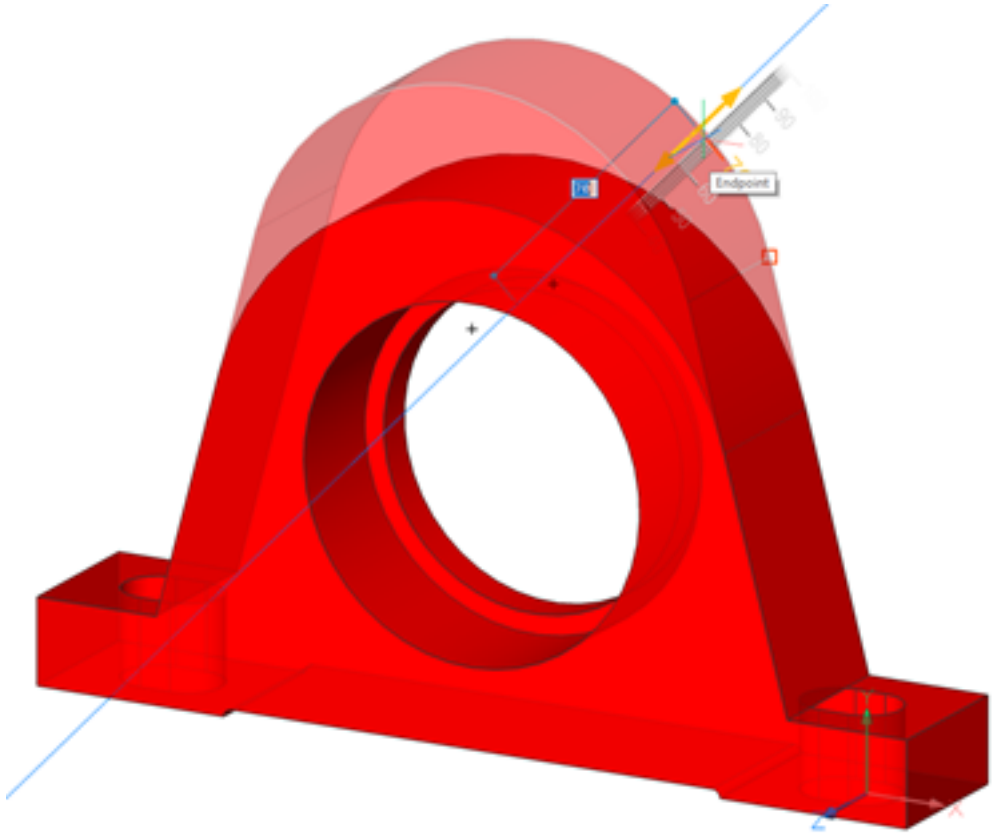

Figure 3.25

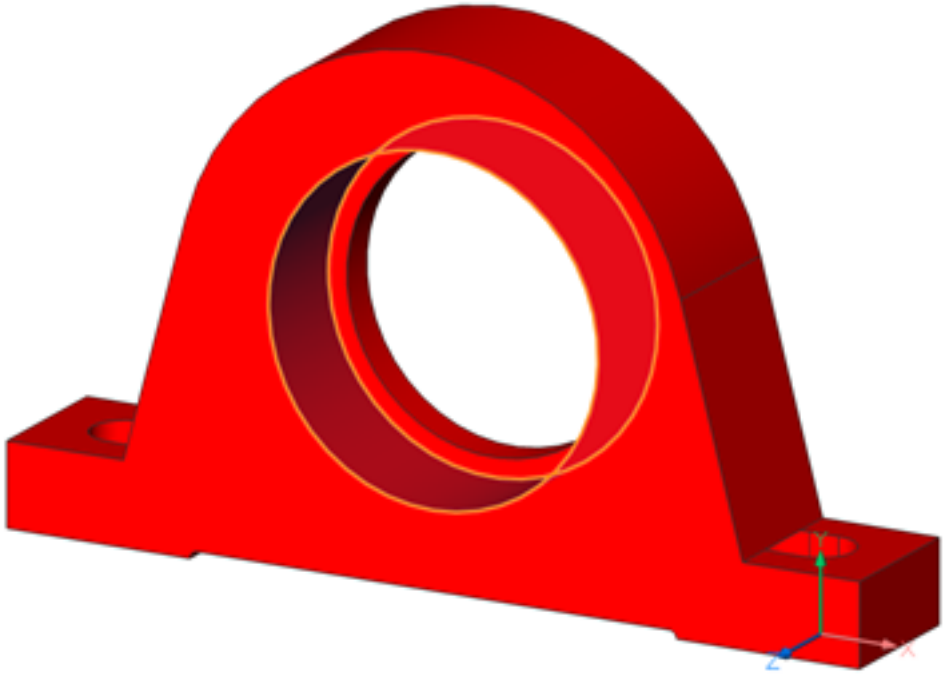

Figure 3.26

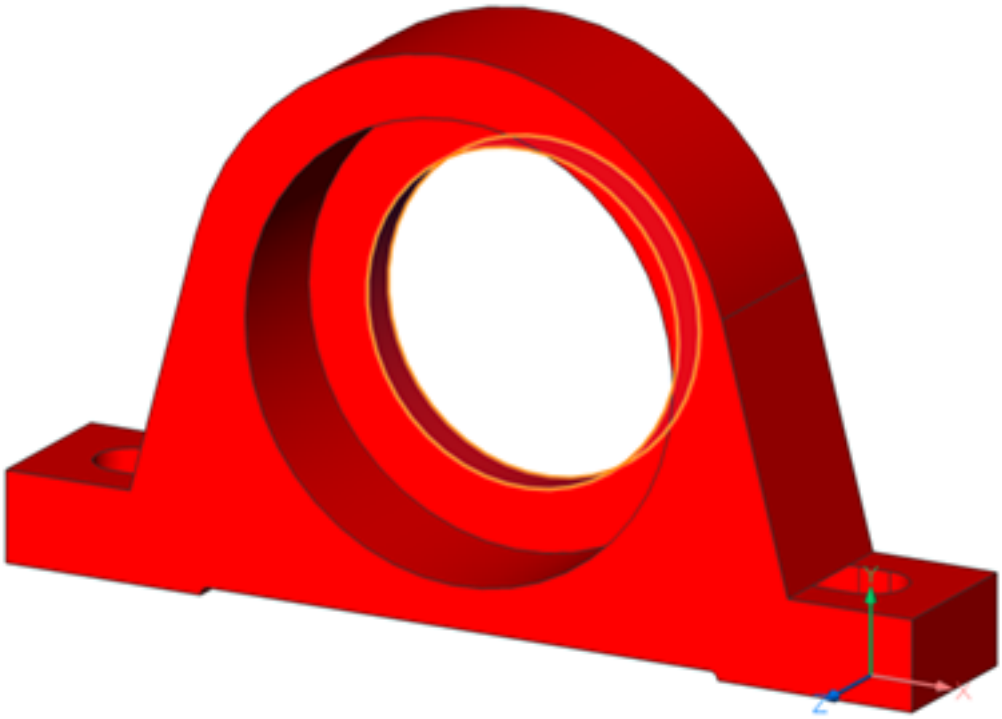

Figure 3.27

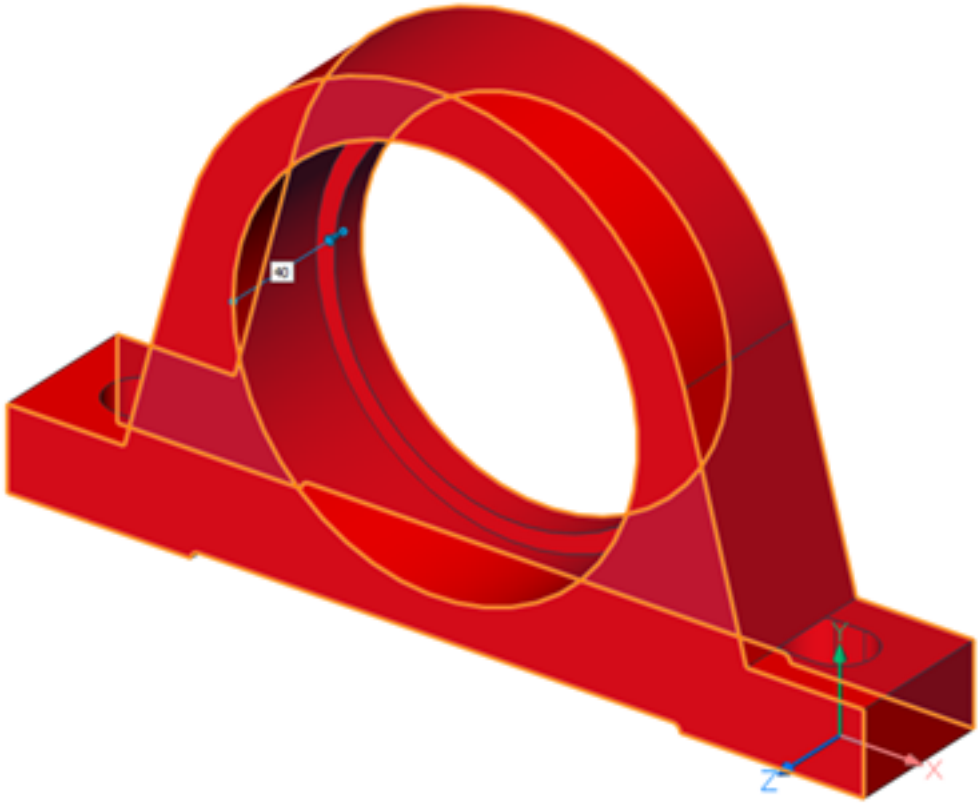

Figure 3.28

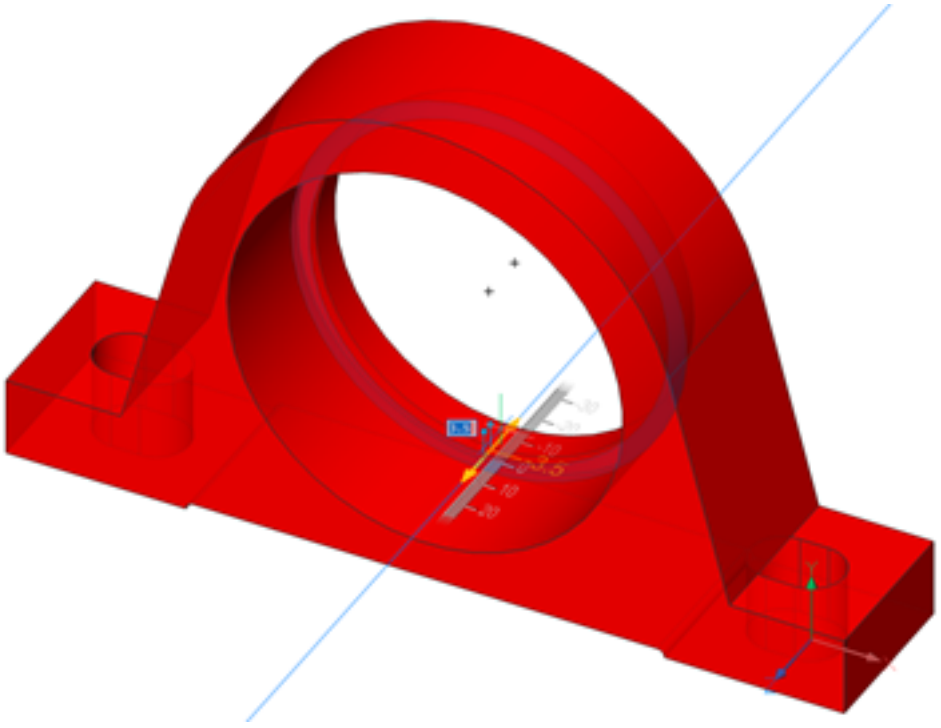
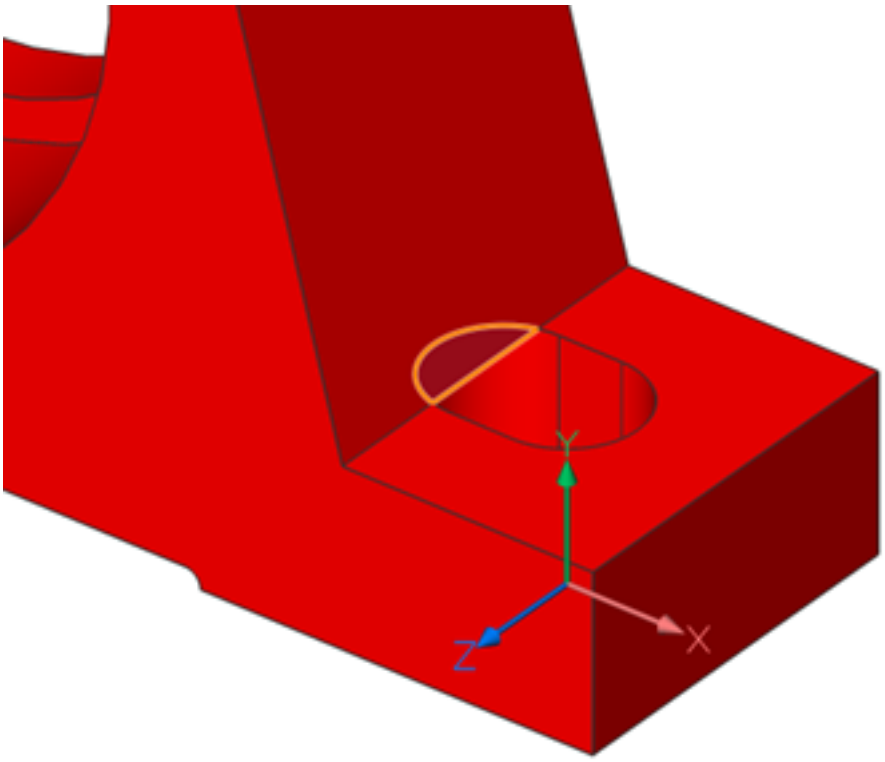


3.2.3 Step 2. Editing the base platform

1. Select the faces as shown in the picture below: (3.29 on the facing page)
2. Select **Solid Extrude (6.12.14)** () from the **Model** section of the Quad (2.3.3). Move the mouse up using the **Subtract** option. (3.30 on page 2632)

Figure 3.29



3. Click the **Slice (6.27.40)** ( ) button on the **Solid | Edit** panel in the Ribbon (1.17.6), select the solid and hit **Enter**.
4. Select the **Object** option. Specify the top face of the supporting platform and hit **Enter**.(3.31 on the following page) (3.32 on page 2633)
5. On one side, change the mounting cut to a distance of **18** using **Push/Pull (2.5.11)** ( ) from the **Model** section of the Quad (2.3.3)**. (3.33 on page 2634)**
6. Select the right vertical edge on the front face. Select **Offset (6.23.3)** ( ) from the **Draw** section of the Quad (2.3.3). Enter an offset distance of **50**, and select the front face for a parallel copy. (3.34 on page 2635)
7. Repeat for this on the back face.
8. Select the two new boundaries. Select **Solid Extrude (6.12.14)** ( ) from the **Model** section of the Quad (2.3.3) and move in an outward direction, with a distance of **8**. (3.35 on page 2636)
9. Select the two bodies and select **Union (6.30.6)** ( ) from the **Model** section of the Quad (2.3.3).

3.2.4 Step 3. Copy faces

1. Select the faces of the updated base platform and then select **Copy Faces (6.12.12)** () from the **Model** section of the Quad (2.3.3). (3.36 on the next page)
2. Select the **midpoint** of the right horizontal edge as a base point: (3.37 on page 2639)
3. Select the **Rotate** option and enter a rotation angle of **180**.
4. Select the **midpoint** of the left horizontal edge as the insertion point. (3.38 on page 2639)

(3.39 on page 2640)

Figure 3.36

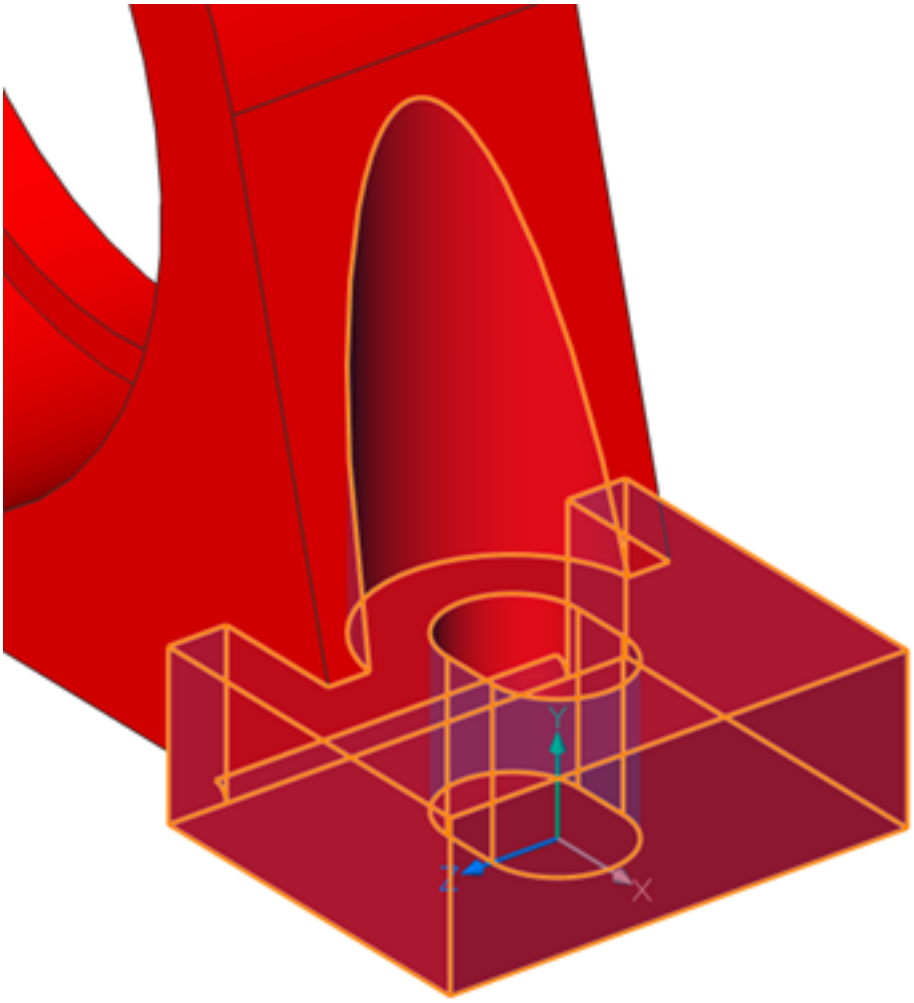

Figure 3.37

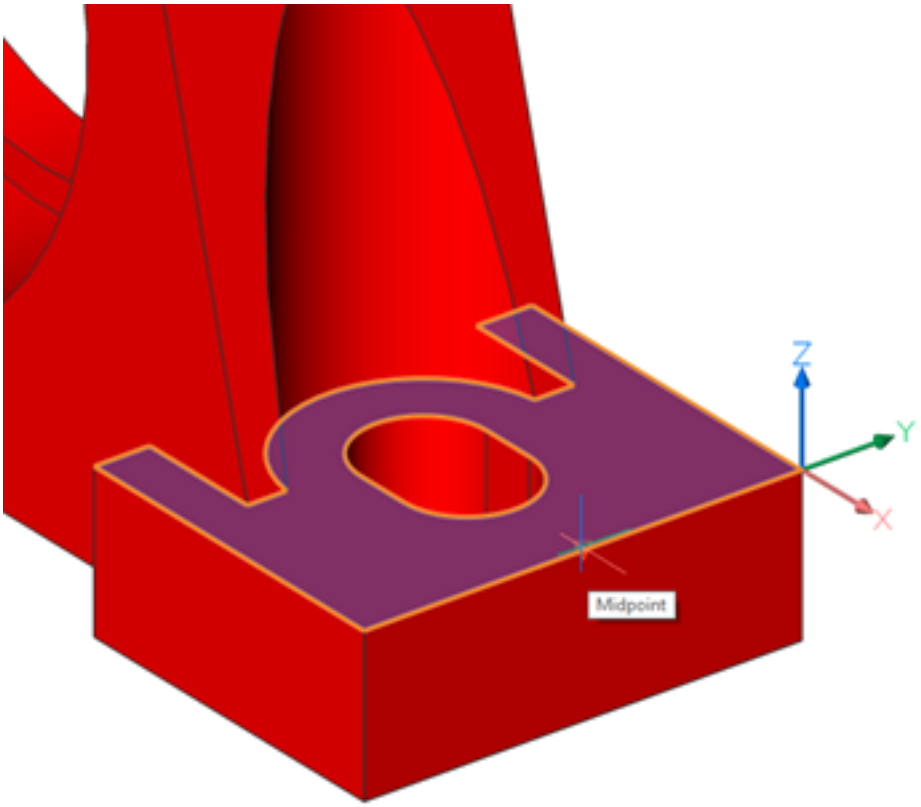

Figure 3.38

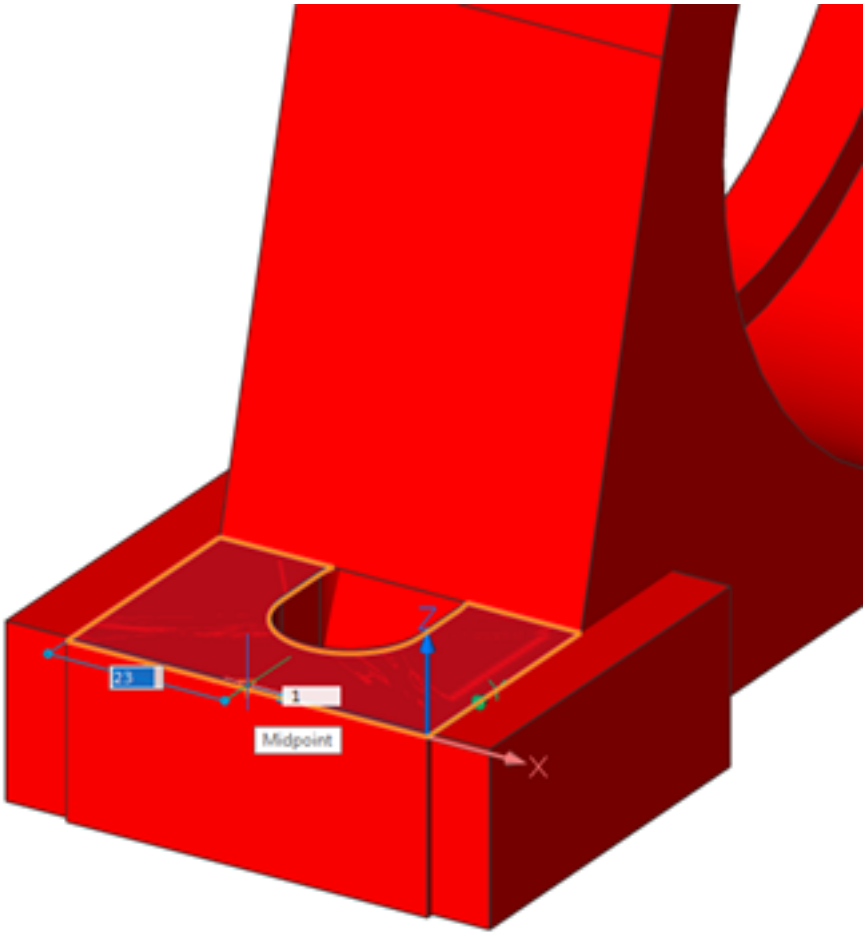

Figure 3.39

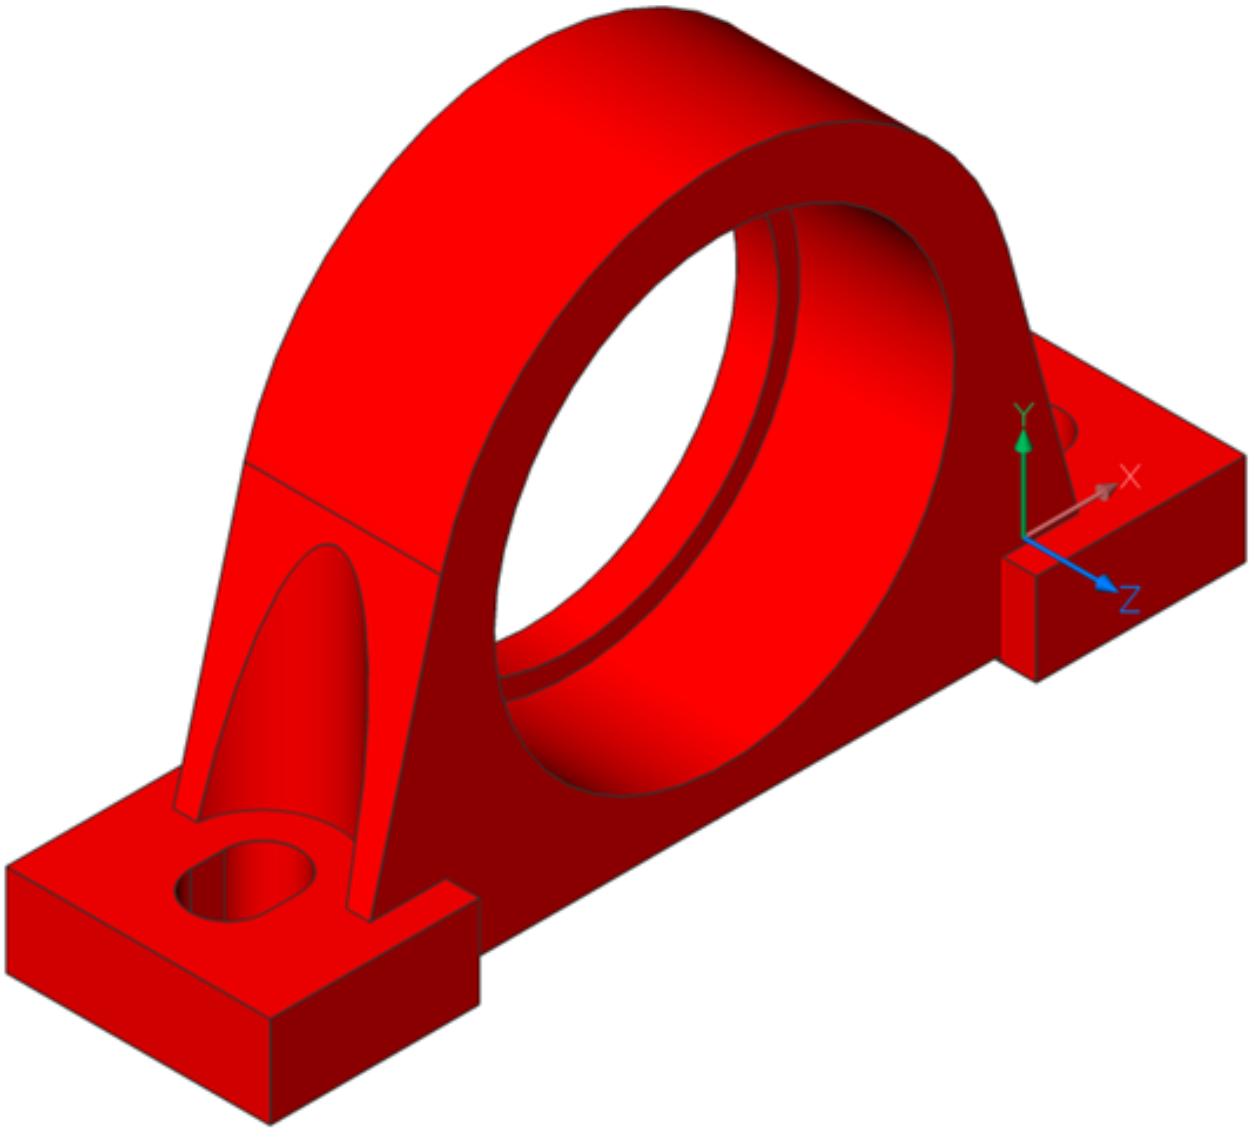

3.2.5 Step 4. Edge smoothing

1. Select all vertical edges and the two edge networks. (3.40 on the next page)
2. Select **Fillet (6.12.13)** () from the **Model** section of the Quad (2.3.3). Specify a fillet radius of **3**.
3. Select the larger circular edge and select **Chamfer (6.12.4)** () from the **Model** section of the Quad (2.3.3). Specify the edge distance as **2.5**.

(3.41 on the following page)

Figure 3.40

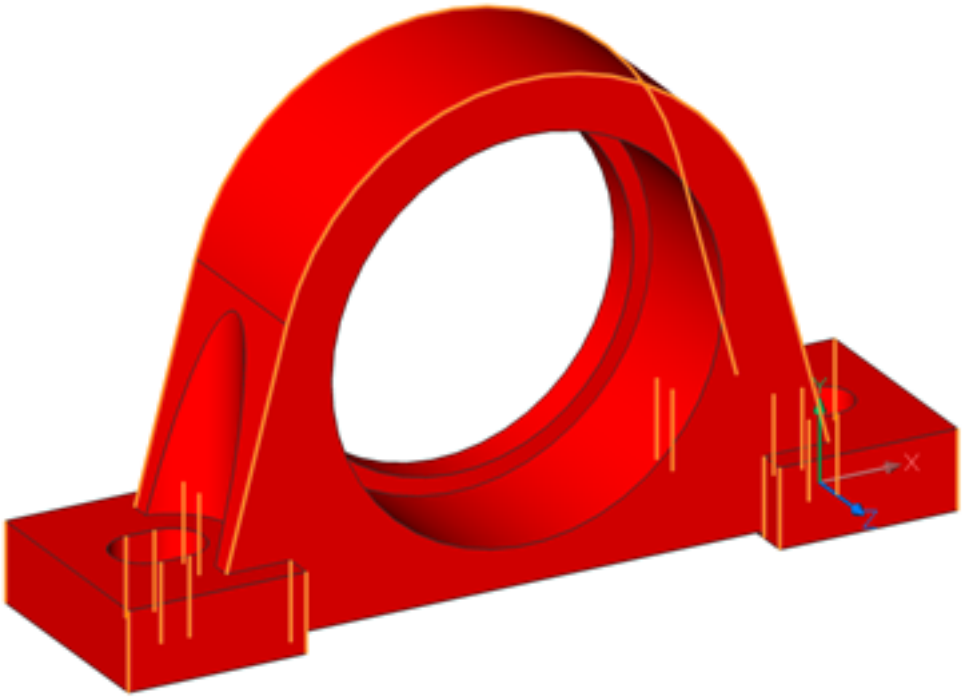

Figure 3.41

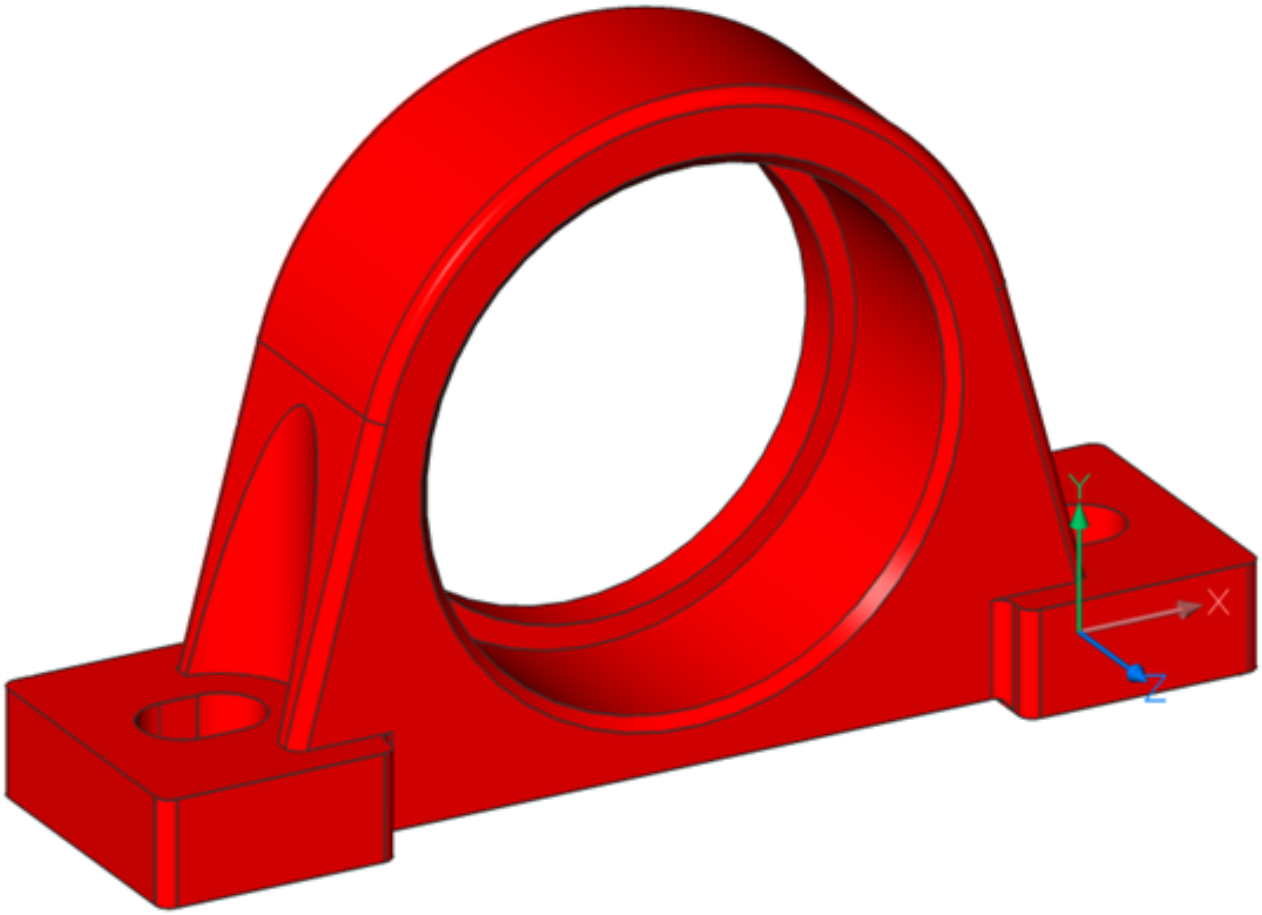

3.2.6 Step 5. Update in assembly

1. Save the file with the new name of Bearing_support_110.dwg and switch to the **Shaft_support.dwg** file.
2. In the Mechanical Browser (3.3.2)**,** replace **Bearing_support** with the new **Bearing_support_110.dwg** file.
3. In the Mechanical Browser (3.3.2), replace **BBRG-22x50 MM** with the ball_bearing.dwg file.
4. Change the **OutsideDiameter** parameter of the **Ball_bearing** component to **110mm.**

(3.42 on the next page)

Figure 3.42

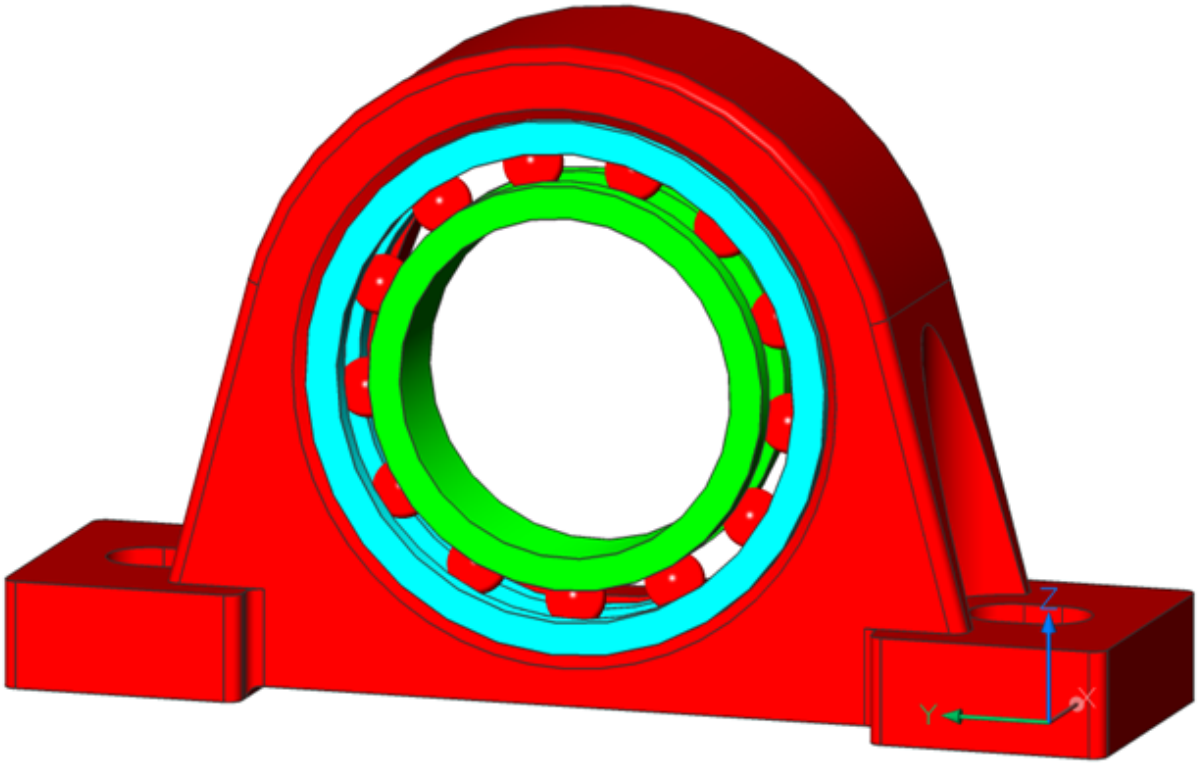

Figure 3.43

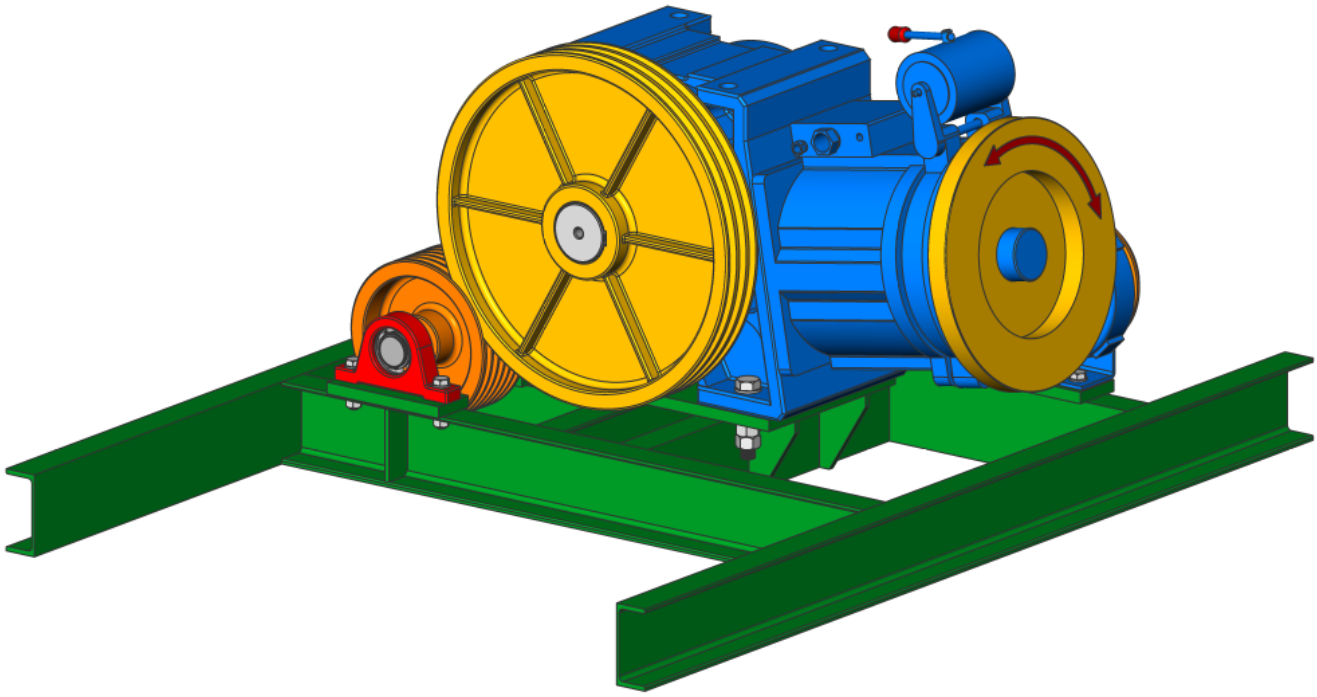

3.2.7 Deflector sheave editing

https://www.youtube-nocookie.com/embed/8ZBDeJ3Au3E You need a **BricsCAD Platinum** license for this tutorial.

1. Open the **Geared_Traction_Machine_2_PMI_assembly.dwg** file from Geared_Traction_Machine_2_PMI_assembly.zip. (3.43)
2. Select **Geared_Traction_Machine_2_PMI** in the Mechanical Browser (3.3.2).
3. Click **Open (6.23.8)** ( ) on the right-click menu.
4. Click the **Form Component (6.8.13)** ( ) tool button on the **Assembly | Modify** panel of the Ribbon (1.17.6).
5. Select **Deflector Sheave**.
6. Select the **center point** of the front face of the **Deflector Sheave** as the base point of the component.
7. Save the file as **Deflector_Sheave_2.dwg**.
8. Select **Deflector_Sheave_2** in the Mechanical Browser (3.3.2).
9. Click **Open (6.23.8)** ( ) on the right-click menu. (3.44 on the next page)
10. In the **Layers** drop-down menu on the **Home | Layers** panel of the Ribbon (1.17.6), select layer **"0"** and click **Color**. (3.45 on the following page)
11. Change the color to **40** and click the **OK** button. (3.46 on page 2647)

12. Switch to **Front** view in the LookFrom (6.20.41) widget by clicking the bottom triangle.
13. Make sure that the **Select Faces** option in the Settings (6.27.25) dialog is switched on (the **Select Faces** ( ) button on the **Home | Setting** panel of the Ribbon (1.17.6)).
14. Using a Green Crossing Window Selection (1.32.7), select the groves on the new deflector sheave. Use the CTRL key to change the selection method. (3.47 on page 2648)
15. Delete the groves on the new deflector sheave.

16. Using the **Select same or less radius fillets (6.12.28)** ( ) button on the **Solid | Select** panel of the Ribbon (1.17.6), select all fillets on the deflector sheave.
17. Delete all fillets.
18. Open the Deflector_Sheave.dwg file.
19. Click the **Copy with base point (6.9.58)** ( ) tool button on the **Home | Edit** panel of the Ribbon (1.17.6).
20. Enter **0,0,0** as the base point.
21. Select **Deflector Sheave** and hit **Enter**.
22. Switch to the **Deflector_Sheave_2.dwg** file.
23. Click the **Paste (6.24.13)** ( ) tool button on the **Home | Edit** panel in the Ribbon (1.17.6).
24. Enter **-300,0,0** as the insertion point.
25. Switch to **Front** view in the LookFrom (6.20.41) widget by clicking the bottom triangle.
26. Using a Blue Window-Inside Selection Box (1.32.7) select the lateral faces of the deflector sheave. Use the CTRL key to change the selection type. (3.48 on the next page)
27. Select **Move (6.12.16)** ( ) from the **Model** section of the Quad (2.3.3).
28. Move the faces left, enter a distance of **12** and hit **Enter**.
29. Select the left face of the internal part of the wheel.
30. Select **Solid Extrude (6.12.14)** ( ) from the **Model** section of the Quad (2.3.3).
31. Move the face right, enter a distance of **10** and hit **Enter**.
32. Select the left face of the external part of the wheel.
33. Click the **Same area faces (6.12.28)** ( ) on the **Solid | Select** section of the Ribbon (1.17.6).
34. Select **Push/Pull (2.5.11)** ( ) from the **Model** section of the Quad (2.3.3).
35. Move the mouse cursor left.
36. Enter a distance of **17** and hit **Enter**.
37. Using the **Same area faces (6.12.28)** ( ) button select the 2 internal cylindrical faces of the deflector sheave. (3.49 on page 2650)
38. Switch to **Left** view in the LookFrom (6.20.41) widget by clicking the left triangle.

Figure 3.48

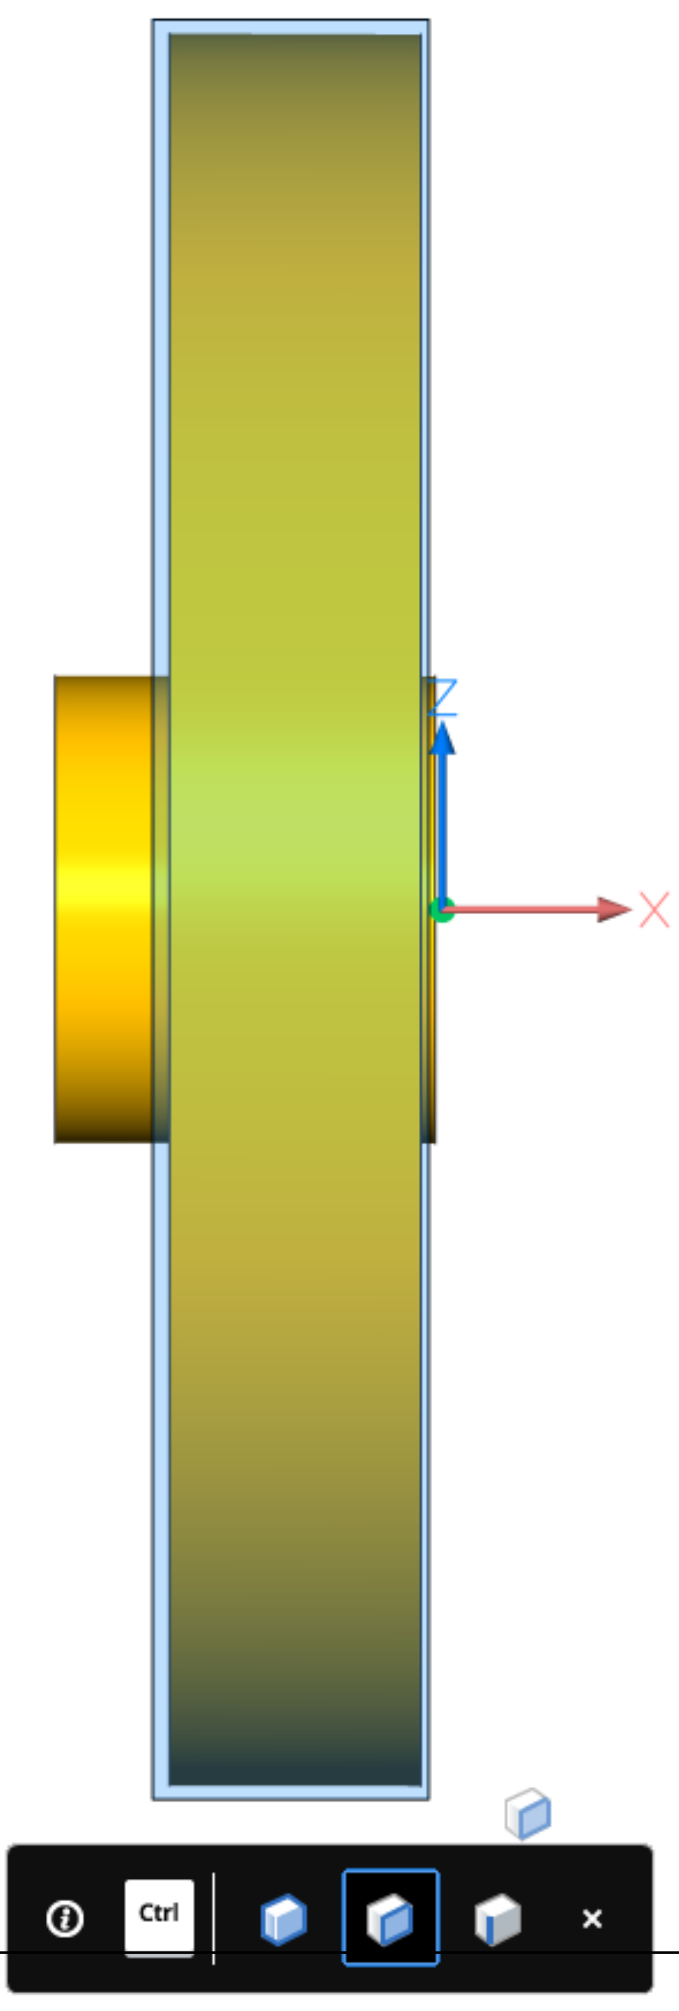

Figure 3.49

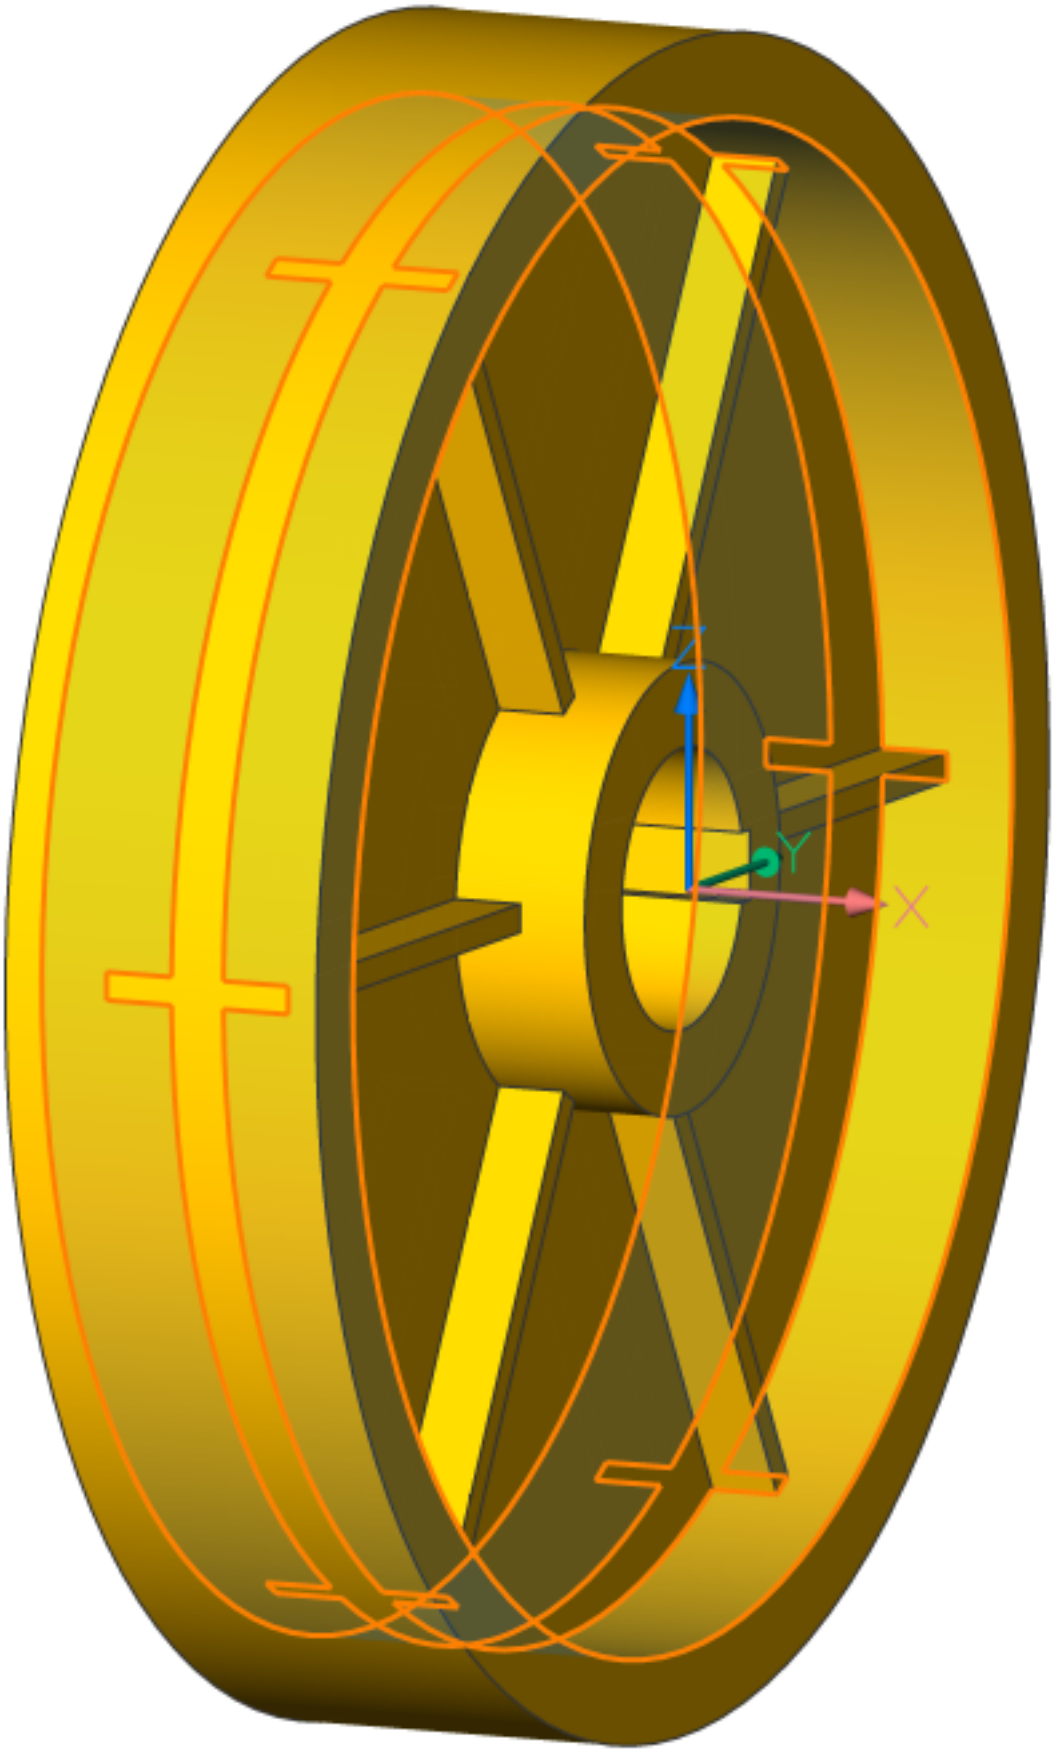

Figure 3.50

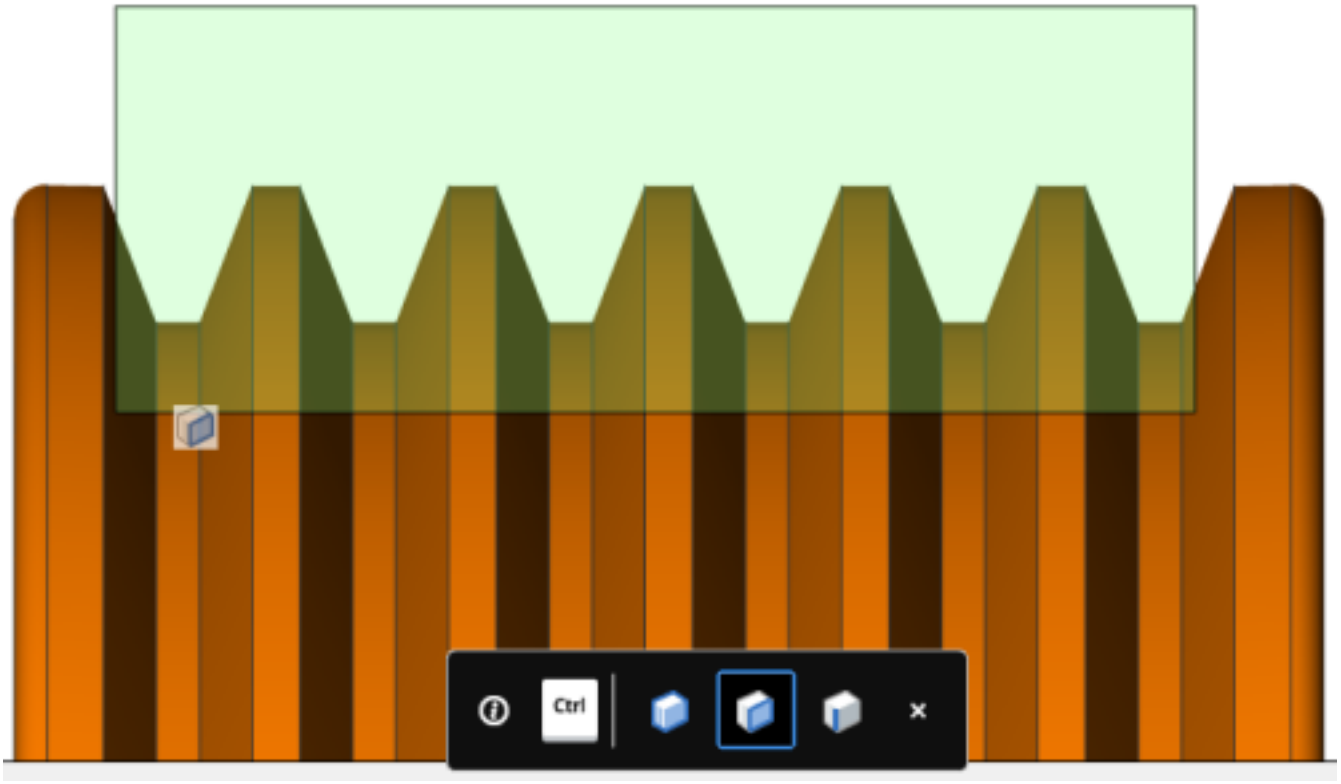
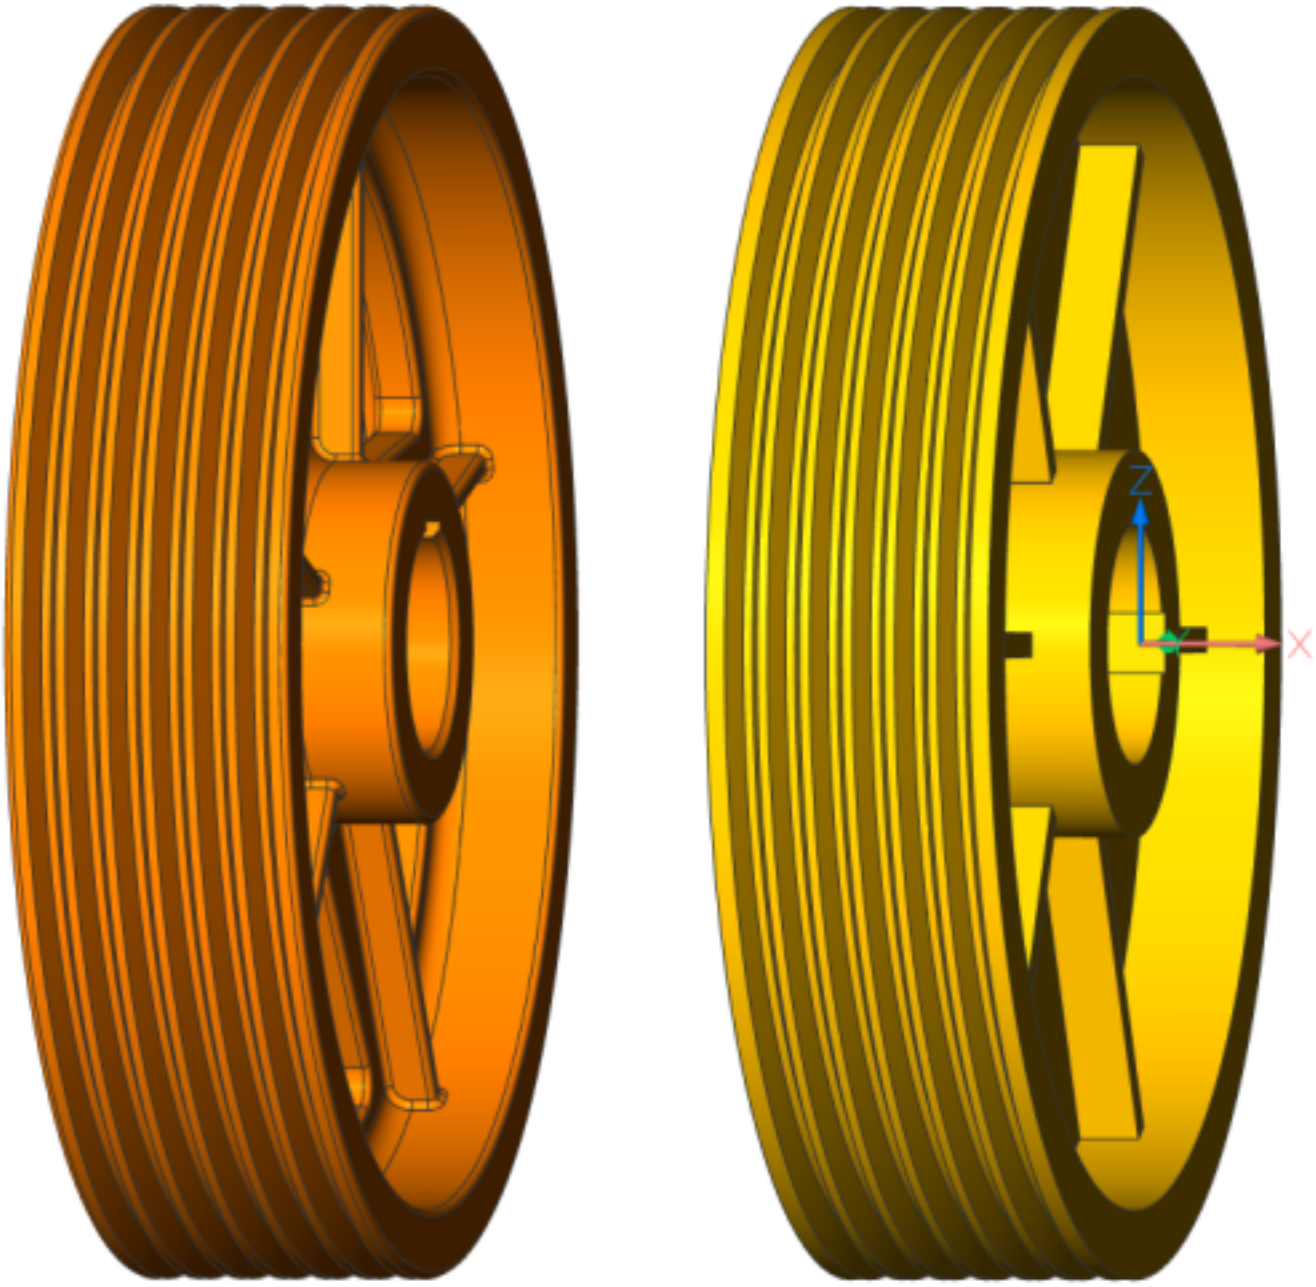


39. Select **Push/Pull (2.5.11)** ( ) from the **Model** section of the Quad (2.3.3).
40. Align with the internal cylindrical face of the original deflector sheave (or enter a distance of **234**) and hit **Enter**.
41. Select the external face of the new deflector sheave.
42. Select **Push/Pull (2.5.11)** ( ) from the **Model** section of the Quad (2.3.3).
43. Align with the external face of the original deflector sheave (or enter a distance of **262.5**) and hit **Enter**.
44. Switch to **Front** view in the LookFrom (6.20.41) widget by clicking the bottom triangle.
45. Make sure that the **Snap to center** option in the Settings (6.27.25) dialog is switched on (Snap to center (6.9.3) ( ) button on the **Home | Entity Snaps** panel of the Ribbon (1.17.6)).
46. Repeat step 15 for select faces of groves on the original deflector sheave. (3.50)
47. Click the **Copy Faces (6.12.12)** ( ) from the **Model** section of the Quad (2.3.3).
48. Select the **center point** on the left face of the original deflector sheave as the base point (hit SHIFT to fix the dynamic UCS).
49. Select the center point on the left face of the new deflector sheave as the insertion point (hit SHIFT to fix the dynamic UCS). (3.51 on the following page)
50. Delete the original deflector sheave. This is no longer needed.
51. Make sure the **Select edges** option in Settings (6.27.25) dialog is switch on (**Select Edges** ( ) button tools on the **Home | Setting** panel of the Ribbon (1.17.6)).
52. Select the edges as shown in the picture below and select **Fillet (6.12.13)** ( ) from the **Model** section of the Quad (2.3.3). **(3.52 on page 2654)**

Figure 3.51



53. Enter a radius of **10** and hit **Enter**.
54. Select the edges as shown in the picture below and select **Fillet (6.12.13)** ( ) from the **Model** section of the Quad (2.3.3). **(3.53 on page 2655)**
55. Enter a radius of **3** and hit **Enter**.
56. Make sure that the **Snap to geometric center** option in the Settings (6.27.25) dialog is switched on (**Snap to geometric center (6.15.5)** ( ) button on the **Home | Entity Snaps** panel of the Ribbon (1.17.6)).
57. Draw a circle in the geometric center of one of the sectors between the ribs using Circle (6.9.12) ( ) from the **Draw** section of the Quad (2.3.3).
58. Enter a radius of **50** and hit **Enter**.
59. Select the circle that was just created. (3.54 on page 2656)
60. Select **Solid Extrude (6.12.14)** ( ) from the **Model** section of the Quad (2.3.3).
61. Enter a distance of **20** with **Subtract** option and hit **Enter**.
62. Select the hole edges and select **Fillet (6.12.13)** ( ) from the **Model** section of the Quad (2.3.3).
63. Enter a radius of **3** and hit **Enter**.
64. Select the depression that was just created.
65. Select the **Copy Faces (6.12.12)** ( ) on the **Solid | Edit** panel of the Ribbon (1.17.6).
66. In the **DMCOPYFACES** menu select the **Multiple** option. (3.55 on page 2656)
67. Select the **geometric center** of the sector as the base point of copying (hit SHIFT to fix the dynamic UCS).
68. Select the **geometric center** of all other sectors as points of insertion. (3.56 on page 2657)
69. Select the **Deflector Sheave** and change **Color** on the Properties panel (1.15.4) to **RGB:255,191,0**.
70. Save the Deflector_Sheave_2.dwg file.
71. Switch to the **Geared_Traction_Machine_2_PMI.dwg** file.
72. Select **Deflector_Sheave_2** in the Mechanical Browser (3.3.2).
73. Click **Update (6.12.34)** ( ) on the right-click menu.
74. Save **Geared_Traction_Machine_2_PMI.dwg** file. (3.57 on page 2658)
75. Switch to the **Geared_Traction_Machine_2_PMI_assembly.dwg** file.
76. Select **Geared_Traction_Machine_2_PMI** in the Mechanical Browser (3.3.2).
77. Click **Update (6.12.34)** ( ) on the right-click menu. (3.58 on page 2658)

3.2.8 Bucket tooth editing

https://www.youtube-nocookie.com/embed/zoZVbwEPJc4 In this tutorial we will edit the teeth of the excavator bucket.

(3.83 on page 2681)	(3.84 on page 2682)
Before	After

1. You need a **BricsCAD Platinum** license for this tutorial.
2. Download and open the **Bucket_Assembly.dwg** file.(3.83 on page 2681)
3. Select **Crown** in the Mechanical Browser (3.3.2).
4. Click Open a copy (6.8.22) ( ) in the right click menu.
5. Save as **Crown_new.dwg.**
6. Hover over the side face and select Generate boundary (6.15.14) ( ) from the **Draw** section of the Quad (2.3.3)**.** (3.59)
7. Hover over the solid and select Move (6.12.16) ( ) from the **Model** section of the Quad (2.3.3) and move the solid along the X-axis by a distance of **200**.
8. Hover over the solid and select Hide entities (6.16.10) ( ) from the **Select** section of the Quad (2.3.3)**.(3.60 on the following page)**
9. Delete the circle.
10. Select the polyline and select Extrude (6.12.14) ( ) from the **Model** section of the Quad (2.3.3)**.** Enter an extrusion distance of **120**.
11. Hover over the filet and select Select same or less radius fillets (6.12.28) ( ) from the **Select** section of the Quad (2.3.3)**. (3.61 on the next page)**
12. Delete all fillets.
13. Select the blade edge. Select Move (6.12.16) ( ) from the **Model** section of the Quad (2.3.3)**.**
14. Click to select a base point, move the edge along the Z-axis. Enter a distance of **60**.(3.62 on page 2661)

Figure 3.60

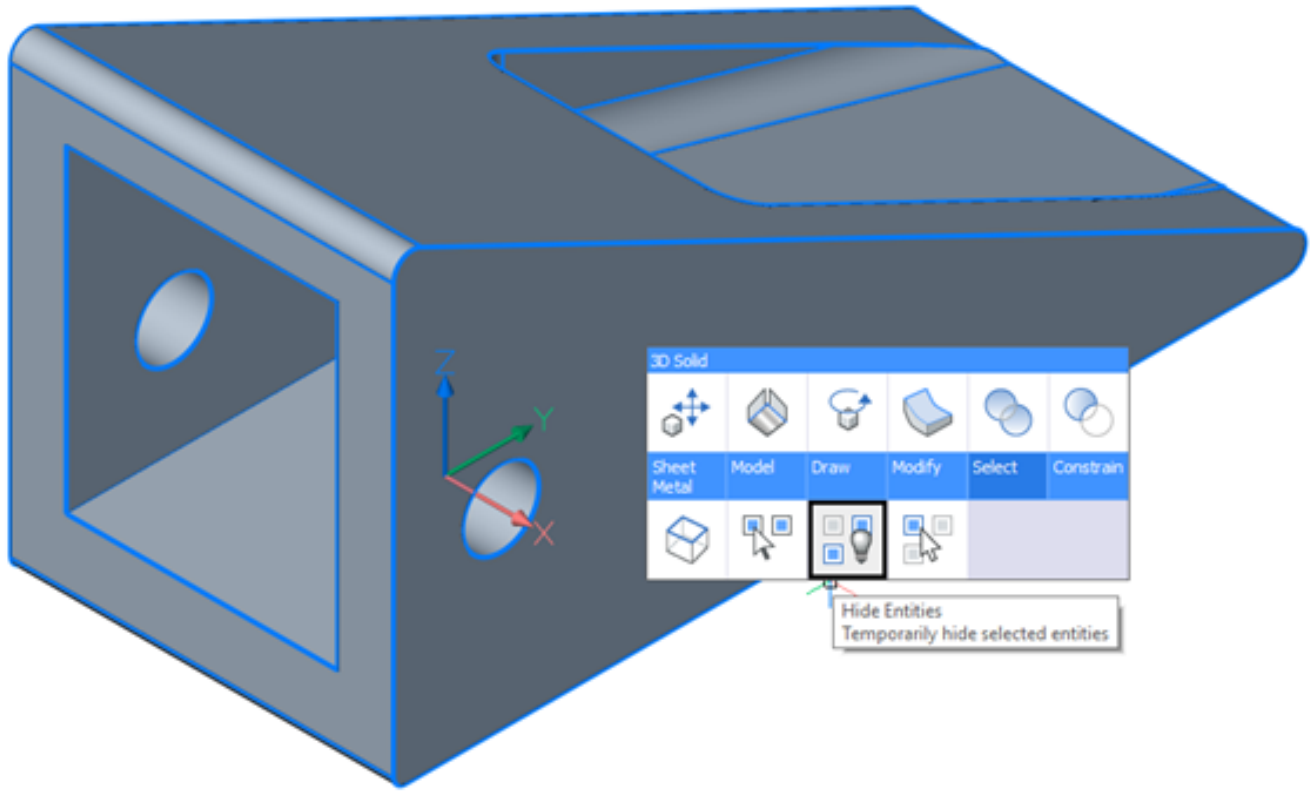

Figure 3.61

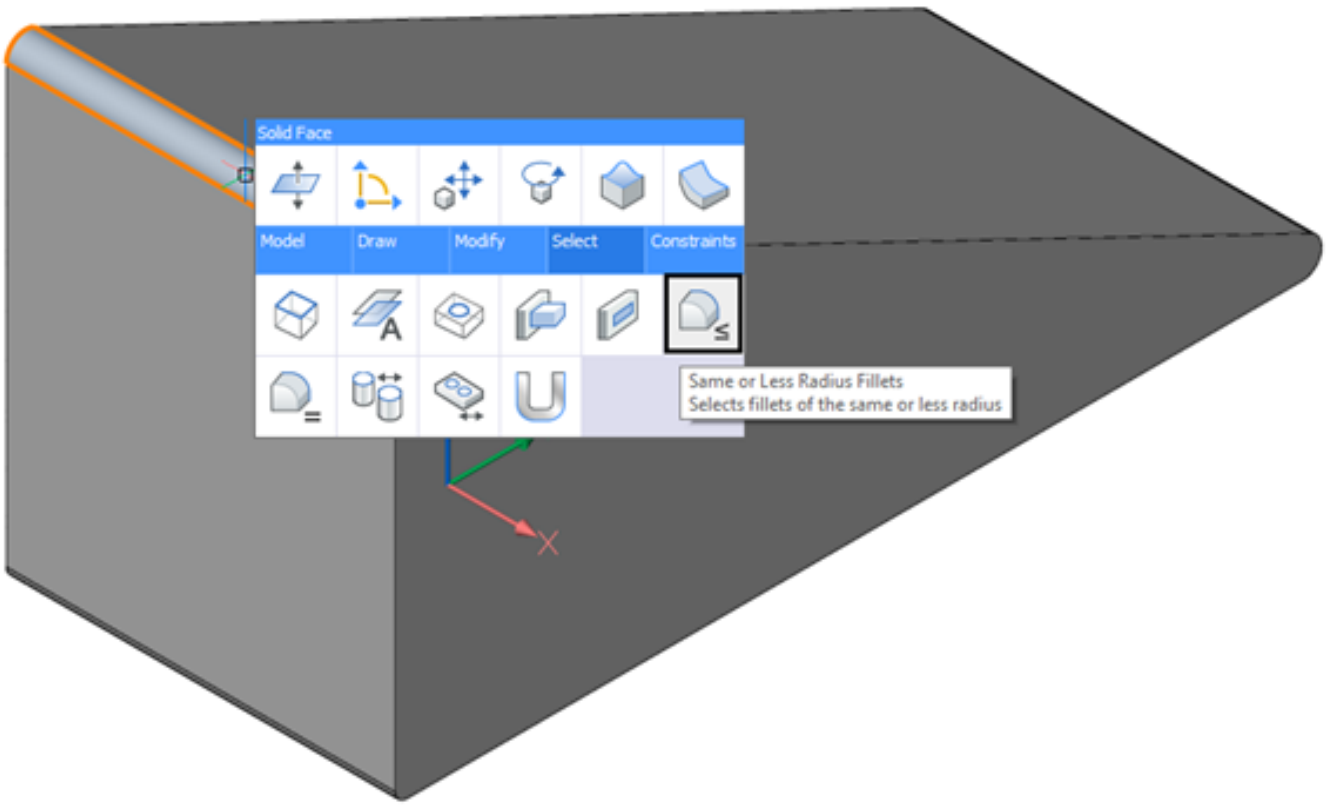

Figure 3.62

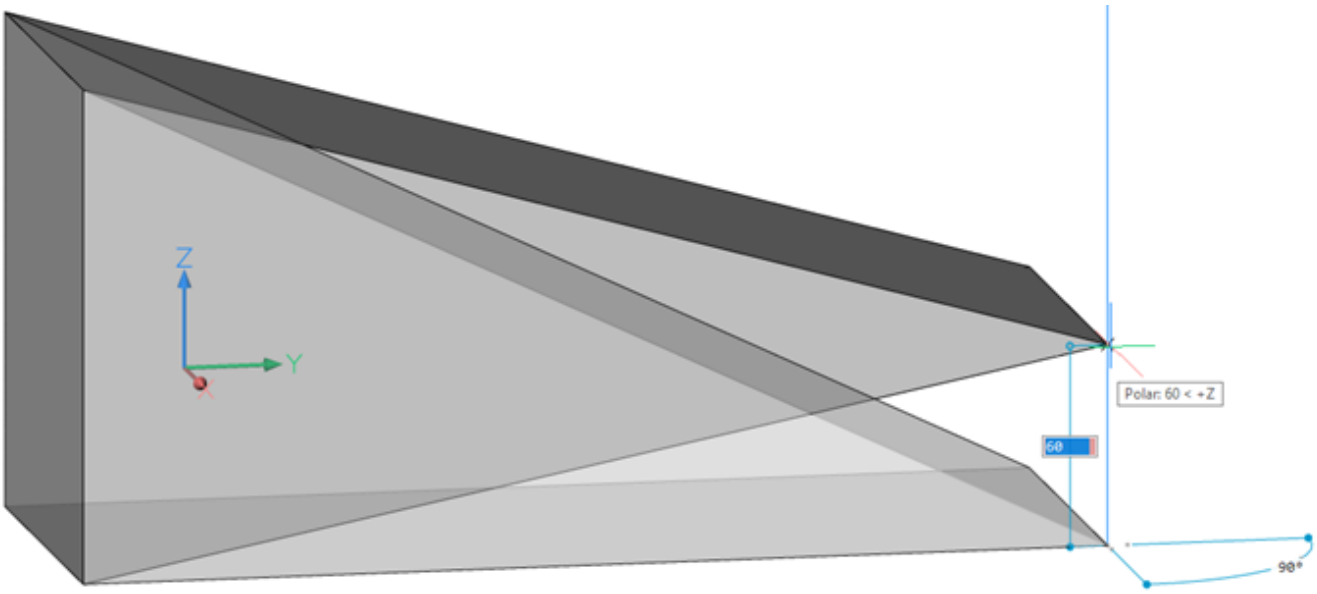

15. Hover over the back face and hold down the left mouse button longer than ¼ second to launch the manipulator widget. (3.63 on the next page)
16. Place the cursor over the Y-axis. Hold down the CTRL key and click.
17. Move the cursor to copy the entity along the Y-axis. Set a distance of **100**.(3.64 on page 2663)
18. Repeat step 16 to create another surface with a distance of **60.(3.65 on page 2663)**
19. Click the Imprint (6.17.12) ( ) button on **Solid | Edit** panel of the Ribbon (1.17.6).
20. Select the solid and the first surface. Enter **Yes** to delete the source surface.
21. Select the second surface. Enter **Yes** to delete the source surface and finish the command.
22. Enable the Edges between coincident faces (1.26.3) ( ) tool button on the **Solid | Design Intent** panel of the Ribbon (1.17.6).
23. Select the 2 triangular blade faces and select PushPull (6.12.25) ( ) from the **Model** section of the Quad (2.3.3)**.** Move the cursor out a distance of **30**. (3.66 on page 2664)
24. Hover over the blade edge. Select Add Fixation (6.12.15) ( ) from the **Constraint** section of the Quad (2.3.3). (3.67 on page 2664)
25. Hover over the second top face. Select Rotate (6.12.24) ( ) from the **Model** section of the Quad (2.3.3)**.**
26. Select the edge between the second and third top faces as the rotate axis. Move the cursor down and enter a rotation angle of **5** degrees. (3.68 on page 2666)

Figure 3.63

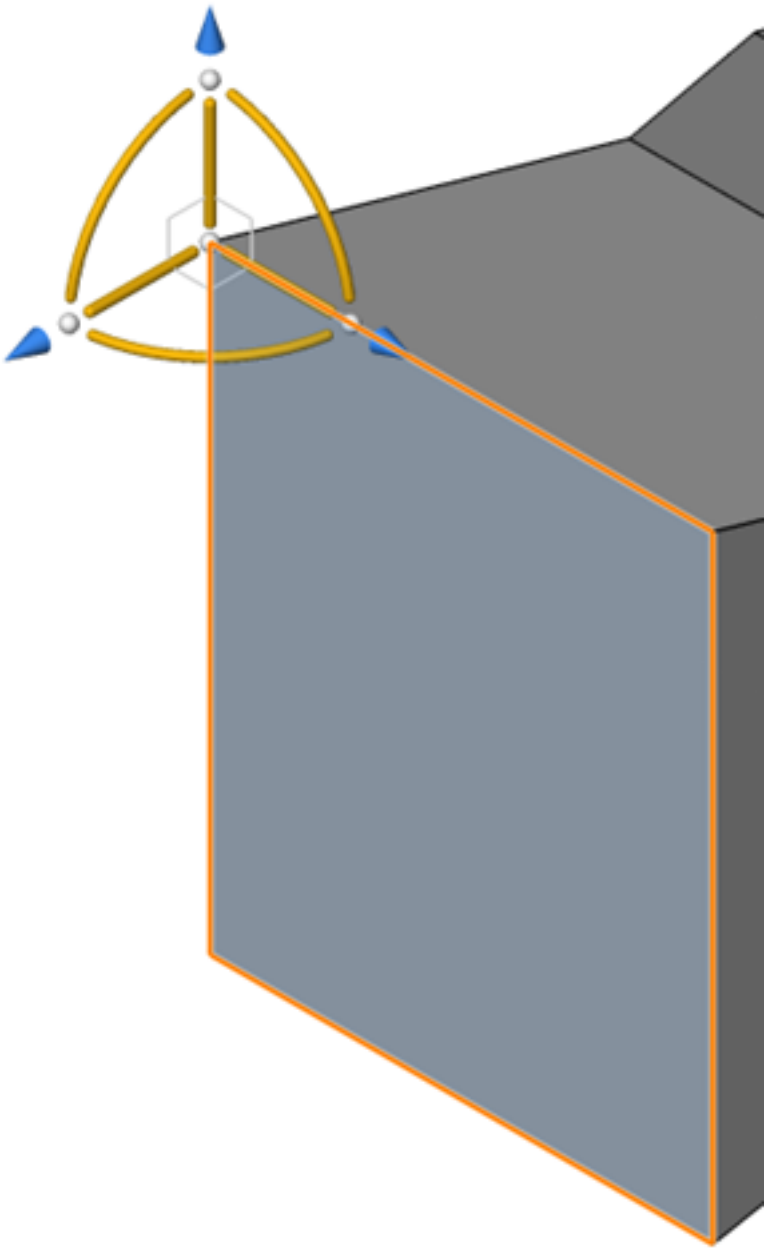

Figure 3.64

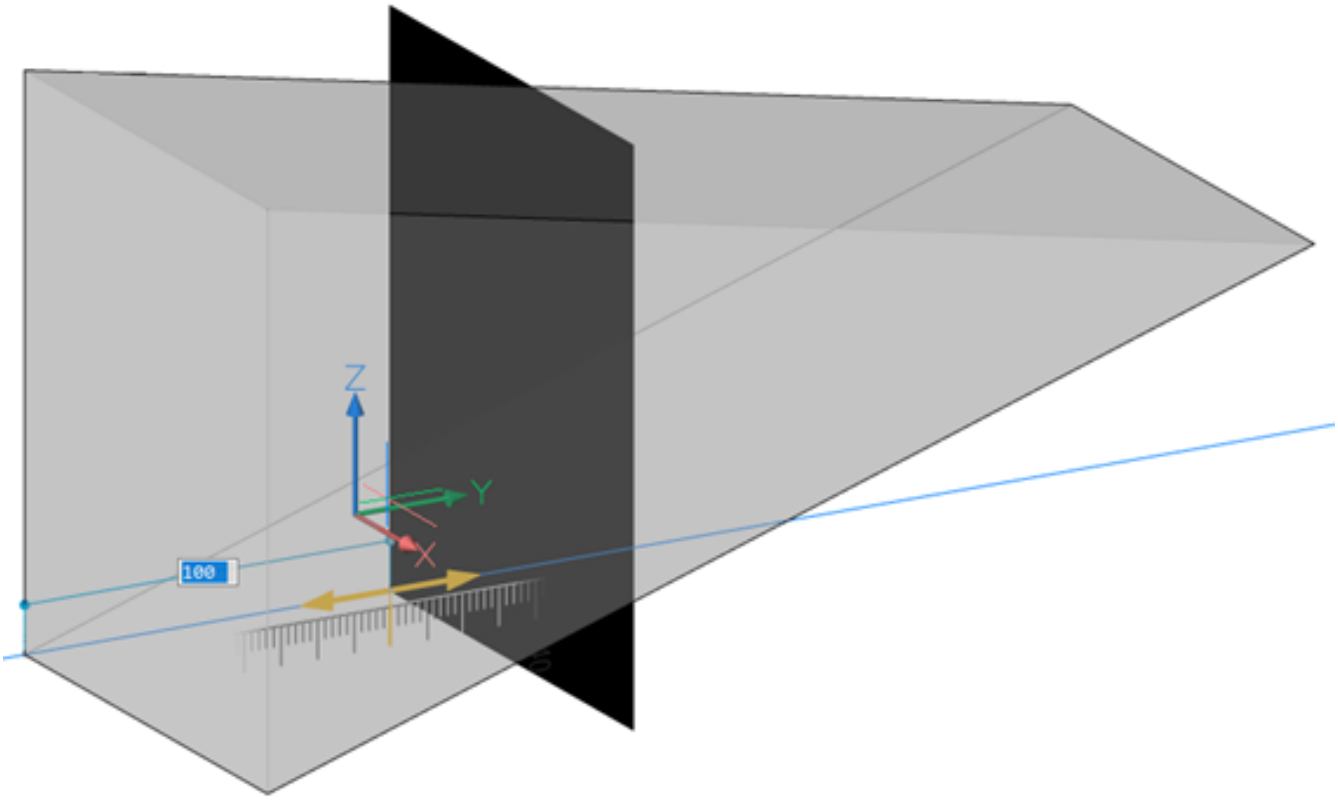

Figure 3.65

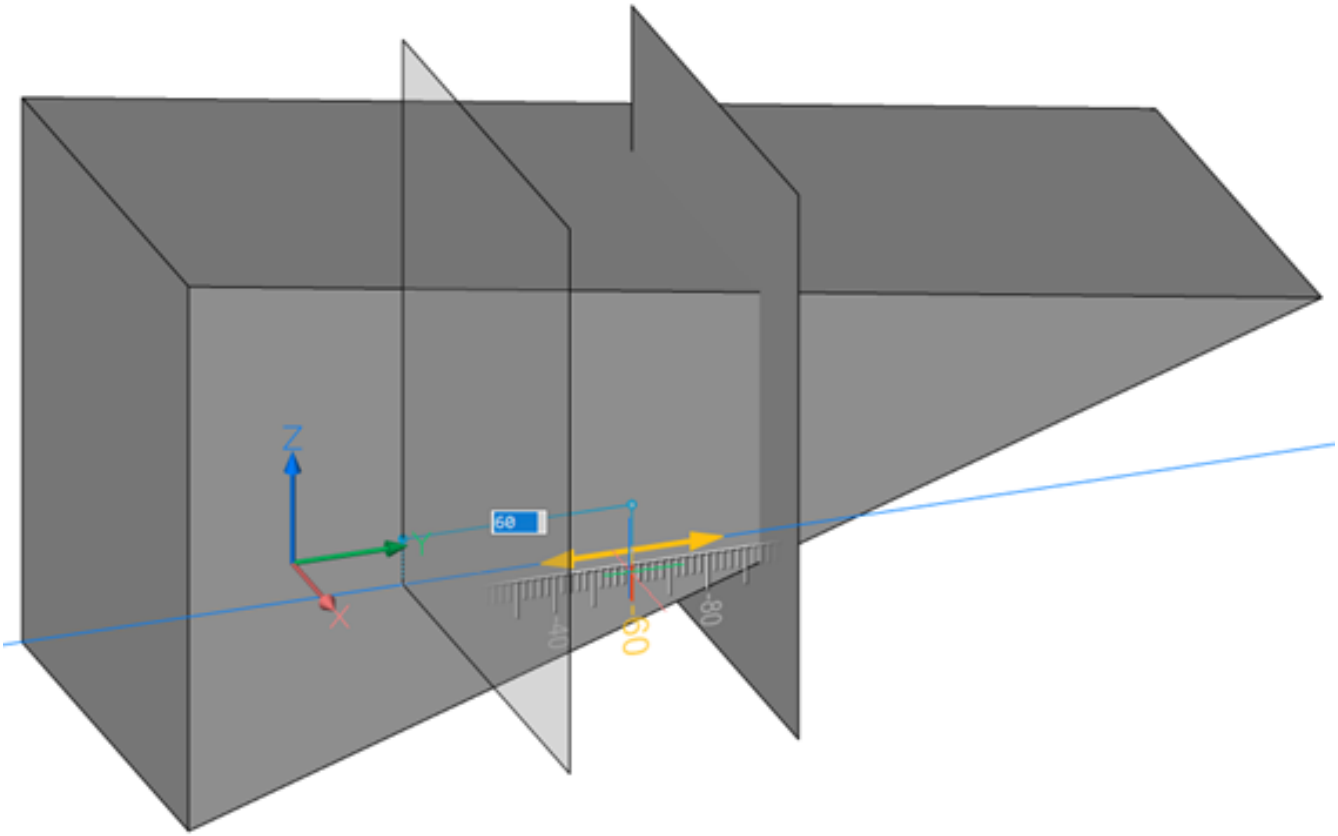

Figure 3.66

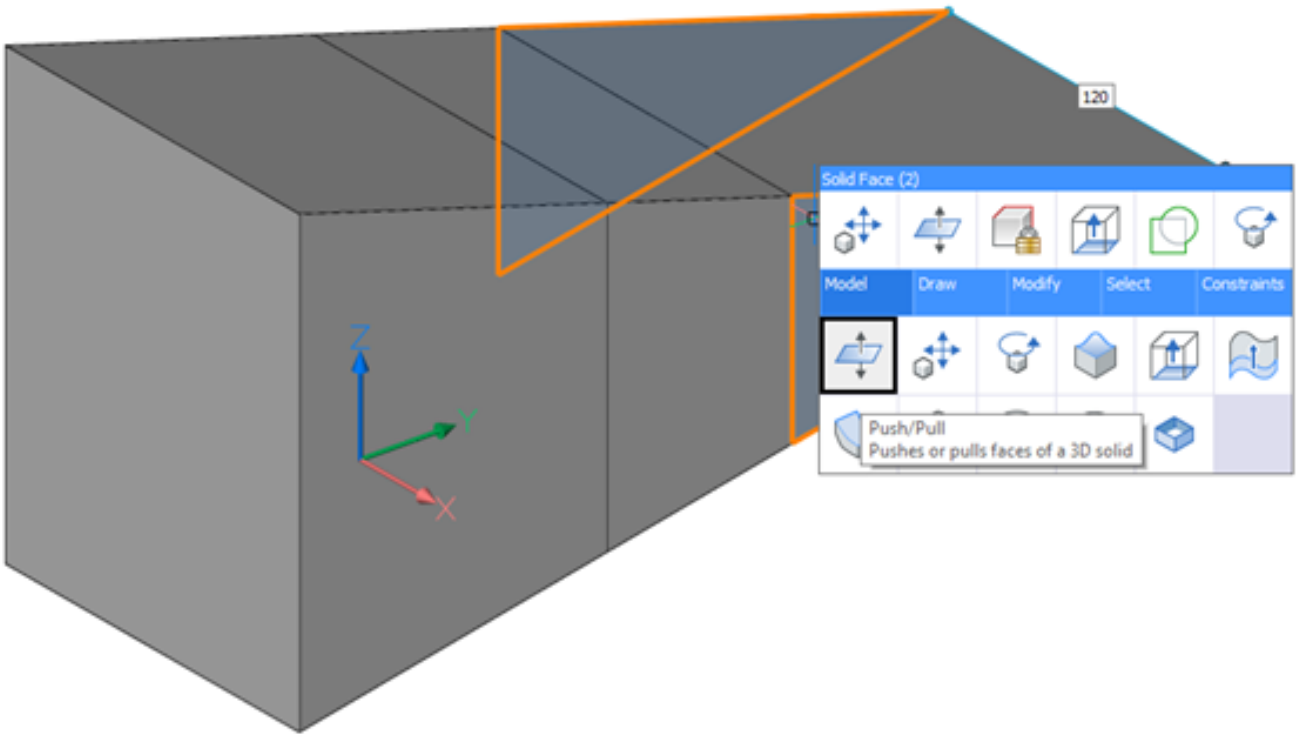

Figure 3.67

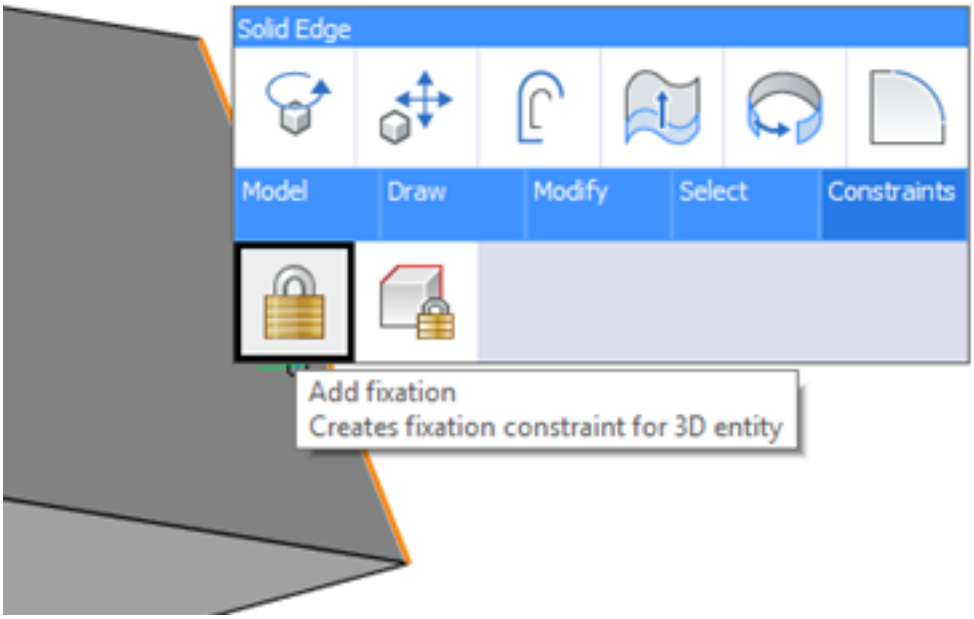

27. Rotate the second bottom face symmetrically to up **5** degrees.
28. Select all horizontal edges. Select Fillet (6.12.13) () from the **Model** section of the Quad (2.3.3). (3.69 on the next page)
29. Enter a radius of **6**.
30. Enable Snap to Midpoint (6.21.16) () (Hold down the Shift key, then right click to open the Esnap context menu.)
31. Click the Rectangle (6.26.6) () tool button in the **Solid | Draw** panel of the Ribbon (1.17.6).
32. Create a rectangle of dimensions **20x200**. Snap to the Midpoint of the blade edge of the top face.

NOTE	To lock Dynamic UCS (1.21.21) to the face, hover over the blade top face and press the SHIFT key during the drawing command.

(3.70 on page 2667)

33. Hover over the rectangle. Select Extrude (6.12.14) () from the **Model** section of the Quad (2.3.3).
34. Enter an extrusion height of **20**. (3.71 on page 2668)
35. Hover over the vertical left face of the new extrusion. Select Extrude (6.12.14) () from the **Model** section of the Quad (2.3.3). (3.72 on page 2669)
36. Enter an extrusion distance of **20** to make the rib symmetrical.
37. Hover over the top front face of the rib.
38. Select Rotate (6.12.24) () from the **Model** section of the Quad (2.3.3).
39. Set the edge between the selected face and the fillet face as the rotation axis.
40. Move the cursor inwards. Enter a rotation angle of **60**.(3.73 on page 2670)
41. Repeat steps 37-40 to rotate the top back face of the rib inwards by an angle of **80**.(3.74 on page 2671)
42. Hover over a face of the rib and select Select Protrusion (6.12.28) () tool button on the **Select** section of the Quad (2.3.3).
(3.75 on page 2672)
43. Click the CopyFaces (6.12.12) () tool button on **Solid | Edit** panel of the Ribbon (1.17.6). Select the main face's middle point as the base point for the copy. (3.76 on page 2673)
44. Use the **Rotate** option of the command, rotate the rib **180** degrees around a vertical axis.
45. Use the **Mode** option of the command, to change the cutting mode to **No cut** and insert the rib symmetrically with the edge midpoint as the insertion point. (3.77 on page 2674)
46. Use the Rotate (6.12.24) () of the **Model** section of the Quad (2.3.3).
47. Rotate side faces by an angle of **15**. (3.78 on page 2676)

48. With nothing selected, right-click to call the Quad (2.3.3). Select Show Entities (6.30.7) ( ) from the **General** section of the Quad (2.3.3).
49. Using the Select Depression (6.12.28) ( ) tool from **Solid | Select** panel of the Ribbon (1.17.6), select the depression and two holes as show below.(3.79 on page 2677)
50. Click the CopyFaces (6.12.12) ( ) tool button on **Solid | Edit** panel of the Ribbon (1.17.6). Select the midpoint of the left vertical edge of the back face of the old crown. Set the insertion point to the midpoint of the left vertical edge of the back face of the new crown.(3.80 on page 2678)
51. Select Erase (6.13.8) ( ) from the **Modify** section of the Quad (2.3.3). Delete the old crown.
52. Save file **Crown_new.dwg**.
53. Switch to the **Bucket_Assembly.dwg** file.
54. Select **Crown** in Mechanical Browser (3.3.2).
55. Click Replace all inserts (6.8.31) ( ) in the right click menu and select the **Crown_new.dwg** file to use as a replacement.

3.2.9 Ball bearing creating

https://www.youtube-nocookie.com/embed/Yz8R88LeETI

3.2.10 Step 1. Preparing for the exercise

You need a **BricsCAD Platinum** license for this tutorial.

1. Create a new file in the **Mechanical** workspace.
2. Make sure that the **UCS orthographic** option in the Settings (6.27.25) dialog is switched on (the UCSORTHO system variable is 1). (3.333 on page 2969)
3. Set the **Facet resolution** option in the Settings (6.27.25) dialog (FACETRES system variable) to **3**.
4. Make sure that the Quad (2.3.3) cursor menu is active.
5. Select the **Solid** panel of the Ribbon (1.17.6). (3.86 on the next page)

Figure 3.85

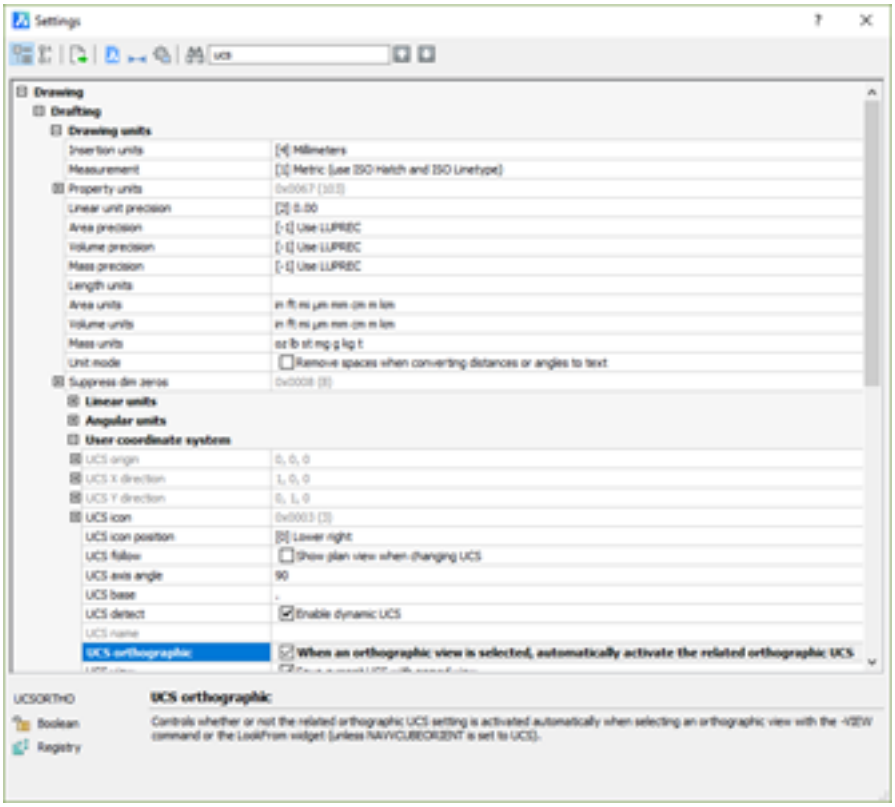

Figure 3.86

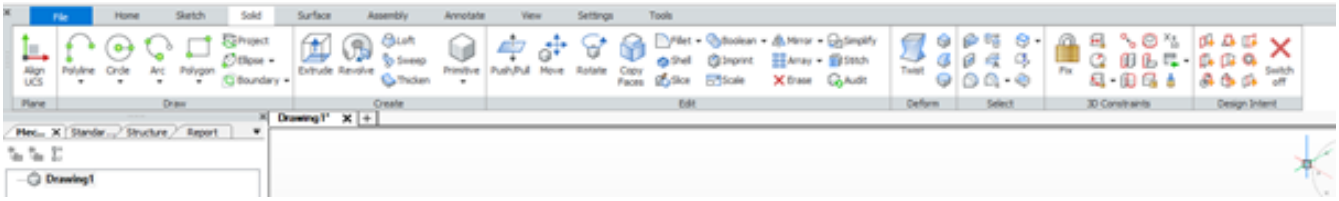

3.2.11 Step 2. Design external and internal rings without grooves

1. Click the **Cylinder (6.9.49)** ( ) tool button on the **Solid | Create** panel in the Ribbon (1.17.6). Set **0,0,-15** as the center point, **115** as the radius, and **30** as the height. (3.87 on the following page)
2. Select the upper edge of the cylinder.
3. Select **Offset (6.23.3)** ( ) from the **Draw** section of the Quad (2.3.3).
4. Enter a distance of **10** and hit **Enter**.
5. Hover over the circle.
6. Select **Solid Extrude (6.12.14)** ( ) from the **Model** section of the Quad (2.3.3). Move the mouse in a negative direction. Extrude until the through-hole appears. (3.88 on the next page)
7. Select the upper internal edge.
8. Select **Offset (6.23.3)** ( ) from the **Draw** section of the Quad (2.3.3).
9. Enter a distance of **10** and hit **Enter**.
10. Select the circle.
11. Select **Solid Extrude (6.12.14)** ( ) from the **Model** section of the Quad (2.3.3).
12. Move the mouse in a negative direction. Enter a distance of **30** and hit **Enter**. (3.89 on page 2687)
13. Select the upper edge of the internal solid.
14. Select **Offset (6.23.3)** ( ) from the **Draw** section of the Quad (2.3.3).
15. Enter a distance of **10**, click **Enter**.
16. Select the circle you just created.
17. Select **Solid Extrude (6.12.14)** ( ) from the **Model** section of the Quad (2.3.3).
18. Move the mouse in a negative direction. Extrude until the through-hole appears (you should now have two rings). (3.90 on page 2687)
19. Select the outer ring.
20. In the **Properties Panel (1.15.4)** click the **Color** field and change the value to **Cyan.** (3.91 on page 2688)
21. Repeat steps 19 and 20 to change the color of the inner ring to **Green**. (3.92 on page 2688)

Figure 3.87

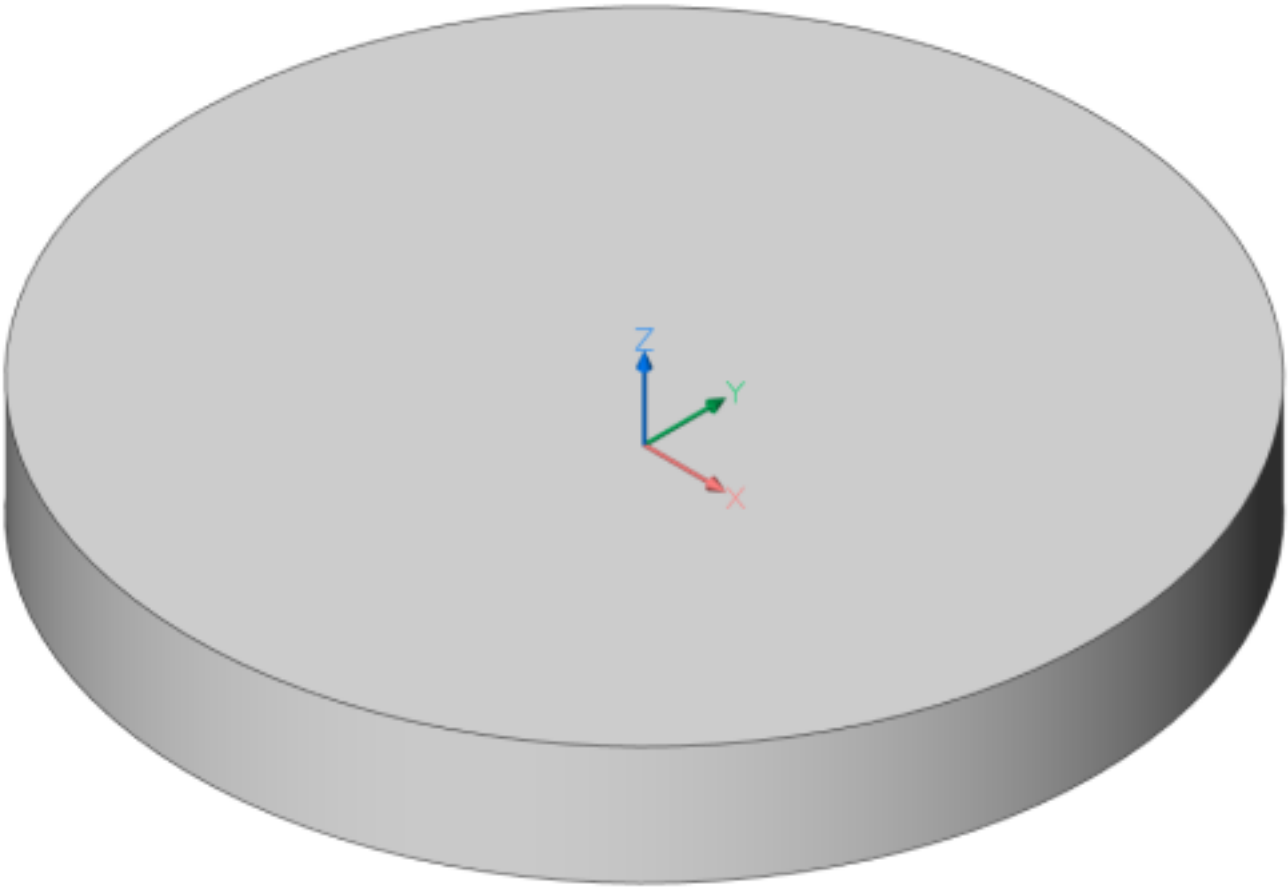

Figure 3.88

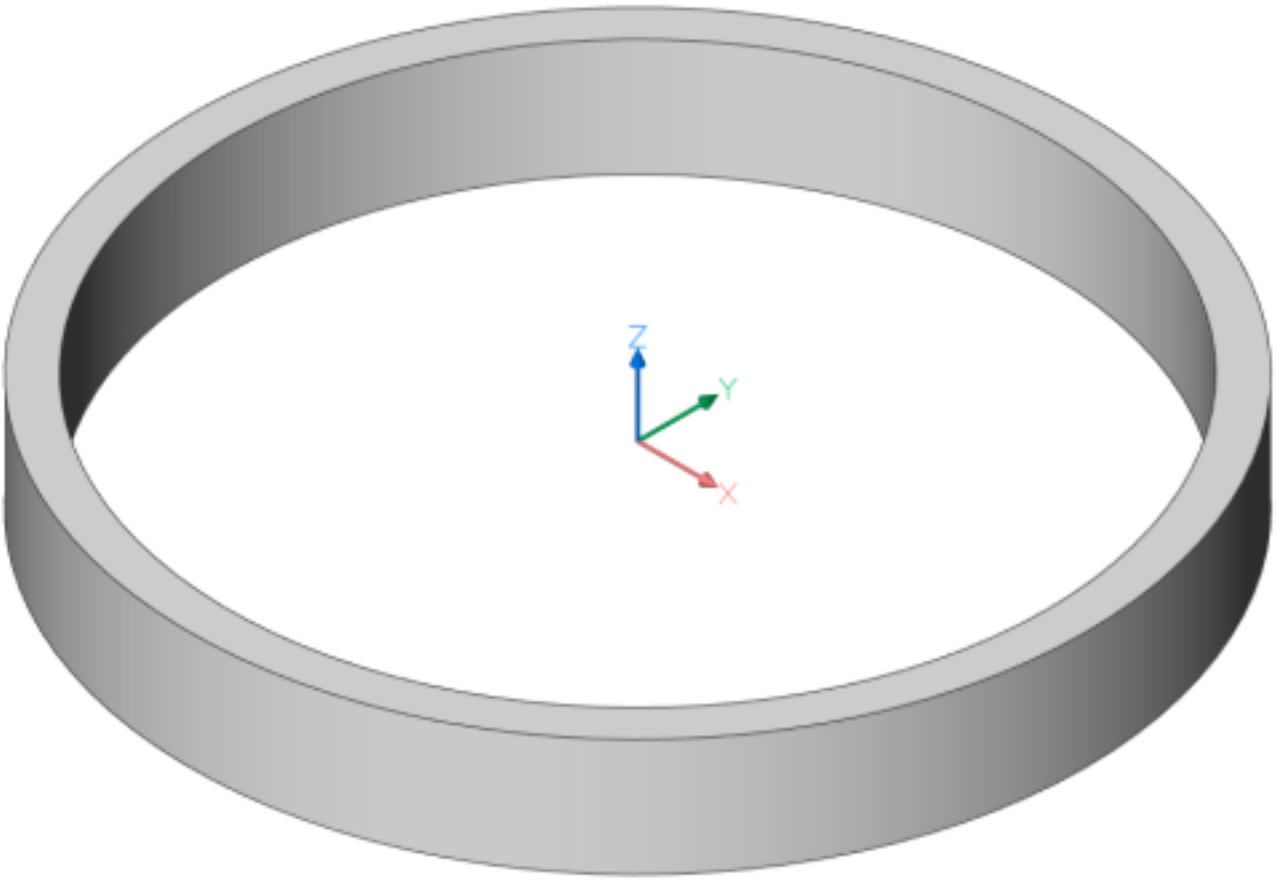

Figure 3.89

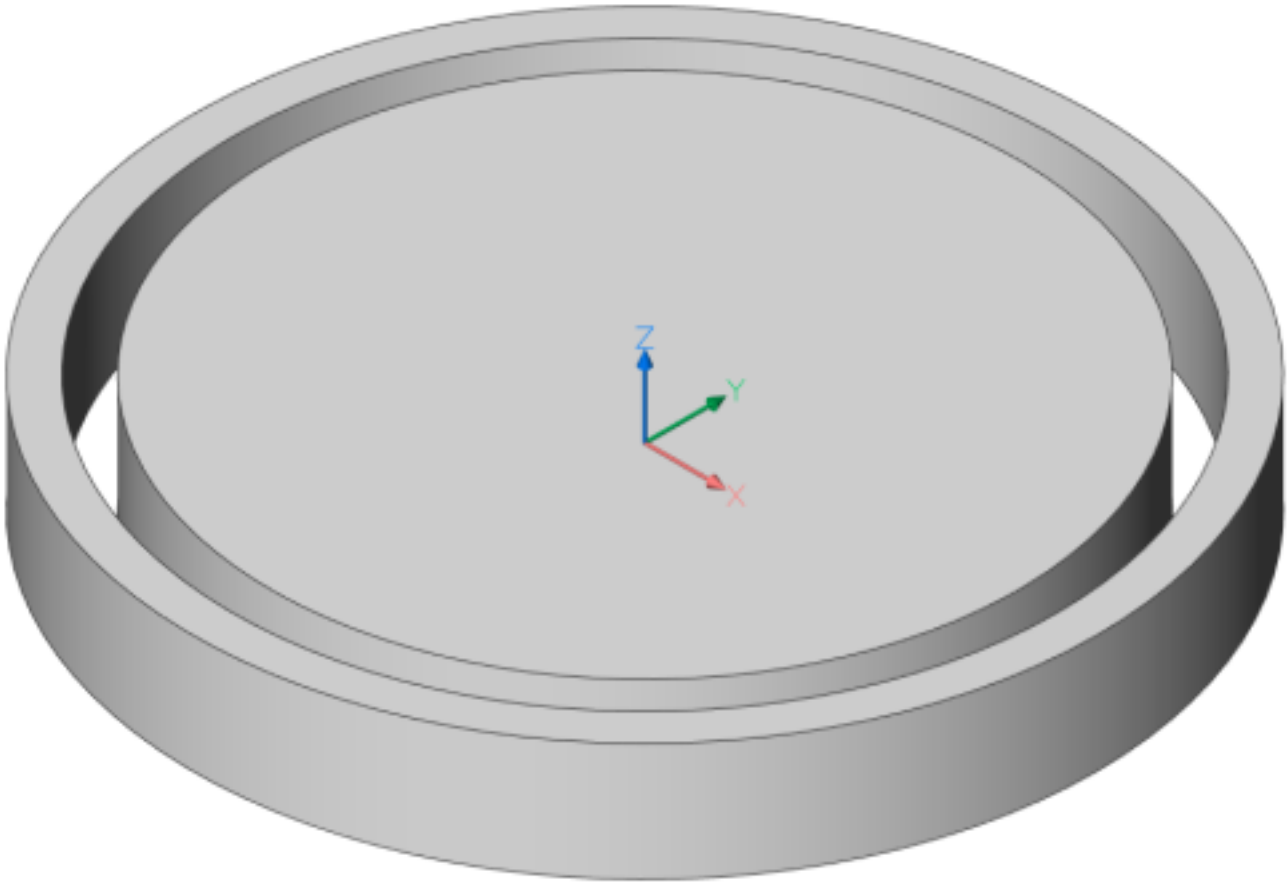

Figure 3.90

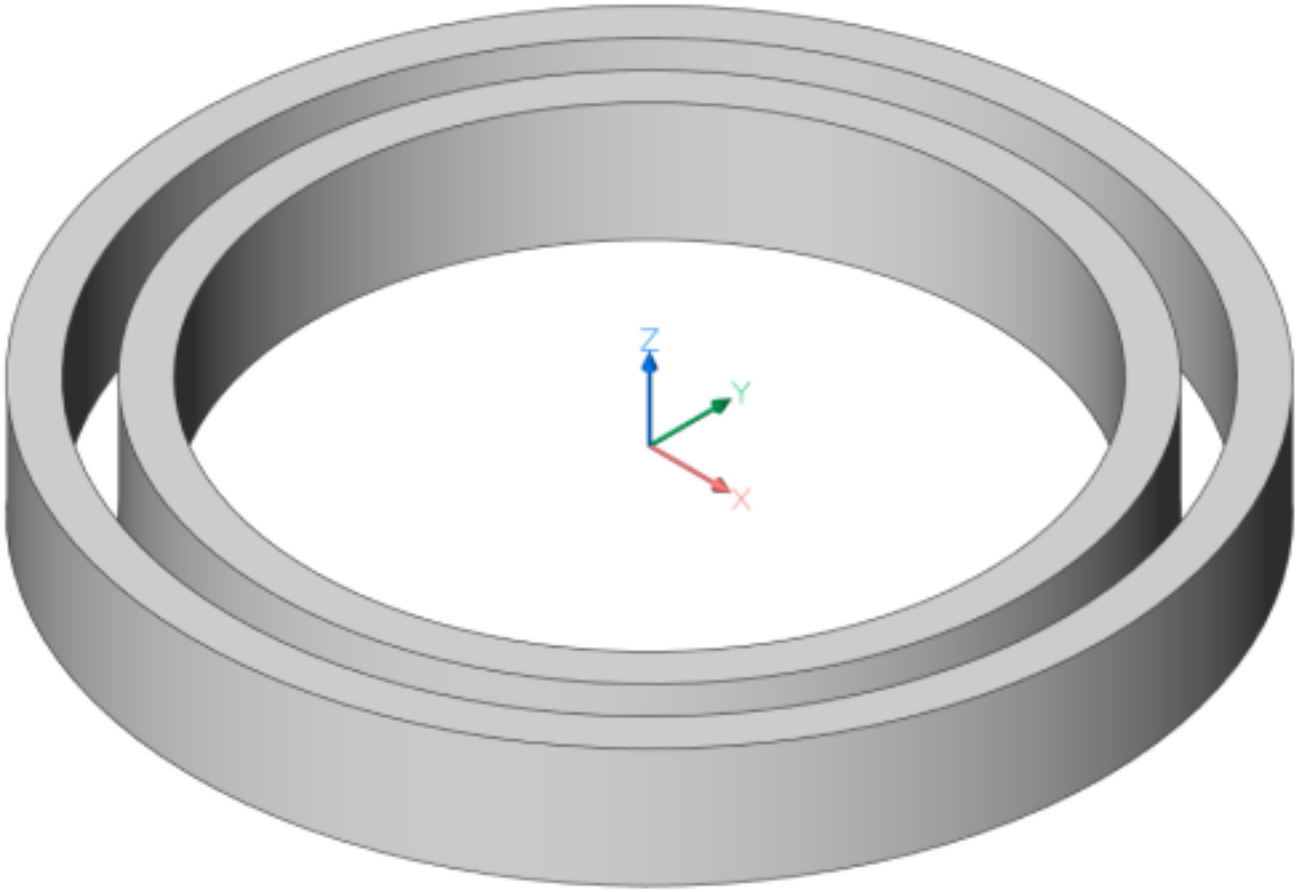

Figure 3.91

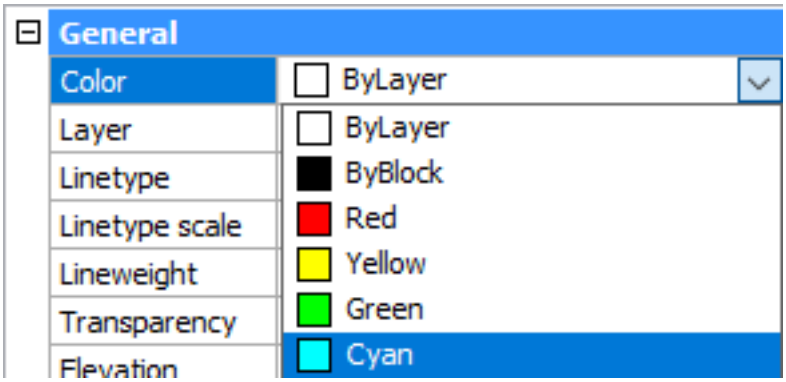

Figure 3.92

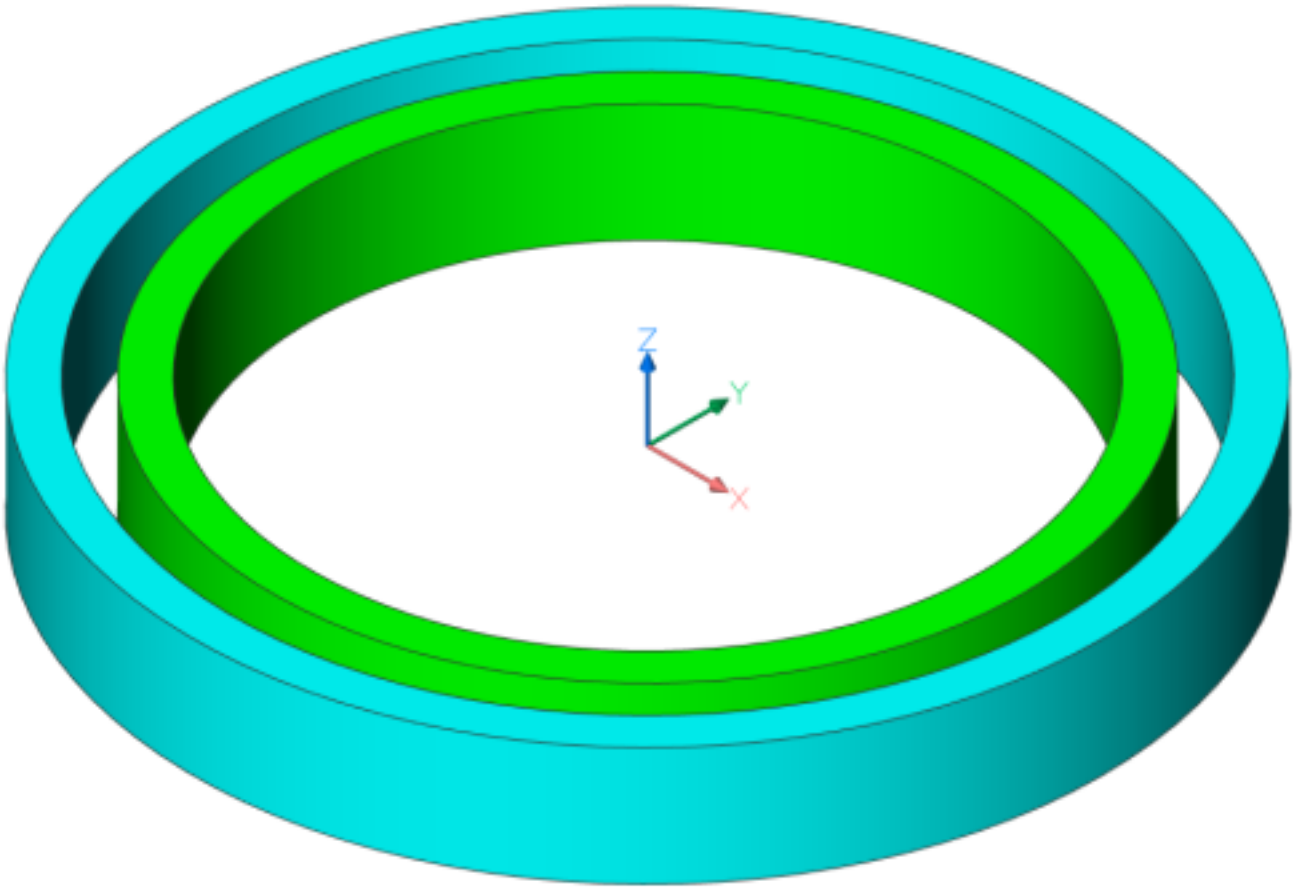

3.2.12 Step 3. Make both rings parametric

1. Call the context menu (right-click menu) on **Drawing*** component in the Mechanical Browser (3.3.2). Click the **Add new parameter (6.24.6)** ( ) button.
2. Select the new parameter (**v***) in the Mechanical Browser (3.3.2). In the bottom part of the Mechanical Browser (3.3.2), click the **Name** field and rename the parameter: **Bore.**
3. In the bottom part of the Mechanical Browser (3.3.2), click the **Expression** field and change parameter value to **170**.
4. In the bottom part of the Mechanical Browser (3.3.2), click the **Units** field and change parameter value to **mm**.
(3.93)
5. Repeat steps 3.1-3.4 to create the other parameters:
   - **OutsideDiameter = 230 mm**;
   - **OverallWidth = 30 mm**;
   - **Cover = (OutsideDiameter-Bore)/6**.

(3.94 on the next page)

Figure 3.93

Parameter	
Name	Bore
Expression	170
Value	170
Description	
Exposed	Auto
Units	mm

6. Select the inside cylinder of the internal ring and select **Radius constraint (6.12.22)** ( ) from the **Constrain** section of the Quad (2.3.3)**.** Enter **Bore/2** as the parameter value.
7. Select the outside cylinder of the internal ring and select **Radius constraint (6.12.22)** ( ) from the **Constrain** section of the Quad (2.3.3). Enter **Bore/2+Cover** as the parameter value.
8. Select the inside cylinder of the external ring and select **Radius constraint (6.12.22)** ( ) from the **Constrain** section of the Quad (2.3.3). Enter **OutsideDiameter/2-Cover** as the parameter value.
9. Select the outside cylinder of the external ring and select **Radius constraint (6.12.22)** ( ) from the **Constrain** section of the Quad (2.3.3)**.** Enter **OutsideDiameter/2** as the parameter value.
10. Select the top planar faces of the internal and external rings and click the **Coincident constraint (6.12.5)** ( ) button tool in the **Solid | 3D constraints** panel of the Ribbon (1.17.6).
11. Select the bottom planar faces of the internal and external rings and click the **Coincident constraint (6.12.5)** ( ) button tool in the **Solid | 3D constraints** panel of the Ribbon (1.17.6).
12. Select the horizontal faces of the external ring.
13. Select **Distance constraint (6.12.10)** ( ) from the **Constrain** section of the Quad (2.3.3)**.** Enter **OverallWidth** as the parameter value.
14. Select the **Distance constraint (6.12.10)** ( ) button tool in the **Solid | 3D constraints** panel of the Ribbon (1.17.6).
15. Select the top planar face of the external ring.
16. Click the **World | XY plane** buttons in the **Prompt menu**.
17. Enter **OverallWidth/2** as the parameter value. (3.95 on the facing page)
18. Change the **Bore**, **OutsideDiameter**, and **OverallWidth** parameters to make sure they work.

Figure 3.94

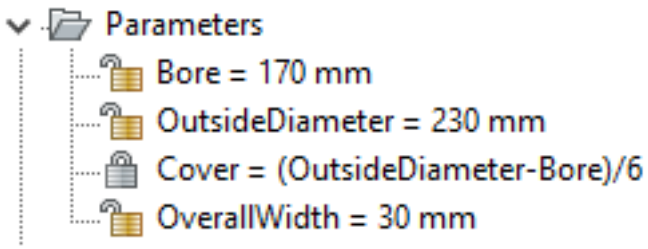

Figure 3.95

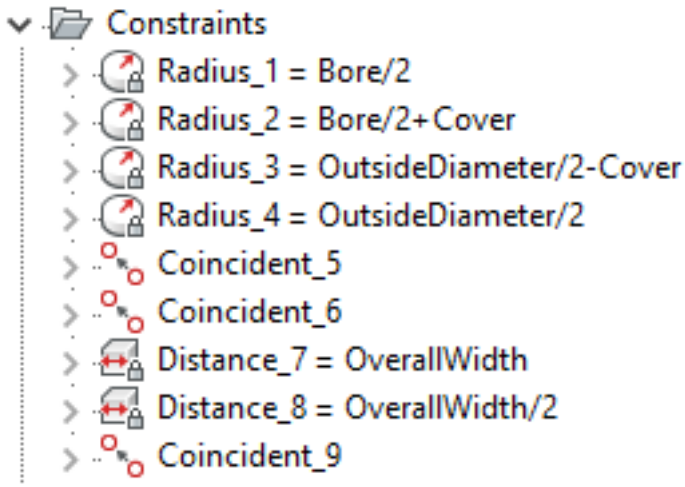

3.2.13 Step 4. Add parametric groves to rings

1. Switch to **Right** view in the LookFrom (6.20.41) widget by clicking the right triangle.
2. Select **Circle (6.9.12)** ( ) from the **Draw** section of the Quad (2.3.3). Set **100,0,0** as a center point. Set a radius value of **10** and hit **Enter**.
3. Switch to **TopFrontRight** view in the LookFrom (6.20.41) widget to restore the vertical orientation of the Z-axis. (3.96 on the next page)
4. Hover over the **circle.** Select **Revolve (6.12.21)** ( ) from the Quad (2.3.3)**.** Enter a rotation angle of **360°,** on the Z-axis. Use the **Subtract** option. (3.97 on the following page)
5. Select the torus faces of the external and internal rings and click the **Coincident constraint (6.12.5)** ( ) button tool in the **Solid | 3D constraints** panel of the Ribbon (1.17.6).
6. Enable the **Equal radius (1.26.3)** ( ) option from the **Solid | Design Intent** panel in the Ribbon (1.17.6).
7. Repeat steps 3.1-3.4 to create a new parameter: **BallDiameter = 20 mm.**
8. Repeat step 3.6 to create a **Tube radius constraint** on the torus faces of the external and internal rings. Enter expressions of **BallDiameter/2**.
9. Hover over the torus face of the external ring and select **Radius constraint (6.12.22)** ( ) from the **Constrain** section of the Quad (2.3.3)**.**
10. Select the **Rotation radius** option in **Prompt menu.**
11. Select the new Rotation radius constraint (**RotationRadius_***) in the Mechanical Browser (3.3.2). In the bottom part of the Mechanical Browser (3.3.2), click the **Expression** field and change the parameter value to **(Bore+OutsideDiameter)/4.**
12. Repeat steps 4.9-4.12 to create a **Rotation radius constraint** on the torus faces of the internal ring. Enter expressions of **(Bore+OutsideDiameter)/4**. (3.98 on page 2693)
13. Change **Bore**, **OutsideDiameter, OverallWidth,** and **BallDiameter** parameters to make sure they work.

Figure 3.96

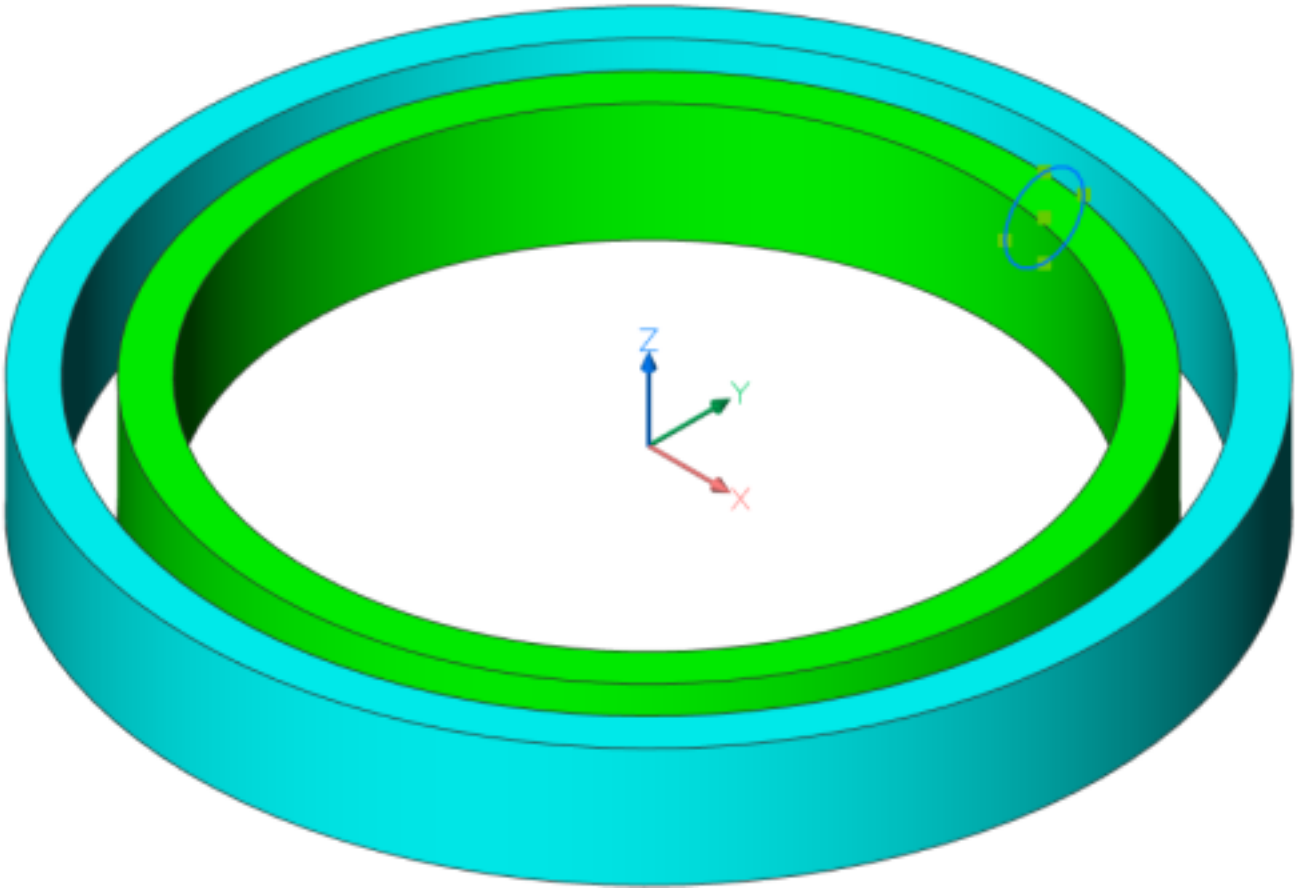

Figure 3.97

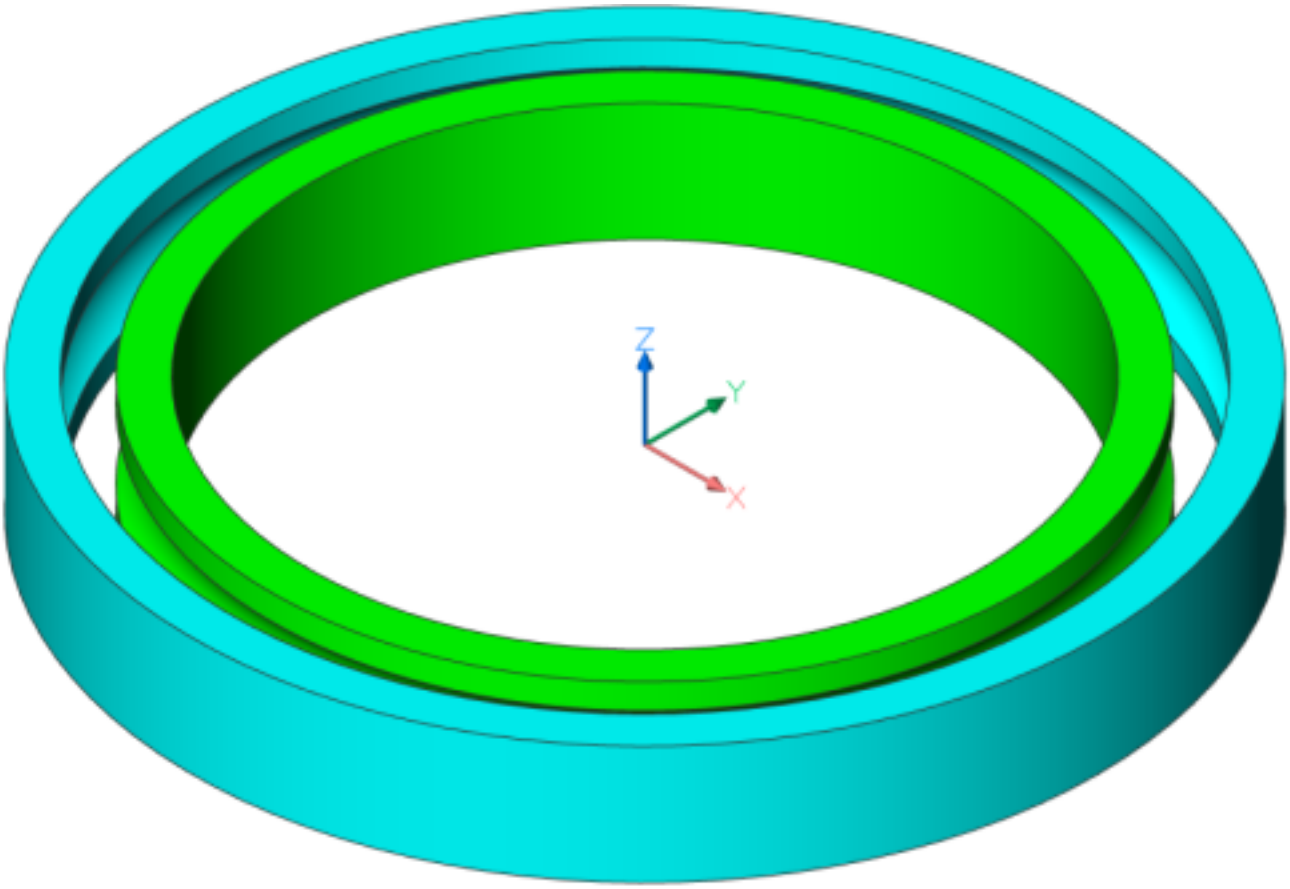

Figure 3.98

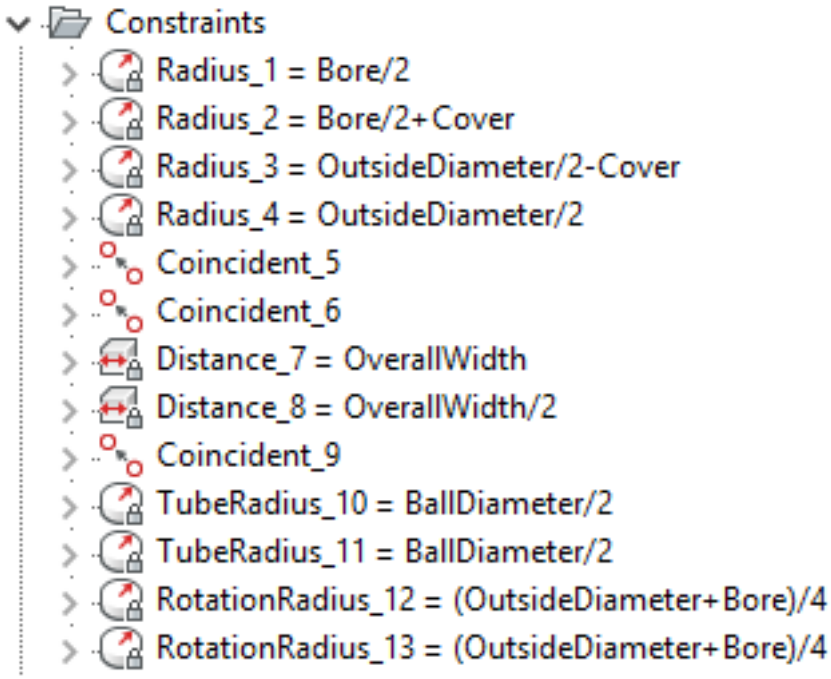

3.2.14 Step 5. Add balls

1. Click the **Sphere (6.27.50)** ( ) button in the **Solid | Create** panel of the Ribbon (1.17.6). Set the center point to **100,0,0**, the radius to **10** and hit **Enter**.
2. Select the sphere you just created.
3. In the **Properties Panel** click the **Color** field and change the value to **Red. (3.99 on the following page)**
4. Select **Radius constraint (6.12.22)** ( ) from the **Constrain** section of the Quad (2.3.3). Enter an expression of **10.**
5. Select the sphere.
6. Click the **Polar Array (6.4.41)** ( ) button tool in the **Solid | Edit** panel of the Ribbon (1.17.6). Enter **0,0,0** as the center point.
7. Select **the radius constraint, inside the array,** in the Mechanical Browser (3.3.2) and enter an expression of **BallDiameter/2**.
8. Repeat steps 3.1-3.4 to create a new parameter: **NumberOfBalls = 6.**
9. Select array (**Polar_***) in the Mechanical Browser (3.3.2)**.** On the bottom part of the Mechanical Browser (3.3.2), click the **Radius** field and change the parameter value to **(OutsideDiameter+Bore)/4, Items=NumberOfBalls** and **Angle=360/NumberOfBalls.(3.100 on the next page)**
10. Change **Bore, OutsideDiameter, BallDiameter,** and **NumberOfBalls** parameters to make sure they work. (3.101 on page 2695)

Figure 3.99

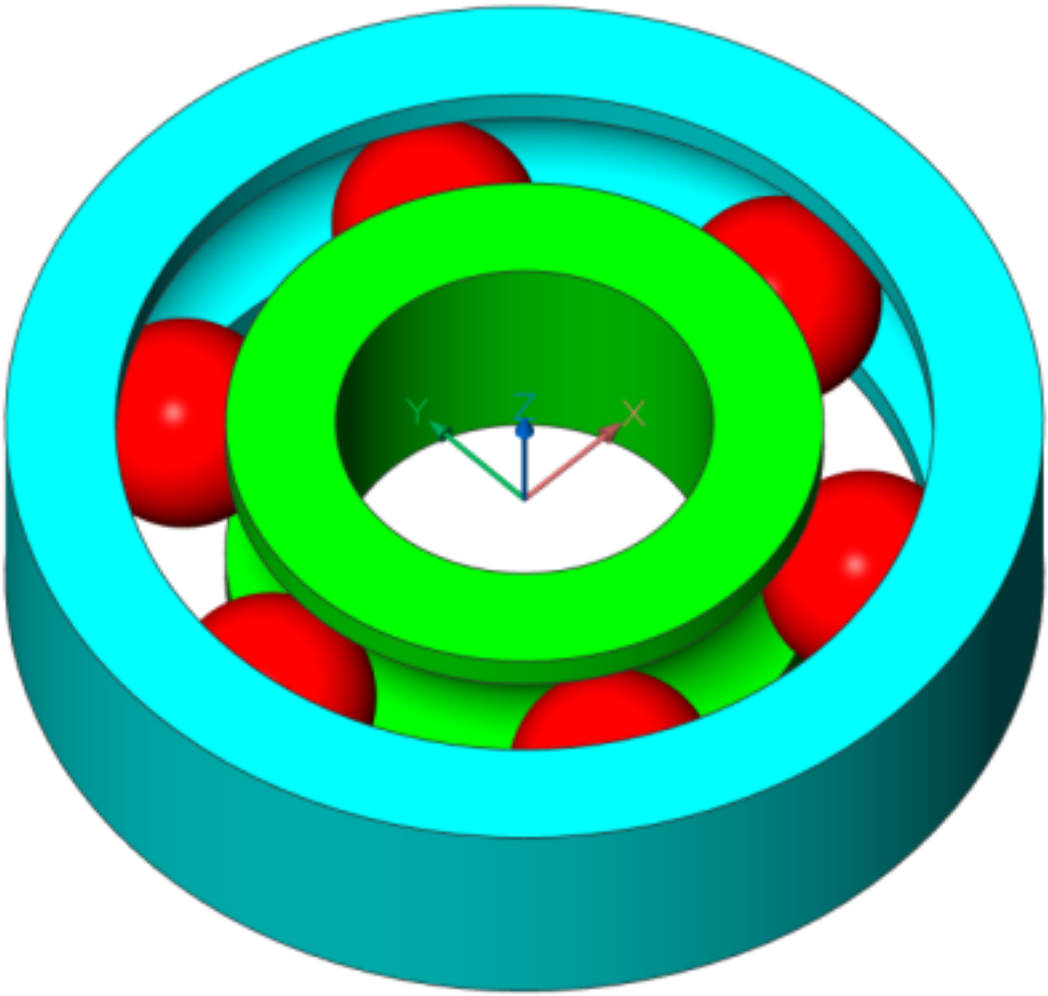
Figure 3.101



3.2.15 Step 6. Add design table

1. Open a BallBearing.xlsx table as a native table using a spreadsheet program. Export it to BallBearing.csv file.
2. Click the **DesignTable (6.10.31)** ( ) button in the **Solid | 3D constraints** panel of the Ribbon (1.17.6) and select the BallBearing.csv file.
3. Select the **Type** parameter in the Mechanical Browser (3.3.2) and select an arbitrary configuration from the drop-down list. (3.102 on the next page)
4. Select **Bore** and **OutsideDimeter** parameters in Mechanical Browser (3.3.2) and set **Exposed** properties to **On** for each of them. (3.103 on the facing page)
5. Save as **ball_bearing.dwg** file.

Figure 3.102

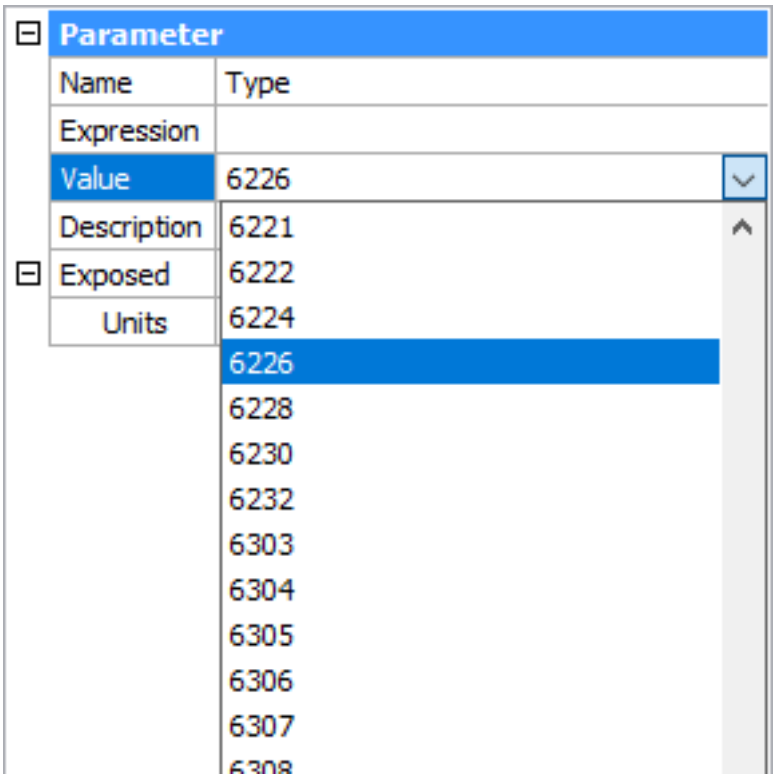


Figure 3.103

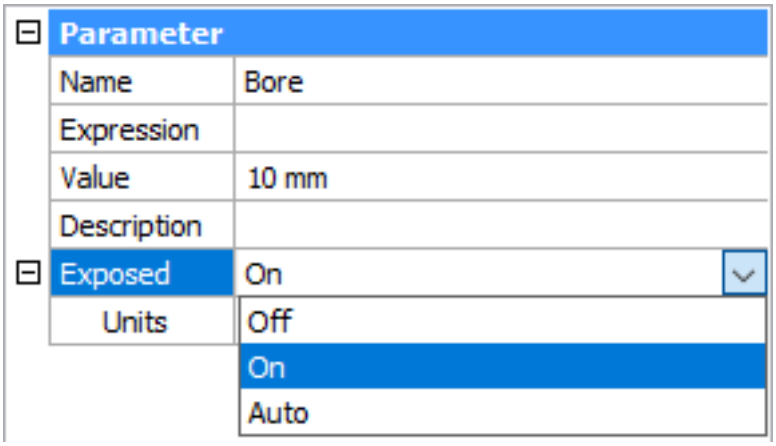

3.2.16 Step 7. Insert the bearing in an assembly

1. Open the Bearing_support_110.dwg file.
2. Click the **Insert Component (6.8.16)** ( ) button tool on the **Assembly | Modify** panel of the Ribbon (1.17.6) and select the ball_bearing.dwg file.
3. Repeat step 3.10 to set the bearing of the axle the correct position using the **Coincident constraint (6.12.5)** ( ).
4. Select the **ball bearing** in the Mechanical Browser (3.3.2). Use the drop-down list for the parameters **Bore** and **OutsideDiameter.** Set an appropriate value for one of them and then repeat for the other.

NOTE	The bearing type is changed automatically.

(3.104 on the next page)

3.3.2 Mechanical Browser panel

Commands: MECHANICALBROWSEROPEN (6.8.32), MECHANICALBROWSERCLOSE. (6.8.36) The Mechanical Browser panel displays the hierarchy of components (3.7.3), features (3.9.3), arrays (3.7.12), parameters (1.27.7) and constraints (1.27.4) for the current drawing in a tree structure. You can expand each node to display its child nodes (for example nested components). The Mechanical Browser allows you to edit the properties of a particular node, which display at the bottom of the panel. (3.107 on the facing page) In the Mechanical Browser panel you can:

- Click an item to highlight the geometry drawing.
- Click an item to edit its name.
- Right-click an item and launch a command in a context menu.
- Edit the properties of a selected item.
- Group 3D constraints and features by entity (), group elements by type (), and sort them alphabetically ().
- Use the **Settings** icon () to control how expressions and parameters display.
- Search the entire tree using the search tool ().

Opening the Mechanical Browser

Do one of the following:

- Launch the MECHANICALBROWSEROPEN (6.8.32) command.
- Place the cursor on a toolbar, right-click and choose **Mechanical Browser** in the context menu. (3.108 on the next page)

Tool	Description
Group by Entity	Groups 3d constraints by entity or by mechanical component. (3.109 on page 2708)
Group by Type	Groups mechanical components and 3d constraints in separate trees. Expand a constraint to see the affected 3D features. (3.110 on page 2709)
Sort Alphabetically	When selected: the mechanical components and 3d constraints are sorted alphabetically. Otherwise, the mechanical components and 3d constraints are listed in the order they were added to the assembly.
Settings for visual representation of parameters	**Expressions of Constraints**: controls whether the numeric value or the assigned parameter name displays. **Components Parameters**: expressions at sub-components control the visual representation of sub-component parameters: numeric value or assigned parameter name. **Expressions of Components Parameters**: sub-component parameters control the visibility of sub-component parameters. **Subcomponents of Standard Parts**: parameters at properties add a parameters section for the selected instance to the Mechanical Browser properties.
Search field	Click the icon to type a search string. Use the Up and Down arrow buttons to go to the next or previous matching item.

3.3.3 3D Comparison

Command: 3DCOMPARE (6.3.3) You can compare two 3D models, i.e. 3D solids and surfaces stored in two .dwg files, including models imported in BricsCAD from other file formats. The tool efficiently processes large models and reports the differences in the Mechanical Browser (3.3.2). Several visualization modes are supported.

Definitions

A 3D model is a .dwg file with one or more 3D solids or surfaces. When comparing two 3D models, BricsCAD first tries to automatically align them in 3D space to obtain the maximal similarity. Next, all faces of these 3D solids and surfaces are compared geometrically with a given tolerance. If for every face in the first file an equal face in the second file exists and vice versa, such models are considered as equal. However, if for a particular face in one file there is no equal face found in another file, or if only part of this face is equal to a part of a face in the other file, a difference is detected. Therefore, a difference is a full face or a part of a face of a 3D solid or a surface, for which there are no equal parts of full faces found in the other file. Two or more differences are grouped together if they are geometrically adjacent to each other. A difference node is created in Mechanical Browser (3.3.2) for every group of adjacent differences. If you expand this node, you can see the particular differences it consists of. When you select the difference in the Mechanical Browser (3.3.2), the corresponding feature is highlighted in the drawing. (3.111 on the facing page)

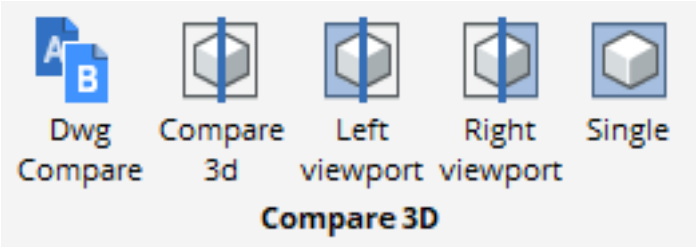
You can access the 3D Comparison procedure by using the tools on the **Compare 3D** ribbon panel on the **Tools** ribbon tab. (3.112)

Figure 3.112



Visualization

The 3DCOMPARE (6.3.3) command creates a new .dwg document named **Compare_<File_1>_<File_2>.dwg**. The compared models are attached as external references to this drawing, A special layout named **Comparison** is created automatically with two viewports, one for each drawing, illustrating the differences between the drawings using colors. (3.113 on the following page) The display is controlled through the 3DCOMPAREMODE (1.17.10) system variable. If the value of 3DCOMPAREMODE (1.17.10) is different from 0 (zero), the corresponding model becomes semi-transparent, while the differences are displayed using different colors (each difference is painted in its individual color). You can zoom in on a particular difference using the Mechanical Browser (3.3.2) context menu. To display the differences, do one of the following:

- Click the **Left Viewport** ( ) and/or the **Right Viewport** ( ) tool button. (3.114 on page 2715) Double-click in one of the viewports and use the mouse/keyboard shortcuts to manipulate the display (for example, zoom in/out or rotate). The display in the other viewport is synchronized automatically, allowing the user to compare the same part in both models in detail.
- Click the **Single** ( ) tool button to see the differences in model space. (3.115 on page 2715)

3.4 Assembly Design - Workflows

3.4.1 How to work with standard parts

https://www.youtube-nocookie.com/embed/lw4tjfFo6cg

Using standard parts in combination with direct modeling in BricsCAD BricsCAD comes with a rich library of more than 30,000 standard parts. In this short movie we will show you how these parts can be used. To access the library, select the corresponding tab in the Mechanical Browser (3.3.2) window. Here you can search for a specific part. Select the standard part. Then, you can see the preview and set the size and length of the part you want to insert. Insert the part by dragging it to a desired position using snapping and dynamic dimensions.

> You can create complex models very easily and rapidly. Use a rich library of standard parts in combination with direct modeling technology.

Back to Tutorial Overview

3.4.2 Introduction to standard parts

https://www.youtube-nocookie.com/embed/CptV_DLk2y8

If you are looking for an affordable 3D mechanical design software with a rich set of standard parts included, then BricsCAD is your right choice.

To access the library of standard parts, open the Mechanical Browser (3.3.2) panel. Then click on the “Library” tab. You can choose between 13 different standards, including ANSI, DIN, and ISO. All the parts are grouped into categories. Expand a category to see its content. To insert the selected standard part into your model, just drag it from the library and drop it in the drawing area. You can use dynamic dimensions and snapping to position the part precisely. For many parts you can also specify the length. If you are looking for an affordable 3D mechanical design software with a rich set of standard parts included, then BricsCAD is your right choice. Back to Tutorial Overview

3.4.3 Solve inverse kinematic problems in real time

https://www.youtube-nocookie.com/embed/zWj3mZ3bkvI

Kinematic Analysis

If you move the car door, you see how the robot follows it's movement. What you are seeing here is called inverse kinematics of a mechanism. This is a typical inverse problem: we know the result – how our door should be moved, but we don't know how to obtain this result – how the robot should move its platform, shoulder, arm, hand and head to reach the desired position for the door. BricsCAD is able to solve this inverse kinematic problem in real time. Our robot has five degrees of freedom and all of them are used to find the position for the door.

The constraints force other components to rotate correspondingly.

(3.116 on the next page) Back to Tutorial Overview

Figure 3.116

3.4.4 Using mass properties in BricsCAD

https://www.youtube-nocookie.com/embed/2n7tlzIbMMw With BricsCAD you can create assemblies of parts with different densities. In this video we'll show you how to design a self-balancing wine bottle holder by using assembly mass properties calculations and 3D constraints. Alternatively, we can simply use Mass Properties to output information on our selection to the text screen. Here you see the combined mass and volume of the selected objects, along with the center of mass, and moments of inertia. You are even given the option to align your UCS with the equilibrium point. To find the equilibrium point for the self-balancing wine holder, simply draw a line from the center of the holder to the center of mass of the assembly. This line represents the normal direction of force caused by gravity relative to the top of our table. To orientate our wine holder to its balance point, we simply have to apply a perpendicular constraint.

A self-balancing wine bottle holder created with BricsCAD Platinum, using assembly mass properties calculations and 3D constraints.

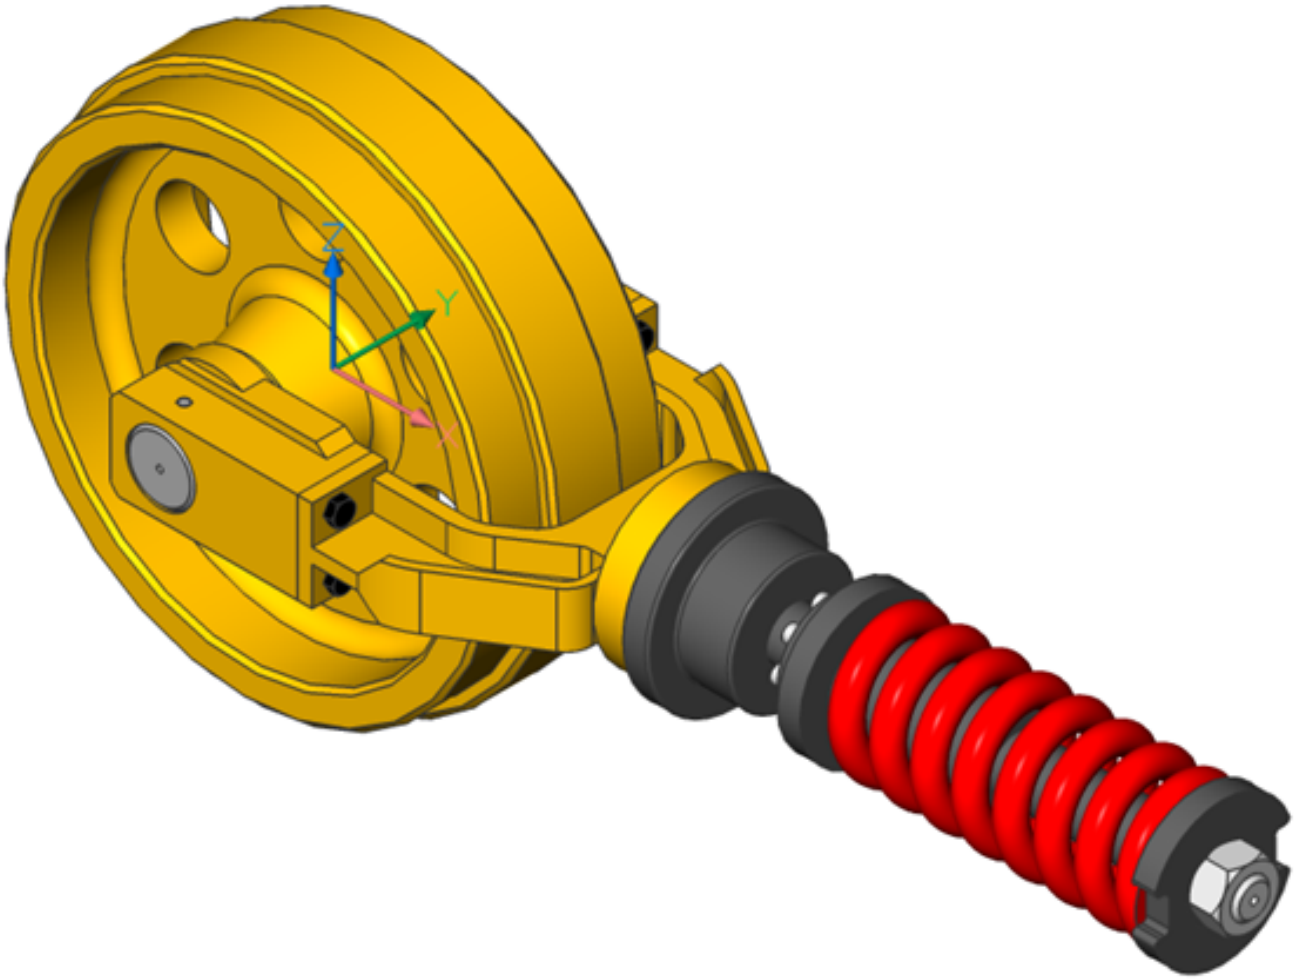
Figure 3.117



3.4.5 Exploded view of assembly

https://www.youtube-nocookie.com/embed/9DcLaHFkwR8 You need a **BricsCAD** Platinum and **Mechanical** licenses for this tutorial.

1. Open the Front_Idler_Assembly.dwg file. (3.117)
2. Click the **Explode (6.8.10)** ( ) tool button on the **Tools** panel of the **Assembly** tab on the Ribbon (1.17.6).
3. Select the **Settings, Bottom** option to create an exploded view to the bottom level of all components.
4. Click the **Linear** options on the **BmExplode** Prompt menu to create an exploded representation of assemblies in a given direction.
5. Select **X-axis** on **BmExplode** Prompt menu as the direction.
6. Enter **3000** in dynamic dimension as the distance. (3.118 on the next page)
7. To edit, click the **Edit** option on the **BmExplode** Prompt menu to open the exploded representation.
8. Select the 4 **DIN 933** bolts. (3.119 on the following page)
9. Select **Move (6.12.16)** ( ) from the **Model** section of the Quad (2.3.3), move the bolts **400** on the **X-axis**.
10. Select the **Linear_Bottom_1** node in the Mechanical Browser (3.3.2).
11. Click **Add new step** from the context menu.
12. Select the 2 pins. (3.120 on page 2723)
13. Select **Move (6.12.16)** ( ) from the **Model** section of the Quad (2.3.3). Move all Pins **400** on the **Z-axis**.
14. Select the **Linear_Bottom_1** node in the Mechanical Browser (3.3.2).
15. Click **Add new step** from the context menu.
16. Select the **wheel** and related parts with Green Crossing Window Selection (1.32.7). (3.121 on page 2723)
17. Click the **Explode Move (6.8.12)** ( ) tool button on the **Tools** panel of the **Assembly** tab on the Ribbon (1.17.6).
18. Select the **wheel** as the base part.
19. Select **Y-axis** on **BmExplodeMove** Prompt menu as the direction.

3.4.6 Inverse and direct analysis of kinematics

https://www.youtube-nocookie.com/embed/mHl2u5rVl34 You need a **BricsCAD** Platinum and **Mechanical** licenses for this tutorial.

1. Open the **Excavator_Assembly.dwg** file: **Kinematic_analysis_inverse_and_direct_kinematics_files.zip**. (3.125)
2. Enable the **UCSOrtho** option in the Settings (6.27.25) dialog (the UCSORTHO system variable is 1). (3.333 on page 2969)

3. Switch to **Right** view with the LookFrom (6.20.41) widget.
4. Hover over the **Bucket.**
5. Click **Move (6.12.16)** ( ) in the **Model** section of the Quad (2.3.3).
6. Move the bucket-stick-boom and its pins up and left.
7. Hover over the **Upper_Platform_Assembly**. Click **Add Fixation (6.12.15)** ( ) from the **Constraint** section of the Quad (2.3.3).
8. Click the **Concentric constraint (6.12.8)** ( ) tool button on the **Assembly | 3D constraints** tab on the Ribbon (1.17.6).
9. Select the cylindrical faces of the **Boom** and of **Pin:1**. (3.127 on the facing page)
10. Hover over the **Bucket.**

Figure 3.126

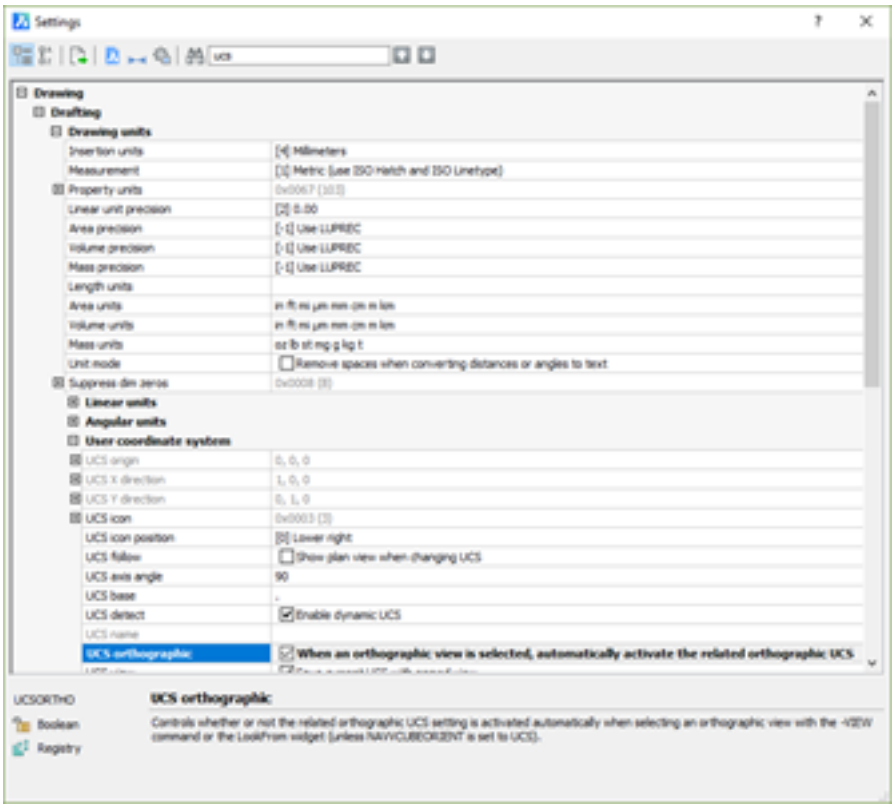

Figure 3.127

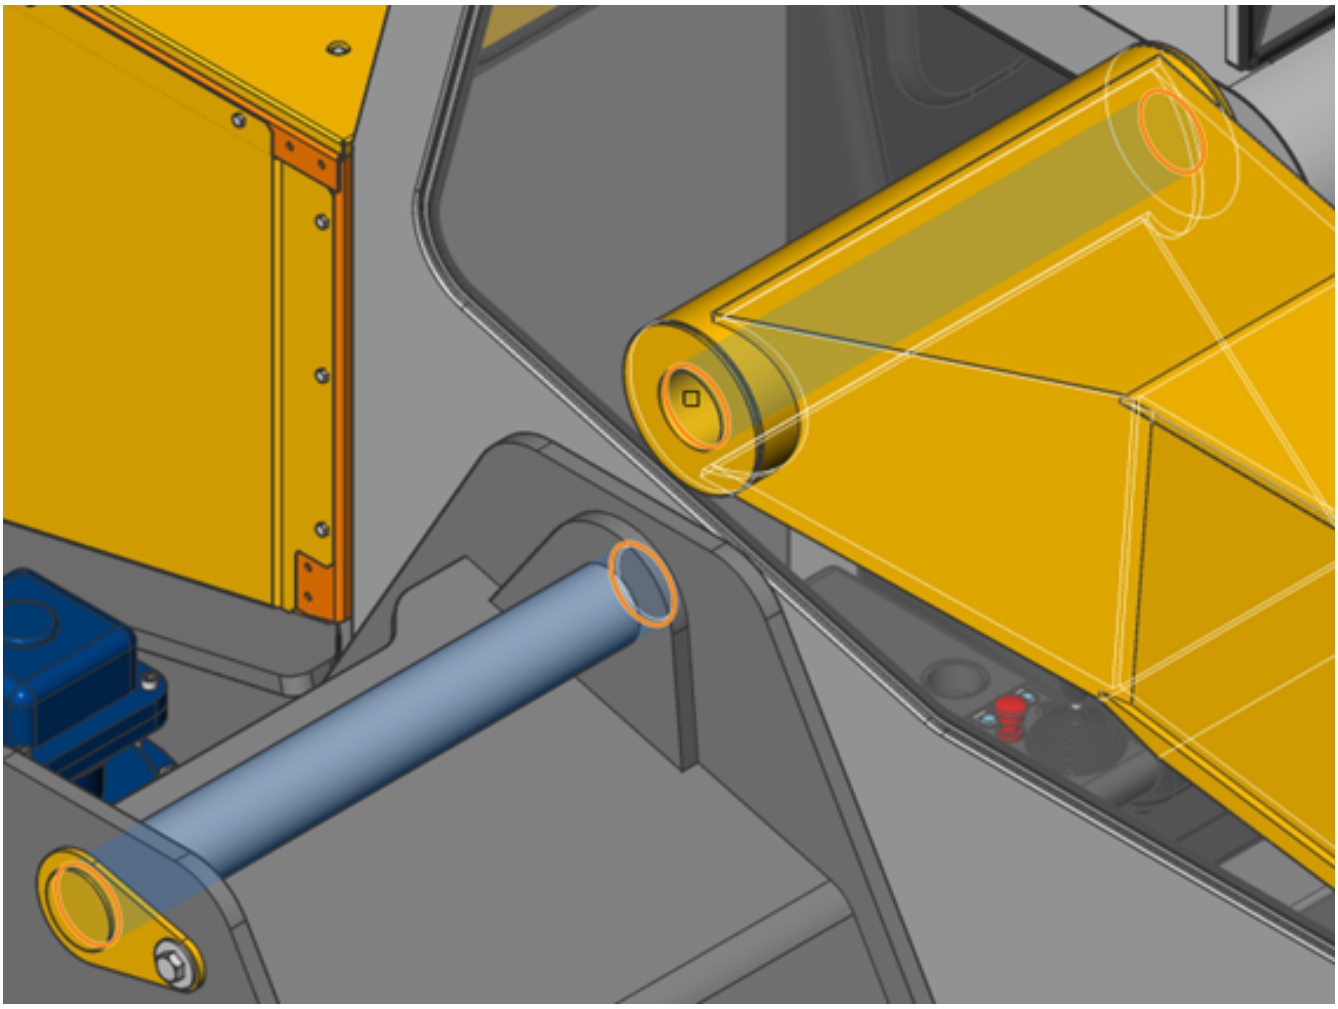

Figure 3.128

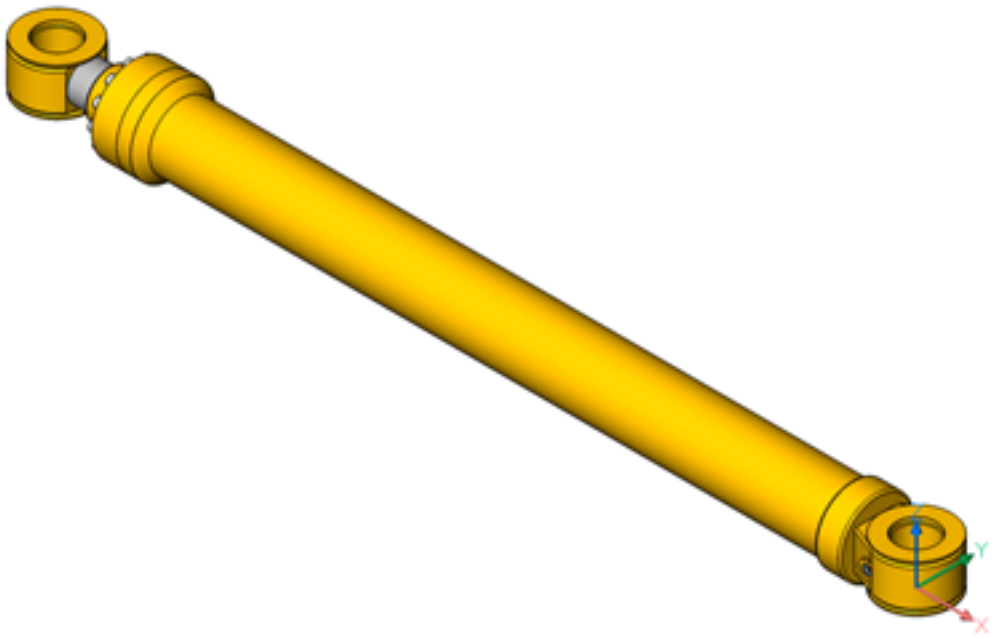

11. Click **Move (6.12.16)** ( ) from the **Model** section of the Quad (2.3.3) to see how the bucket moves with the new constraints. Hit ESC to cancel moving.
12. Open **Hydrailic_Cylinder_Assembly** with the Mechanical Browser (3.3.2). (3.128)
13. Hover over the **Cylinder.** Select **Add Fixation (6.12.15)** ( ) from the **Constraint** section of the Quad (2.3.3).
14. Use a Green Crossing Window Selection (1.32.7) and select the **Stock,** 2 **Washers,** and the **Pipe Plug. (3.129 on the facing page)**
15. Click **Add Rigid Set (6.12.23)** ( ) from the **Constraint** section of the Quad (2.3.3).
16. Call the context menu (right-click menu) on **Hydrailic_Cylinder_Assembly** component in the Mechanical Browser (3.3.2).
17. Click the **Add new parameter (6.24.6)** ( ) button.
18. Select the new parameter (**v1**) in the Mechanical Browser (3.3.2).
19. On the bottom part of the Mechanical Browser (3.3.2), click the **Name** field and rename the parameter to **Offset.**
20. In the bottom part of the Mechanical Browser (3.3.2), click the **Expression** field and change the parameter value to **0**.
21. Click the **Distance constraint (6.12.10)** ( ) tool button on the **Assembly | 3D constraints** panel on the Ribbon (1.17.6).
22. Select the cylindrical faces of the **Stock** and of the **Cylinder**. (3.130 on the next page)
23. Enter **2200+Offset** as the distance value.
24. Repeat step 20 to change the **Expression** of the **Offset** parameter to **500** on the bottom part of the Mechanical Browser (3.3.2). (3.131 on the facing page)
25. Click the **Animate** tool button in the context menu (right-click menu) of the **Offset** parameter in the Mechanical Browser (3.3.2) to make sure it works. (3.132 on page 2730)
26. Repeat step 20 to change the **Expression** of the **Offset** parameter to **0** on the bottom part of the Ribbon (1.17.6).
27. Click the **Save (6.27.1)** ( ) tool button on the **Home | File** panel on the Ribbon (1.17.6) to save the **Hydrailic_Cylinder_Assembly.dwg** file.
28. Switch to the **Excavator_Assembly.dwg** file.
29. Select **Hydrailic_Cylinder_Assembly** from the Mechanical Browser (3.3.2).
30. Click **Update (6.8.29)** ( ) on the context menu.
31. Select the **Offset** parameter of the **Hydrailic_Cylinder_Assembly:1** component on the Mechanical Browser (3.3.2).
32. Click **Link to parameter** in the context menu (right-click menu)

3.4.7 Mass properties and BOM

https://www.youtube-nocookie.com/embed/20N0Hsc0b_A You need **BricsCAD Platinum** and **Mechanical** licenses for this tutorial.

1. Open the **Excavator_Assembly.dwg** file from Excavator_Assembly.zip. (3.139)
2. Enable the **UCSOrtho** option in the Settings (6.27.25) dialog (the UCSORTHO system variable is 1). (3.333 on page 2969)
3. Click **Mass Properties (6.21.2)** ( ) on the **Assembly | Inquire** panel on the Ribbon (1.17.6).
4. Hit **Enter** to select the entire model.
5. Select the **Yes** option on the **BmMassProp** prompt menu to keep the UCS aligned with the principal moment axes. (3.141 on the facing page)
6. Change the **Expression** of the **Rotate_Angle** parameter to **90**.
7. Repeat steps 4-6 for different positions. (3.142 on page 2736) Make sure that, in all positions, the excavator is stable.
8. Switch to the **Top** view on the **LookFrom** widget to activate **World UCS**.
9. Click Bill of material (6.8.3) ( ) on the **Assembly | Inquire** panel on the Ribbon (1.17.6).
10. Select the **Configure, Material, Mass** options on the **BmBom** prompt menu.
11. Click **Back** on the **BmBom** prompt menu to return to the main menu.
12. Select the **Hierarchical** option on the **BmBom** prompt menu.
13. Set the insertion point. (3.143 on page 2736) (3.144 on page 2737)
14. Hover over the **BOM table** and click the Export table (6.29.4) ( ) tool button on the **Modify** section fo the Quad (1.15.5).
15. Save the file as **Hierarchical_BOM.csv.**
16. Open the **Hierarchical_BOM.csv** table as a native table with a spreadsheet software package. (3.145 on page 2738)

3.4.8 Assembly design using BricsCAD Communicator

Youtube The assembly design functions have been extended in BricsCAD V16. The BricsCAD communicator module enables CAD data exchange by providing import and export capabilities in various native and neutral file formats. Supported formats include neutral ones, such as STEP and IGES; native formats, such as CATIA, Inventor, and SolidWorks; and kernel formats, such as Parasolid. All editions of BricsCAD export drawings and models in ACIS, DWG, 2D PDF, and a variety of raster formats.

> **In V16 it's now possible to import not only the geometry, but also the product structure from other CAD assembly files.**

In this tutorial, we import a SolidWorks conveyor assembly into BricsCAD. In the settings panel, you can enable "import product structure". BricsCAD now generates the full assembly structure.

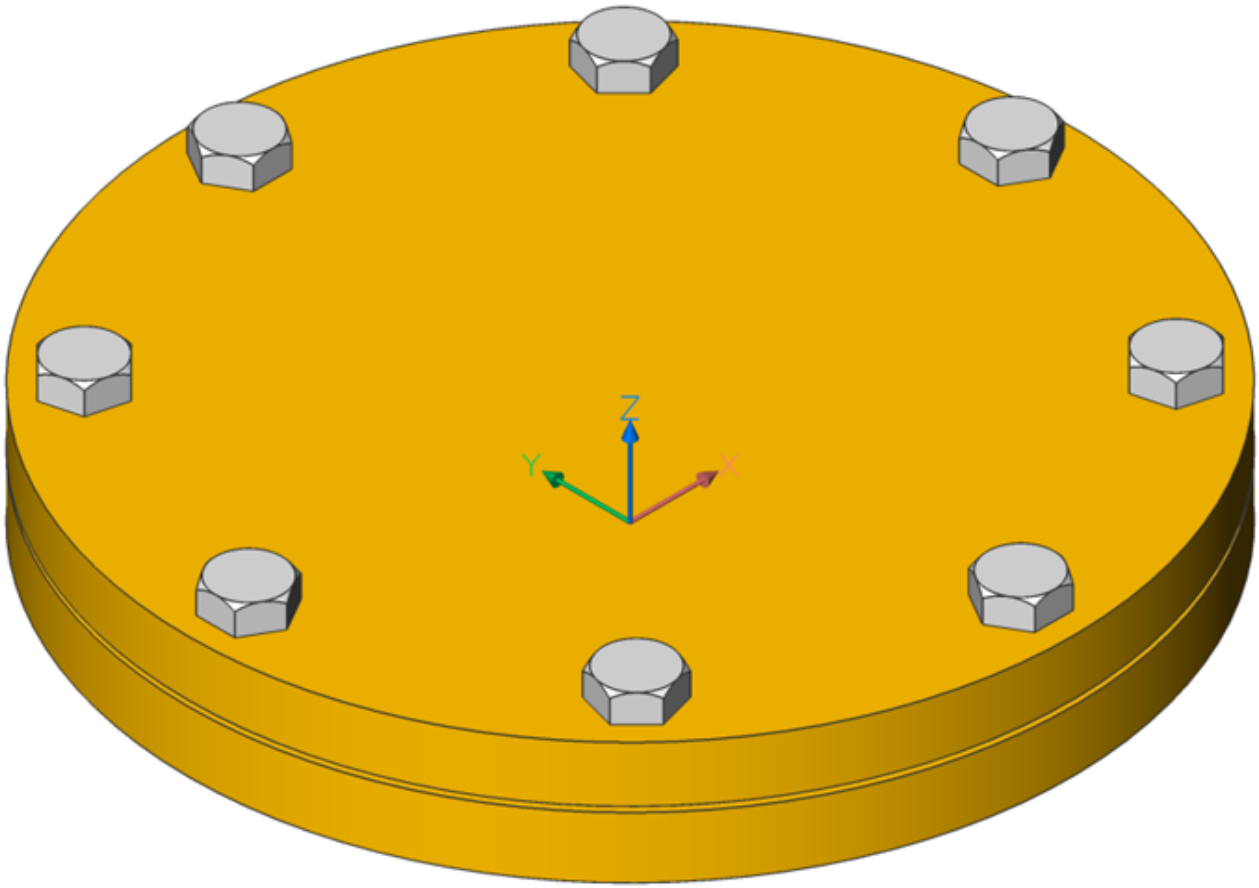
Import CAD assemblies including their product structure

You can navigate through the product structure using the Mechanical Browser (3.3.2). Imported parts and sub-assemblies are represented by local components. ===ERROR WITH DOWNLOADED IMAGE===

Copy local components into a new document using "open as a copy" The "Open as a copy" command allows you to copy a local component into a new document. Change the color of the part and add radius constraints to make this component parametric. After a modification the component can be saved.

Replace components The new "Replace component" function allows you to replace all inserted components with a modified one. Note that all components now have a parameter to control the roller radius. Create a new common parameter to control all these internal parameters simultaneously. All rollers are changed parametrically. By changing one parameter at the assembly level, you can automatically obtain different configurations of the model The "Replace component" function also takes into account the current values of components parameters. While replacing components BricsCAD automatically maintains the values and expressions specified for the assembly. Read more about BricsCAD Communicator Back to Tutorial Overview

Figure 3.146



3.4.9 Flange assembly creation

In this tutorial, you will learn how to create a flange assembly. (3.146)

3.4.10 Step 1. Prepare for the exercise

You need a **BricsCAD Platinum** license for this tutorial.

1. Create a new file in the **Mechanical** workspace.
2. Save the file as **Flange.dwg**.
3. Make sure that the Quad (2.3.3) cursor menu is active.

3.4.11 Step 2. Design a flange

1. Click the **Cylinder (6.9.49)** ( ) tool button on the **Home | Solid Editing** panel in the Ribbon (1.17.6). Set **0,0,0 -** as the center point, **70** as the radius and **16** as the height. (3.147 on the facing page)
2. Select the upper edge of the cylinder.
3. Select **Offset (6.23.3)** ( ) from the **Draw** section of the Quad (2.3.3).
4. Enter a distance of **25** and hit **Enter**.
5. Hover over the circle.
6. Select **Solid Extrude (6.12.14)** ( ) from the **Model** section of the Quad (2.3.3). Move the mouse downwards. Extrude until the through-hole appears.

(3.148 on the next page)

Figure 3.147

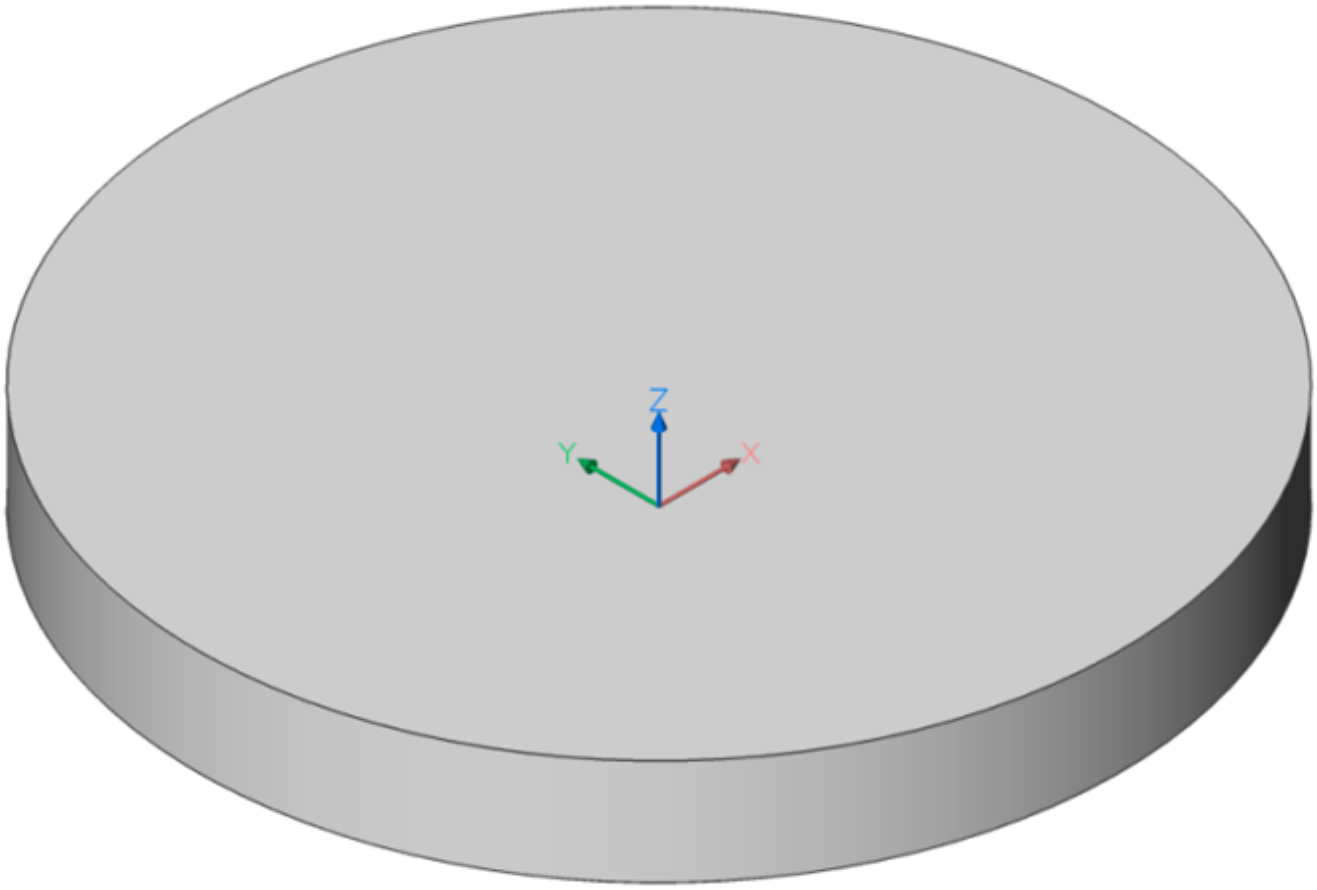


Figure 3.148

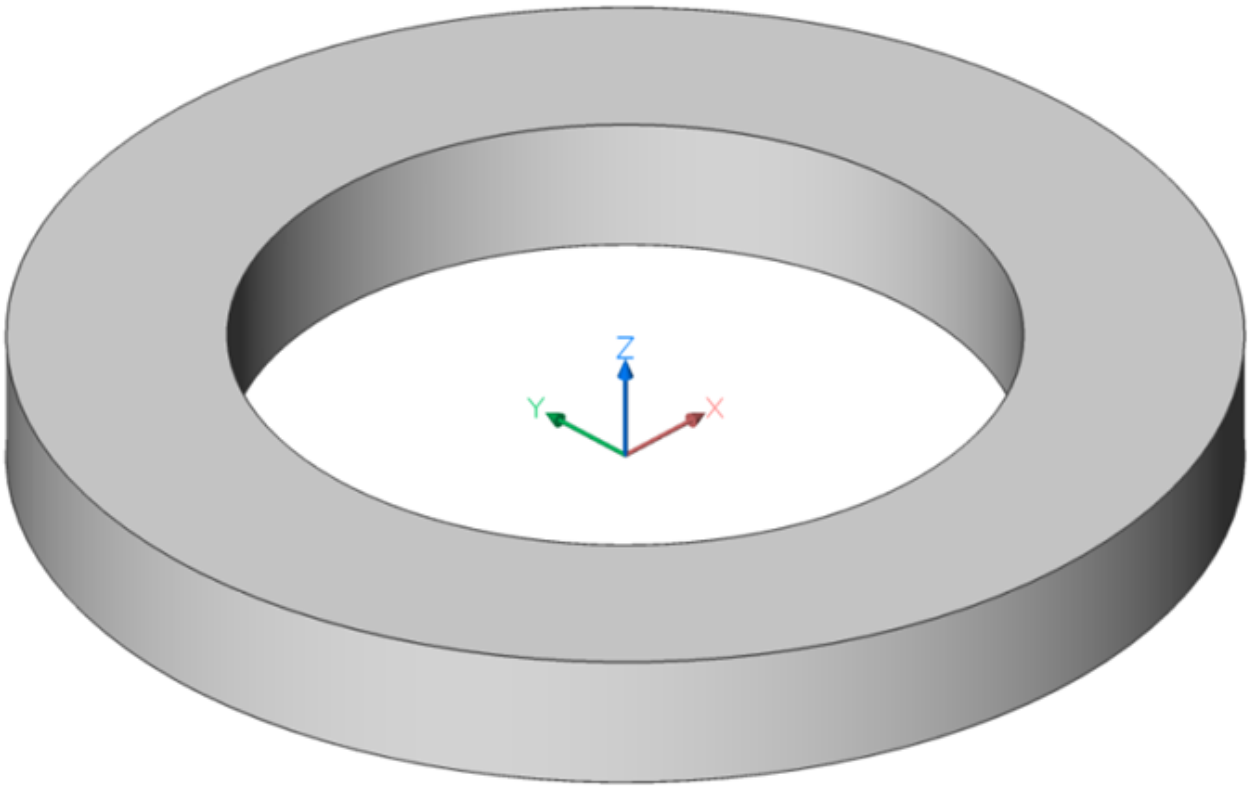


3.4.12 Step 3. Make a flange parametric

1. Click the **User parameter (6.24.6)** ( ) tool button on the **Home | Solid Editing** panel in the Ribbon (1.17.6).
2. Select the new parameter (**v***) in the Mechanical Browser (3.3.2). In the bottom part of the Mechanical Browser (3.3.2), click the **Name** field and rename the parameter: **D** – overall diameter**.**
3. In the bottom part of the Mechanical Browser (3.3.2), click the **Expression** field and change the parameter value to **140**.
4. In the bottom part of the Mechanical Browser (3.3.2), click the **Units** field and change the parameter value to **mm**. (3.149)

5. Repeat steps 3.1-3.4 to create the other parameters:

- **d5 = 58.1 mm** – internal diameter;
- **b = 16 mm** – flange thickness.

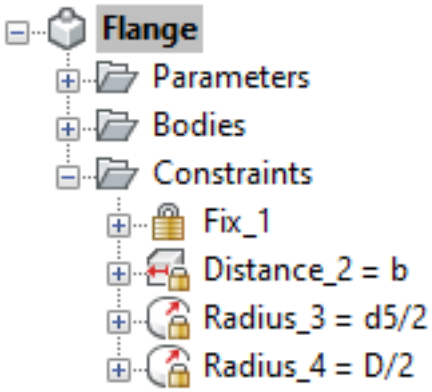
6. Hover over the bottom horizontal face of the flange. Select **Add Fixation (6.12.15)** ( ) from the **Constraint** section of the Quad (2.3.3).
7. Select the horizontal faces of the flange.
8. Select the **Distance constraint (6.12.10)** ( ) from the **Constrain** section of the Quad (2.3.3)**.** Enter **b** as the parameter value.
9. Select the inside cylinder face and select **Radius constraint (6.12.22)** ( ) from the **Constraint** section of the Quad (2.3.3)**.** Enter **d5/2** as the parameter value.
10. Select the outside cylinder face and select **Radius constraint (6.12.22)** ( ) from the **Constraint** section of the Quad (2.3.3). Enter **D/2** as the parameter value.

(3.150 on the next page)

Figure 3.149

Parameter	
Name	D
Expression	
Value	140
Description	
Exposed	Auto
Units	mm

Figure 3.150



3.4.13 Step 4. Add parametric holes to a flange

1. Insert a **Hole** on **top** face from **Home | Holes** section of the Components (6.9.26) panel at coordinate point **55,0.** (**3.151 on the following page**)
2. Select **Hole:1 | Diameter** parameter in the Mechanical Browser (3.3.2), click **Link to parameter** from the **Context menu**.
3. In the bottom part of the Mechanical Browser (3.3.2), change the **Diameter** parameter value to **mm**.
4. Select **Hole:1 | Depth** parameter in the Mechanical Browser. Enter **b** as the parameter expression.
5. Select the **Diameter** parameter the Mechanical Browser (3.3.2), hit “F2” and enter **Thread=12** to rename parameter.
6. Select the **Hole** component.
7. Click the **Polar Array (6.4.41)** ( ) button tool in the **Home | Modify** panel of the Ribbon (1.17.6). Select the center point of the top face as the center point.
8. Select the **Distance constraint (6.12.10)** ( ) button tool in the **Home | Parametrize** panel of the Ribbon (1.17.6).
9. Select the top planar face of the flange.
10. Click the **Block** buttons in the **Prompt menu, select the array block, click the XY plane** button in the **Prompt menu**.
11. Select **Distance_5** constraint in the Mechanical Browser (3.3.2), in the bottom part of the Mechanical Browser (3.3.2), click the **Exposed** field and change parameter value to **Off**. (3.152 on the next page)
12. Repeat steps 3.1-3.4 to create new parameters:
    - **N = 4** – number of holes;
    - **K = 110 mm** – hole diameter.
13. Select array (**Polar:1**) in the Mechanical Browser (3.3.2). On the bottom part of the Mechanical Browser (3.3.2), click the **Radius** field and change the parameter value to **K/2**, **Items=N**, and **Angle=360/N**. (3.153 on page 2745)
14. In the **Layers** drop-down menu on the **Access3D** toolbar, select layer **“BC_SUBTRACT”** and click **Off**. (3.154 on page 2745) (3.155 on page 2747)

Figure 3.151

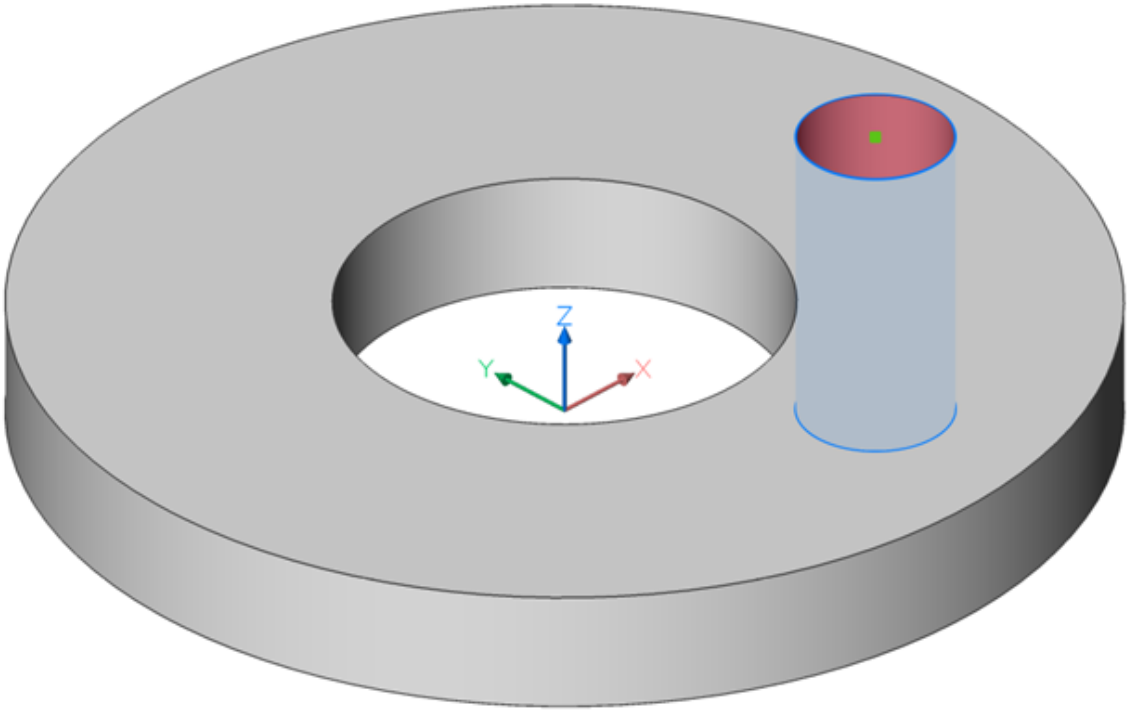


Figure 3.152

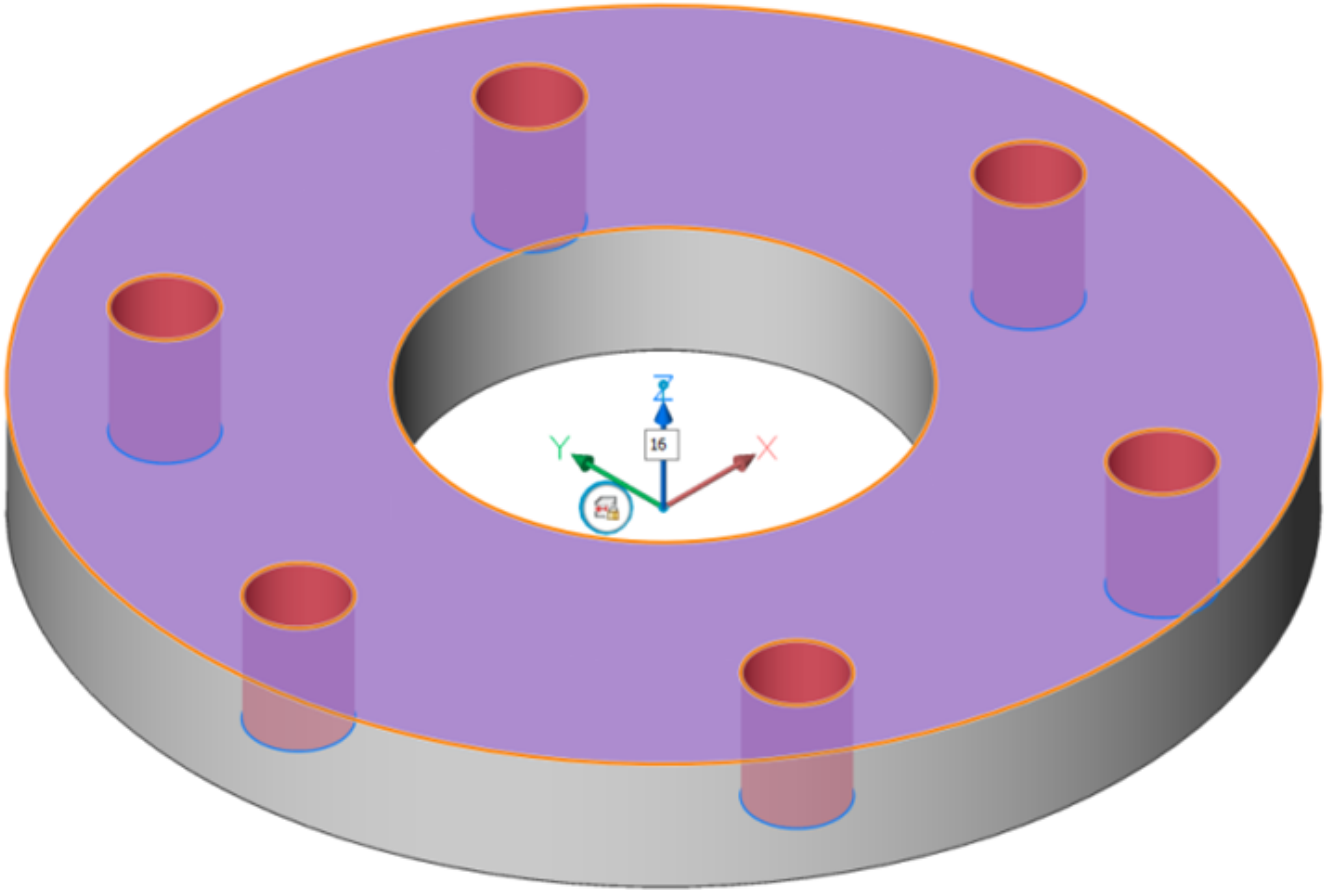

Figure 3.153

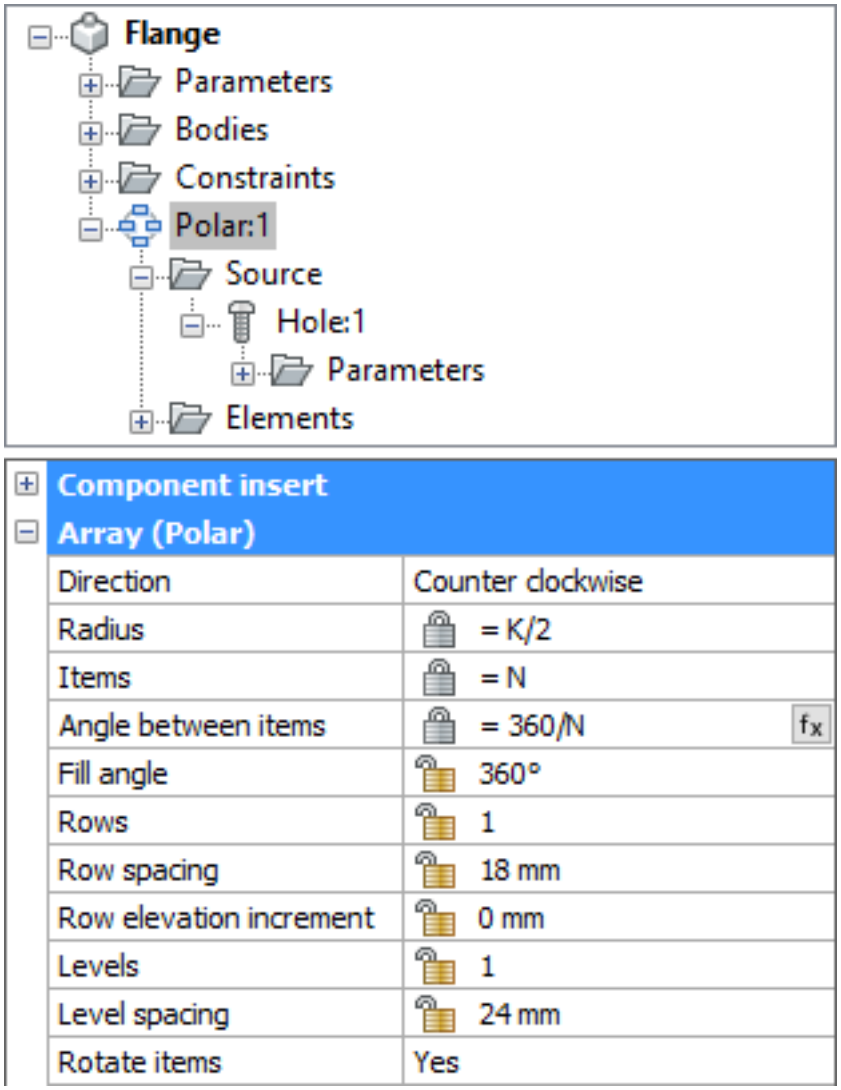

Figure 3.154

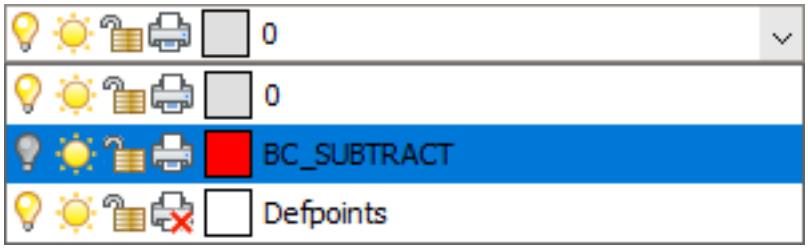

15. Select the flange.
16. In the Properties Panel (1.15.4) click the **Color** field and change the value to **"By block".** This is to enable color change via the assembly properties**.** **(3.156 on the next page)**

Figure 3.155

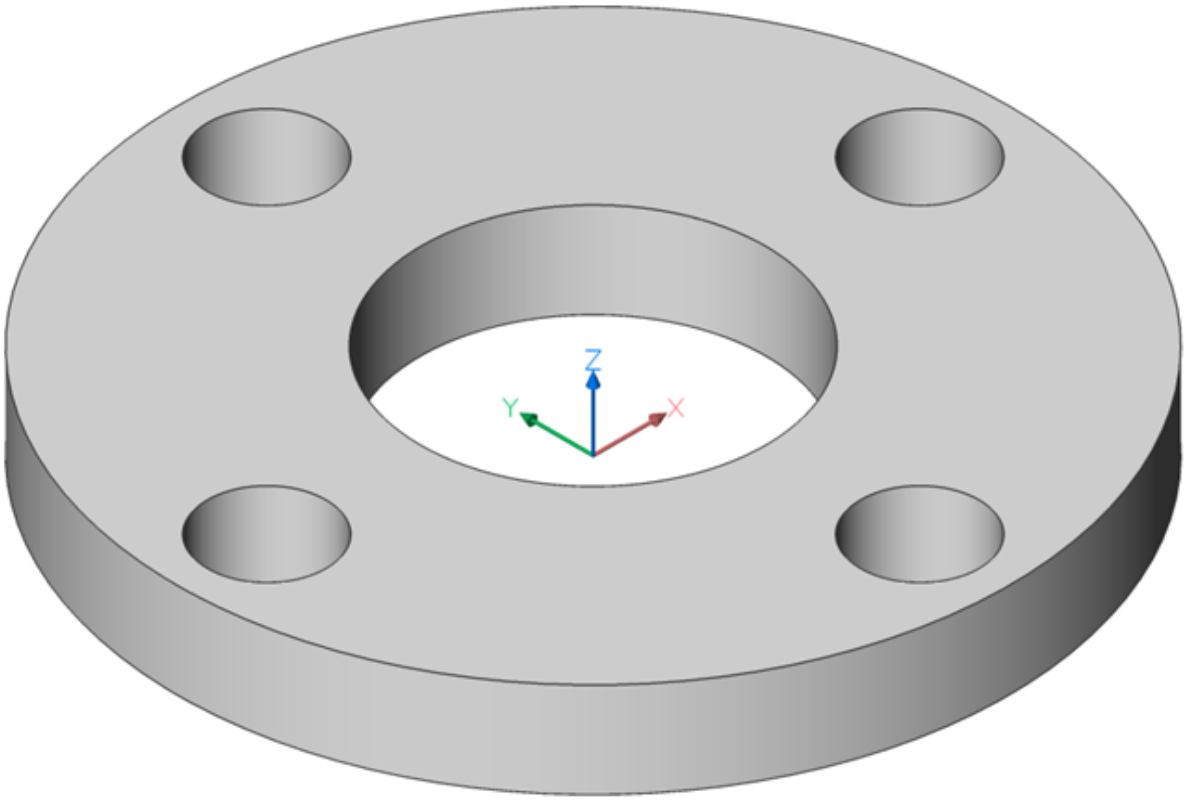

Figure 3.156

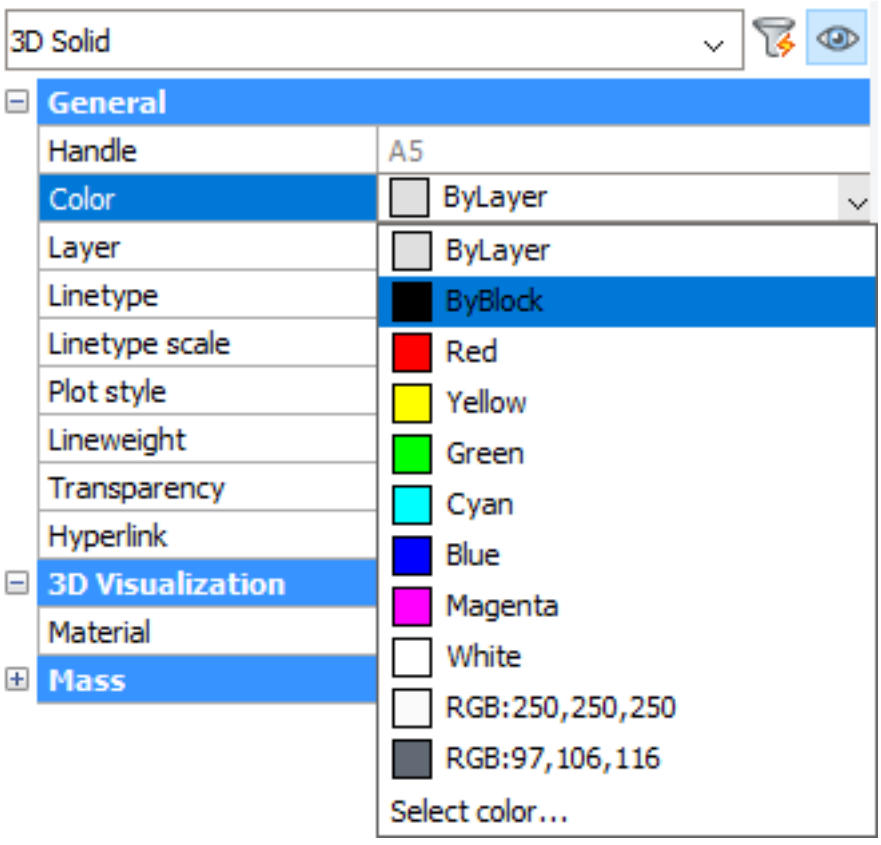

3.4.14 Step 5. Create a standard part

1. Select the root **Flange** component in the Mechanical Browser (3.3.2). On the bottom part of the Mechanical Browser (3.3.2), click the **Standard component** field and change the parameter value to **Yes**. (3.157 on the facing page)
2. Save as **Flange.dwg** file.
3. Open the **Components panel | Home**
4. Click the **"Create component (6.8.7)"** tool button, enter component name **"Flange"**, select **User** category and click "OK". (3.158 on the next page)

(3.159 on page 2750)

Create component

3.4.15 Step 6. Create a flange assembly

1. Create a new file in the **Mechanical** workspace.
2. Insert **Flange** from the **Home | Holes** section of the Components panel (6.9.26) at coordinate **0,0,0.**
3. Click the **Insert Component (6.8.16)** () button tool on the **Home | Assembly** panel of the Ribbon (1.17.6) and select the **Gasket.dwg** file.
4. Select the top planar face of the Flange and the bottom planar faces of the Gasket and click the **Coincident constraint (6.12.5)** () button tool in the **Home | Parametrize** panel of the Ribbon (1.17.6).
5. Select the inside cylinder of the Flange and Gasket and click the **Concentric constraint (6.12.8)** () button tool in the **Home | Parametrize** panel of the Ribbon (1.17.6). (3.160 on the next page)
6. Click the **Insert Component (6.8.16)** () button tool on the **Home | Assembly** panel of the Ribbon (1.17.6) and select the **Blind_Flange.dwg** file.
7. Select the top planar face of the Gasket and the bottom planar faces of the Blind Flange and click the **Coincident constraint (6.12.5)** () button tool in the **Home | Parametrize** panel of the Ribbon (1.17.6).
8. Select the outside cylinder of the Flange and Blind Flange and click the **Concentric constraint (6.12.8)** () button tool in the **Home | Parametrize** panel of the Ribbon (1.17.6). (3.161 on the following page)
9. Select the **Flange** and **Blind_Flange** components, change the color to **40**.
10. Select all the parameters of the Flange, Gasket and Blind Flange in the Mechanical Browser (3.3.2), click **Link to parameter** from the **Context menu**.

(3.162 on page 2753)

Figure 3.160

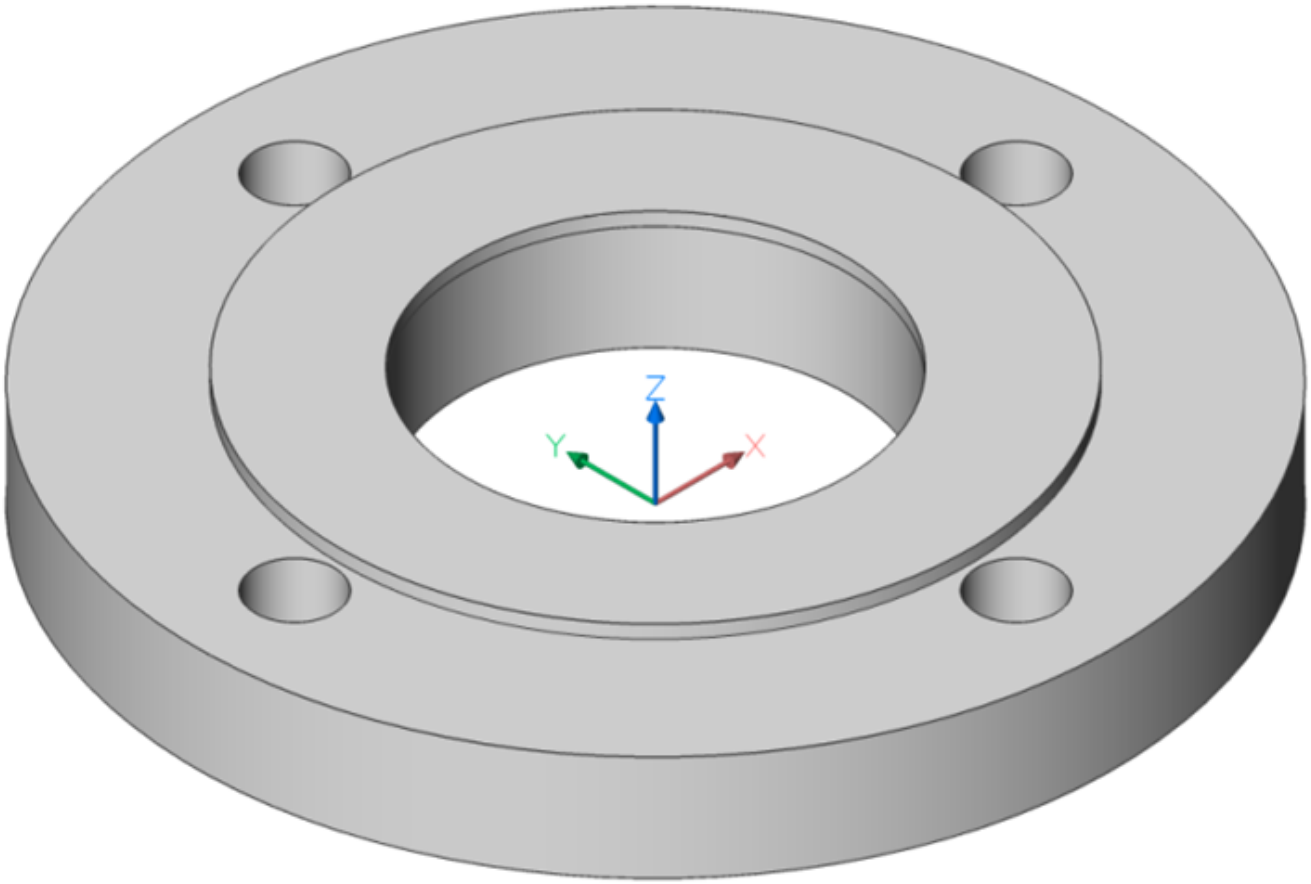

Figure 3.161

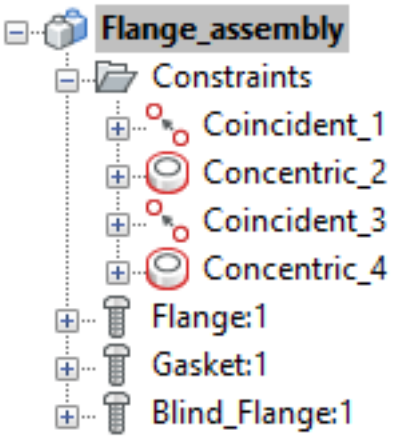

Figure 3.162

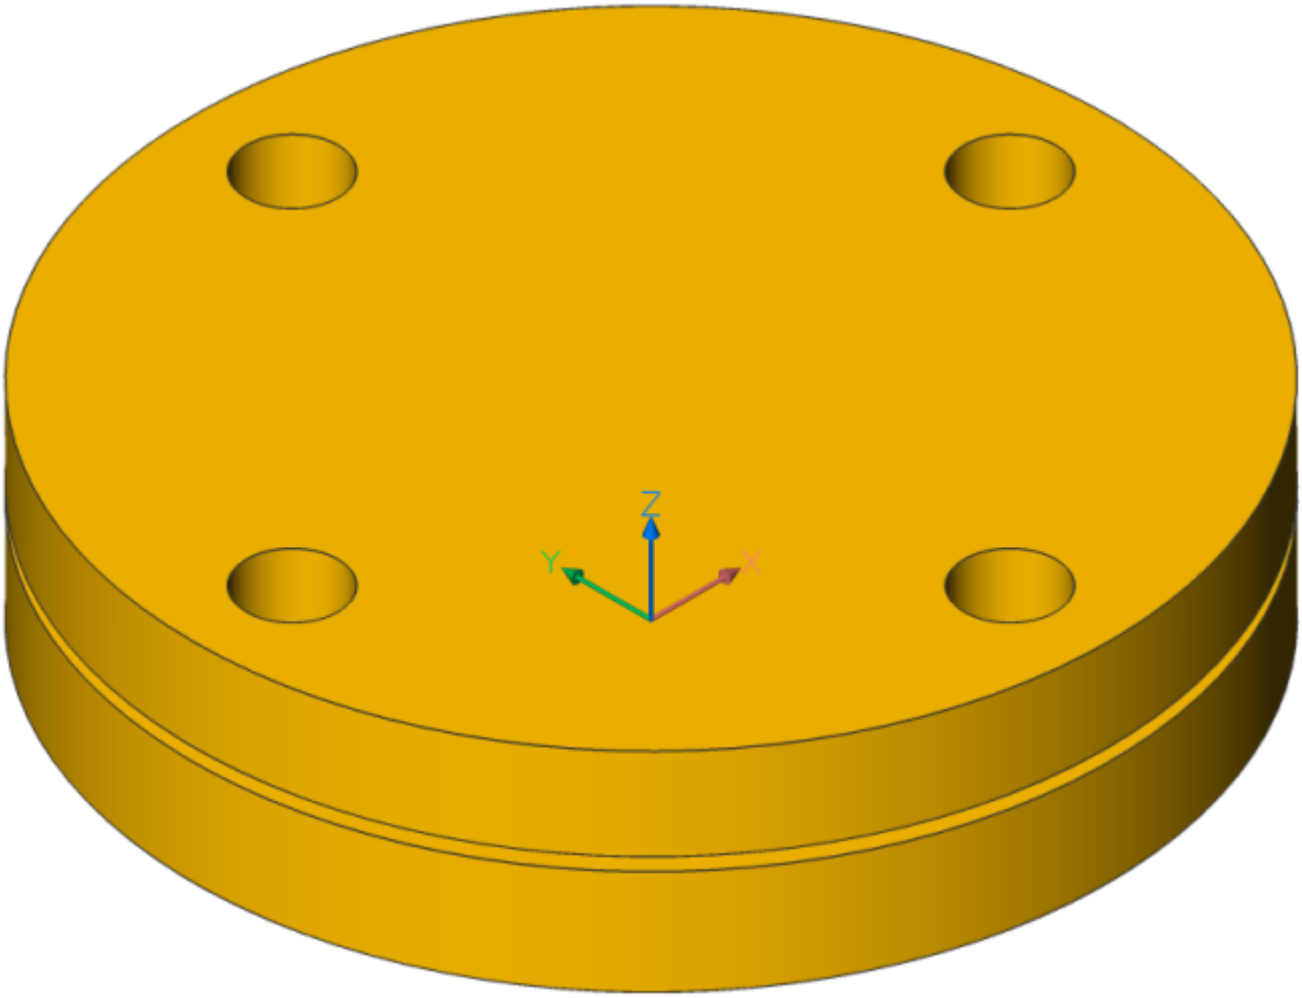
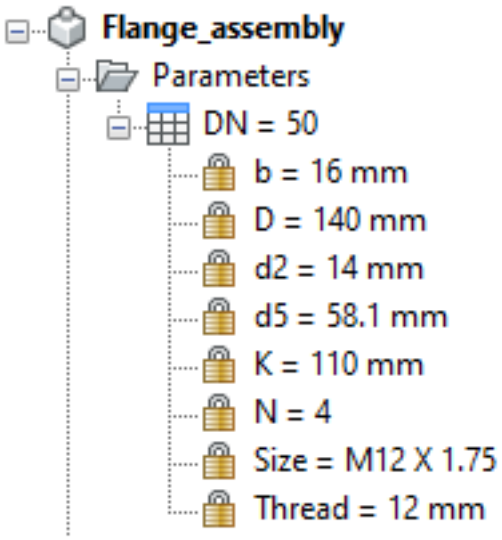


3.4.16 Step 7. Add a design table

1. Click the **DesignTable (6.10.31)** ( ) button in the **Home | Parametrize** panel of the Ribbon (1.17.6) and select the **DIN_2573_PN6.csv** file. (3.163)
2. Select the **DN** parameter in the Mechanical Browser (3.3.2) and select an arbitrary configuration from the drop-down list, change the **DN** parameter to **100**.

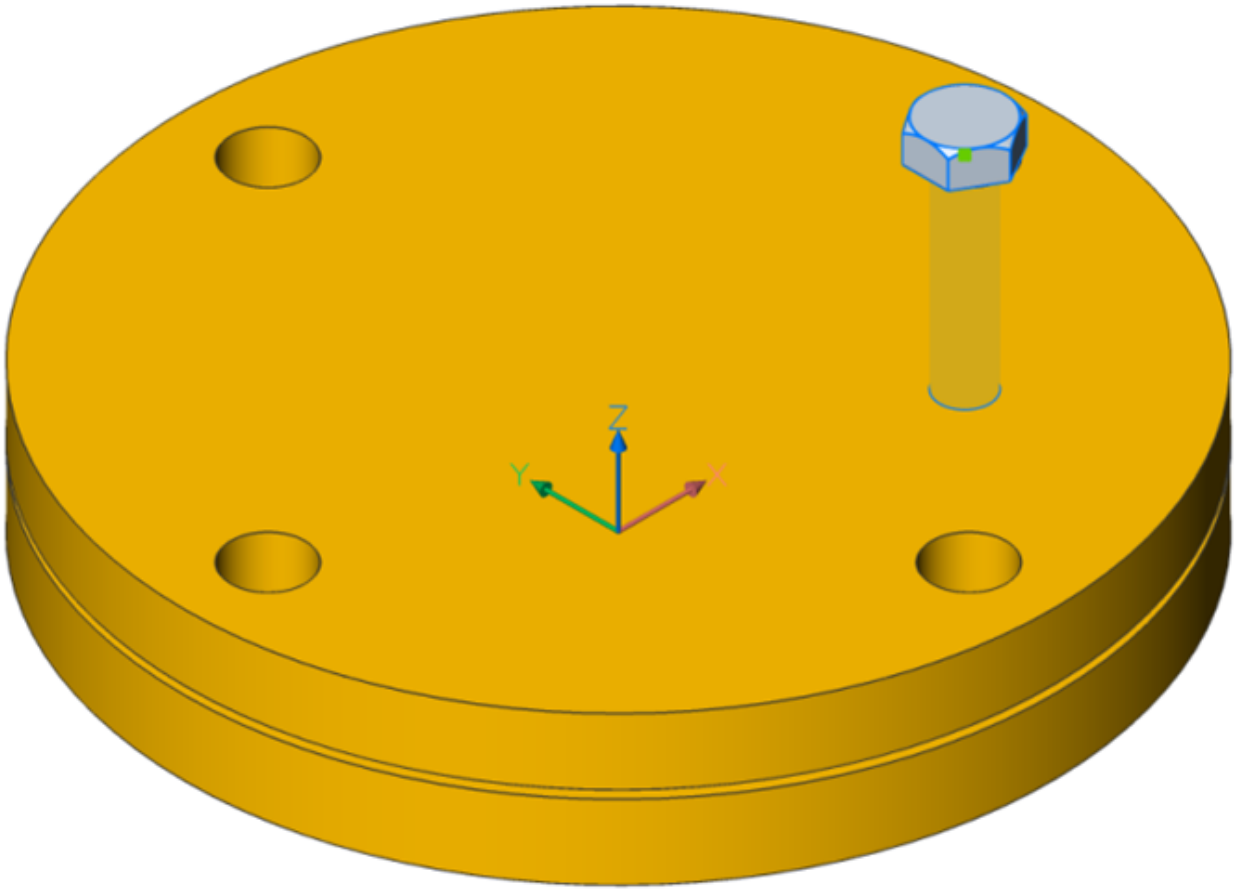
Figure 3.163



3.4.17 Step 8. Add parametric bolts to an assembly

1. Insert **DIN** 933 from **Home | Standard parts | BOLT | HEX HEAD| DIN** section of the Components panel (6.9.26).
2. Select **PartNumber** = M12 X 1.75 X 50.0000 in Properties panel (6.24.54) before insertion.
3. Insert the bolt into the center of the hole of the blind flange. (3.164 on the next page)
4. Select the **Size** parameters of the **DIN 933:1** component in the Mechanical Browser (3.3.2), select **Link to parameter** from the **Context menu**.
5. Select the **Length** parameters of the **DIN 933:1** component in the Mechanical Browser (3.3.2). In the bottom part of the Mechanical Browser (3.3.2), click the **Expression** field and change parameter value to **round(b*2/5)*5**.
6. Select the **DIN 933:1** component.
7. Click the **Polar Array (6.4.41)** () button tool in the **Home | Modify** panel of the Ribbon (1.17.6). Select the center point of the top face of the Blind Flange as the center point.
8. Select the **Distance constraint (6.12.10)** () button tool in the **Home | Parametrize** panel of the Ribbon (1.17.6).
9. Select the top planar face of the flange.
10. Click the **Block** buttons in the **Prompt menu,** select the array block, click the **XY plane** button in the **Prompt menu**.
11. Select **Distance_5** constraint in the Mechanical Browser (3.3.2), in the bottom part of the Mechanical Browser (3.3.2), click the **Exposed** field and change the parameter value to **Off**.
12. Select array (**Polar:1)** in the Mechanical Browser (3.3.2). On the bottom part of the Mechanical Browser (3.3.2), click the **Radius** field and change the parameter value to **K/2**, **Items=N**, and **Angle=360/N**. (3.165 on page 2757)

Figure 3.164



13. Select the **DN** parameter in the Mechanical Browser (3.3.2) and select an arbitrary configuration from the drop-down list, change the **DN** parameter to **200**.

(3.166 on the next page)

3.4.18 Assembly design and kinematic analysis tutorial

The source files for this tutorial are installed in the **[BricsCAD Installation folder]\Samples\Mechanical\piston** folder. Assembly design is a typical application where constraints are commonly used. BricsCAD Platinum allows users to assemble mechanisms and run a kinematic analysis. This tutorial shows you how to start working with assemblies in BricsCAD. You will learn how to assemble the different parts in a 3D model, which lets you control the final result. There are two approaches in MCAD (Mechanical Computer-Aided Design) to build an assembly: top-down and bottom-up. In the top-down approach, you start with an empty assembly and the geometry of each component is then created, one by one, in the assembly. In the bottom-up approach, each component is first created as a single entity. All components are then inserted into the assembly. The position of each component is controlled through 3D constraints. We will now assemble a simplified - in comparison with a real-world engine - a model of a piston engine. ===ERROR WITH DOWNLOADED IMAGE===

Step 1: Preparing for the exercise

1. You need a **BricsCAD Platinum** license for this tutorial.
2. Make sure the **Assembly** and **3D Constraints** toolbars are open. ===ERROR WITH DOWNLOADED IMAGE=== ===ERROR WITH DOWNLOADED IMAGE=== To open a toolbar: move the cursor over an open toolbar, then right click and select the required toolbars from the toolbar list. Toolbars that are already open are marked in the list.
3. Make sure that the Quad (2.3.3) cursor menu is active. (3.167) Click the **Quad** field in the Status bar (1.15.2) if necessary.
4. Make sure that the **Exclude entities in Xrefs** option of the PREVIEWFILTER (1.17.10) system variable is switched off. (3.168 on the next page)
5. Open the Mechanical Browser (3.3.2) dialog box. Do one of the following:
   - Click the **Mechanical Browser** tool button ( ) on the **Mechanical | Tools** panel in the ribbon.
   - Click the **Mechanical Browser** tool button ( ) on the **Mechanical** toolbar.
   - Choose **Mechanical Browser** in the **Mechanical** menu.
   - Type MechanicalBrowserOpen (6.8.32) in the command bar.

   ===ERROR WITH DOWNLOADED IMAGE===
6. Make sure **Selection Modes** = 3 Do one of the following:
   - Type **selectionmodes** in the command bar, then type **3**.
   - Set the **Selection Modes** toolbar as indicated below. (3.169 on the facing page)

Figure 3.167

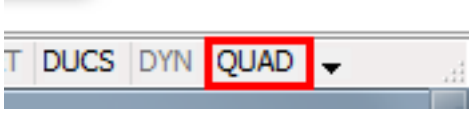

Figure 3.168

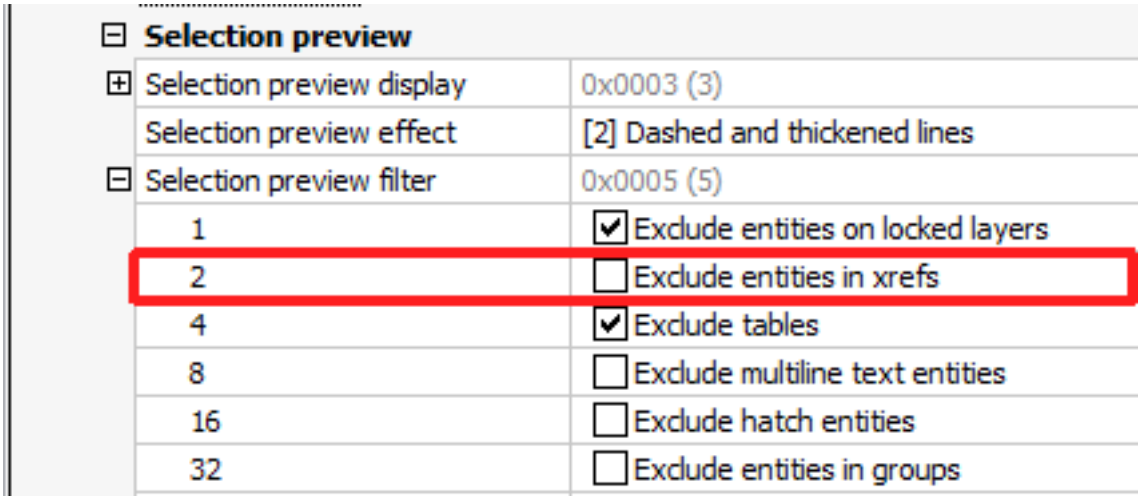

Figure 3.169

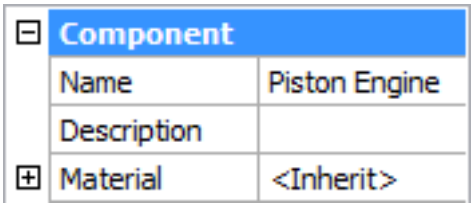
Step 2: Creating the assembly drawing

1. Click the **New Component** tool button ( ) on the **Mechanical | Create** panel in the ribbon. A new drawing of the name **Component_1.dwg** is created and **Component_1** is added in the Mechanical Browser (3.3.2).
2. In the bottom part of the Mechanical Browser (3.3.2), click the **Name** field and rename the main component: **Piston Engine**. (3.170) The drawing name automatically matches the main component name.
3. Save the drawing.

Figure 3.170



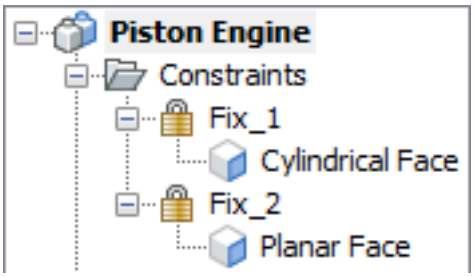
Step 3: Adding the components

1. Click the **Insert Component** tool button ( ) on the **Mechanical | Modify** panel in the ribbon. The **Insert Mechanical Component** dialog displays: Open the **[BricsCAD Installation folder]\Samples\Mechanical\piston** folder. ===ERROR WITH DOWNLOADED IMAGE===
2. Select the crankshaft.dwg, then double click or click the **Open** button. The component is attached to the cursor with its origin point. Dynamic dimensions display distance from the origin of the current coordinate system.
3. We will consider the crankshaft as the anchor component of the assembly and therefore insert it at the origin (0,0,0). Please make sure the insertion point is exactly at 0,0,0, otherwise the kinematic analysis in **step 5** might fail. ===ERROR WITH DOWNLOADED IMAGE===
4. Use the Look From (1.23.7) widget to adjust the view orientation.
5. Repeat the previous steps to insert the other components: cylinder (1), piston (2), pin (3) and connecting rod (4). Avoid visual intersection of the components. ===ERROR WITH DOWNLOADED IMAGE===

Step 4: Positioning the components

1. Click the **Fix** tool button (===ERROR WITH DOWNLOADED IMAGE===) on the **Solid | 3D Constraints** panel in the ribbon. You are prompted: **Select an edge, face or 3D solid:**
2. Move the cursor over the largest cylindrical face of the crankshaft. Click when the face highlights.
3. Repeat the DmFix3d (6.12.15) command. Move the cursor over the currently obscured circular face of the crankshaft. Hit the TAB key until the face highlights and click when the face highlights. ===ERROR WITH DOWNLOADED IMAGE=== The position of the selected faces of the crankshaft is now locked, as indicated in the **Constraints** tree in the Mechanical Browser (3.3.2). (3.171) Clicking a constraint highlights the solid, face or edge it applies to.
4. Place the connecting rod near the crankshaft.
5. Click the **Coincident** tool button (===ERROR WITH DOWNLOADED IMAGE===) on the **Solid | 3D Constraints** panel in the ribbon. You are prompted: **Select a pair of subentities or [Autoconstrain] <Autoconstrain>:**
6. Move the cursor over two planar faces of the crankshaft (1) and the connecting rod (2) as indicated in the image below. Click when the correct face highlights. Hit the TAB key to select the obscured face of the connection rod and click when the face highlights. ===ERROR WITH DOWNLOADED IMAGE===
7. Click the **Concentric** tool button ( ) on the **Solid | 3D Constraints** panel in the ribbon. You are prompted: **Select the first entity:**
8. Move the cursor over two cylindrical faces of the crankshaft (1) and the connecting rod (2) as indicated in the image below. Click when the first face highlights, then select the second face. ===ERROR WITH DOWNLOADED IMAGE=== The connecting rod is automatically moved to the right position according to our design intent. ===ERROR WITH DOWNLOADED IMAGE===
9. Click the **Concentric** tool button ( ) on the **Solid | 3D Constraints** panel in the ribbon. You are prompted: **Select the first entity:**
10. Move the cursor over two cylindrical faces of the piston (1) and the pin (2) as indicated in the image below. Click when the first face highlights, then select the second face. ===ERROR WITH DOWNLOADED IMAGE=== ===ERROR WITH DOWNLOADED IMAGE===
11. Click the **Tangent** tool button ( ) on the **Solid | 3D Constraints** panel in the ribbon. You are prompted: **Select the first entity:**
12. Move the cursor over two cylindrical faces of the piston (1) and the pin (2) as indicated in the image below. Click when the first face highlights, then select the second face. ===ERROR WITH DOWNLOADED IMAGE=== ===ERROR WITH DOWNLOADED IMAGE===

Figure 3.171



13. Click the **Coincident** tool button (===ERROR WITH DOWNLOADED IMAGE===) on the **Solid | 3D Constraints** panel in the ribbon. You are prompted: **Select a pair of subentities or [Autoconstrain] <Autoconstrain>:**
14. Move the cursor over two planar faces of the connecting rod (1) and the piston (2) as indicated in the image below. Click when the first face highlights, then select the second face. Hit the TAB key to select the interior face of the piston. ===ERROR WITH DOWNLOADED IMAGE===
15. Click the **Concentric** tool button ( ) on the **Solid | 3D Constraints** panel in the ribbon. You are prompted: **Select the first entity:**
16. Move the cursor over two cylindrical faces of the connecting rod (1) and the pin (2) as indicated in the image below. Click when the first face highlights, then select the second face. ===ERROR WITH DOWNLOADED IMAGE=== ===ERROR WITH DOWNLOADED IMAGE===
17. Click the **Concentric** tool button ( ) on the **Solid | 3D Constraints** panel in the ribbon. You are prompted: **Select the first entity:**
18. Move the cursor over two cylindrical faces of the piston (1) and the cylinder (2) as indicated in the image below. Click when the first face highlights, then select the second face. ===ERROR WITH DOWNLOADED IMAGE=== ===ERROR WITH DOWNLOADED IMAGE===
19. Click the **Distance** tool button ( ) on the **Solid | 3D Constraints** panel in the ribbon. You are prompted: **Select the first entity or specify [measurement Mode]:**
20. Move the cursor over the cylindrical faces of the crankshaft (1) and the planar bottom face of the cylinder (2) as indicated in the image below. Click when the first face highlights, then select the second face. Hit the TAB key to select the bottom face of the cylinder. ===ERROR WITH DOWNLOADED IMAGE=== Type 120 in the dynamic distance field.
21. (optional) Edit the **Expression** field of the distance constraint in the Mechanical Browser (3.3.2) panel to adjust the vertical position of the cylinder.
22. Click the **Fix** tool button ( ) on the **Solid | 3D Constraints** panel in the ribbon. You are prompted: Select an edge, face or 3D solid:
23. Click the outside cylindrical face of the cylinder.

Step 5: Kinematic Analysis

In this assembly the crankshaft is the driving component. To run the kinematic analysis we will rotate the crankshaft around its axis, which in this case is the Y-axis of the WCS.

1. Move the cursor over the crankshaft, then choose **Rotate** ( ) in the **Model** command group in the Quad (2.3.3) cursor menu. ===ERROR WITH DOWNLOADED IMAGE=== You are prompted: **Select axial entity or define axis by [2Points/Xaxis/Yaxis/Zaxis] <2Points>:**
2. Do one of the following:
   - Type **Y**, then press Enter.
   - Choose **Y axis** in the prompt menu.

   You are prompted: **Pick start point in the rotation plane:**
3. Pick a point in the drawing, then move the mouse to define the rotation angle. The piston and the connecting rod move dynamically along with the rotation of the crankshaft, while the cylinder stays at its fixed position. ===ERROR WITH DOWNLOADED IMAGE===

Step 6: Material assignment

1. Select the **piston** on the Mechanical Browser (6.8.32).
2. Click **Open** (===ERROR WITH DOWNLOADED IMAGE===) on the right click menu.
3. In Property of the Mechanical Browser select the **Material** field, then click ===ERROR WITH DOWNLOADED IMAGE=== button and specify the **Steel** material in the **Physical Materials** dialog box. Click the **OK** button. ===ERROR WITH DOWNLOADED IMAGE===
4. Save **piston.dwg** file.
5. Return to **Piston Engine.dwg** file.
6. Click **Update** button (===ERROR WITH DOWNLOADED IMAGE===) on the right click menu for the piston. The value of the **Material** setting has changed. ===ERROR WITH DOWNLOADED IMAGE===
7. Repeat the 2-8 steps for the other components: **crankshaft, cylinder, pin,** and **connecting rod.**

Step 7: Mass properties

1. Open the Settings (1.17.10) dialog box.

2. Expand the **Property units** settings under **Drawing | Drafting | Drawing** units. ===ERROR WITH DOWNLOADED IMAGE===
3. Check the **Format mass properties** checkbox to enable formatting of mass values with appropriate units.
4. Select the **Mass units** field, then click the **Browse** button (===ERROR WITH DOWNLOADED IMAGE===) and specify the desired mass units in the **MASSUNITS** dialog box.
5. Check the **Slugs** checkbox. ===ERROR WITH DOWNLOADED IMAGE===
6. Specify the 0.00 precision in the **Linear units precision** and **Mass precision** fields.
7. Close the Settings (1.17.10) dialog box.

Step 8: Drawing generation

1. Select all components.
2. Click the **Base Views** tool button (===ERROR WITH DOWNLOADED IMAGE===) on the **Annotate | Drawing Views** panel in the ribbon.
3. Enter new or existing layout name or click **Enter** to take **<Layout1>**.
4. On the **VIEWBASE** menu select the **Projection type | First angle.**
5. On the **VIEWBASE** menu select the **Orientation | Front.**
6. On the **VIEWBASE** menu select the **Scale | Custom scale.**
7. Enter scale**: 0.005.**
8. Select positions for base views.

Step 9: Exploded view

1. Switch to model space.
2. Click the **Explode** tool button (===ERROR WITH DOWNLOADED IMAGE===) on the **Assembly | Tools** panel in the ribbon.
3. In the **BMEXPLODE** dialog box select **Table by Level.**
4. In the **BMEXPLODE** dialog box select **Generate drawing views.**
5. Enter new or existing layout name or click Enter to take **<Layout1>**.
6. Select position of the exploded representation.
7. Freeze **"Drafting Viewports"** layer in the drop-down **Layers control** menu on the **Home | Layers** panel in the ribbon.

Step 10: Bill of Materials

1. Click **Bill of Materials** tool button (===ERROR WITH DOWNLOADED IMAGE===) on the **Annotate | Assembly** panel in the ribbon.
2. On the **BMBOM** menu select the **Configure | Volume, Mass, Materials.**
3. Select the insertion point.
4. Enter EXPLORER (6.13.15) command in the Command line.
5. On **Drawing Explorer** menu select **Text styles.**
6. Change **Standard** style:
   - Font: **Isocpeur;**
   - Width Factor: **0.8.**
7. Close **Drawing Explorer** menu.
8. Select **Bill of Materials Piston Engine** table. Use the knobs to align the width of the table to the width of the layout.

Step 11: Balloons

1. Click the **Balloon** tool button (===ERROR WITH DOWNLOADED IMAGE===) on the **Annotate | Assembly** panel in the ribbon.
2. Select a first component on the View ports with Exploded view. Pick a point to place balloon.
3. Repeat the previous step for the other components**.**
4. Select balloons the 2-5 numbers. In **Property** panel select **Leader arrow | Dot small. ===ERROR WITH DOWNLOADED IMAGE===**

Back to Tutorial Overview

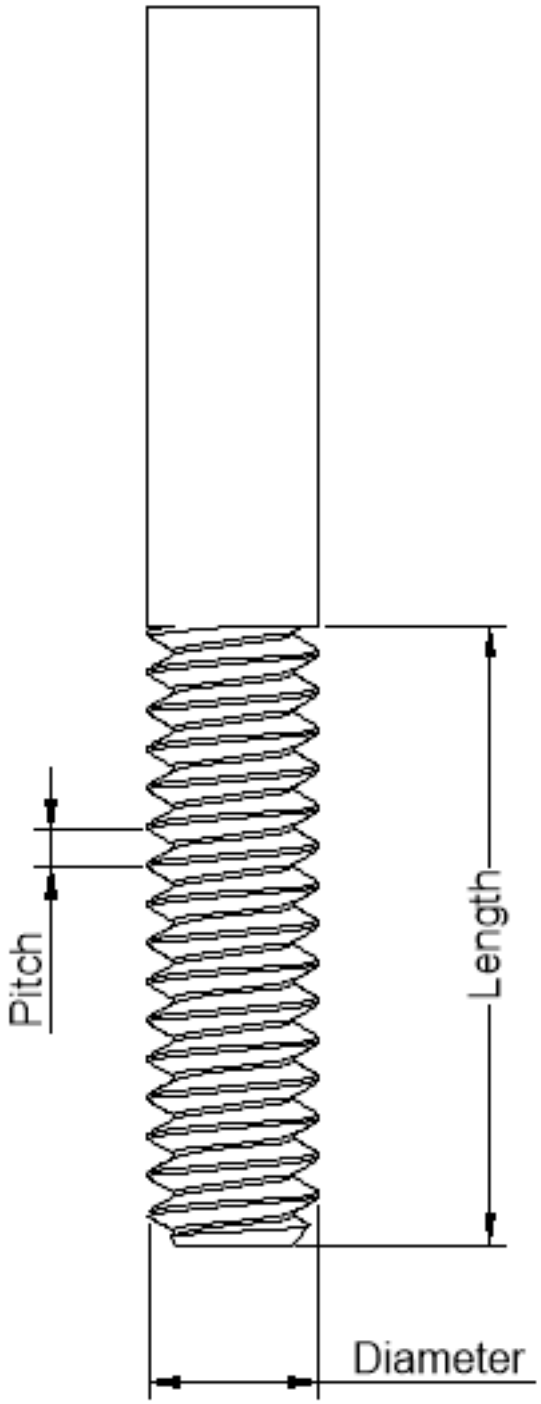
3.5 Part Design

3.5.1 Thread Feature

The Thread feature is created by the DmThread (6.12.31) command. The following picture demonstrates the thread structure: (3.172 on the next page) A Thread feature has the following parameters:

- **Thread standard**. It is a set of standard threads. This list can be extended with a custom thread. When changing the standard, the geometry will be rebuilt automatically.
- **Pitch** of the thread.
- **Length** of the thread.
- **Diameter** of the thread.
- **Type** of the thread – male or female. If the type is auto, the type will be determined automatically.

Figure 3.172



How to add a thread configuration

1. Right-click on the feature in the mechanical browser. (3.173 on the following page)
2. Execute the **Replace Table** command.
3. Select a CSV file with following configuration:

```
Size,Diameter,Pitch Name1, Diameter_value1, Pitch_value1 Name2, Diameter_value2, Pitch_value2 Name3, Dia
```

3.5.2 Part Design Methods

BricsCAD Mechanical allows you to create and modify 3D models. Ways to create a 3D model.

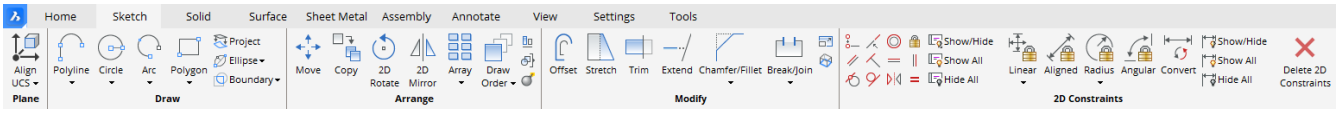
- Create a 3D solid primitive - a box, a cylinder, etc.
- Sketching a 2D profile and extrude or revolve it to make a 3D solid.
- Model a 3D surface and thickening it to make a 3D solid, or stitching several surfaces together to create a watertight 3D solid.
- Import existing 3D solid and surface geometry from other CAD programs.

Ways to edit and add more details to your 3D models

- By Pushing/Pulling, moving and rotating faces.
- By creating Fillets or Chamfers on the model edges.
- By applying Holes.
- By adding protrusion and depressions and by using Boolean operations, Direct Editing and Deformable Modeling tools.

No parent-child dependencies = history FREE approach BricsCAD Mechanical does not create parent-child dependencies between geometric primitives and features. All changes made to your part are local; they do not force geometry regeneration. This history-FREE approach allows you to concentrate on your design instead of thinking about how it can be changed in the future. **3D Constraints = Parametric** BricsCAD Mechanical provides a powerful toolset to make your part parametric by adding 3D constraints to its faces and edges and link them with global parameters using expressions and design tables.

Figure 3.174

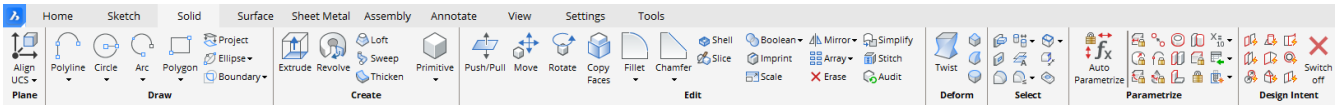


3.5.3 Sketching

The sketching toolset allows you to draw 2d profiles, which can be extruded or revolved to create 3d solids and surfaces or to add/subtract volume to/from existing entities. The sketching tools to are available on the **Sketch** tab of the **Mechanical** workspace Ribbon: (3.174) Sketches are created in the XY plane of the current User Coordinate System (UCS) (1.21.21). Since the dynamic UCS is enabled by default you can create 2d entities on the 3D solid face under the cursor. Use the Align UCS (6.30.1) tool to position the UCS according to your needs. The drawing tools include familiar 2d primitives like a rectangle (6.26.6)/polygon (6.24.61), a circle (6.9.12)/arc (6.4.21)/ellipse (6.13.5), a polyline (6.24.27), a spline (6.27.63),... Use the Move (6.21.29), Copy (6.9.35), 2d Rotate (6.26.29), 2d Mirror (6.21.17) and Array (6.4.19) tools to manipulate the sketches. Use Offset (6.23.3), Stretch (6.27.52), Trim (6.29.35), Extend (6.13.21), Fillet (6.14.6)/Chamfer (6.9.9), and Break (6.6.21) commands to edit the sketches. Use 2d constraints (1.21.6) to make the sketches parametric.

NOTE	Whether sketching entities are deleted when used by DMEXTRUDE (6.12.14) or DMREVOLVE (6.12.21) to create 3d solids or surfaces, is controlled through the value of the DELOBJ (1.26.1) (Delete Entity) system variable.

Figure 3.175

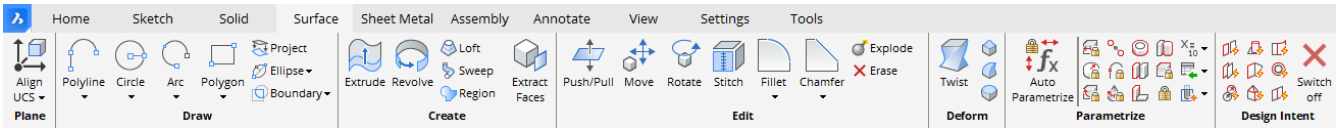


3.5.4 Solid Modeling

BricsCAD Mechanical provides a rich toolset for solid modeling, including traditional 3D modeling tools like Extrude or Subtract and intuitive Direct Editing tools like; Push/Pull, Copy Faces and powerful 3D Constraints which allow you to adjust the shape and size of your 3D part. 3D solids tools are available on the **Solid** ribbon tab of the **Mechanical** workspace: (3.175) On the Solid tab, you find the sketching (3.5.3) tools as well as tools to create 3D solids from sketches: Extrude (2.5.10), Revolve (6.12.21), Loft (6.20.37), Sweep (6.27.68), and Thicken (6.12.30). 3D solids can be created directly, with no underlying sketches using **solid primitives**: Box (6.6.18), Cylinder (6.9.49), Cone (6.9.46), Pyramid (6.24.64), Wedge (6.33.6), Sphere (6.27.50), Torus (6.29.29). All 3D solids can be edited using the following tools: Push/Pull (6.12.25), Move (6.12.16), Rotate (6.12.24), Copy Faces (6.12.12), Fillet (6.12.13)/Chamfer (6.12.4), which are applied to their faces and/or edges. Other editing tools that apply to 3D solids are: Shell (6.27.42), Slice (6.27.40), Boolean operations (Union (6.30.6), Subtract (6.27.58), Intersect (6.17.20), Separate (6.27.42)), Scale (6.27.6), Mirror (6.21.20), Array (6.4.19). The Erase (6.13.8) tool can be applied to the whole 3D solid as well as to a set of its faces forming a **feature** (e.g. a fillet or a hole). The Audit (6.12.2) tool is useful to find and fix errors in imported geometry. The Simplify (6.12.27) tool allows you to automatically recognize canonical faces (planar, cylindrical, conical, spherical, toroidal) from spline faces of your 3D solid, which is often needed before applying 3D constraints. The Stitch (6.12.29) tool allows you to stitch touching surfaces and regions, that form a watertight boundary, into a single 3D solid, The Deformable modeling toolset allows you to deform your 3D solid uniformly. It includes Twist (6.12.33), Move Point (6.12.9), Move Edge (6.12.11), and Transform Curve (6.12.7). The Smart Selection (6.12.28) tools allow you to select faces and edges of your 3D solids based on particular geometric and topologic criteria - such as length, area and smoothness. 3D Constraints (1.27.3) can be added to faces and edges of 3D solids to align and resize them, and will make your 3D part parametric (1.27.1). Many geometric 3D constraints like parallel/perpendicular, coaxial, tangent can be applied automatically using Design Intent recognition (1.26.3).

NOTE	BricsCAD is a history-free modeler; it does not create parent-child dependencies between features, nor regenerates geometry on parameter change. Full-blown parametric control can be embedded into any 3D part (including imported ones) using 3D constraints (1.27.3).

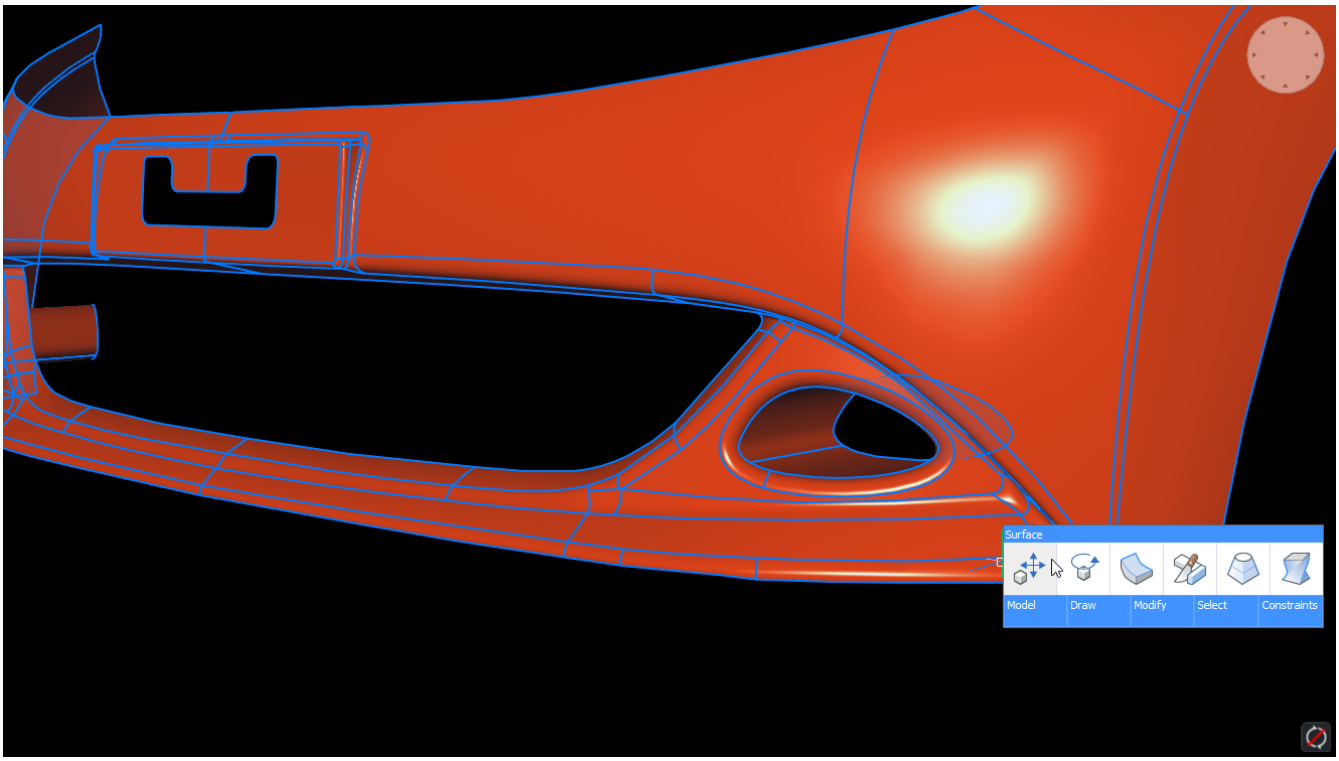
Figure 3.176



3.5.5 Surface Modeling

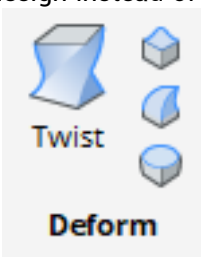
BricsCAD Mechanical provides a powerful toolset for surface modeling and conversion of 3D solids to surfaces and vice versa. Surface Modeling tools are available on the **Surface** ribbon tab of the **Mechanical** workspace: (3.176) Surface modeling tools are much like solid modeling tools in editing (1.26.1) and applying 3D constraints (1.27.3). The only difference is that surface Extrude/Revolve/Loft (6.20.37)/Sweep (6.27.68) tools can create surface entities from closed 2D profiles and also accept non-cloned profiles. The Region tool (1.32.37) creates a region entity from a closed 2D profile and regions can be stitched (6.12.29) together to create a larger surface. Some other methods to create a surface are to extract (6.34.3) one or more adjacent faces of a 3D solid/surface, and by exploding (6.13.16) a 3D solid into a set of surfaces and regions.

Figure 3.177



3.5.6 Freeform Modeling

Add complex distortions to your solid or surface models by using BricsCAD Mechanical deform tools to create smoother, or more organic, looking shapes. Deform your solids and surfaces by moving, rotating and twisting their edges to change the geometry independently with no design history. History-FREE approach allows you to concentrate on your design instead of thinking about how it can be changed in the future. (3.177) **Freeform Modeling - Deform tools**



- Move Edge (**DmDeformMove (6.12.11)**) - deforms faces by moving and rotating their edges.
- Move Point (**DmDeformPoint (6.12.9)**) - deforms the selected set of faces by moving a point.
- Transform Curve (**DmDeformCurve (6.12.7)**) – deforms faces by changing the geometry of their edges.
- Twist (**DmTwist (6.12.33)**) - deforms 3D object by twisting a portion around a given axis.

Tutorial: Use surface modeling and deformable modeling Click here to watch (1.18.11)

3.6 Sheet Metal - Tutorials

3.6.1 User interface

https://www.youtube-nocookie.com/embed/gl4Mqvn1JxY

TRANSCRIPT Welcome to BricsCAD Sheet Metal. Let's explore the user interface. The ribbon on the top of the screen gives you fast access to the most used tools. Many top-level tools offer submenus. Hover over the icon, left click and hold. The submenu will fly out to show the additional tools. Next, hover your cursor over any model element and the Quad cursor menu will appear. Move your cursor onto the Quad button. The Quad opens and shows you the tools that you can use on the selected element. The panel on the left side of your screen is the Mechanical Browser. It gives you access to sheet metal features and their properties in your model.

3.6.2 BricsCAD respects your design intent

https://www.youtube-nocookie.com/embed/jaPScAM1W_w

TRANSCRIPT During modeling operations, BricsCAD respects your design intent. When creating a flange, its initial position places a body above XY plane. It is like your design is laying on the table. The bottom face of the newly created flange is called a reference face. You can distinguish it with a slightly different color. The reference face maintains its position when you change its thickness. You can control the position of the flange with the Control hotkey. Your overall design intent of the initial flange size is maintained during the creation of other sheet metal features. As you can see here; the overall dimension of L-shape model is still 50. If the length of the vertical flange is 50 and we add a horizontal flange - overall vertical height of the model is 50 Let's switch to the second case. It is dimensioned polyline. While extruding the polyline, you see that all dimensions are kept. This is important for proper design.

3.6.3 What about edges

https://www.youtube-nocookie.com/embed/HSnYGhKqfr0

TRANSCRIPT By using the flange edge tool, a new flange can be easily created. Just, hover over an edge and use the tool. Length and angle can be specified during mouse cursor movement. Use the Tab hotkey to switch between fields. There are several other parameters which can be used during flange creation. For example; the width of the flange is controlled by using the width option of the tool. If the default radius of the bend is not suitable. It can be changed during creation with radius option. You can also create two flanges simultaneously. Use the taper angle option, if the side faces of the new flange are inclined.

3.6.4 Base flange creation

https://www.youtube-nocookie.com/embed/MkswHon9w8M To create a sheet metal base flange:

1. Do one of the following:
   - Create a 2D profile,
   - Use boundary detection for a more complex 2D contour boundary selection. When you move the mouse cursor inside the contour, a special highlight appears, indicating that the boundary is detected.
2. Launch the flange base (6.28.10) tool.
3. Repeatedly press the Ctrl key to set the base flange position in relation to the 2D profile: Up (or Right), Middle or Down (Left). When HOTKEYASSISTANT = ON, the current position is indicated in the Hotkey Assistant widget at the bottom of the screen.
4. You can change the flange thickness in the Sheet Metal properties section of the Mechanical Browser (3.9.6) panel.

3.6.5 2D polyline to Sheet Metal

https://www.youtube-nocookie.com/embed/lrYSaOp4FVw

TRANSCRIPT Using the Polyline tool is a great way to create Sheet metal bodies. Sheet metal extrude command can easily convert 2D polylines to a sheet metal body. Keeping with our design intent by avoiding possible intersections, the body was added to the outside of other components.

3.6.6 Lofted shapes

https://www.youtube-nocookie.com/embed/5VbGaY4H3nI

TRANSCRIPT BricsCAD can easily work with sheet metal lofted shapes. You can create a variety of different profiles using the sheet metal loft tool. When creating the lofted body, you can control thickness, corners fillet radius, and material position. Each lofted bend feature has the number of subdivision settings which controls the number of bends needed to produce the shape. By adding more subdivisions, will result in the part being smoother.

3.6.7 Associative unfolded representations

https://www.youtube-nocookie.com/embed/ZuGBEH5woes

TRANSCRIPT In some cases, modifications on sheet metal models can be quite difficult and not evident. The associative mode of sheet metal unfolding can help. In this mode, you can see folded and unfolded representations of your model. Two windows can be placed side-by-side. They have bi-directional associativity. Switching to the sheet metal features, changes the bends that automatically propagates to the unfolded state. Some changes can be done precisely only in unfolded representation. In the unfolded representation state allows you to use the direct editing tools for modifications. Switch to a folded model state to see modifications.

3.6.8 Unfold a sheet metal body

https://www.youtube-nocookie.com/embed/VOt4gXeI16Q

TRANSCRIPT Use the Quad to access tools to create a flat or unfolded representation of your model. For production, you can save your unfolding to a DXF file. The DXF file contains all necessary information, such as: bend positions, radiuses, angles of bending, overall dimensions, material and its thickness. Depending on the material and production tools, the length of unfolded representation may vary. Bend tables are a more reliable way to express material deformation properties and this information can be stored in CSV file, which can be attached to the model. After applying a bend table, you can see the size of unfolding has changed.

3.6.9 Working with hard edges

https://www.youtube-nocookie.com/embed/F9Rg_6PkJZU

TRANSCRIPT The model represented is a shell and is not manufacturable. To make the model manufacturable, we need to convert the hard edges. Create corner reliefs to avoid material conflicts. Hover over a flange, using the Quad, select the create relief tool. Convert all hard edges to a bend or a junction edge. Use the Quad cursor, it's fast and easy.

3.6.10 Working with reliefs

https://www.youtube-nocookie.com/embed/ldT1gAOKGIE

TRANSCRIPT Use Corner Reliefs to convert corners to circular, rectangular or V-type reliefs for production. Corner reliefs are built on corners which have three or more adjacent flanges. The size can be controlled by corner relief feature properties. Corner relief can be deleted or re-created if necessary. There are other types of corner relief. Use Bend reliefs to avoid material conflicts during bending operations and are created on the start and end of a flange edge. Apply rip, round or smooth shapes. The width of the bend relief is controlled by the properties. Bend and Corners reliefs can be applied to the manufacturing process.

3.6.11 Direct editing of a sheet metal model

https://www.youtube-nocookie.com/embed/i5oQPLg_qHk

TRANSCRIPT You can use BricsCAD Direct modeling functionality on your sheet metal bodies. For example: to cut a slotted hole, all you need is a 2D profile and use the direct editing extrusion feature. Unnecessary details of the model can be simply deleted. During Push/Pull operations, the flange thickness is maintained automatically. The corresponding angle of the existent flange can be changed, also. If cutouts are not needed anymore, use the window selections in combination with the erase tool to delete them.

3.6.12 Working with shell

https://www.youtube-nocookie.com/embed/zlSfmSlcCyo

TRANSCRIPT In many cases, we are forced to shell a model to get our sheet metal body. In BricsCAD, the SmConvert command simplifies this, by automatically recognizes flanges, bends and lofted bends. During bending operation, small cuts corners are typically required because of the material conflict. The SmReliefCreate tool automatically creates reliefs on hard edges, bends, and corners for the entire model." To make the model unfoldable, some edges need to be converted to junctions. Use a window or one-by-one selection method to choose necessary edges. Convert the remaining hard edges to bends. Now it's time to generate the unfolded representation with manufacturing information. The unfolded representation of the model can be placed near the initial model.

3.6.13 Working with bends

https://www.youtube-nocookie.com/embed/XYGnRYflixU

TRANSCRIPT Bend features are important components of sheet metal design. Reordering bends and junctions can be useful for optimization and future manufacturing. Bends have several parameters, such as: radius which can be global, absolute or depend on material thickness. If the bend radius is too large, it can be substituted by a lofted bend for sequential bending operations. On the unfolded representation multiple bends appear. The number of sub-bends is controlled by the number of subdivisions property.

3.6.14 How to fill the gap in the corner

https://www.youtube-nocookie.com/embed/N4O8gvpoyTY

TRANSCRIPT In some cases, non-orthogonal connections of flanges corners are not actually closed. Use the Flange connect tool to close the corners. Select two side faces and the tool will connect flanges. The Flange connect tool does more than just 45 degrees angles. When creating junctions, use the Sheet Metal Imprint tool to extend to several side faces. This will add more edges to your model, giving you more control to modify.

3.6.15 Split lofted bend

https://www.youtube-nocookie.com/embed/QF92fDWMq_E

TRANSCRIPT Lofted bends are widely used when the bend radius must be significantly big. Following the goal of material usage and optimal nesting, you can split lofted bends. To make a split you just need to select the lofted bend and specify a point on it. The split will be created along a straight line through a given point.

3.6.16 How to split a flange

https://www.youtube-nocookie.com/embed/Ft6qqhxuelU

TRANSCRIPT Using the Split tool is an effective way to help in the unfolding of your sheet metal parts. The split tool makes a thin cutout to separate flange that creates a miter feature. Use the smart split tool to automatically find the closest corner. Use the control modifier to change the split between diagonal, vertical and horizontal. The miter properties control its size and position. Use a polyline to create a custom split path.

3.6.17 Creating parametric sheet metal model

https://www.youtube-nocookie.com/embed/Ur-dAzY0AtY

TRANSCRIPT With BricsCAD you can create parametric sheet metal models using 3D constraints. The Parametrize tool creates a consistent set of geometrical and dimensional constraints for a selected sheet metal part. You can easily change the size of the model with respect to all other dimensions. To modify the shape, choose a constraint and change its value.

3.6.18 How to bend an existing flange

https://www.youtube-nocookie.com/embed/zywiRHgi3sg

TRANSCRIPT All existent flanges can be bent by using the flange bend tool. Using the Quad, launch the tool by hovering over the target flange. Draw or select a bend line and then specified which side to move. The bending angle is the final step. The target flange can have cutouts, also.

3.6.19 Working with form features

https://www.youtube-nocookie.com/embed/6NiBVV805GM

TRANSCRIPT BricsCAD has a library of parametric Form Features, to access Form Features, open components panel. To use a Form Feature in the model just choose a necessary type and position it on a face. The parameters control the dimensions of each Form Feature such as length, width, height, and diameter. To position a form feature, dynamic dimensions can be used. Use the Replace tool to replace one Form Feature with another. Need to create an array of a Form Feature, you can with the Array option when inserting. An array of Form Features can be oriented along a custom direction, like along the edge.

3.6.20 Smart selection

https://www.youtube-nocookie.com/embed/IWIcZHnWLpE

TRANSCRIPT Use Smart Selection tool helps reduce the number of steps when modifying your model. With one click BricsCAD selects all hard edges in the model. Smart Selection tool also allows you to select faces and edges of your 3D solids based on geometric and topologic criteria.

3.6.21 Assembly batch processing

https://www.youtube-nocookie.com/embed/8AQhDbw2e0A

TRANSCRIPT BricsCAD can process assemblies in batch mode. The result of batch processing is HTML report which gives the user all necessary information about sheet metal components in the assembly. The command validates each component for correctness by indicating poor sheet metal components and non-sheet metal components.

3.6.22 Sheet Metal context: browser, properties & settings

https://www.youtube-nocookie.com/embed/ZyzqdXD34Os

TRANSCRIPT When Sheet Metal context is initialized you see the L-shape icon near the root of the mechanical browser. Once Context is initialized the Sheet Metal properties section appears in the mechanical browser. This section contains all necessary Sheet Metal parameters, such as material thickness, bend radius, size of reliefs, K-factor and bend table. Sheet Metal settings can be expanded into four categories. The first is Commands, this is where the behavior of particular sheet metal command can be controlled. The second is Feature Colors, these are the colors of Sheet Metal features can be controlled. The third is the Initial Parameters section, this is where the values are located. The fourth is the Modeling section, which controls model behavior during modeling operations. Layers and Unfolding section controls the display representation of annotations by layers. Sheet Metal features colors can be turned ON or OFF by ribbon button.

3.6.23 Convert an imported sheet metal design

https://www.youtube-nocookie.com/embed/s2OxAL5PRCg

TRANSCRIPT BricsCAD Communicator can import 3D CAD data from all the major MCAD programs. After the import, converted the model to Sheet Metal bodies for unfolding. All import models are not alike. BricsCAD detects defects and has the tools to fix problems. In this model, the bends are not correct to unfold. Some are non-concentric, some have hard edge instead of an internal cylinder. Use the Repair command to convert the wrong bends to regular bends.

3.6.24 Working with ribs by trajectory

https://www.youtube-nocookie.com/embed/IqkXNSWn4vo

TRANSCRIPT Rolled ribs provide additional strength to the sheet metal component. To create a Rib Feature, first draw the rib path and select the target flange and then click on the path. Ribs can have open and closed paths. The rib has two parameters: profile and round radius. All Ribs have associative curve paths and are updated automatically when its defining profile is changed. BricsCAD can identify ribs on imported models and use a curve path for modifications.

3.6.25 Working with junctions

https://www.youtube-nocookie.com/embed/DjK6h9srpZU

TRANSCRIPT Junction is a sheet metal feature where two adjoining flanges are met, but not connected. The junction has two types of connection: flanges or symmetric. The type can be switched by using Quad or in the properties of the mechanical browser. All bends can be changed to a junction or deleted. The junction gap is controlled by the value in the properties section of the mechanical browser. It can be changed individually for each junction feature or for the whole model. Junctions can be created in case of curved edges either.

3.7 Assembly Design

3.7.1 Bottom-up and Top-down Assembly Design

Assembly modeling represents the structure of a designed product and consists of using components (1.30.25) to group geometric entities in hierarchies. Assembly modeling is commonly used in Mechanical Computer-Aided Design (MCAD) applications, it simplifies the design of complex products containing thousands or millions of geometric entities. The following terms are used across this topic:

- An **assembly** is a component that contains inserts of other components and a subassembly is a separate assembly that is inserted into another assembly.
- A **part** is a component that does not contain inserts of another component.

An assembly with inserted components (which in turn can be assembled with other inserted components) forms a tree that is called a mechanical structure of the 3D model. This tree is displayed in the Mechanical Browser (3.3.2). There are two main ways to design mechanical products: **top-down** and **bottom-up** approaches. You can also add mechanical structure to existing geometry, designed in BricsCAD or imported from another source. BmNew (6.8.20) command is called to create a new document for a new mechanical component. BmMech (6.8.19) command can be used to convert existing blocks and external references to components, while BmUnmech (6.8.28) does the opposite.

Bottom-Up Design

With bottom-up approach users start to design a product by detailing its low-level component. These components are then grouped into higher-level components. The process is continued until the very top component is corresponding to the product itself. The main command for bottom-up design is BmInsert (6.8.16), which is used to insert an existing component into the current drawing.

Top-Down Design

With top-down approach users start to design a product by defining but not detailing its first-level components. Each component is then refined in more detail by defining its sub-components. The process is continued till all low-level components are defined and detailed. BmForm (6.8.13) command creates a new subcomponent for an existing component.

Adding Mechanical Structure to Existing Geometry

BricsCAD users can add component hierarchy to any existing drawing created in BricsCAD or imported from a different CAD format. BmForm (6.8.13) converts a selected set of geometric entities to a subcomponent of the current drawing.

Changing Mechanical Structure

During design process users may realize that a particular component should be moved up or down in the component hierarchy. BmForm (6.8.13) command forms a new subcomponent for the current drawing that will contain a selected set of a component. BmDissolve (6.8.8) deletes a component and moves all its subcomponents to the level of the dissolved component.

Using Standard Components

Some of the standard components are: screws, nuts, washers, bearings and holes. BricsCAD supplies a huge library of standard components, more than 30,000 details in a variety of sizes. Users can significantly increase design performance by using standard parts. Use the Components panel (6.9.26) to insert standard components into your parts and assemblies.

Assembly Constraints

Assembly constraints are ordinary 3D Constraints (1.27.3), that link faces and edges of bodies to represent the components of an assembly. You can link 3D Constraints (1.27.3) at the top-level and at the subcomponents level.

Component Visibility

A component within a complex assembly may seem invisible due to other components surrounding it. For example, a piston is invisible inside a cylinder block. To make such a component visible user may need to hide the other components surrounding it. Users can hide any subcomponent inserted into the current drawing or any subcomponents, on any level of nesting. You can also make a component transparent and/or visualize it as a wireframe model. BmHide (6.8.14) hides a particular subcomponent. BmShow (6.8.26) unhides a hidden subcomponent.

3.7.2 Assembly Design Commands and Toolbars

Icon	Command	Description
	BmNew (6.8.20)	Creates a new mechanical component as a new drawing file
	BmMech (6.8.19)	Convert the current drawing into a mechanical main component.
	BmInsert (6.8.16)	Inserts an existing mechanical component into the current drawing.
	BmInsert (6.8.16)	Inserts an existing mechanical component into the current drawing with automatical resizing of the new part and connecting it to the parent part.
	BmHardware (6.8.23)	Opens the Components Panel (2.4.24) with the Standard Mechanical Components (3.7.4)
	BmForm (6.8.13)	Creates a new mechanical component and inserts it into the current drawing.
	BmConnect (6.8.1)	Connects two Piping standard parts by creation of 3D constraints between their connection entities.
	BmReplace (6.8.31)	Replaces a component insert.
	BmLocalize (6.8.17)	Switches external components to local components.
	BmExternalize (6.8.11)	Switches local components to external components.
	BmOpen (6.8.21)	Opens the source drawing of an external mechanical component.
	BmOpenCopy (6.8.22)	Opens a copy of a component insert as a new drawing.
	BmDissolve (6.8.8)	Dissolves a mechanical component inserted into the current drawing.
	BmLink (6.8.15)	Changes target 3D solids of component-based features (1.30.25).
	BmUnlink (6.8.37)	Breaks the connection between a component insert (e.g. a Window) and a 3D solid (e.g. a Wall) retaining the opening.
	BmHide (6.8.14)	Hides a mechanical component or subcomponent in the current drawing.
	BmShow (6.8.26)	Shows a previously hidden mechanical component or subcomponent in the current drawing.
	BmVStyle (6.8.30)	Applies a visual style to a mechanical component

	BmBalloon (6.8.2)	Creates associative balloon entities for assembly components in Model Space and for their generated views in a Paper Space layout.
	BmBalloon (6.8.2)	Allows automatic placement of associative balloons on all components in a particular drawing view in a Paper Space layout.
	BmBom (6.8.3)	Inserts the Bill-of-Materials (BOM) table in the current drawing
	BmMassProp (6.8.18)	Computes mass properties for the current model using densities assigned to its components.
	BmUpdate (6.8.29)	Reloads all referenced components from external files and updates BOM tables.
	BmUpdate (6.8.29)	Reloads all selected referenced components from external files and updates BOM tables.
	BmExplode (6.8.10)	Creates an exploded representation for an assembly by moving components to make them all visible, stores it in a new block and inserts the block in Model Space.
	BmExplodeMove (6.8.12)	Moves selected parts to form an exploded representation in a given direction, taking into account possible physical collisions between components (similar to the Linear option of BmExplode (6.8.10) command).
	BmTrailingLines (6.8.27)	Creates all necessary trailing lines (3.7.8) for the selected parts.
	MechanicalBrowserOpen (6.8.32)	Displays the Mechanical Browser.
	ParametersPanelOpen (6.24.10)	Displays the Parameters Manager.
	BmDependencies (6.8.9)	Lists all files in the command window, containing component definitions inserted in the assembly, .
	BmRecover (6.8.24)	Recovers a broken mechanical structure
	BmUnmech (6.8.28)	Converts the current mechanical component into a plain drawing.
	BmXConvert (6.8.34)	Converts X-Hardware solids in the current drawing to mechanical components.

Tools to work with mechanical components are available:

- On the **Assembly** toolbars:
  - **Assembly** (3.178 on the next page)
  - **Assembly Insert**

Context Menus

Main Component context menu

Right-click the main component name: (3.184 on page 2812)

- **Update**: updates the hierarchy of mechanical components for the current drawing in case referenced drawing files of sub-components have been modified.
- **Visual Style**: **All by Viewport**: applies the current Visual Style (6.31.15) to all components in the assembly (see the ShadeMode (6.27.31) command). (3.185 on page 2812)
- **Insert standard hardware**: inserts a standard hardware part as a mechanical component in the current drawing.
- **Switch all to local**: switches all components to internal components (see the BmLocalize (6.8.17) command).
- **Switch all to external**: switches all components to external components (see the BmExternalize (6.8.11) command).
- **Add new parameter**: creates a new parameter (6.24.6) in the assembly.
- **Select all**: selects all components with the same definition.
- **Select same**: selects all components with the same name and the same parameter values.
- **Highlight all**: highlights all components with the same definition.
- **Highlight same**: highlight all components with the same name and the same parameter values.
- **Create exploded view (6.8.10)**: creates a block with an exploded representation of the current assembly.
- **Collapse all**: collapses the main component and all components and subcomponents.
- **Expand all**: expands the main component and all components and subcomponents.

Component context menu

Right-click a component name. External components context menu (left), local components context menu (right): (3.186 on page 2813) (3.187 on page 2814)

- **Open**: opens the referenced drawing (see the BmOpen (6.8.21) command).
- **Open a copy**: opens a copy of a component insert as a new drawing (see the BmOpenCopy (6.8.22) command).
- **Update**: reloads all referenced components from external files and updates BOM tables (see the BmUpdate (6.8.29) command).
- **Replace**: replaces a component insert (see the BmReplace (6.8.31) command). Replacing a local insert turns it into an external insert.
- **Replace all inserts**: replaces all inserts that refer to the same source (see the BmReplace (6.8.31) command). Replacing local inserts turns them into external inserts.
- **Switch to local**: switches an external component to an internal component (see the BmLocalize (6.8.17) command).
- **Switch to external**: switches an internal component to an external component (see the BmExternalize (6.8.11) command).
- **Set material to component...** : assigns a physical material to local component.
- **Removes material from component...** : removes the physical material definition from local component.
- **BOM status**: parameter to control the appearance of the component in BOM tables (6.8.3).
- **Dissolve**: dissolves a mechanical component inserted in the current drawing (see the BmDissolve (6.8.8) command).
- **Unlink**: breaks the connection between a component insert (for example a Window) and a 3D solid (for example a Wall) retaining the opening.
- **Hide** () / **Show** (): hides or shows the selected component.
- **Exclude all inserts from section**: sets the **Sectionable** property of all similar inserts to **NO**. Defines whether an insert is affected by the ViewSection (6.31.12) command.
- **Visual Style**: displays the **Visual Style** menu. All Visual Styles (6.31.15) that are saved in the current drawing are available.
  - **By parent component**: renders the selected component according to the shademode of the parent component (see the ShadeMode (6.27.31) command).
  - **All by Viewport**: renders all components according to the current viewport shademode (see the ShadeMode (6.27.31) command). (3.188 on page 2815)

Zoom to: zooms to the selection set. **Select all**: selects all components with the same definition. **Select same**: selects all components with the same definition and the same parameter values. **Highlight all**: highlights all components with the same

Subcomponent context menu	External subcomponents context menu (left), local subcomponents context menu (right): (3.189 on page 2815) (3.190 on page 2816) • **Open**: opens the referenced drawing (see the BmOpen (6.8.21) command) • **Open a copy**: opens a copy of a component insert as a new drawing (see the BmOpenCopy (6.8.22) command). • **Hide** () / **Show** (): hides or shows the selected subcomponent. • **Exclude all inserts from section**: sets the **Sectionable** property of all similar inserts to **NO**. Defines whether an insert is affected by the ViewSection (6.31.12) command. • **Visual Style**: see Component Visual Style (6.8.32). • **Zoom to**: zooms to the selection set. • **Select all**: selects all components with the same definition. • **Select same**: selects all components with the same definition and the same parameter values. • **Highlight all**: highlights all components with the same definition. • **Highlight same**: highlights all components with the same and the same parameter values. • **Collapse all**: collapses the main component and all components and subcomponents. • **Expand all**: expands the main component and all components and subcomponents.
Component parameter context menu	Right-click a parameter: (3.191 on page 2816) • **Link to parameter**: creates a link between one or more component parameters and assembly parameters. • **Collapse all**: collapses the main component and all components and subcomponents. • **Expand all**: expands the main component and all components and subcomponents.

Properties

Main component properties	Click the main component name: (3.192 on page 2817) • **Name**: type a name for the main component. By default, the name of the main component equals the file name. • **Description**: optional description of the main component. • **File**: shows the path and name of the drawing. • **Extension type**: allows to identify the component as a BIM Component or a Sheet Metal Feature. • **Insert as**: select either **Internal Component** or **External Component**. • **Sectionable**: defines whether the component is affected by the ViewSection (6.31.12) command. • **Standard component**: defines whether this component is a standard component or not. • **BOM status**: defines the behavior of this component in a BOM table. • **Material**: material of the main component. The **Name**, **Density**, and the optional **Description** are defined in the **Physical Materials (2.7.17)** dialog box. Select the **Material** node and do one of the following: – Click the **Browse** button () to open the Physical Materials dialog and choose a material in the Project or Library list. The Density property of the selected material is used by the BmMassProp (6.8.18) command. – Click the **Delete** button (). The Material field now reads <Inherit>. When the component is inserted in an assembly, the Material definition is copied from the main component of the assembly.

Component insert properties	Click the component name: (3.193 on page 2818) • **Name**: type a name for the component. By default, the name of the component equals the source file name. • **Component name**: name of the component as defined in the source file. • **Description**: description of the component as defined in the source file. • **Visible**: allows to show or hide the component in the assembly. Click the **Visible** field and: – Click the down-arrow button and choose **Yes** or **No**. or – Double-click the **Visible** field to toggle the visibility of the component. **Sectionable**: defines whether the component is affected by the ViewSection (6.31.12) command. **Standard component**: defines whether this component is standard or not. **BOM status**: defines the behavior of this component in a BOM table. **Visual style**: allows to control the visual style for the component. By default, the visual style is inherited from the viewport. Click the Visual style field and click the down-arrow button and choose a visual style in the list. **File**: shows the path and name of the referenced drawing. **Material**: shows the material of the component. If set to <Inherit>, the material is copied from the main component. If the material is defined explicitly in the source file, this material is used.
Subcomponent properties	Click the subcomponent name: (3.194 on page 2819) • **Name**: name of the component as defined in the source file of the parent component. • **Component name**: name of the component as defined in the source file. • **Description**: description of the component as defined in the source file. • **Visible**: allows to show or hide the component in the assembly. Click the **Visible** field and: – Click the down-arrow button and choose **Yes** or **No**. or – Double click the **Visible** field to toggle the visibility of the component. **Sectionable**: defines whether the component is affected by the ViewSection (6.31.12) command. **Standard component**: defines whether this component standard or not. **BOM status**: defines the behavior of this component in a BOM table. **Visual style**: allows to control the visual style for the component. By default, the visual style is inherited from the viewport. Click the Visual style field, click the down-arrow button and choose a visual style in the list. **File**: shows the path and name of the referenced drawing. **Material**: shows the material of the subcomponent. If set to <Inherit>, the material is copied from the main component. If the material is defined explicitly in the source file, this material is used.

Selection Methods	
Select component(s) in the model	The component(s) highlights in the Mechanical Browser.
Click a component in the Mechanical Browser panel	The component highlights in the drawing. Press the Space bar to select the component.

3.7.4 Standard Mechanical Components

Command: ComponentsPanelOpen (6.9.26) Youtube BricsCAD comes with a library of more than 1,000 standard mechanical parts available in more than 170,000 different sizes. They are available in the Library panel (6.9.26), and can be drag-and-dropped from the library into your assembly. You can adjust the parameters in the Properties panel (6.24.54), which temporarily lists parameters of the component being inserted. After insertion parameters can be edited in Mechanical Browser (6.8.32) and the Properties panel. In the Mechanical workspace, the Library panel contains three categories:

- Standard Parts
- Holes
- Sheet Metal

Standard Parts (Hardware)

The Standard Parts category contains parametric standard hardware grouped into four subcategories:

- Fasteners - bolts, nuts, washers, and etc.
- Machine Parts - bearings, sprockets, and etc.
- Piping - pipes, elbows, flanges, and etc.
- Structural Shapes - beams, channels, bars, and etc.

The content of each subcategory is further structured by type, subtype, and standards (example: Standard Parts / Fasteners / Bolts / Hex Head Bolts / ISO / ISO 4017). (3.195 on the facing page)

NOTE

There are two specific settings you can configure for Standard Parts in Settings (6.27.25) dialog:

- **Thread representation (THREADDISPLAY)** is used to represent a 3D thread for bolts and nuts or be not represent which allows to decrease the memory consumption and increase the performance for large assemblies;
- **Maximum number of sprocket teeth (GEARTEETHNUMBER)** is used to limit the number of teeth for sprocket wheels (available under Standard Parts / SPROCKET), which also allows to decrease memory consumption and increase the performance.

By default, these settings are set Off, in order to optimize the performance of the model. When changed, the settings apply to all new documents.

To place a standard component into the current drawing:

1. Choose a category.
2. Choose a standard.
3. Select a type.
4. Click on desired standard component.
5. Edit the parameters in properties panel.
6. Click in the drawing area to insert the selected component.

To create your own standard component

You can create your own standard parts and add them to Components panel using the BmCreateComponent (6.8.7) command.

To control the display of threads

1. Open the Settings (6.27.25) dialog.
2. Find the **Thread representation** variable (**THREADDISPLAY**).
3. Enable the setting.
4. If necessary, update the document in order to make threads appear on existing parts:
   - Temporarily set the **Assembly components updating mode** (**BMUPDATEMODE**) to **[1] Update all components.**
   - Update the document using BmUpdate (6.8.29) tool, which might take time in large models.
   - Return the **Assembly components updating mode** (**BMUPDATEMODE**) to the previous value if necessary.

To control the number of sprocket teeth

1. Open the Settings (6.27.25) dialog.
2. Find the **Maximum number of sprocket teeth** variable **(GEARTEETHNUMBER).**
3. Set the value to be sufficient for used sprockets (i.e., 500). Larger values slow down the update of standard sprockets. If the value is smaller than the required number, only that number of sprockets teeth displays.
4. If necessary, update the document in order to make sprockets teeth appear on existing parts:
   - Temporarily set the **Assembly components updating mode** (**BMUPDATEMODE**) to **[1] Update all components.**
   - Update the document using BmUpdate (6.8.29) tool, which might take time in large models.
   - Return the **Assembly components updating mode** (**BMUPDATEMODE**) to the previous value if necessary.

3.7.5 Assembly mass properties

Command: BmMassProp (6.8.18) An assembly can consist of multiple parts made from different materials. To correctly compute the mass, center of gravity (centroid), and inertia of such assemblies, BricsCAD supports individual densities for components. A physical material (2.7.17) for a mechanical component is defined in the Material (1.30.25) property in the Mechanical Browser (3.3.2). By default, a component inherits the density of the assembly, into which it was inserted into or formed from.

To set the mass units

1. Open the Settings dialog box (1.17.10).
2. Expand the **Property units** settings under **Drawing / Drafting / Drawing** units. (3.199 on the facing page)
3. Check the **Format mass properties** checkbox to enable formatting of mass values with appropriate units.
4. Select the **Mass units** field, then click the **Browse** button (...) and specify the desired mass units in the **MASSUNITS** dialog box. (3.200 on the next page)
5. Specify the desired precision in the **Mass precision** field.
6. Close the Settings dialog box (1.17.10).

NOTE	The **Mass units** setting affects the mass values only. Other mass properties such as density or moments of inertia will be formatted in SI units for the metric system and in imperial units for the imperial system, regardless of the value of the **Mass units** setting.

Figure 3.199

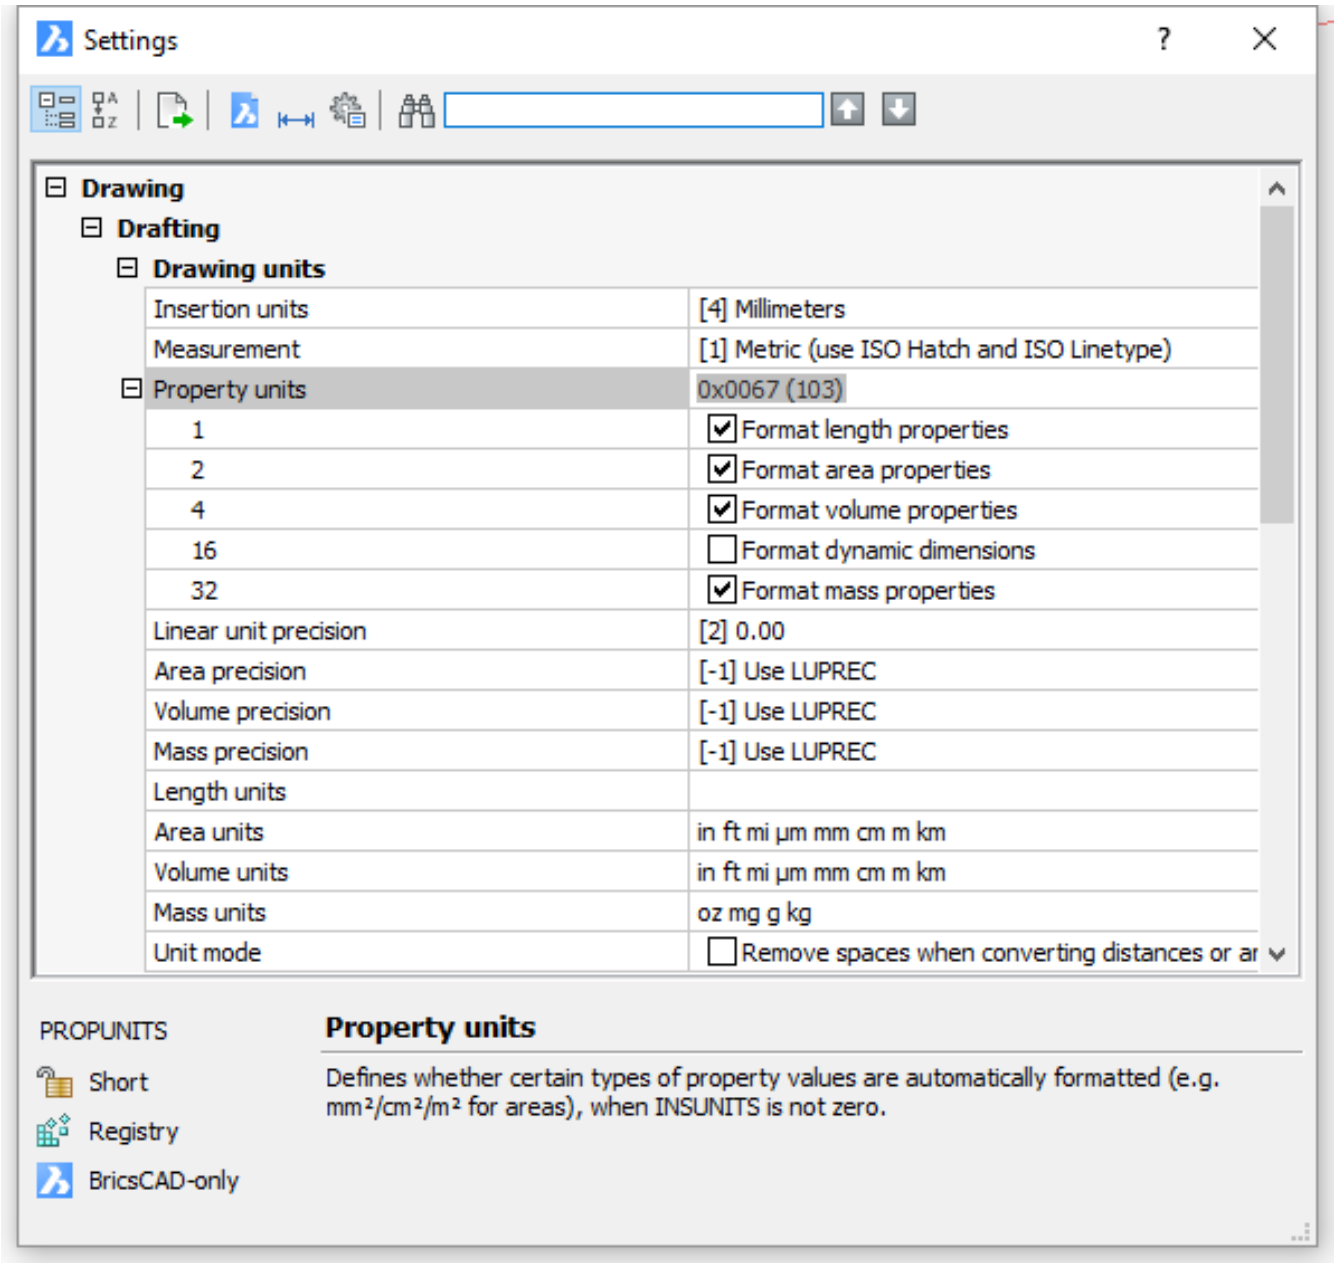

Figure 3.200

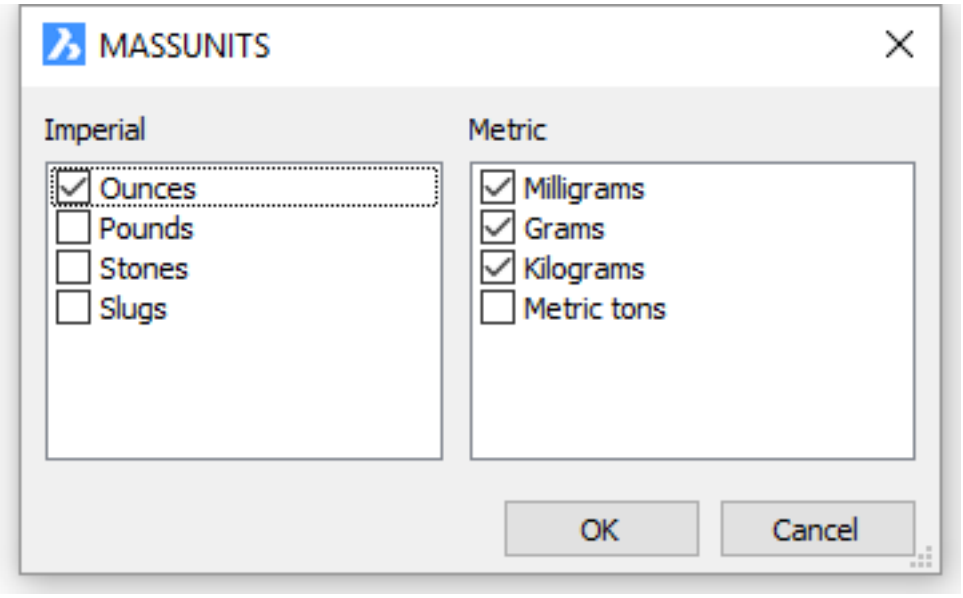
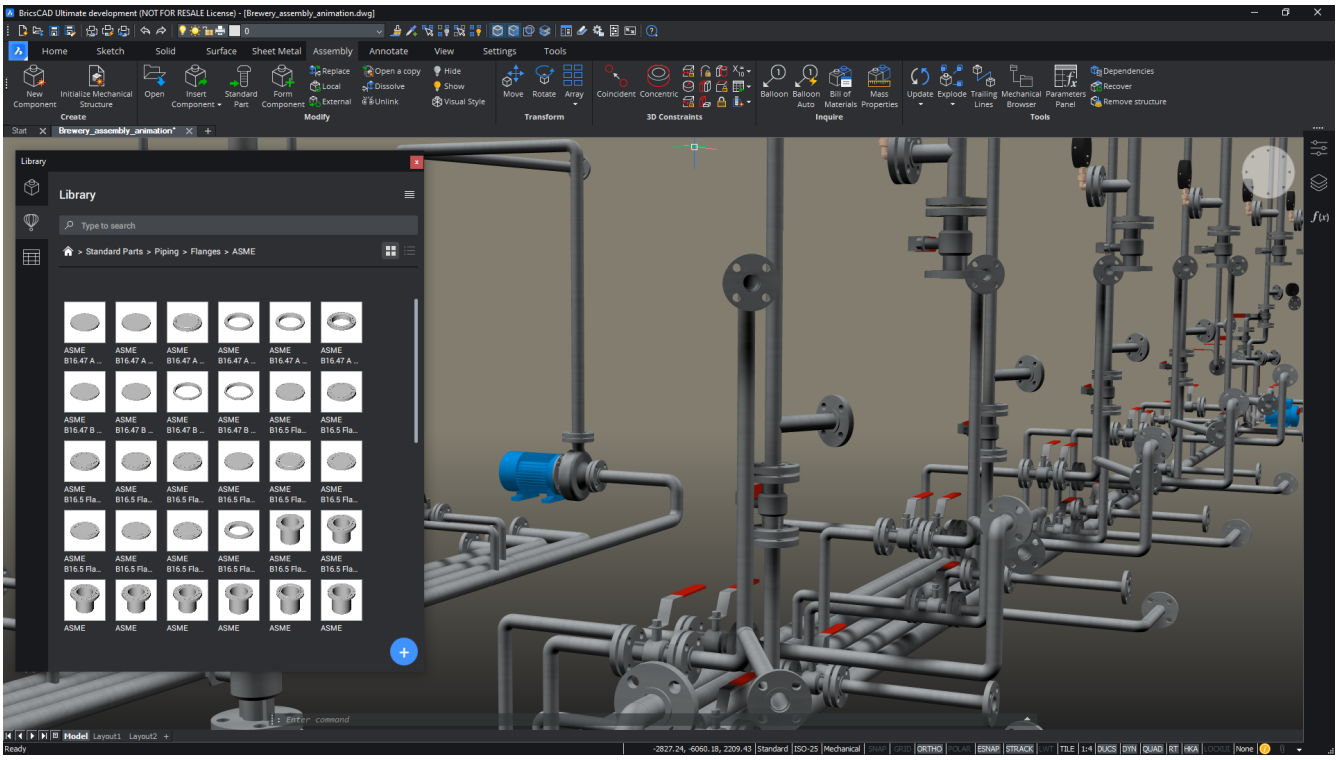


To compute the mass properties

Execute the BmMassProp (6.8.18) command. You can compute mass properties for the entire model or for a selection of 3D solids and/or subcomponents. The values of mass, volume, centroid, moments of inertia, products of inertia, radii of gyration, principal moments and X-Y-Z directions about centroid are reported in the command bar. Optionally you can align the User Coordinate System with the inertia axes, as a result, the center of mass-centroid of the component lies at the origin of UCS, which can be useful to investigate the behavior of a product under gravity force.

Figure 3.201



3.7.6 Piping in Assembly Design

Commands: BMINSERT (6.8.16), BMCONNECT (6.8.1), BMBOM (6.8.3) (3.201) Seamless and welded pipes, elbows, tees, crosses, reducers and flanges are widely used in machinery, automotive, and aviation industries; they are also found in oil-and-gas, chemical industry, and water supply. BricsCAD has a rich library of parametric piping parts of different standards: ASME, DIN, ISO, and others. These standard parts are parametric, so you can easily adjust their parameters, link them to different global parameters, and use 3D constraints to properly connect the parts. BricsCAD allows you to streamline these routine operations using the **Smart mode** of BmInsert command and a dedicated BmConnect command.

Inserting piping parts in your assembly

Drag and drop any piping standard part from the Library panel (6.20.23) into your assembly. By default, all parts from the Piping category are inserted in Smart mode, which means that if you hover over a previously inserted piping part, BricsCAD:

- Copies parameter expressions of that part to the corresponding parameters of the part being inserted.
- Adds a set of 3D constraints to connect the parts.

Note: Press the Ctrl-key to switch between Smart mode and Regular mode, in which 3D constraints with other parts are not generated.

Creating 3D constraints between piping standard parts manually

Piping standard parts have a set of wireframe entities (points and lines) on the STD_PARTS_PIPING_CONNECTION layer, which is switched Off by default.

Constraining a fitting To constrain a fitting (elbow, reducer, flange, ...) with another fitting or a pipe, create two Coincident 3D (6.12.5) constraints between:

- two points of the fittings, which should coincide,
- two lines of the fittings, which should be collinear.

Constraining a pipe Constraining pipes is more complex because a pipe can have any length. If a pipe is already constrained with a fitting at one side using two Coincident 3D constraints (as explained in the previous paragraph), then constraining it from the other side should be different. You have to create:

- A Coincident 3D constraint between the line, which represents the axis of the pipe, and the corresponding line of the other fitting,
- A geometry-driven Distance 3D constraint between the planar face of the pipe on the opposite (already constrained) side and the corresponding point of the fitting, which is being connected.

You must then type the name of the distance constraint in the expression field for the Length parameter of the pipe. Because geometry-driven constraints allow controlling of a particular dimension, the pipe will always have the correct length, and such a parametrization will not limit any further editing of your assembly using direct manipulation of additional non-geometry-driven dimensional constraints.

Automatically connecting piping parts

The set of constraints described above are created automatically using the Smart mode of the BmInsert (6.8.16) command or a dedicated BmConnect (6.8.1) command to connect two standard parts.

Creating a Bill of Materials for a piping assembly

In a BOM you may want all pipes of the same type and size (PartNumber), but with different lengths, listed as the same part. To do so, use the Aggregate function of the BOM Manager (3.7.9) to combine all such parts in a single row with their total length.

3.7.7 Arrays of Components

Commands: ARRAY (6.4.19), ARRAYRECT (6.4.28), ARRAYPOLAR (6.4.41), ARRAYPATH (6.4.26), BMINSERT (6.8.16)
BricsCAD allows you to insert the same component multiple times in a regular way: all inserts can be distributed uniformly (at the same distance) along a line, a circle, or an arbitrary curve. Higher-order patterns (for example, rectangular or cylindrical) are also supported. This is achieved by using the technology of **associative arrays:** rectangular, polar, and path. Associative arrays are persistent entities, which can be edited (manually or automatically) at any moment after creation - to change the number of elements or distance between them. All arrays in your model are listed in the Mechanical Browser, where they can be edited. Any component can be arrayed - including parts, subassemblies, standard parts, and holes.

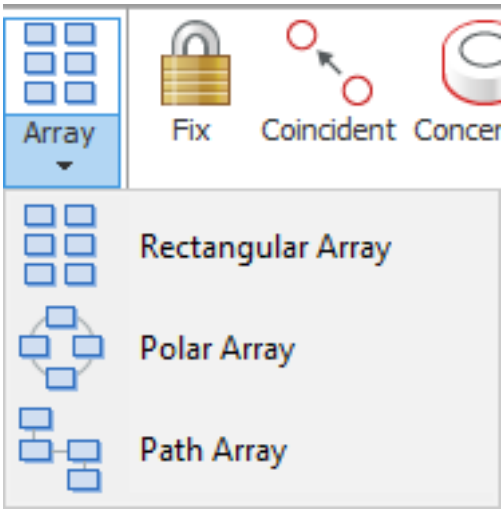
Creating an Array of Components

Use one of the array tools available in Assembly ribbon panel of Mechanical workspace:

- Rectangular Array (6.4.28)
- Polar Array (6.4.41)
- Path Array (6.4.26)

(3.202) Another way to create an array of component is to use Multiple/Array option of Insert Component (6.8.16) tool: 

Figure 3.202



Arrays of Components in the Mechanical Browser

(3.203 on the facing page) Arrays of components are represented as special nodes in the Mechanical Browser: they are named after the array type (Rectangular, Polar, or Path) followed with semicolon and the index of the array (for example, **Rectangular;1**, **Polar;2**, **Path;3**). These nodes have the same properties (3.7.12) as regular associative arrays. The properties can be used to change the number of elements in the array, distance/angle between them, and other array parameters. You can also assign a persistent expression to any property - it will be used to automatically recompute the value of the property upon changing its driving parameters. Each array node has two child nodes: **Source** and **Elements**. Under Source node you can find the inserted component and its parameters, while Elements node can be expanded into a list of array elements with the possibility to hide or change visual style of a particular element inside the array.

Arrays of Components and Bill of Materials

Arrays of components are transparent for product structure: components inside arrays are considered as inserted directly into the same assembly. So in top level BOM, components inserted into top level arrays are listed as top level components. The **Quantity** column in BOM is filled with the total number of inserts of the same component including the components inside arrays.

Arrays of Parametric Components, Standard Parts, and Holes

If a parametric component is inserted as an array, its parameters are still available for editing and linking with global parameters. Technically the parameters are associated with the source element of an array, and when this source element is edited parametrically, all other elements of the array are changed after it. Standard Parts and Holes are parametric components and you can edit their parameters inside the arrays. You can easily create a part with many holes and you can control the hole number, positions, and size parametrically plus insert a parametric bolt. This powerful technology allows you to create parametric flange assembly with multiple configurations.

3.7.8 Exploded Representations

Commands: BMEXPLODE (6.8.10), BMEXPLODEMOVE (6.8.12), BMTRAILINGLINES (6.8.27), VIEWBASE (6.31.4). The exploded representation functionality creates associative exploded representations of assemblies and does not modify the assembly itself. Exploded representations are stored in dedicated blocks which can be edited and inserted according to your needs. You can also generate drawing views from the exploded representations. Exploded representations are associative. Each part in an exploded representation is linked with the corresponding part in the assembly. Use BMBALLOON (6.8.2) to update exploded representations to the current state of the assembly as well as place balloon annotations on the corresponding drawing view(s). (3.204)

Levels of the exploded representation

Exploded representations contain references to the components which makes them quite lightweight. Two levels of the exploded representation are supported: Top and Bottom.

- **Top Level**: The exploded representation contains references to the top-level components only. Top-level components are components inserted directly into the main assembly. A top-level component in such as an exploded representation is not exploded further - all its parts and subassemblies remain assembled. A top-level exploded representation allows you to see the basic composition of your assembly.
- **Bottom level**: The exploded representation contains references to the bottom-level components only. Bottom-level components are terminal parts, which do not contain other parts or subassemblies. Bottom-level exploded representations allow you to view all parts in isolation.

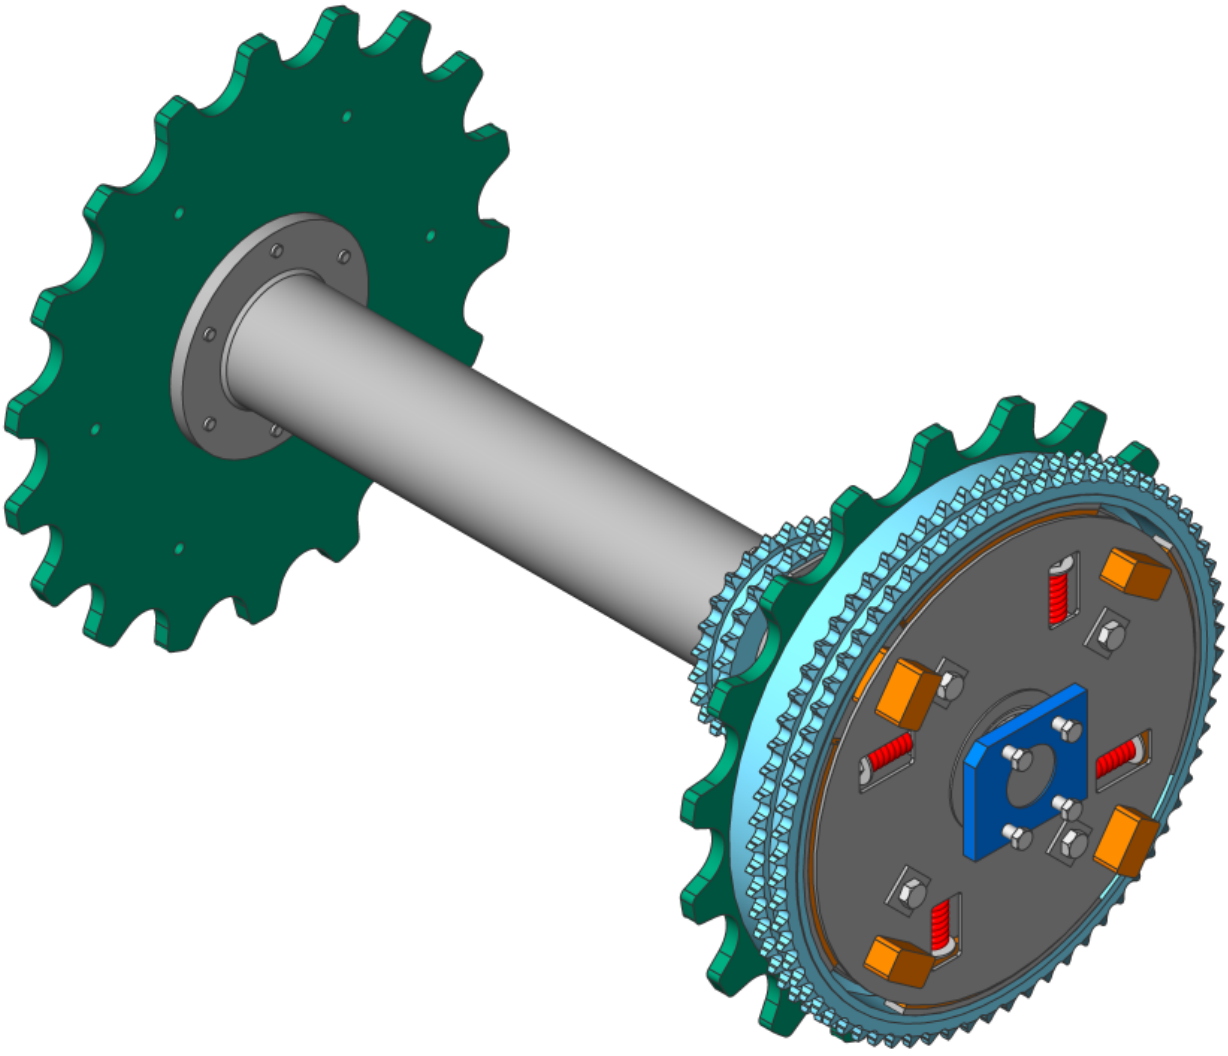
NOTE	If **Bottom level** is selected and there are some middle-level components containing not only inserts of components but also other entities, these entities will be lost in the exploded representation because it is not possible to reference them correctly. Those entities should be converted into corresponding bottom-level components first.

Algorithms

BricsCAD provides three algorithms to automatically create exploded representations and a Manual mode.

- The **Table by Type** algorithm creates a table-like explosion where components of the same type are grouped in rows.
- The **Linear** algorithm finds the disassembly sequence of components in a given direction and orders the components. **Note:** It takes into account possible physical collisions between components. The compo-

Figure 3.205



Steps and animations

Exploded views may contain one or several steps, which describe a particular assembly or disassembly sequence. Each step corresponds to a set of components that should be moved at this particular stage in order to assemble or disassemble the main assembly. All exploded representation algorithms automatically create all the required steps. You can also delete, merge, split, move, or add extra steps. Each step has a unique name that can be used to describe the step. It is possible to animate a particular step as well as the entire sequence of steps, both indirect and reverse directions (to get disassembly and assembly animations). In order for the animation to work properly, an initial step that defines the initial state of the assembly must be present in the exploded representation. Use the **Auto hide** property of the exploded representation to automatically hide components that are not important for a particular step during the animation.

Edit exploded representations

Because each exploded representation is stored as a block, it is possible to edit the exploded representation with the block editor (1.30.4). **Warning:** Do not use the REFEDIT (6.26.13) command to edit exploded representations. This command is incompatible with exploded representation steps. To open the exploded representation for edit: right-click at the required exploded representation in the Mechanical Browser (6.8.32) and select "Edit" from the context menu. The block editor (1.30.4) will open automatically. You can also open the exploded representation for edit at the end of the BMEXPLODE (6.8.10) command. When the exploded representation is open for edit, you can change the state of the current step. By default, this is the last step made by the algorithm. However, you can change this. Use the **Current step** property of the exploded representation in the browser, or right-click at the desired step in the Mechanical Browser (6.8.32) and select "Apply" from the context menu.

NOTE	If you change the current step you will discard all unsaved modifications as well as any operation on steps. Make sure that all modifications are saved before you change the current step or perform any other operation.

Use DMMOVE (6.12.16), MOVE (6.21.29), DMROTATE (6.12.24), and BMEXPLODEMOVE (6.8.12) to move components, inside the exploded representations, to the required positions. BMEXPLODEMOVE (6.8.12) will automatically add all necessary steps after the current step. For other operations save the current step after the edit is complete. Only the difference between the current step and the previous one is stored. It is also possible to change the exploded representation by performing operations on steps. For example, if you remove a step, all components moved at this step will be returned to their respective positions before that step. Save the current step once you have finalized the edit, otherwise, changes will be discarded.

Trailing lines

(3.206 on the next page) Trailing lines help explain the relationship between parts. It is a 3D polyline that represents a trajectory and displays the movement of a part during the disassembly process. Use BMTRAILINGLINES (6.8.27) to add trailing lines to an exploded representation that is open for edit. This tool will create all trailing lines. The information from the exploded view steps is used to do this. You can generate trailing lines for all parts or for a subset of parts. For a subset, trailing lines will be built for parts from that subset only (although only necessary trailing lines will be added. Some parts may not have trailing lines at all). You can also manually select two parts to add a trailing line between. When a trailing line is computed, the algorithm automatically determines the location of the part and the location from where the part was removed to compute the trajectory. It takes into account the movements of both parts. Each trailing line is displayed in the mechanical browser. With the mechanical browser, you can see all trailing lines in the model; highlight, select and zoom to parts connected with the selected line; rename or remove the trailing line. You can edit the trailing line(s) with the standard 3D polyline edit tools. (3.207 on the following page)

Figure 3.206

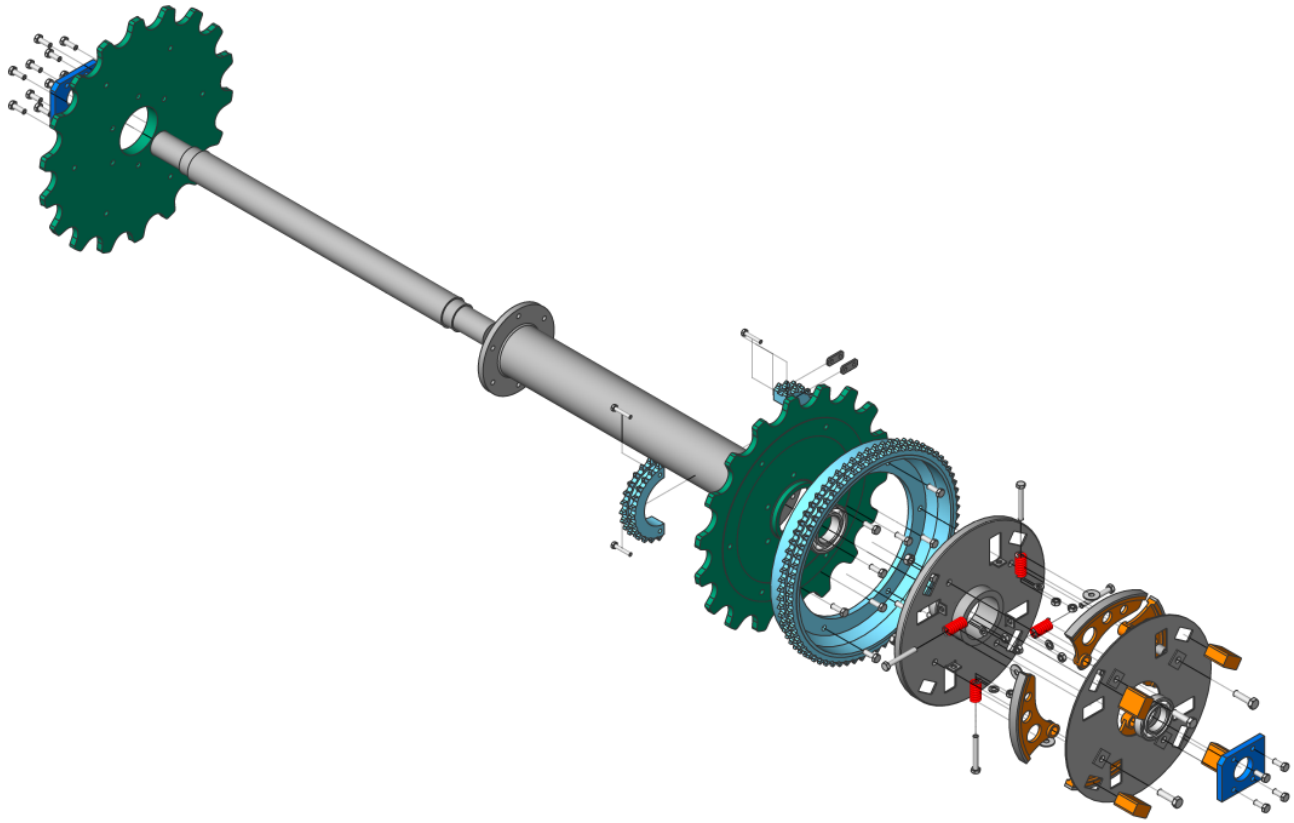


Figure 3.207

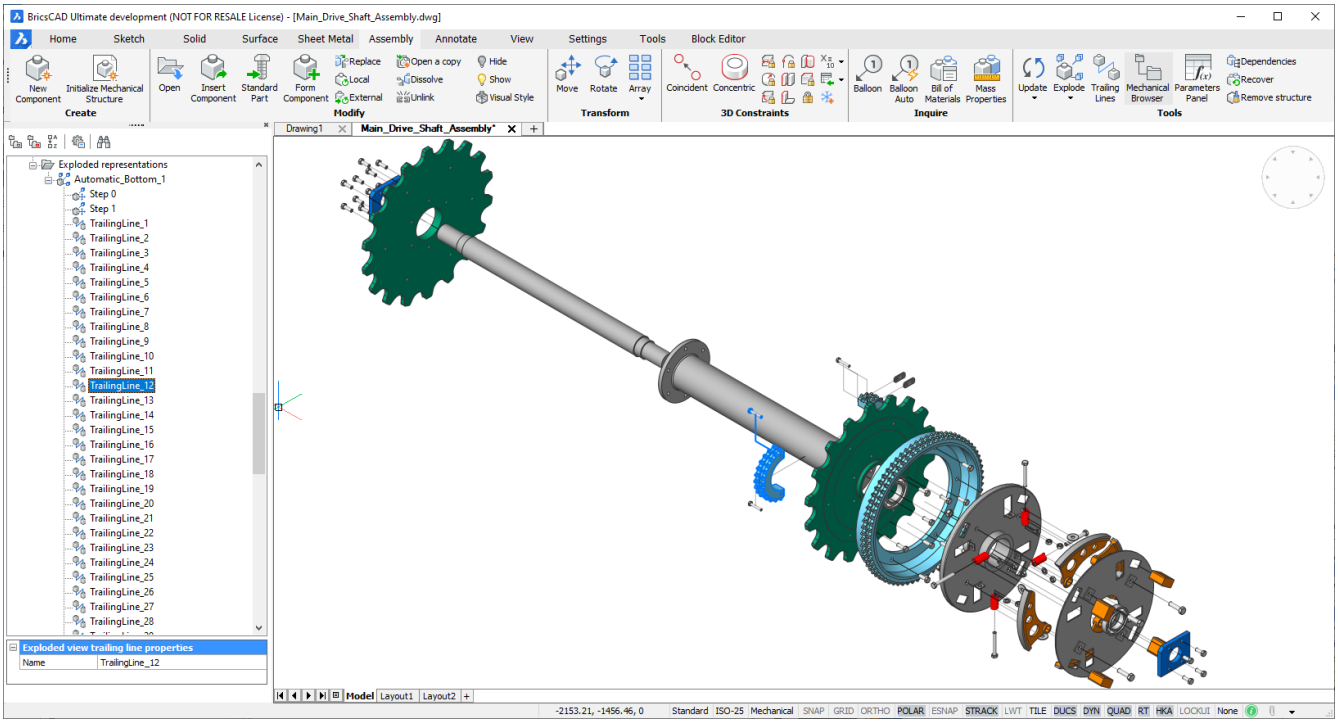

To create an exploded representation

The BMEXPLODE (6.8.10) command creates an exploded representation of the current assembly. **Note:** You must have at least one insert of a part in the assembly for the command to work.

1. To launch the BMEXPLODE (6.8.10) command, do one of the following:
   - Click the **Explode** tool button ( )on the **Tools** panel of the **Assembly** ribbon tab;
   - Click the **Explode** tool button ( )on the **Assembly** toolbar;
   - Select **Explode** in the **Assembly** menu;
   - Type **bmexplode** in the command bar. **You are prompted:** Select explosion algorithm [Table by types/Linear/Manua
2. (Option) Set the **Level** and the **Name** of the exploded representation using the **Settings** option.
3. Select the algorithm. **You are prompted:** Select exploded view behavior [Edit/Generate drawing views/Finish]:
4. Select **Edit** to edit the exploded representation. Select **Generate drawing views** to generate drawing views of the exploded representation. Select **Finish** to finish the command.

To generate drawing views of the exploded representation

1. Launch the VIEWBASE (6.31.4) command. **You are prompted:** Select objects or [Entire model/preseTs/Special views] <Entire model>:
2. Select the **Special views** option. **You are prompted:** Select view [Exploded view/Back] <Back>:
3. Select the **Exploded view** option. A dialog to select the exploded representation will be opened. Select the exploded representation from the dialog. **You are prompted:** Enter new or existing layout name to make current <Layout1>:
4. (Optional) Enter the **Layout name** of the layout for the exploded representation.
5. Position the generated drawing views of the exploded representation in the paper space layout.

NOTE	To use balloons (see BMBALLOON (6.8.2) command) with drawing views of exploded representations, the GENERATEASSOCVIEWS (1.17.10) system variable must be ON.

To update an exploded representations

Execute the BMUPDATE (6.8.29) command to synchronize exploded representations with the current state of the assembly. If necessary, adjust the exploded representation. Such adjustments, for example, may be required because of the addition and/or deletion of some parts.

NOTE	The position of parts in exploded representations created in **Manual** and **Linear** modes are not updated automatically.

To manage exploded representations

(3.208 on the next page) Open the Mechanical Browser (6.8.32) to see all exploded representations in the document. All exploded representations will be listed under the **Exploded representations** group. Open the context menu for the selected exploded representations to see all supported operations in this context.

Properties of exploded representations Each exploded representation has a set of properties, some of them can be edited by the user.

- **Algorithm -** the name of the algorithm used to create this exploded representation.
- **Name -** Name of the exploded representation. This must be unique for all exploded representations as well as for all the blocks in the model.
- **Type -** Type of the exploded representation: **Top** or **Bottom**.
- **Animation** - the direction of animation. Can take one of two values:
  - **Direct** - from start to end.
  - **Reverse** - from end to start.
- **Auto hide** - if set to **Yes**, all none important parts for a particular step will be hidden during the animation.
- **Step duration** - default duration of each step during the animation, in milliseconds. The default value is 1000, which is equal to 1s duration.
- **Current step** - the current step that corresponds to the state of the exploded representation.

Operations on exploded representations The supported operations depend on whether or not the exploded representation is opened for edit. If the exploded representation is not opened for edit, the following operations are possible:

- **Edit** - opens the exploded representation for edit. You can also edit the exploded representation using Bedit (6.6.7).
- **Delete** - removes the exploded representation and the associated block from the document.

If the exploded representation is opened for edit, the following operations are possible:

- **Animate** - animates the entire sequence of steps.
- **Save current state** - saves the current positions of parts in the current step.
- **Add a new step** - adds a new step after the last one. **Note:** the new step will be automatically set as current. All unsaved modifications of the exploded representation will be lost.
- **Delete** - removes the exploded representation and the associated block from the document.

In addition, all steps will be listed in the Mechanical Browser (6.8.32) for this exploded representation.

To manage exploded representation steps

Open the Mechanical Browser (6.8.32) and open the required exploded representation for edit. All steps will be listed under the corresponding node in the tree.

Properties of steps

- **Name** - the name of the step. Must be unique for this exploded representation.
- **Duration, ms** - the duration of the step. By default, this is equal to the **Step duration** set for the exploded representation.
  - **Duration type** - specifies if the duration should be taken from the exploded representation, or if it is specific for this particular step.
  - **Duration value** (only for **Absolute** duration type) - the duration for this step in milliseconds.

Operations on steps

- **Apply** - sets the step as the current and updates the parts in the exploded representation according to this step.
- **Animate** - animates the selected step.
- **Set as previous** - clears the step, so the positions of all parts will be the same as at the previous step.
- **Merge with previous** - merges this and the previous step and removes the previous step.
- **Split** - splits the step to a sequence of steps, each of them corresponding to exactly one part.
- **Move step up** - moves the step one position up in the tree.
- **Move step down** - moves the step one position down in the tree.
- **Delete** - completely removes the step as well as the associated movements of parts. After that, it updates the positions of parts in the exploded representation accordingly.

To edit exploded representations

1. Select the exploded representation in the Mechanical Browser (6.8.32).
2. Right-click at the exploded representation and select **Edit** from the context menu **Or** Run the Bedit (6.6.7) command and select the block with the exploded representation
3. Perform the necessary operations to get the desired exploded representation. Do not forget to save the current step.
4. Save changes using Bclose (6.6.4) with the option **Save**.

NOTE	Avoid using the **Discard** option of Bclose (6.6.4), as it can lead to an inconsistent state of the block and exploded representation steps. Use Undo (6.30.5) instead.

To add trailing lines

1. Open the exploded representation for editing (see To edit exploded representations)
2. Run BMTRAILINGLINES tool
3. Select the subset of parts to create trailing lines for or select the entire model.
4. Select what points of the parts should be used to create the trajectory: origin or center.
5. Edit the resulted trailing lines if necessary.
6. Save changes.

3.7.9 Bill of Materials Manager

Commands: BMBOMPANELOPEN (6.8.5), BMBOMPANELCLOSE (6.8.4), BMBOM (6.8.3) The Bill of Materials manager allows you to browse, create and edit bills of materials (BOMs) (3.7.11) in the current drawing. Use the manager to interactively configure, both new and existing, bills of materials. You can save the configuration of a bill of materials as a template file and reuse it later in other drawings. You can also add a bill of materials that is not linked to a table in the drawing. (3.215 on the following page) With the Bill of Materials Manager, you can:

- Browse existing bills of materials in the drawing.
- Create a new bill of materials using either a standard type (such as top-level, bottom-level, hierarchical) or an existing BOM template.
- Edit bills of materials:
  - Add or remove columns (includes formula columns).
  - Move selected columns to new positions.
  - Rename the columns.
  - Configure how the BOM table is sorted.
  - Configure the footer value for each individual column.
  - Configure the units and how they are displayed for each column.
  - Configure the width of each column with column properties.
  - Configure the visibility of each individual column.
  - Filter the components with a filter expression.
  - Change the title of both the title row and the footer row.
- Search for components in the table.
- Highlight and select component instances.
- Save the BOM configuration as a template file.
- Load a BOM table configuration from a template file.
- Place the BOM table in a drawing.
- Delete BOM tables.

A Mechanical or Ultimate license is required to modify or create bills of materials. However, the manager is available with a Pro license.

Bill of materials properties

Title	Bill of material <NAME>
Type	Hierarchical
Property set	Mechanical only
Filter	
Sorting mode	Automatic order
Counting mode	Count instances in parent component
Max level	All
Footer title	TOTAL:
Fixed corner	Top left
CSV delimiter	; (Semicolon)
Warning messages	On

Open the Bill of Materials Manager

Do one of the following:

- Place the cursor on a toolbar and right-click and choose **BOM Manager** from the context menu.
- Launch the BMBOMPANELOPEN (6.8.5) command.

Tools

Most of the configuration operations in the manager are available in the main menu. A context menu is available for selected columns or rows. You can also change the properties of the selected columns and the BOM itself in the properties section of the manager. To work with a particular column, select it in the BOM grid. Multiple columns can be selected simultaneously.

Main menu Click the **Menu** button ( ) at the top right corner of the BOM Manager panel. (6.566 on page 3843)

	**New BOM**	Opens a submenu: (6.567 on page 3844) • **Top level:** creates a new, top-level BOM. • **Bottom level:** creates a new bottom-level BOM. • **Hierarchical:** creates a new hierarchical BOM. • **Create from template:** opens a dialog to select a BOM configuration template file. • **Copy the current table**: creates a new BOM based on the current table.
	BOM tables in the document	Opens a submenu: (6.569 on page 3844) • **Go to first table**: switches to the first BOM table in the document. • **Go to previous table**: switches to the previous BOM table in the document. • **Go to next table**: switches to the next BOM table in the document. • **Go to last table**: switches to the last BOM table in the document. • **<Name of the BOM>**: switches to the corresponding BOM table in the document.

 **Place/update BOM table**	Starts the interactive placement of a table in the drawing. If the table is already placed in the drawing, it updates the table. **Note:** all editing operations update the associated table in the drawing automatically.
Export to CSV	Saves the content of the current table to a CSV file. Opens a dialog to select the location for the CSV file: (6.570 on page 3845) **Note:** you can adjust the separator for CSV values using the table properties.
 **Replace from template**	Replaces the current BOM table configuration with the selected template. Opens a dialog to select the template file.
 **Save as template**	Saves the configuration of the current BOM table as a template. Opens a dialog to select the location for the new template file.
 **Delete current BOM**	Deletes the current BOM table from the document.
 **Set filter**	Opens a dialog to configure the main filter: (6.573 on page 3846)
 **Refresh**	Updates the current BOM and lists all BOM tables in the drawing.
 **Insert column after**	If a column is selected: inserts a column from the **Column selector** after the selected column in the table. If no column is selected: a new column is added after the last column in the table.
 **Insert column before**	If a column is selected: inserts a column from the **Column selector** before the selected column in the table. If no column is selected: a new column is added as the first column in the table.

	Insert formula column	Opens a dialog to configure a formula column: (6.576 on page 3848) Click **OK** to add a new formula column after the selected one. If no column is selected, a new formula column is added after the last column in the table.
	Insert template column	Opens a dialog to configure a template column: (6.577 on page 3848) Click **OK** to add a new template column after the selected one. If no column is selected, a new template column is added after the last column in the table.
	Edit evaluated column	Opens a dialog to edit the selected formula or template column.
	**Delete column**	Removes the selected column from the table. You can also select a column in the **BOM grid** and hit the **Delete** key to remove a column.
	**Move column left**	Moves the selected column(s) one column to the left.
	**Move column right**	Moves the selected column(s) one column to the right.
	**Make column visible**	Shows the selected column in the associated table in the drawing.
	**Make column invisible**	Removes the selected column from the associated table. Invisible columns remain visible in the BOM manager but are marked with a diagonal hatch pattern in the background.

Associated table

Opens a submenu: (6.578 on page 3849)

- **Zoom to:** zooms to the table. If necessary, sets the table layout as the current one.
- **Select:** selects the table. If necessary, sets the table layout as the current one.
- **Delete:** deletes the table from the document.
- **Detach:** detaches the table. The table in the document is no longer updated when the BOM table is modified.

Footer

Opens a submenu: (6.579 on page 3849) For each of the selected columns:

- **No footer:** removes the footer.
- **Sum:** displays the sum in the footer.
- **Average value:** displays the average in the footer.
- **Minimal value:** displays the minimum value in the footer.
- **Maximal value:** displays the maximum value in the footer.

See the Bill of Materials/Footer (3.7.11) for more details.

Sorting

Opens a submenu: (6.580 on page 3849)

- **Automatic order:** sorts the table automatically.
- **Natural order:** sort the table by the natural order of component instances in the document.
- **Ascending order:** sorts the selected columns in ascending order.
- **Descending order:** sorts the selected columns in descending order.

See Bill of Materials/Sorting (3.7.11) for more details.

	Disable/Enable warnings	Controls the display of warning messages during the creation or update of BOM tables.

Toolbars (3.217)

(6.581 on page 3849)	**Main menu** **BOM Selector**	Opens the main menu. Selects the current BOM table. The selection is stored in the drawing. When the drawing is closed and re-opened, the selected BOM is re-stored in the manager. When selected, the table is updated to the current state of the drawing.
	Refresh	Updates both the current BOM and the list of all BOM tables in the drawing.
	Place/update table	Starts the interactive placement of a table in a drawing. Updates the table if it already exists. **Note:** all edit operations automatically update the associated table in the drawing.
(6.582 on page 3849)	**Category selector**	Selects a properties category.
(6.583 on page 3849)	**Column selector**	Selects the column to be added to the current BOM. You can also use this to enter a formula for a formula field. To add a formula, type an expression starting with "=", such as "=<Mass>*<Quantity>". The formula may refer to other columns. Use their display names enclosed in <>.
	Insert column after	If a column is selected: inserts the column from the **Column selector** after the selected column in the table. If no columns are selected: the new column is added after the last column in the table.

Figure 3.217

	**Find**	Toggles the search field on and off. **Ctrl+F** also toggles the search field.
(3.257 on page 2890)	**Search field**	Enter a search string; wildcard characters are supported.
	**Find previous**	Selects the previous match in the BOM table. You can also use **Ctrl+F3**.
	**Find next**	Selects the next match in the BOM table. You can also use **F3**.
	**Select all found**	Selects all matches in the BOM table.

Column context menu Right-click a column label to open the context menu. The column is added to the current selection. (6.557 on page 3838)

	Add template column from selected	Opens a dialog to configure a new template column. The selected columns will be automatically added to the template expression.
	**Delete column**	Removes the selected column(s) from the table. You can also select a column in the **BOM grid** and press the **Delete** key.
	**Footer**	Opens a submenu: (6.579 on page 3849) For the selected column(s): • **No footer:** removes the footer. • **Sum:** displays the sum in the footer. • **Average value:** displays the average values in the footer. • **Minimal value:** displays the minimum value in the footer. • **Maximal value:** displays the maximum value in the footer. See Bill of Materials/Footer (3.7.11) for more details.

Sorting

Opens a submenu: (6.580 on page 3849)

- **Automatic order:** sorts the table automatically.
- **Natural order:** sorts the table by the natural order of component instances in the document.
- **Ascending order:** sorts the selected columns by ascending order.
- **Descending order:** sorts the selected columns by descending order.

See Bill of Materials/Sorting (3.7.11) for more details.

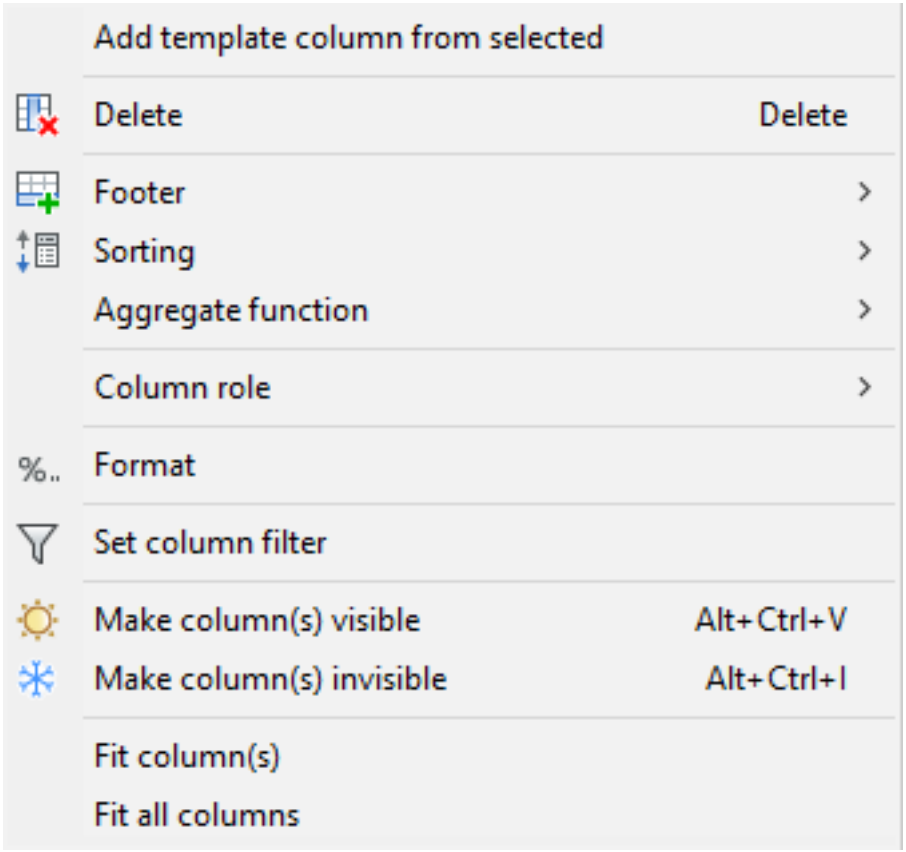
Aggregate function

Opens a submenu: (3.260 on page 2891) For the selected column(s):

- **No function:** removes the aggregate function.
- **Sum:** displays the sum of all values in the group.
- **Average value:** displays the average of all values in the group.
- **Minimal value:** displays the minimum of all values in the group.
- **Maximal value:** displays the maximum of all values in the group.
- **Concatenation**: displays a concatenation of all values in the group in ascending order separated by a specified delimiter ('; ' by default)
- **Concatenation with count**: displays a concatenation of all values in the group with their corresponding number of encounters in ascending order. Value and count pairs are separated by a specified delimiter ('; ' by default)

	Column role	Opens a submenu: (3.261 on page 2891) For the selected column: • **Number**: the column will be used as a source of numbers by the bmBalloon (6.8.2) command. • **Name**: the column will be used as a source of names by the bmBalloon (6.8.2) command. • **Quantity**: the column will be used as a source of quantities by the bmBalloon (6.8.2) command. • **Regular**: the column will have no specific role.
	**Format**	Sets the specified format for selected column(s). Opens a dialog: (3.269 on page 2896)
	**Set column filter**	Opens a dialog to configure the column filter: (3.263 on page 2893)
	**Make column visible**	Displays the selected columns in the associated table in the drawing.
	**Make column invisible**	Removes the selected column from the associated table. Invisible columns remain visible in the BOM manager but are marked with a diagonal hatch pattern in the background.
	Fit column(s)	Fits the width of the selected column(s) to their content. The column width automatically fits the content unless the width has been changed manually.
	Fit all columns	Fits the width of all columns to their content. The column width automatically fits the content unless the width has been changed manually.

Figure 3.218



Row context menu Right-click on any cell to open the context menu. (6.556 on page 3838)

Zoom to Zooms to the select part(s) in the model

Select Selects the part(s). Replaces an existing selection.

Add to Selection Adds part(s) to the selection.

Remove from Selection Removes the parts from the selection.

Remove highlighting Removes highlighting.

Clear selection Clears a selection.

Collapse Collapses the subassembly group in the BOM grid.

Expand Expands the subassembly group in the BOM grid.

Expand this level Expands all subassembly groups at the same level of the assembly tree as the current one.

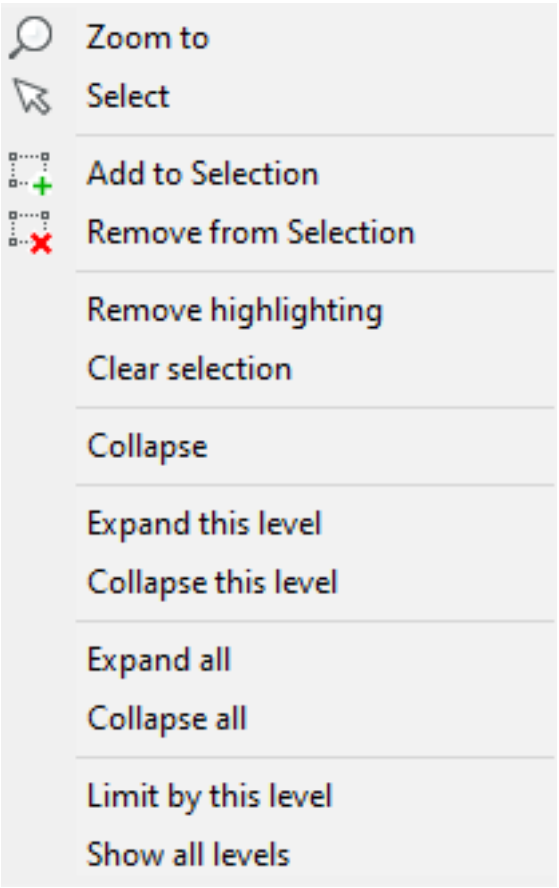
Collapse this level Collapses all subassembly groups at the same level of the assembly tree as the current one.

Expand all Expands all subassembly groups in the current BOM.

Collapse all Collapses all subassembly groups in the current BOM.

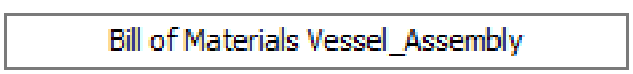
	Limit by this level	Sets the current level as the maximal level for hierarchical BOM tables.
	Show all levels	Removes the maximal level limit for hierarchical BOM tables.

Figure 3.219



BOM Title (3.220) Displays the title of the current BOM, as displayed in the drawing. Left-click on this control to edit the drawing. In this mode, the **BOM title** control shows the **title template** instead. The **title template** is a string that may contain a **<NAME>** placeholder, which will be replaced by the assembly name.

Figure 3.220



Grid (3.221 on the next page) The grid displays the content of the selected BOM table. Each row is linked with its corresponding instances. When a row is selected, the corresponding parts are highlighted in the drawing. Use the context menu, to select corresponding parts, add or remove them from the current selection and to zoom to those parts. Double-click on any cell in the row to zoom to the corresponding parts.

Moving a column To move a column in the BOM table drag and drop it to its new position.

Visible and invisible columns (3.222 on the facing page) You can make any column in the BOM table invisible, so it does not show in the resulting table, invisible. Invisible columns remain visible in the BOM grid with a hatched background. You can change the visibility of columns in the main menu, the column context menu or by editing the **Visible** property of a column in the **Properties grid.**

Width adjustment You can adjust the width of any column in the BOM grid, which is independent from the width in the associated table. If the width of the column is less than needed to display the text of the cell, the height of the corresponding row increases to fit the text. When the column width is adjusted manually, the width remains the same regardless of the content of the table. The width is also stored in the BOM configuration. All adjusted column widths remain the same even when the drawing is closed and reopened. To fit the column width to the content automatically, do one of the following:

- Select the column(s) and right-click the context menu. Then select **Fit column(s)**. or
- Double-click the separator in the column header.

Sorting a BOM Use the grid to control how the table of content should be sorted. Double-click a column label to change the order between ascending, descending, and unordered. If a column is used to sort the table, its label has a symbol added (for ascending and for descending). Double-click the label to revert the sorting order. You can use multiple columns to sort. The sort symbols of these columns have a subscript to denote the sort order. For example, if you want to sort by quantity in descending order and then by component name in ascending order, the **Quantity** column will have a symbol and the **Component** column will have a symbol.

Expand/collapse groups (3.223 on page 2866) In hierarchical BOMs, each subassembly forms a group that can be collapsed or expanded in the BOM grid. To collapse or expand a group, do one of the following:

- Click on the node icon in the first column of the BOM grid or
- Right-click on the row, then select **Collapse** or **Expand** from the context menu.

You can also collapse or expand all groups or all groups corresponding to the same assembly level using the context menu.

NOTE	The subassembly group status (collapsed or expanded) is not stored within the document. When the BOM table is closed and reopened, all subassembly groups are expanded by default.

Properties (3.224 on the facing page)

The properties grid is located at the bottom of the manager's panel. To adjust its size, use the splitter control, located between the grid and the properties grid. The properties grid contains the properties of the current table; title, type, filter, sorting mode and footer title. If any columns are selected, the grid will also display their common properties. You can change any common property for all the selected columns at once. Column properties change the title, visibility, and width of the column. For numerical values, you can set the footer type, unit placement, and the units mode (if the column has units that can be changed). The **unit placement** defines where the units are displayed: in the column title, in the same cell as the value itself or in its own column. The **units mode** defines how the displayed unit should be obtained; the best unit for all values, the best unit to display a particular value in the cell, or a specified unit. You can choose the **Units mode** for distance, area, volume or mass properties.

Figure 3.224

Bill of materials properties	
Title	Bill of material <NAME>
Type	Top level
Property set	Mechanical only
Filter	"Is standard" == "Yes"

Units mode	User-defined
Unit	kg

Filter

It is possible to add a custom filter to the current BOM. To apply a filter, do one of the following:

- use the **Filter** property in the **Bill of materials properties** section of the **Property grid** or
- use the **Set filter** command from the **Main menu.**

In both cases, the filter dialog box displays: (6.573 on page 3846) Each row in this dialog represents an elementary condition. It is possible also to add groups to group several elementary conditions and/or groups together. Groups allow to create complex filters.

Adding a new elementary condition Do the following:

1. (Optional) If necessary, choose the required category to limit the list of properties to that particular category.
2. Select the required property from the list of properties. When selected, a condition for the property is added automatically.
3. (Optional) Set the required condition type:
   - Not equal to
   - Less than
   - Greater than
   - Not less than
   - Not greater than
4. Set the target value. For text values, you can select the target value from the drop-down list of all possible values. For numerical values, you can specify the unit of the target value. The value will be automatically converted to the document unit.

Removing one or more conditions Do the following:

1. Select the conditions to remove. You can use the Ctrl-key to select several conditions, and Shift-key to select a range of conditions.
2. Click the **Delete** tool ( ) or Right click the row you want to delete and select **Remove condition** in the context menu.

Adding a new group of conditions Do the following:

1. Click the **Add** tool ( ).
2. Select **Add "All of" group** to add a new "All of" group or
   Select **Add "Any of" group** to add a new "Any of" group.
3. Add the necessary conditions.

Grouping selected conditions Do the following:

1. Select the conditions to remove. You may use Ctrl-key to select several conditions, and Shift-key to select a range of conditions.
2. Right-click the row you want to group, then: select **Form "All of" group from selected** to form a new "All of" group or select **Form "Any of" group from selected** to form a new "Any of" group.

To apply the filter, click **Ok**. For more details, see Bill of Materials/Filtering. (3.7.11) See also: To set a custom filter for the current BOM.

Figure 3.225

No.	Part category	Component	Quantity

2	FLANGE	ASME B16.5 Flange SO RF	177
3	FLANGE	ASME B16.5 Flange SO RF	4

Figure 3.226

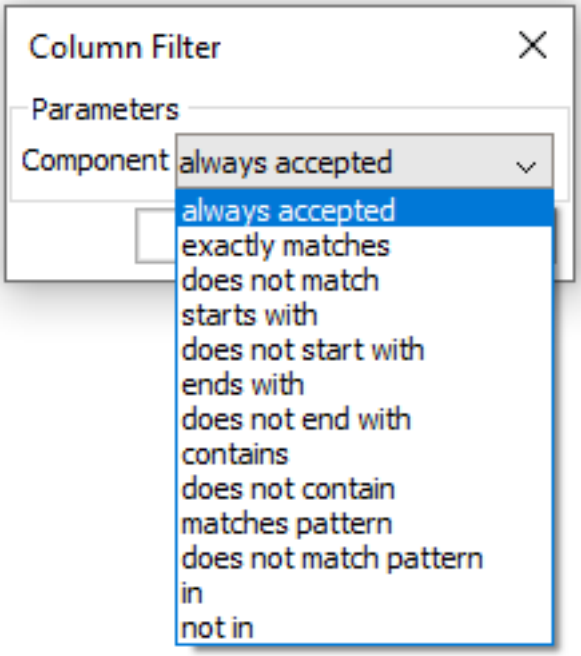

Figure 3.227

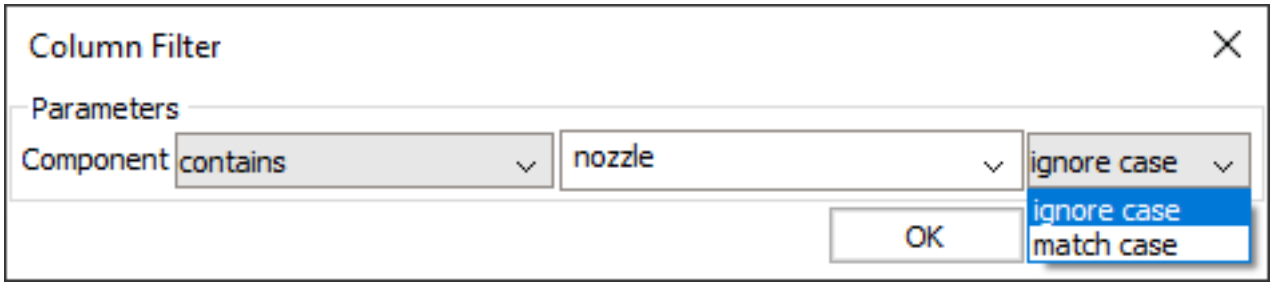

Figure 3.228

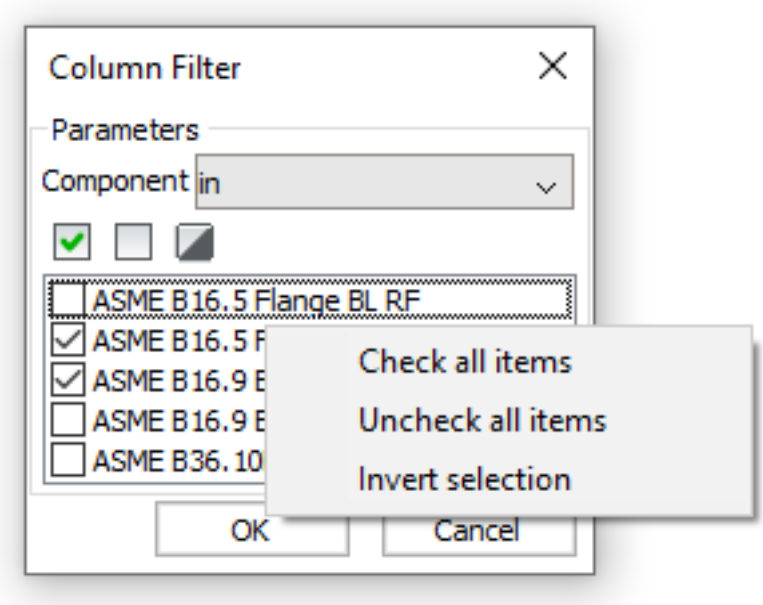


Column filters

Column filters allow you to set the conditions on which rows to include in the table. Each column filter sets a condition that column values should meet in order to be included. For example, you may set a column filter to include only parts with quantities larger than a certain number, or parts whose names contain **Nozzle**. A column can have no more than one filter; however, it is possible to simultaneously set filters for as many columns as you need. Columns with active filters are marked with a filter icon ( ) in their title. (3.225 on the preceding page) To add a column filter, right click the column title and select **Set column filter** in the context menu. A **Column filter** dialog box displays: (6.565 on page 3842) Select the required filter type. Next, you will need to set the target value(s) for the filter, depending on the filter type and the column content. (3.227 on the preceding page) For columns with numerical content, you can set the unit for the target value. The target value will be automatically converted to the document unit internally. For text filters, you can choose between **ignore case** and **match case** options. **In** and **Not in** filters show you the list of all possible values for this column (with respect to already applied filters). Check the values that you want to be included or excluded correspondingly. You can also check all values, uncheck all values or invert the current selection by using the corresponding buttons on toolbars or commands from the context menu. (3.228) To apply the column filter, click **OK.** To remove a column filter, right click on the column title and select **Remove column filter** from the context menu. For more details, see Bill of Materials/Filtering. (3.7.11)

Sort

BOM tables support several sort modes (see Bill of Materials/Sorting (3.7.11) for more details). To switch between these modes, use the **Sorting mode** property in the **Bill of materials properties** section of the **Properties grid.** Use the **Sorting mode** drop-down menu or double-click the column labels in the **Grid** to toggle between ascending, descending or natural order for the respective column.

Column units

It is possible to change the **Unit placement** and **Units mode** for most numerical properties with units. Select the required columns in the **Grid** and use the **Column properties** section of the **Properties grid** to change the **Unit placement** and the **Units mode**. For more details, see Bill of Materials/Column units. (3.7.11) See also: Change the units and unit placement modes for the column.

Evaluated columns

A BOM supports evaluated columns. There are two types of evaluated columns: formula and template columns. For more details about formula fields, such as expression syntax, see Bill of Materials/Evaluated columns (3.7.11) See also: Add an evaluated column

Formula columns To add a formula column, do the following:

1. Select the **Evaluated column** category using the **Category selector**.
2. Select **Formula column** in the **Column selector**.
3. Use **Insert column after** or **Insert column before** tools.

or Use the **Insert formula column** option from the **Main menu**. In both cases, an **Expression configurator** dialog displays: (6.576 on page 3848) **The Expression configurator dialog box.** This dialog allows you to configure the title, unit and expression for the formula column. It also shows a preview of the formula results. The expression field supports autocompletion. To add a reference to a column or a property to the expression at the cursor position, select the required property from the list of properties. You can also click the **Add column reference** tool () and select the property from the menu, or click the **Add function** tool ( ) to select the required function. To add a formula column to the BOM table, click **Ok**.

Template column To add a formula column, do one of the following:

1. Select "**<Evaluated column>"** category using the **Category selector**.
2. Select "<**Template column>"** in the **Column selector**.
3. Use **Insert column after** or **Insert column before** tools.

or

1. Use the **Insert template column** option from the **Main menu**.

In both cases, a **Template configurator** dialog will be shown. (6.577 on page 3848) **The Template configurator dialog box.** This dialog allows you to configure title, expression and, if necessary, unit for your template column. It also shows a preview of the results. The expression field supports autocompletion. Template columns may contain more than one template subexpression. In that case, they will be evaluated from first to last, and the first subexpression yielding in non-empty result will be used. The **Template configurator** allows you to add, delete and switch between template subexpressions using the toolbar. It also allows to change the order of template subexpressions. Note that in the expression field, all subexpressions are shown at once, where each subexpression is enclosed in {} brackets. To add a subexpression, click . To delete the current subexpression, use click . Note that when the last subexpression is removed, it will be actually replaced with an empty one. To change the current subexpression, select the number of the required subexpression from the drop-down list. Use  and  to change the order of the subexpressions. The currently selected subexpression can be configured using the **Template** section. Each column in this section represents an item of the template expression, which you can change. The types of template items are:

- **Column reference**: represents a reference to a BOM column or a property. To add a column reference, select the required column from the list of properties. It will be automatically added after the last selected column, or, if no column is selected, after the last column. If necessary, a **Delimiter** will be added in front of the **Column reference** automatically.
- **Delimiter**: represents a separator between two items. The delimiter text will appear in the final result only if the text on both sides of it is not empty. For example, if you have PartNumber and Length column references with the **"X"** delimiter between them, the **"X"** will be added to the final text only if both PartNumber and Length are not empty. In most cases, delimiters are added automatically. However, you can add delimiters by using the  button and selecting **Add delimiter** from the drop-down list. Alternatively, you can add a delimiter from the context menu.
- **Text**: represents a custom text. You can add custom text by clicking  and selecting **Add text** from the drop-down list. Alternatively, you can add a custom text from the context menu.
- **Evaluated text**: represents an item that should be added to the final expression as is. Evaluated text may contain functions or other special symbols that will modify the result. You can add an evaluated text by using the  button and selecting **Add expression** from the drop-down list. Alternatively, you can add an evaluated text from the context menu.

At any moment, you can change the content of any item in the template. You can also delete items by selecting them and using the  button, or by choosing **Delete column** in the context menu. To move an item, select a column in the template and then drag and drop it at the desired position. Any modifications of the template will be reflected in the expression field. Similarly, any changes in the expression field will be reflected in the template area. To add a template column to the BOM table, click **Ok**.

Figure 3.229

No.	Part ▲	Thickness, mm	∑Length, m
1	PIPE D= 1"	1.65	107.88
2	PIPE D= 2"	1.65	60.61
3	PIPE D= 6"	2.11	1.74
4	PIPE D= 6"	2.77	7.14

Footer row

A BOM table can include a footer row. To add a footer row, specify the footer type for one or more columns. By default, the title of the footer row is **TOTAL:.** Change the footer title with the **Footer title** property in the **Bill of materials property** section of the **Properties grid.** For more information about a footer row in a BOM, see Bill of Materials/Footer (3.7.11). See also: Add a footer for the column.

Aggregated columns

In top-level and bottom-level BOM tables, almost any column can be assigned with an aggregate function. Aggregate functions group values of several rows in a BOM (that differ only in those values) into a single value. For example, aggregate functions can be used to compute the total length of pipes with respect to their size and thickness, or to concatenate all sizes of bolts and nuts used in the assembly in a single cell. For more details, see Bill of Materials/Columns. (3.7.11) To set an aggregate function, do one of the following:

- Right-click on the column title and select the required aggregate function from the **Aggregate function** submenu. or
- Select the column and change the aggregate function in the corresponding column property.

Aggregated columns are marked with the ∑ symbol in their title. (3.229)

Templates

You can save BOM configurations as templates. Use the BOM manager to create a new table from a template and to replace the current table configuration with one from a template. You can save the configuration as a template at any moment. You can change a loaded template configuration with the regular tools and save it as another template. For more information about BOM templates, see Bill of Materials/Templates (3.7.11)

Searching

(6.584 on page 3849) The BOM manager has a search field that allows you to search for a particular value in the table. You can also use **Wildcard characters** in the search field. By default, BricsCAD searches the entire table. To limit the search area select the required columns. If the value is found, the cursor moves to that cell. If no columns are selected, the row is selected. The **Grid** automatically scrolls to make the cell visible. To find another value, use the  or  buttons. You can also use **F3** or **Ctrl+F3**. To select all found results, use  button. By default, the text in the search field is searched for. However, you can also use **wildcard characters.** The following special symbols are supported:

Name	Character	Description
Back quote	‘	Escapes the next character (takes it literally).
Comma	,	Separates patterns.
Asterisk	*	Matches any character sequence, including a null sequence, anywhere
Question Mark	?	Matches a single character.

Figure 3.230

Period	.	Matches a single non-alphanumeric character.
At sign	@	Matches a single alphabetic character.
Pound sign	#	Matches a single numeric character.
Tilda	~	If the first character in a pattern matches anything but the pattern.
Brackets	[...]	Matches a single enclosed character.
Tilda brackets	[~...]	Matches a single non-enclosed character.
Hyphen	-	In brackets, matches a single character in the specified range.

To open the search field, use the **Search** tool on the toolbar or use **Ctrl+F**.

Associated table

Each BOM table in the manager can have an associated table in the document, which updates when the BOM configuration is changed. A BOM table can have one associated table only. However, you can create BOM tables that do not have an associated table in the document. To create an associated table, use **Place/Update table**. If the BOM table was created with BmBom (6.8.3), the associated table is created automatically. You can locate the associated table in the document with **Associated table - Zoom to** or **Associated table** - **Select**. If necessary, the active layout switches to the associated table layout. You can delete the associated table with **Associated table** - **Delete**. Alternatively, you can detach the associated table from the BOM table with **Associated table** - **Detach**. After it is detached, the associated table loses its link to the BOM table and will not update with the BOM.

Updating the BOM

From BricsCAD V20.2, the BOM manager automatically updates the table content in the panel when the assembly is modified or updated. For large assemblies, this may be inconvenient. The BOM manager automatically updates the table when active. To avoid the automatic update, close the BOM manager to make the BOM Manager panel inactive. You can manually refresh the BOM manager content using **Refresh**.

NOTE	The associated table is not updated automatically when the assembly is changed or modified. Use **Place/Update table** to update the associated table.

Adding a new bill of materials

1. Use the **New BOM** submenu of the **Main menu:** (6.567 on page 3844)
2. Select the BOM type or select **From template** to choose the template file for a BOM.

Selecting the current BOM

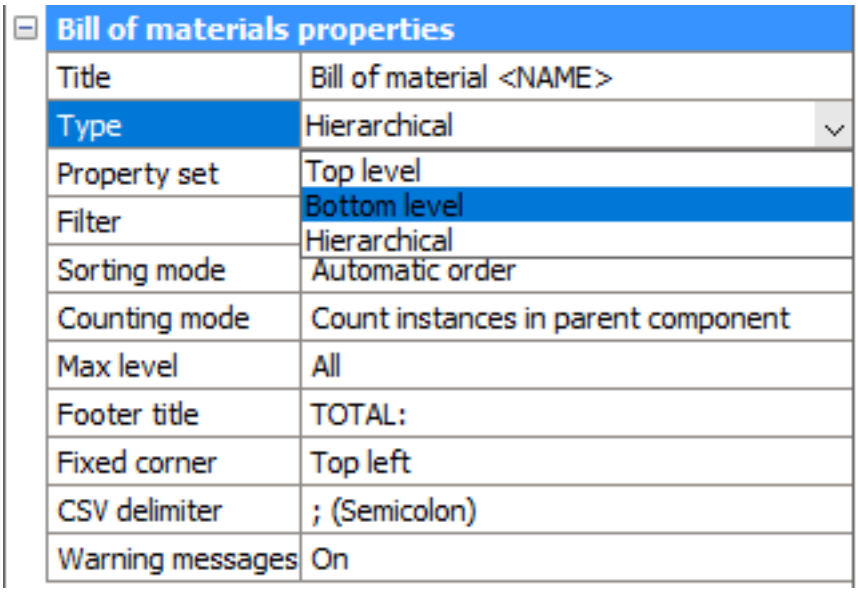
Use the **BOM selector** to select an existing bill of materials.

NOTE	The table will automatically update to the current state of the assembly and the associated table in the drawing (if it exists).

Changing the type of the current BOM

Change the **Type** property in the **Bill of materials properties** section of the **Properties grid**. (3.231 on the next page)

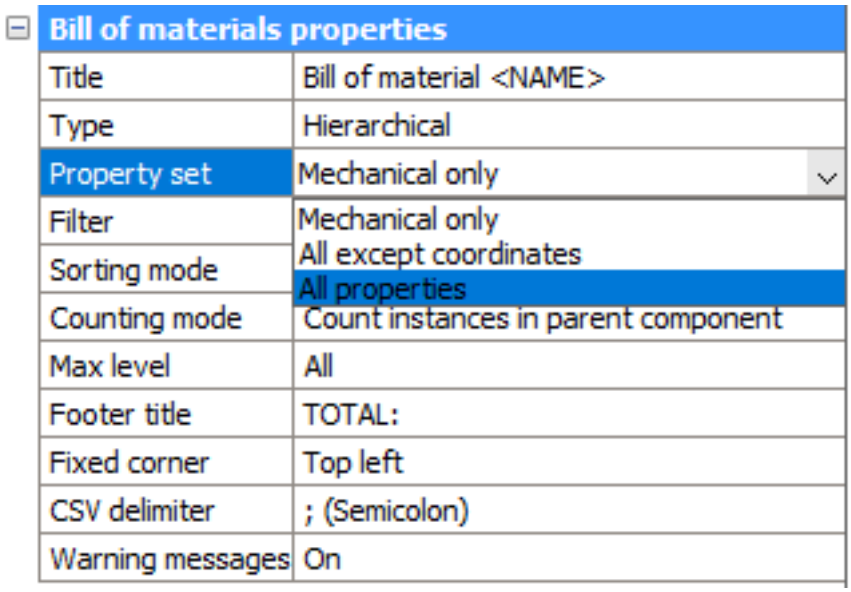
Figure 3.231



Changing the property set of the current BOM

Change the **Property set** property in the **Bill of materials properties** section of the **Properties grid**. (3.232 on the facing page)

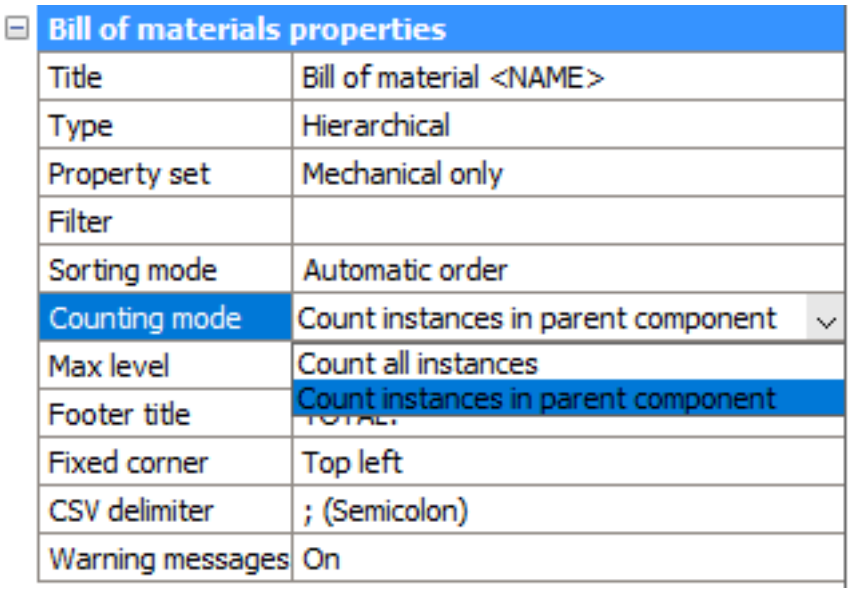
Figure 3.232



Changing the counting mode of a hierarchical BOM

Change the **Counting mode** property in the **Bill of materials properties** section of the **Properties grid**. (3.233 on the next page)

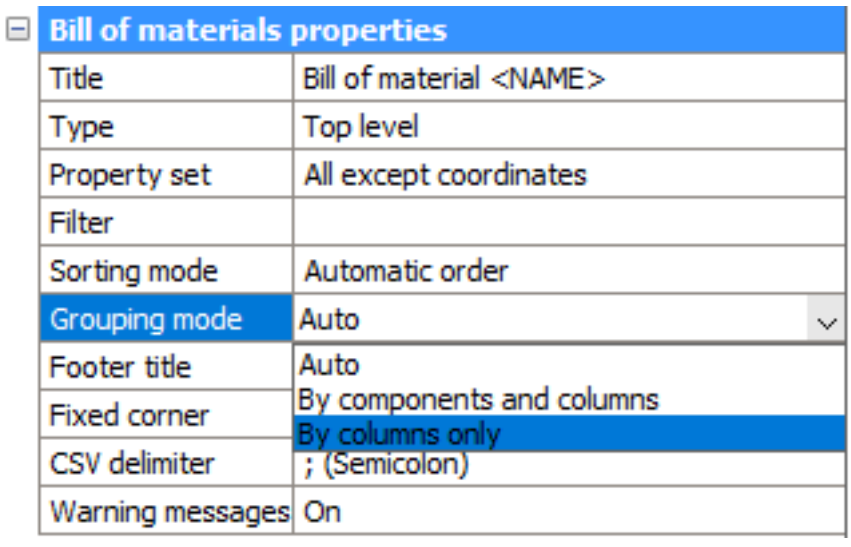
Figure 3.233



Changing the grouping mode of top- or bottom-level BOM

Change the **Grouping mode** property in the **Bill of materials properties** section of the **Properties grid**. (3.234)

Figure 3.234



Setting a custom filter for the current BOM

1. Select the **Set filter** option from the **Main menu**. A **Filter Configurator** dialog box displays.
2. Configure the filter using the dialog tool. See Filter for details.
3. Press **OK** to apply the filter. (6.573 on page 3846)

Adding new columns to the current BOM

1. (optional) Use the **Category** selector to select the category of the properties you want to add: (3.235 on the following page)
2. Select the property to add from the list of the available columns. This list contains all columns from the selected category which are not yet added to the BOM. If you start to type the name of the field BricsCAD automatically suggests names to you. Click to select it from the list. (3.236 on the next page)
3. (optional) Select the column in the BOM you want to place the new column next to.
4. Click the **Insert the column after** button () to place the new column after the selected one, or the **Insert the column before** button () to place the new column before the selected one. If no column is selected, the new column is placed as the last or the first position respectively.

Figure 3.235

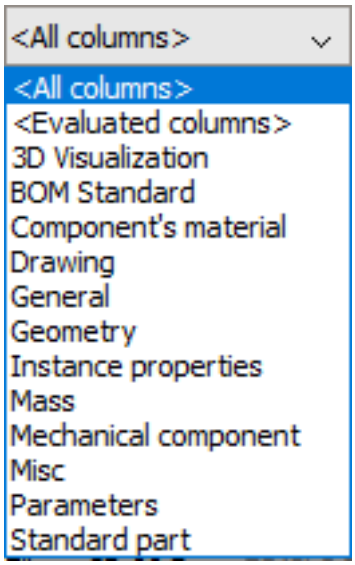


Figure 3.236

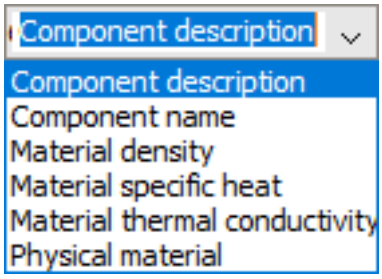


Adding an evaluated column

1. Select the **Evaluated columns** category using the **Category selector**.
2. Select **Formula column** to create a formula column or select **Template column** to create a template column.
3. Click the **Insert the column after** button ( ) to place the new column after the selected one, or **Insert the column before** button ( ) to place the new column before the selected one. If no column is selected, the new column is placed as the last or the first position respectively. A dialog box to configure the evaluated column displays.
4. Change the **Title** of the column.
5. Change the **Unit** if necessary.
6. Configure the expression using the dialog tools.
7. Press **Ok** to add the column to the BOM table.

Adding a template column from selected columns

1. Select the columns to be combined in a template column. Use the Ctrl-key to select multiple columns or the Shift-key to select a range of columns.
2. Right click on the title of one of the selected columns.
3. Select **Add template column from selected** from the context menu. A dialog box to configure the evaluated column displays.
4. Change the **Title** of the column.
5. Change the **Unit** if necessary.
6. Configure the expression using the dialog tools.
7. Press **Ok** to add the column to the BOM table.
8. If necessary, remove or hide no longer necessary columns.

Changing an evaluated column

1. Right click on the column title in the **BOM grid**.

2. Select **Edit column expression** from the context menu. A dialog box to configure the evaluated column will be shown.
3. Modify the column title, unit and expression as necessary.
4. Press **Ok** to apply the changes.

Removing a column from the current BOM

1. Select the column in the grid.
2. Click the **Remove the column** tool () or
   Press **Delete**.

Changing the BOM title

Use **BOM Title** to edit the title or
Use the **Title** property in the **Bill of materials properties** section of the **Properties grid.** You can use the **<NAME>** placeholder to refer to the assembly name.

Changing the footer row title

Use the **Footer title** property in the **Bill of materials properties** section of the **Properties grid.**

Adding a prefix or suffix to numbers

1. Select the **Number** column.
2. Select **Number prefix** property in the **Column properties** section. (3.237 on the following page)
3. Enter the new prefix string if necessary.
4. Select **Number suffix** property in the **Column properties** section.
5. Enter the new suffix string if necessary.

Figure 3.237

Column properties	
Title	No.
Category	BOM Standard
Role	Number
Number prefix	A
Number suffix	
Number type	Full
Delimiter	.
Format	
Visible	Yes
Width	Auto
Filter	No filter

Changing the delimiter between numbers in a hierarchical BOM

1. Select the **Number** column.
2. Select **Delimiter** property in the **Column properties** section. (3.238 on the next page)
3. Enter the new delimiter string.

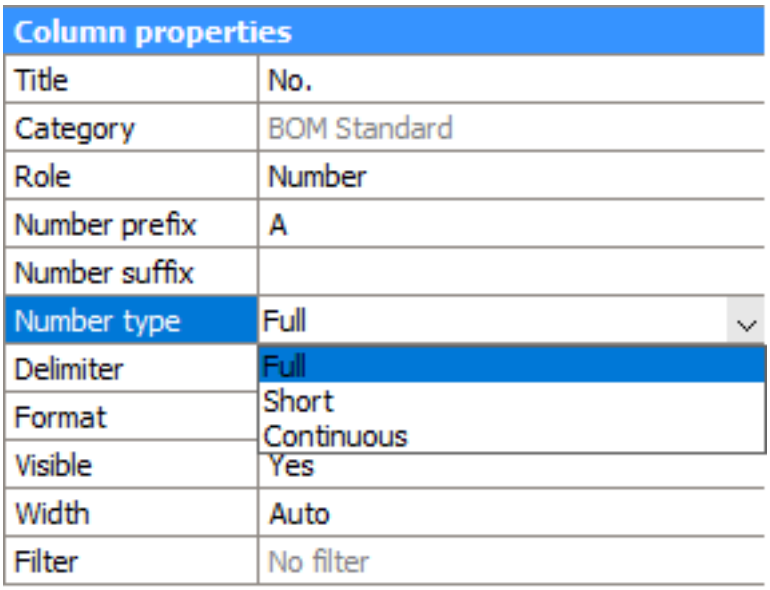
Figure 3.238

Column properties	
Title	No.
Category	BOM Standard
Role	Number
Number prefix	A
Number suffix	
Number type	Full
Delimiter	.
Format	
Visible	Yes
Width	Auto
Filter	No filter

Changing the number type in hierarchical BOM

1. Select the **Number** column.
2. Select **Number type** property in the **Column properties** section. (3.239 on the following page)
3. Select the required number type.

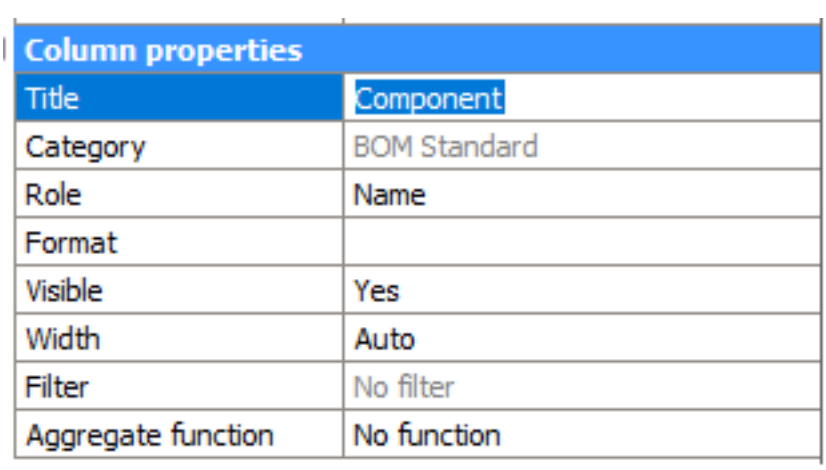
Figure 3.239



Change the column title

1. Select the column in the BOM grid.
2. Select **Title** property in the **Column properties** section. (3.240)
3. Change the **Title** property value to the new title of the column.

Figure 3.240



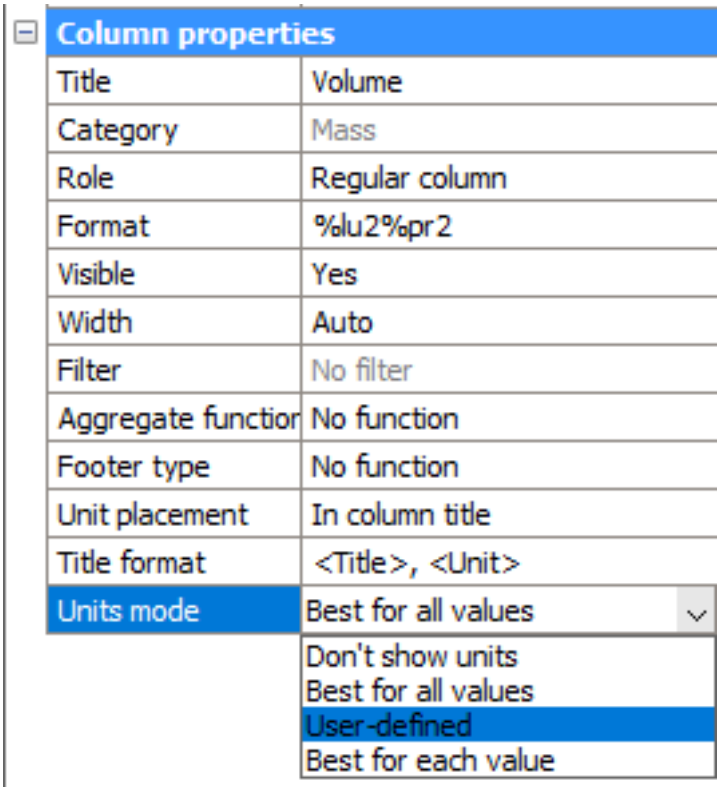
Change the column format

1. Select the column(s).
2. Right click on the title of a selected column.
3. Select **Format** in the context menu. The **Format** dialog displays. (3.269 on page 2896)
4. Define the desired format.
5. Click **Ok** to apply the changes.

Changing the units and unit placement modes for a column

1. Select the column(s).
2. (Optional) Change the **Unit placement** property in the **Column properties** section.
3. (Optional) Change the **Units mode** property in the **Column properties** section. (3.241 on the next page)
4. (Optional) Change the **Title format**.
   - – <Title> adds the column title
   - – <Unit> adds the column unit.
   - – Use "\n" to add a line break.

Figure 3.241



Adding a footer to a column

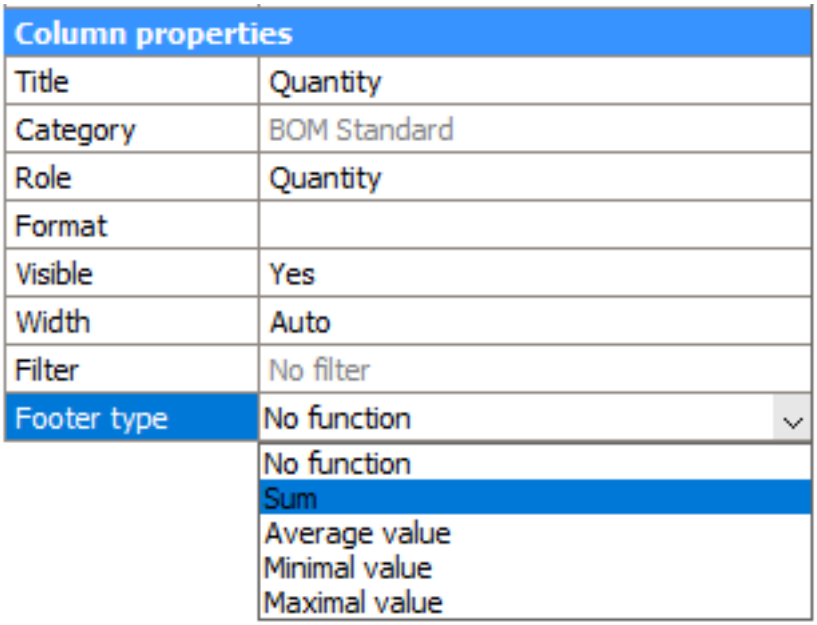
1. Select the column(s).
2. Use the **Footer** submenu of the **Main menu** to select the type of footer value or Right-click on the column label and then select **Footer** submenu: (6.579 on page 3849) The following types are available:
   - **Sum**
   - **Average value**
   - **Minimal value**
   - **Maximal value**
   - **No footer** (the column will be removed from the footer. If there is no column with another footer type, the footer row will be removed completely)

Alternatively:

1. Select the column(s).
2. In the **Properties grid,** select the **Footer type** property and choose the footer type. (3.242 on the next page)

NOTE To toggle between **Sum** and **No footer**, press the **Footer** button.

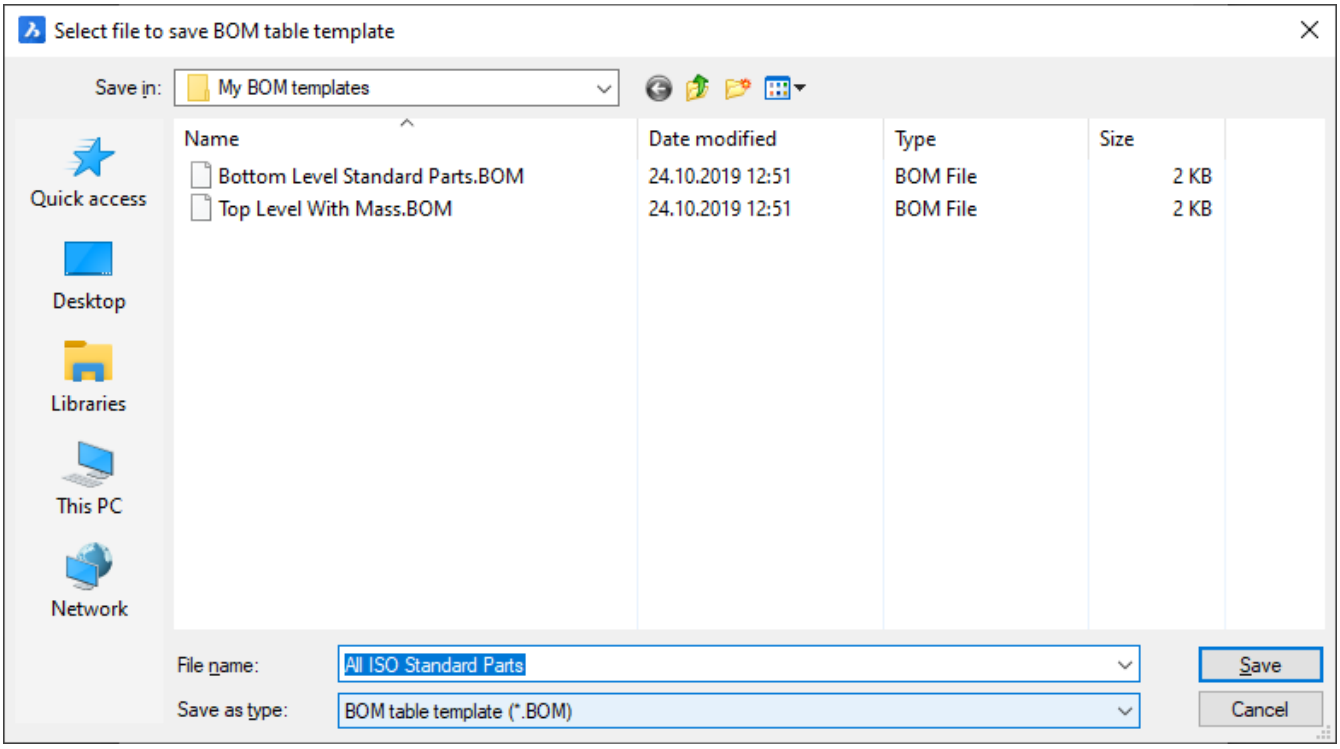
Figure 3.242



Saving the current configuration as a template

1. Choose **Save as template** ( ) in the main menu ( ). The dialog to select the name and location for a template file displays:(6.572 on page 3846)
2. Specify the name and location of the template file.
3. Click the **Save** button.

Figure 3.243



Exporting the current table to CSV

1. (Optional) Adjust the **CSV delimiter** property of the table: (3.244 on the next page)
2. Choose **Export to CSV** in the main menu ( ). The dialog to select the name and location for a CSV file displays. (6.570 on page 3845)
3. Specify the name and location of the CSV file.
4. Click the **Save** button.

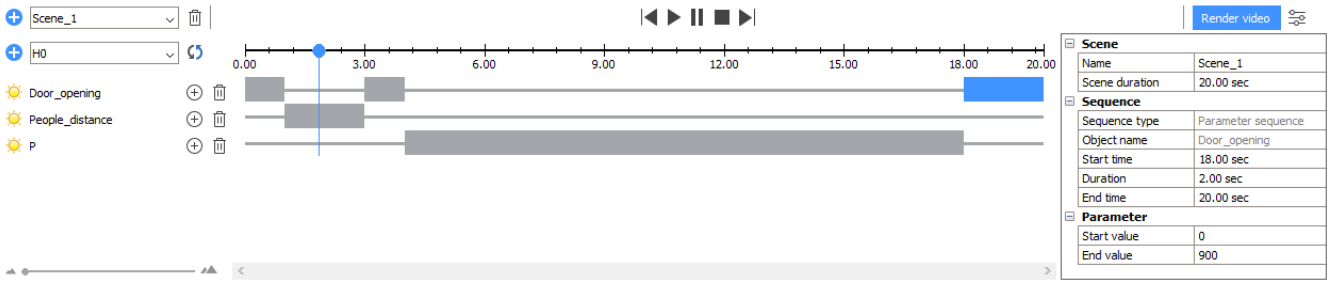
Figure 3.272



3.7.10 Multi-parametric 3D animations

Commands: ANIMATIONEDITOROPEN (6.4.12), ANIMATIONEDITORCLOSE (6.4.11) You can animate several parameters and program camera movements with the Animation Editor panel. Once the animation is programmed, you can play it in BricsCAD or render it as a 2D video. Each parameter animation has its own "timeline". You can add as many animation sequences to a parameter as you like, so long as these sequences do not overlap. There also is a special timeline for camera movements. You can add as many camera sequences as you like. You can set both the point of focus and the position of the camera with either a polyline or a point. This is similar to the ANIPATH (6.4.13) command. (3.272)

Scenes, Timelines, and Animation Sequences

Scenes A scene consists of one or more **timelines** and each of these timelines has one or more **animation sequences**. When the editor is launched for the first time it automatically creates a scene. A scene sets the duration of the animation. Together, they define the **animation schedule** used for playback and render. Currently, you can only render the current scene with the Animation Editor. However, you can have many scenes in the same document and can switch between them.

Animation sequences An animation sequence is the basis of an animation. It represents the single, continuous animation of an object. An animation sequence has an associated start time and duration. It also has values specific to the animated object, such as start and end values for parameters, or camera and viewpoint paths for camera sequences:

- **Parameter** - an animation sequence represents the continuous change of a parameter from a start to an end value. E.g.: a distance constraint between two faces: the animation will move one face to a maximum and minimum distance value.
- **Camera** - an animation sequence corresponds to a continuous camera movement on a path. You can adjust various camera movements with the camera timeline.

Timelines A timeline is a visual representation of an animation sequence for an object. The timeline displays how and when the parameters will animate. Each parameter has its own timeline in a scene. Animation sequences cannot overlap. A timeline can be temporarily disabled to exclude it from an animation. All timelines are independent. This means that you can animate many parameters at the same time and see their combined effects.

To open the Animation Editor

Do one of the following:

- Place the cursor on a toolbar, right-click, and choose **Animation Editor** from the context menu.
- Click the **Animation Editor** tool on the **View** section of the ribbon.
- Choose **Animation Editor** from the **View** menu.
- Type ANIMATIONEDITOROPEN (6.4.12) into the command line.

The Animation Editor Interface

The Animation Editor is a panel. It has 3 main areas:

- **Toolbar** - Contains tools to select a scene, adjust an animation and render a video.

- **Timelines area** - Use to add and edit the timelines and animation sequences.
- **Configurator** - Use to configure the parameters of the current scene and the selected animation sequence.

Toolbar (3.273) The toolbar contains tools to:

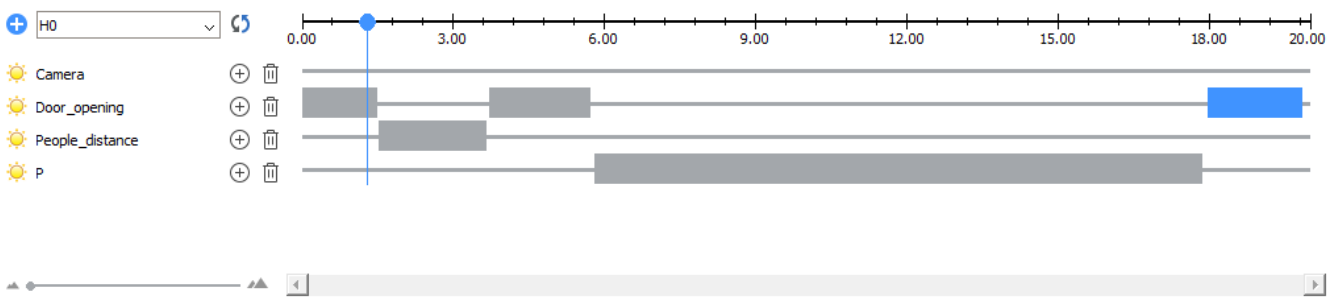
- add and remove scenes.
- control the playback of the animation.
- set the duration of the current scene.
- add a camera timeline.
- start a render.

Tool	Name	Description
	**Add Scene**	Adds an empty scene with a default duration
(6.70 on page 3401)	**Scene Selector**	Selects the current scene
	**Remove Scene**	Removes the current scene from the document
	**To previous sequence**	Jumps to the start of the previous animation sequence
	**Play**	Starts the animation
	**Pause**	Pauses the animation
	**Stop**	Stops the animation and returns the cursor to the start position
	**To next sequence**	Jumps to the start of the next animation sequence
	**Render video**	Opens a dialog to start the render of a 2D video
	**Toggle configurator**	Toggles the configurator panel

Figure 3.273

Timelines Area Use the Timelines Area to add and remove timelines, to add and remove animation sequences and to display the animation schedule. Click on an animation sequence to select it or drag the start or end of the bar to adjust the duration. The selected animation sequence will display in blue, other sequences will display in gray. Each timeline in the timelines area can be temporarily disabled to exclude it from the animation. (3.274) The Timelines Area has a cursor that represents the current position in the animation. When the animation is played, the cursor represents the current playback position. You can also manually move the cursor to a new position at any time. When the cursor is moved, all parameters will change to match the current frame. The camera position will also update. To make sure that the model state corresponds to the current animation position, click the button. **Note** You can adjust this manually at any moment but this will not affect the animation.

Figure 3.274



Time Scale (3.275)

Tool	Name	Description
	**Add Timeline**	Adds the selected parameter to the timeline
(6.73 on page 3402)	**Object Selector**	Selects the object to add to the timeline
	**Update model**	Updates the model state with respect to the current cursor position
(3.283 on page 2910)	**Time Scale**	Displays the time marks along the timeline
	**Cursor**	Displays the current position of the playback

Figure 3.275

Timeline (3.276)

Tool	Name	Description
	**Timeline Enabled**	Indicates that the timeline is enabled. Click to disable the timeline.
	**Timeline Disabled**	Indicates that the timeline is disabled. Click to enable the timeline.
	**Timeline Object**	Displays the name of the associated object.
	**Add Sequence**	Adds a new animation sequence, at the cursor position.
	**Remove Timeline**	Removes a timeline from the animation.
	**Animation Sequence**	Represents the duration and position of an animation sequence. Left-click to select the sequence.
	**Selected Animation Sequence**	Represents the duration and position of the selected animation sequence. You can see and change the properties in the **Configurator.** Move the mouse to the end of the sequence, until the cursor changes to a double-sided arrow. Then left-click and drag to change the start time, end time and duration. Left-click at the middle of the sequence and drag to a new position at the timeline, without changing the duration.

Figure 3.276

Configurator Access all the properties of the animation scene and the selected sequence via the Configurator. All properties are grouped by object. (3.277 on page 2905)

- **Scene** - properties of the current scene:
  - **Name** - name of the scene.
  - **Duration** - duration of the scene, in seconds.
- **Sequence** - properties of the selected sequence.
  - **Sequence type** (read only) - the type of the sequence
  - **Object name** (read only) - the name of the object controlled by that sequence.
  - **Start time** - start time of the sequence, in seconds. The duration will be adjusted, the end time will remain unchanged.
  - **Duration** - duration of the sequence, in seconds. When changed, the end time will be adjusted with respect to the start time and duration.
  - **End time** - end time of the sequence, in seconds. When changed, the duration will be adjusted, the start time will remain unchanged
- **Parameter** (for parametric sequences)
  - **Start value** - start value of the parameter.
  - **End value** - end value of the parameter.
- **Camera** (for camera sequence)
  - **Camera path type** - camera path entity type. May take one of the following values:
    - **Point** - the camera will be fixed in the given point
    - **Path** - the camera will move along the given path.
  - **Camera point** (when the **Camera path type** is set to **Point**) the following controls are displayed:

(3.288 on page 2910)	List of previously used points. Select the point from the drop-down list to use one.
	Click to select the point in the model. After the point is selected, displays the dialog: (3.289 on page 2910) **Name** - enter the point name **Ok** - click to accept the point selection **Cancel** - click to cancel the point selection.
	Click to remove the point from the list.

  - **Camera path** (when the **Camera path type** is set to **Path**) - the following controls are displayed:

(3.290 on page 2911)	List of previously used paths. Select the path from the drop-down list to use one.
	Click to select the path in the model. After the path is selected, the dialog is displayed: (3.291 on page 2911) **Name** - enter the path name **Ok** - press to accept the path selection **Cancel** - press to cancel the path selection.
	Click to remove the path from the list.

  - **Target path type** - type of the target path. Target defines the point the camera will look at at the given moment. May take one of the following values:
    - **Point** - the target will be fixed to a given point
    - **Path** - the target will move along a given path.
  - **Target point** (when the **Target path type** is set to **Point**) the following controls are displayed:

(3.288 on page 2910)	List of previously used points. Select the point from the drop-down list to use one.

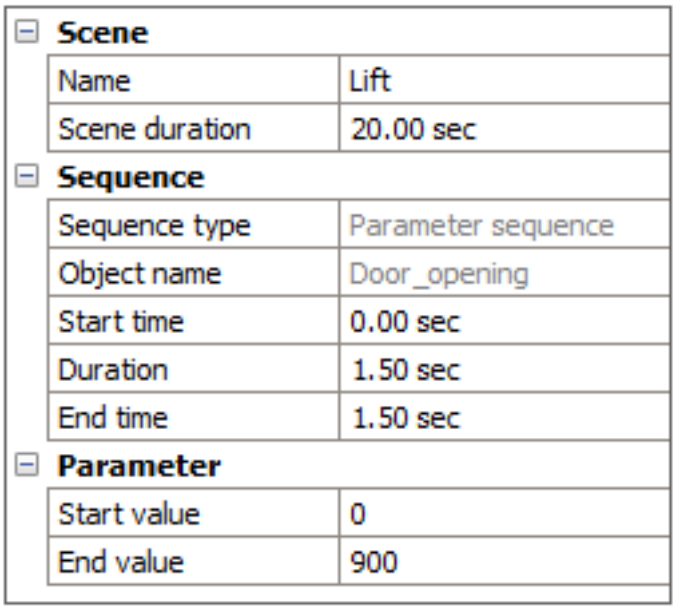
	Click to select the point in the model. After the point is selected, the dialog is displayed: (3.289 on page 2910) **Name** - enter the point name **Ok** - press to accept the point selection **Cancel** - press to cancel the point selection.
	Click to remove the point from the list.

– **Target path** (when the **Target path type** is set to **Path**) the following controls are displayed:

(3.290 on page 2911)	List of previously used paths. Select the point from the drop-down list to use one.
	Click to select the path in the model. After the path is selected, the dialog is displayed: (3.291 on page 2911) **Name** - enter the path name **Ok** - press to accept the point selection **Cancel** - press to cancel the point selection.
	Click to remove the path from the list.

Note Similar to ANIPATH (6.4.13), all selected points and paths are stored in the drawing.

Figure 3.277



Animation Playback

Use the animation playback controls to preview an animation.

- To **start** an animation, click the Play button. The playback will start from the cursor position.
- To **pause** the animation, click the Pause button.
- To **stop** the animation and move the cursor to the start of the animation, click the Stop button.

You can jump to the next or the previous animation sequence (in chronological order) with the **Jump to Next Sequence** and **Jump to Previous Sequence** tools respectively.

NOTES

- During playback, the parameters involved in the scene and the camera position are changed directly in the drawing. For complex models, the recalculation of the model may take a significant amount of time. You can use the cursor to check the key moments of the animation instead.
- During playback, the camera will move with any set camera sequences. If no camera sequences are present, the current view will be used. (The output video will be the same as the current viewport.)
- After the playback finishes, the model will automatically revert to the state before the animation was started. In some cases, it may cause the model to be in a different state than the cursor position would dictate. To update the model with respect to the current cursor position, use button.

Render

To render the animation as a 2D video, click the **Render video** button. The **Render video** dialog displays: (6.71 on page 3401) Use the dialog to adjust the render parameters:

- **Render frame rate (fps)** - the frame rate.
- **Resolution** - the resolution of the video.
- **File format** - the format of the video. (**avi, .mpg** and **.wmv** formats are supported).
- **Start time** - the time position the render will start.
- **End time** - the time position the render will end.

Once the parameters are set, click the **Render** button to start the render. A file dialog displays: (6.72 on page 3402)

Figure 3.278

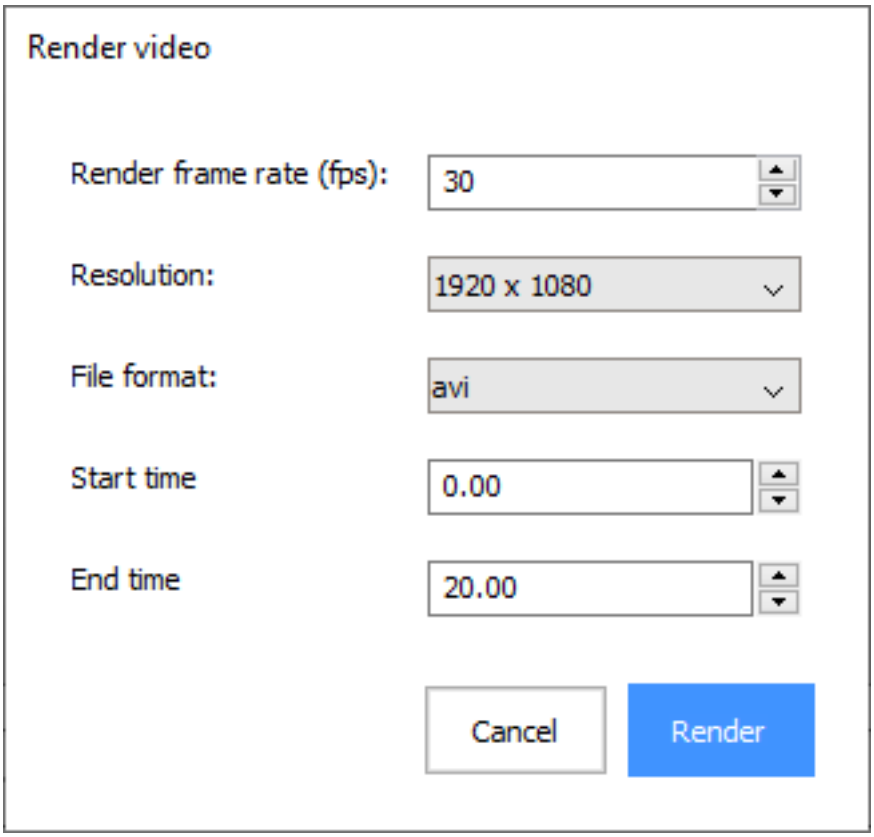


Figure 3.279

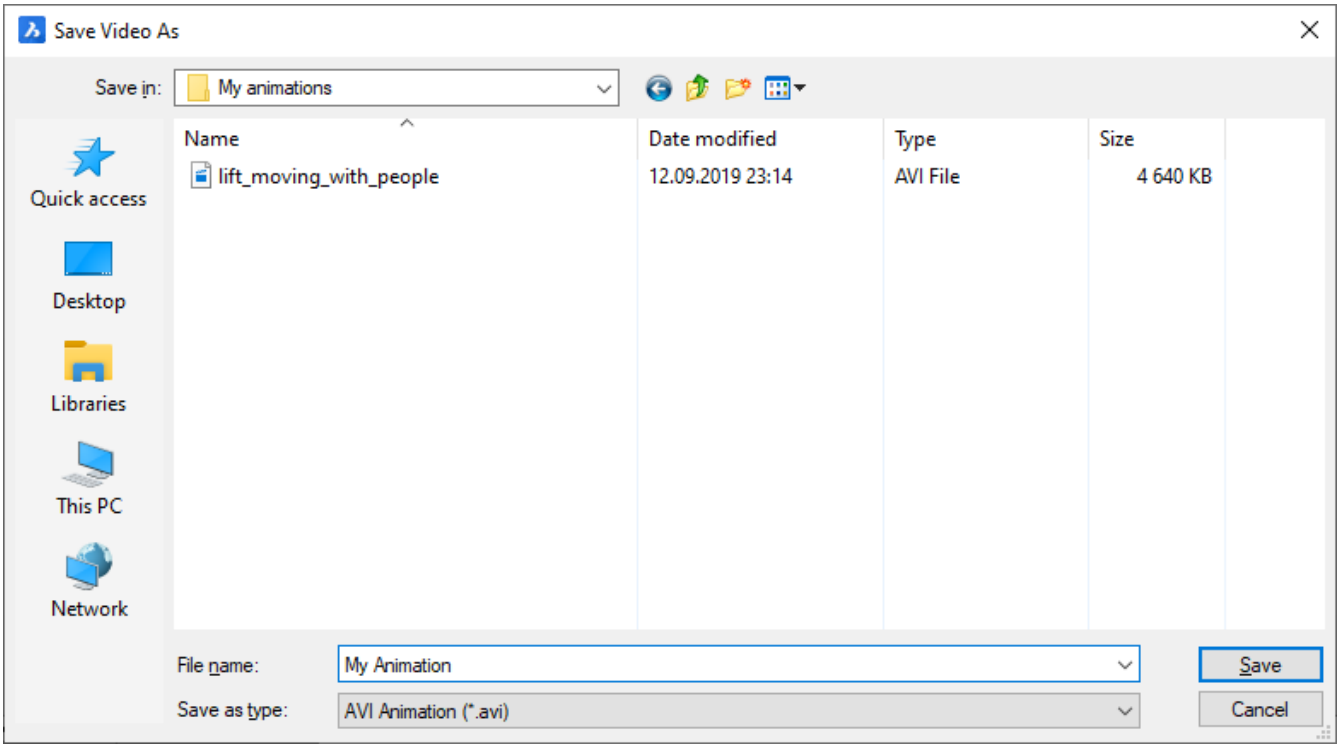
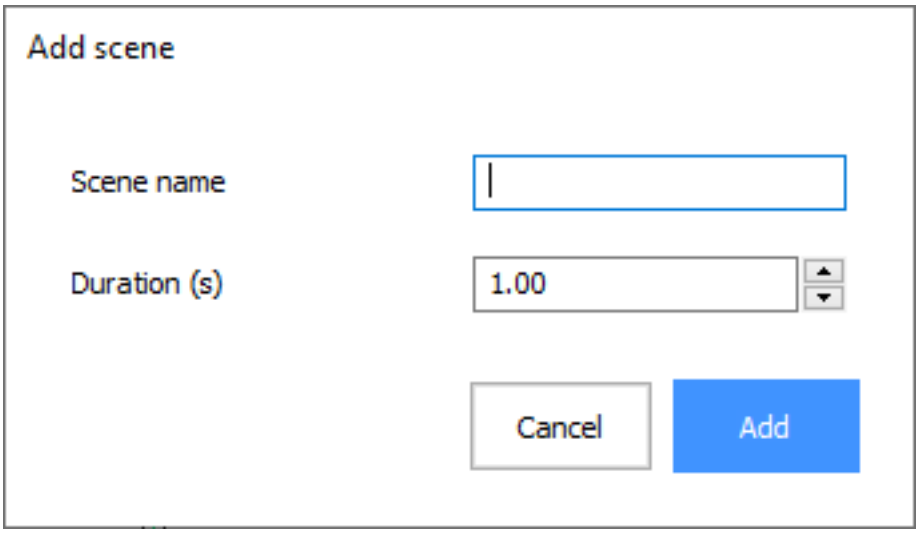


To add a new scene

1. Click the **Add Scene** button. The **Add scene** dialog displays: (6.69 on page 3401)
2. Enter the scene name.
3. Enter the scene duration in seconds.
4. Click **Add** to add the scene.

Figure 3.280



To remove a scene

1. Select the scene with the **Scene Selector**.
2. Use the **Remove Scene** tool.

To add an animation of a parameter

1. Add the desired parameter to the timeline:
   - Select the parameter with the **Parameter Selector.**
   - Use the **Add Timeline** tool to add a new timeline.
2. Place the cursor at the desired start position on the **Time Scale.**
3. Use the **Add Sequence** tool to add a new animation sequence or Double click at the timeline where you want to add a new sequence.
4. Drag to adjust the desired duration of the sequence. or
   Use the **Configurator** to set the desired start time, end time or duration, in seconds.
5. Use the **Configurator** to set the desired start and end values for the parameter.

To add a camera movement

1. Add a camera timeline if necessary by selecting **Camera** from the **Object selector**.
2. Place the cursor at the desired start position on the **Time Scale.**
3. Use the **Add Sequence** tool on the camera timeline to add a new camera sequence or
   Double click at the timeline where you want to add a new camera sequence.
4. Click and drag to adjust the desired duration of the sequence. or
   Use the **Configurator** to set the desired start time, end time or duration, in seconds.
5. Use the **Configurator** to set the camera path:
   - Choose the **Camera path type** from the following:
     - **Point** to specify that the camera position should be fixed, or
     - **Path** to specify that the camera should move along the given path.
   - Use the **Camera point** property to select the point or the **Camera path** to select the path.
   - Select the property for editing, then use  button to select the path or the point on the model. or
     Select one of the previous points or paths from the drop-down list.
6. Use the **Configurator** to set the target path. The **target** is the point where the camera will focus on. To choose the **Target path type** do one of the following: **Point** to specify that the target should be fixed or **Path** to specify that the target should move along the given path. Use the **Target point** property to select the point or the **Target path** to select the path: Select the property for editing, then use  button to select the path or the point on the model; or Select one of the previous points or paths from the drop-down list.

To remove an animation sequence

1. Right-click the sequence.
2. Select **Delete** from the context menu.

or

1. Left-click the sequence.
2. Hit the **Delete** key.

To disable or enable a timeline

1. Check the timeline status icon. If the icon is , then the timeline is disabled. If the icon is , the timeline is enabled.
2. Click the timeline status icon to toggle the status.

Animation sequences on disabled timelines are not included in the animation.

To animate an exploded view

As the animation editor is not supported in Block editor (1.30.4) or reference editing (6.26.13) modes, only exploded views (3.4.5) inserted in the model space can be animated.

1. Insert the exploded view in model space.
2. (Optional) Suppress (1.27.5) the exploded view and the model, if you want to hide or show them during animation.
3. Select the exploded view object in the **Object selector**.
4. Click  to add a timeline.
5. Use the **Add Sequence** tool on the exploded view timeline to add a new exploded view sequence or Double click at the timeline where you want to add a new sequence.
6. Click and drag to adjust the desired duration of the sequence. or Use the **Configurator** to set the desired start time, end time or duration, in seconds.
7. (Optional) Use the **Configurator** to set the start step and the end step of the exploded view, or to enable the autohide option.

To render a video

See the Rendering section.

3.7.11 Bill Of Materials

Commands: BMBOM (6.8.3), BMBOMPANELOPEN (6.8.5), BMBOMPANELCLOSE (6.8.4) An engineering Bill of Materials (BOM) is a list of unique mechanical components used in an assembly. In BricsCAD, the list is represented as a table entity (see Tables (1.29.24)) and can be placed anywhere in the drawing. Each entity has its own serial number (starting with 1), name, and number of occurrences. You can view and configure Bills of Materials in the Bills of Materials Manager (3.7.9).

Bill of Materials types

There are three BOM types in BricsCAD:

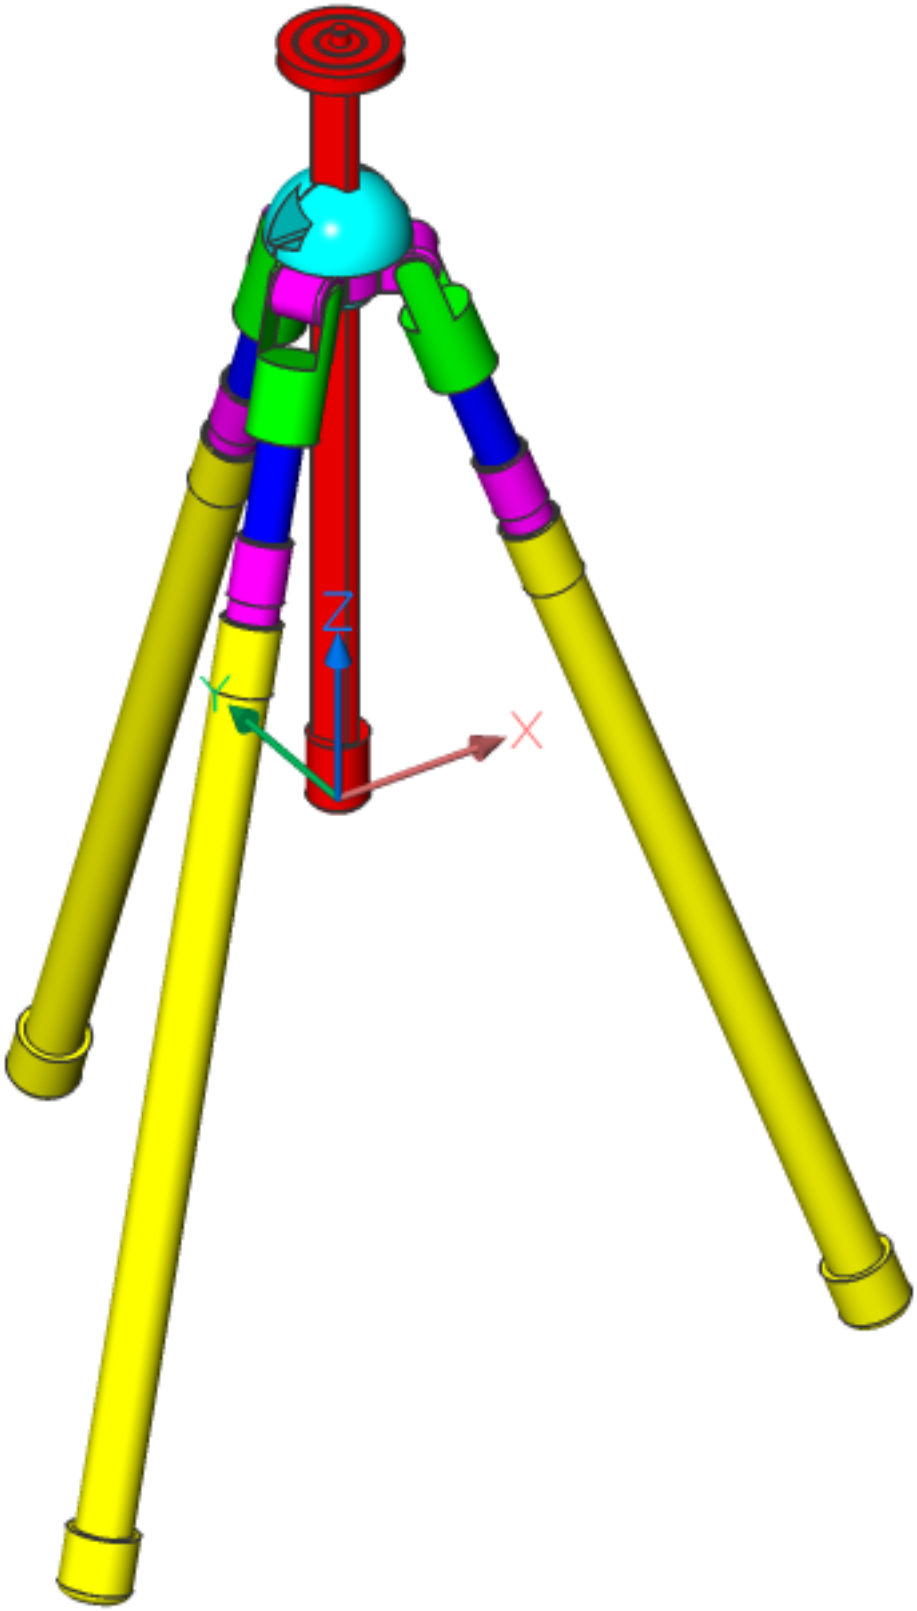
- **Top level**: contains top-level components only. Top-level components are components inserted directly into the main assembly. This type of BOM lists the main components only with no details of subcomponents.
- **Bottom level**: contains bottom-level components (parts) only. Bottom-level components are parts that do not contain other parts or subassemblies. This type of BOM lists all parts in the main assembly, regardless of which component the parts belong to.
- **Hierarchical**: contains all components with their subcomponents listed directly below. The serial numbers of subcomponents is a sequence of numbers separated by dots (for example, "1.2.3"). This BOM type shows the hierarchical structure of the assembly.

NOTE	The **BOM status** property controls which parts are included in a Bill of Material. The level of a component in a BOM table is set with respect to the **BOM status** of all related components. For example, a component with a Terminal BOM status is always considered as bottom-level, even if it contains other parts or subassemblies.

Example: Tripod assembly (3.292 on the next page)

Type	**Bill of Material**
Top level	(3.303 on page 2930)
Bottom level	(3.304 on page 2931)
Hierarchical	(3.305 on page 2931)

Figure 3.292



Counting mode and maximal level

For hierarchical BOM tables, two counting modes are supported:

- **Count all instances**: the total number of subassemblies and parts in the entire assembly.
- **Count instances in parent component**: the total number of subassemblies and parts in the parent component. The parent component is considered as the root component.

For example, the main Tripod assembly contains 3 Tripod foot assemblies. Each instance of a Tripod foot assembly contains 1 Bond assembly and 1 Tube assembly. If the **counting mode** is set to **Count all instances**, the result is: Bill of Materials Tripod Assembly (count all instances) No. Component Quantity 1 Tripod assembly 1 1.1 Tripod foot assembly 3 1.1.1 Bond assembly 3 1.1.2 Tubes assembly 3 If the **counting mode** is set to **Count instances in parent component,** the result is: Bill of Materials Tripod Assembly (count instances per component) No. Component Quantity 1 Tripod assembly 1 1.1 Tripod foot assembly 3 1.1.1 Bond assembly 1 1.1.2 Tubes assembly 1 The default value for the **counting mode** is **Count instances in parent component.** You can change the counting mode in the BOM Manager (3.7.9) or using the BMBOM (6.8.3) command.

NOTE	Before BricsCAD V20.2, all hierarchical BOM tables used the **Count all instances** mode by default. When such tables are updated in BricsCAD V20.2 or later, the default mode is set to **Count instances in parent component**. This may result in different quantities for some parts. If necessary, manually set the counting mode in the BOM Manager (3.7.9).

By default, hierarchical bills of materials show all levels in the model. It is possible to limit a hierarchical BOM to a certain level using **Max level** property. When the maximal level is set, only parts up to that level will be included. For example, if **Max level** = 2, only top level components and subcomponents directly included in top level components will be listed.

BOM columns

By default, the BOM table contains the Number, Name and Quantity columns. Using the Configure option of the BmBom (6.8.3) command you can add more columns, such as Description, Density, Volume, Mass, Material, Thickness (for sheet metal parts), and Parameters (for parametric components (1.30.25)). It is possible to add any built-in property of components, instances or block references to the BOM table. Custom evaluated columns are also supported, using the DataExtraction (6.10.4) technology. (3.293 on the next page) **BOM with Density, Volume, and Mass.**

Figure 3.293

Bill of Materials tripod_main_assy					
No.	Component	Quantity	Density	Volume	Mass
1	tripod_axis_assy	1	8000.00 kg/m³	330.77 cm³	2.65 kg
1.1	tripod_axis_prt	1	8000.00 kg/m³	194.42 cm³	1.56 kg
1.2	tripod_crosspiece_prt	1	8000.00 kg/m³	60.06 cm³	0.48 kg
1.3	tripod_sphere_prt	1	8000.00 kg/m³	76.29 cm³	0.61 kg
2	tripod_foot_assy	3	8000.00 kg/m³	166.24 cm³	1.33 kg
2.1	bond_assy	3	8000.00 kg/m³	21.32 cm³	0.17 kg
2.1.1	tripod_bond_prt	3	8000.00 kg/m³	21.32 cm³	0.17 kg
2.2	tubes_assy	3	8000.00 kg/m³	144.92 cm³	1.16 kg
2.2.1	lower_tube_prt	3	8000.00 kg/m³	62.85 cm³	0.50 kg
2.2.2	middle_tube_prt	3	8000.00 kg/m³	34.83 cm³	0.28 kg
2.2.3	upper_tube_prt	3	8000.00 kg/m³	47.24 cm³	0.38 kg

Grouping modes BOM tables list unique components only; multiple inserts of the same components are grouped, according to the Grouping mode. Starting from BricsCAD V21, the following grouping modes are supported:

- **Auto** - default mode. Multiple inserts of the same components are grouped together with respect to their parameters and added properties. It means that multiple inserts of the same parametric component (1.30.25) are always grouped in separate BOM rows with respect to their parameters, regardless if those parameters are added to BOM as columns.

(3.294)

- **By components and columns** - in this mode, multiple inserts of the same components are grouped together with respect to added properties only. It means that multiple inserts of the same parametric component (1.30.25) could be grouped in the same row even if their parameters are different, depending on what columns are added to BOM. However, instances of different components are always grouped in different rows. This mode is useful, if some parameters correspond to different states of components but not result in being different parts.
- **By columns only** - in this mode, inserts of components are grouped with respect to their properties added to the BOM, regardless if they are inserts of the same component. This mode is useful to get summary tables, such as list of all physical materials or list of all sizes of pipes.

Figure 3.294

Bill of Materials Bookshelf					
No.	Component	Quantity	L	T	W
1	Frame Board	2	360.0	20.0	200.0
2	Frame Board	2	700.0	20.0	200.0
3	Shelf Board	2	266.7	2.5	200.0
4	Shelf Board	2	466.7	2.5	200.0

Visible and invisible columns It is possible to make any column in the BOM table invisible. Invisible columns will not appear in the table in the document. However, you still can use these columns in formulas. Invisible columns will also be displayed in the BOM Manager. (3.7.9)

Aggregated columns Starting from BricsCAD V21, it is possible to set an aggregate function to almost every column in top- or bottom-level BOM tables. Aggregate functions group values of several rows in BOM (that differ only in those values) into one single value. Following aggregate functions are supported:

- **Sum** - sums the grouped values.
- **Average** - finds the average value of grouped values.
- **Minimum** - finds the minimal value of grouped values.
- **Maximum** - finds the maximal value of grouped values.
- **Concatenate** - concatenates all unique values in the group in ascending order.
- **Concatenate with counts** - concatenates all unique values with their number of counts in the group.

For example, take the following BOM table:

Component	Width	Length	Height	Quantity
Beam	16	250	10	1
Beam	16	200	10	2
Beam	16	220	20	1
Beam	20	215	20	3
Beam	20	225	20	1

and apply an aggregate function to the **Length** column. The results are combined in the following table:

Component	Width	Height	Length (sum)	Length (average)	Length (minimal)	Length (maximal)	Length (concat
Beam	16	10	650	216.6667	200	250	200; 250
Beam	16	20	220	220	220	220	220
Beam	20	20	870	217.5	215	225	215; 225

For "concatenated with counts" columns, it is possible to:

- adjust the position of the number of counts (in front or behind the value).
- add the delimiter between values.
- add the delimiter between values and their number of counts.
- define the postfix and/or prefix for the number of counts.

If an aggregated column is used in an evaluated column, the final values will be used by default. However, it is possible to apply an aggregate function to an evaluated column. In this case, the results for such an evaluated column will be first computed for all original values (before aggregation), and then the resulted values will be aggregated.

Number column and column roles A number column is a special column to enumerate rows. It assigns numbers automatically for all rows in the BOM table, without skips and independently of other tables. Rows are numbered starting from 1. Following settings can be changed for the number column:

- **Prefix** - a string that will be added in front of any number. E.g. you want all number to start with "A".
- **Suffix** - a string that will be added after the number. E.g. you want to add "-1" to all numbers.

For a hierarchical BOM, the following settings are available:

- **Number type** - specifies which number format:
  - **Full** - numbers will be formatted as "1.2.3"
  - **Short** - only numbers for the current level show. It is supposed to be used together with the Level column, which shows the level of the current part in the assembly.
  - **Continuous** - all components will be numbered continuously starting from 1, regardless of their level.
- **Delimiter** - specifies the symbol to separate numbers for different levels when the number type is set to **Full**.

In general, the number column is used as the source to annotate the drawing by the BmBalloon (6.8.2) command. However, any column in the table can be used as the source for the annotation balloons, by changing its role. The following column roles are available:

- **Number** - the column contains numbers for annotations.
- **Name** - the column contains part names for annotations.
- **Quantity** - the column contains quantities of parts for annotations.
- **Regular** - the column has no special role.

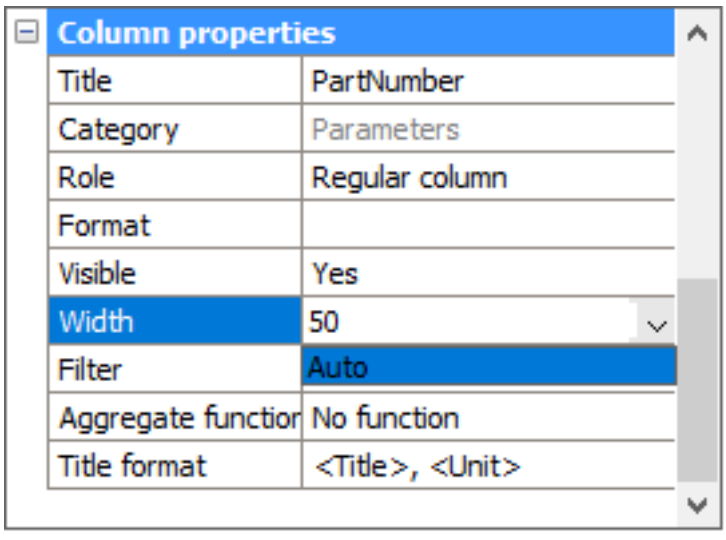
Only one column can have a **Number, Name** or **Quantity** role. If no column has one of these roles assigned, automatic annotations are not possible.

Column width (3.295) By default, the width of each column is set automatically, so its content fits without additional line breaks. However, it is possible to set a fixed column width. To set the column width, do one of the following:

- Select the required column in the BOM manager, then type a value for the **Width** property in layout units. or
- Change the width of the required column in the associated table. Starting from BricsCAD V20.2, BOM tables will automatically keep the width of columns that have been changed manually.

To restore the automatic width mode, select the column in the BOM manager and select **Auto** in the drop-down list for the **Width** property .

Figure 3.295



Column format (3.296 on the facing page) You can format column values. Select the required column in the BOM manager and choose the **Format** option in the context menu. Define the desired format in the **Format dialog (1.29.23)**. The available settings depend on the data type of the selected column. You can select multiple columns of the same type to format them equally.

Property sets Because BOM tables use DataExtraction (6.10.4) technology, you can list properties of mechanical components and entity properties, for example block references in BOM tables. However, these properties are not always necessary. In large assemblies, these properties could negatively affect performance. This is because BricsCAD caches properties during BOM table creation. Property sets are built-in sets of properties. You can choose the most optimal set of properties for your needs. Currently, the following property sets are supported:

- **Mechanical only** - only properties of mechanical components will be listed. Default property set.
- **All except coordinates** - lists all properties of components except coordinate ones. Coordinate properties are typically used only for component instances. They may take significant time to compute.
- **All properties** - lists all possible properties of components and component instances.

You may change the property set for a BOM table in the BOM Manager (3.7.9) or use BMBOM (6.8.3) when you add a new table.

Filter a BOM table

It is possible to filter parts that will form the Bill of Material. Starting with BricsCAD V21, there are two filter types: main and column.

Main filter A Main filter works in the same way as the DataExtraction (6.10.4) command: First, all parts in the assembly, at the required level (top, bottom or hierarchical), are matched against the filter expression. Then, only those parts that have passed the filter will be included in the BOM. The filter expression may not refer to BOM columns because filtering is done before the BOM is generated. For example, it is possible to create a filter for all standard parts because **Is standard** is a normal property of the component. However, it is not possible to set the main filter to filter out all parts with a quantity greater than 1; you should use Column filters for that.

Filter configurator The easiest way to configure the main filter is to use the **Filter Configurator** in the BOM manager (3.7.9). (3.297 on the next page) The Filter Configurator allows to define a set of conditions. Each condition defines a relation between a selected property and a target value. Possible relations are "Equal to", "Not equal to", "Less than", "Greater than", "Less than or equal to" and "Greater than or equal to". Conditions can be added to a group, which defines how those conditions should be treated. There are two group types:

- **"All of"** group - is "true" if all conditions in that group are "true." This is the same as the "and" operator.
- **"Any of"** group - is "true" if at least one condition in that group results in "true." This is the same as the "or" operator.

A group may contain an arbitrary number of conditions. It can also contain nested groups, thus making complex filters possible. To add a condition:

- Select a property from the list of properties.
- Select a required relation operator and specify the target value. For text values, a target value can be selected from the list of all possible values also. For numerical values, their target unit can be specified also in order to automatically convert the value with respect to the default unit of the document.

For text values, "Equal to" and "Not equal to" relations support wildcard characters. The Filter Configurator automatically converts the set of conditions into a filter expression, which can be made visible by pressing the  button: (3.298 on the facing page) This expression is fully editable and two-way associative with the set of conditions.

Syntax description: Relational operators:

Operator	Meaning
==	equal to
!=	not equal to
<	less than
>	greater than
<=	less than or equal to
>=	greater than or equal to

- Property names need to be enclosed in quotes.

Figure 3.297

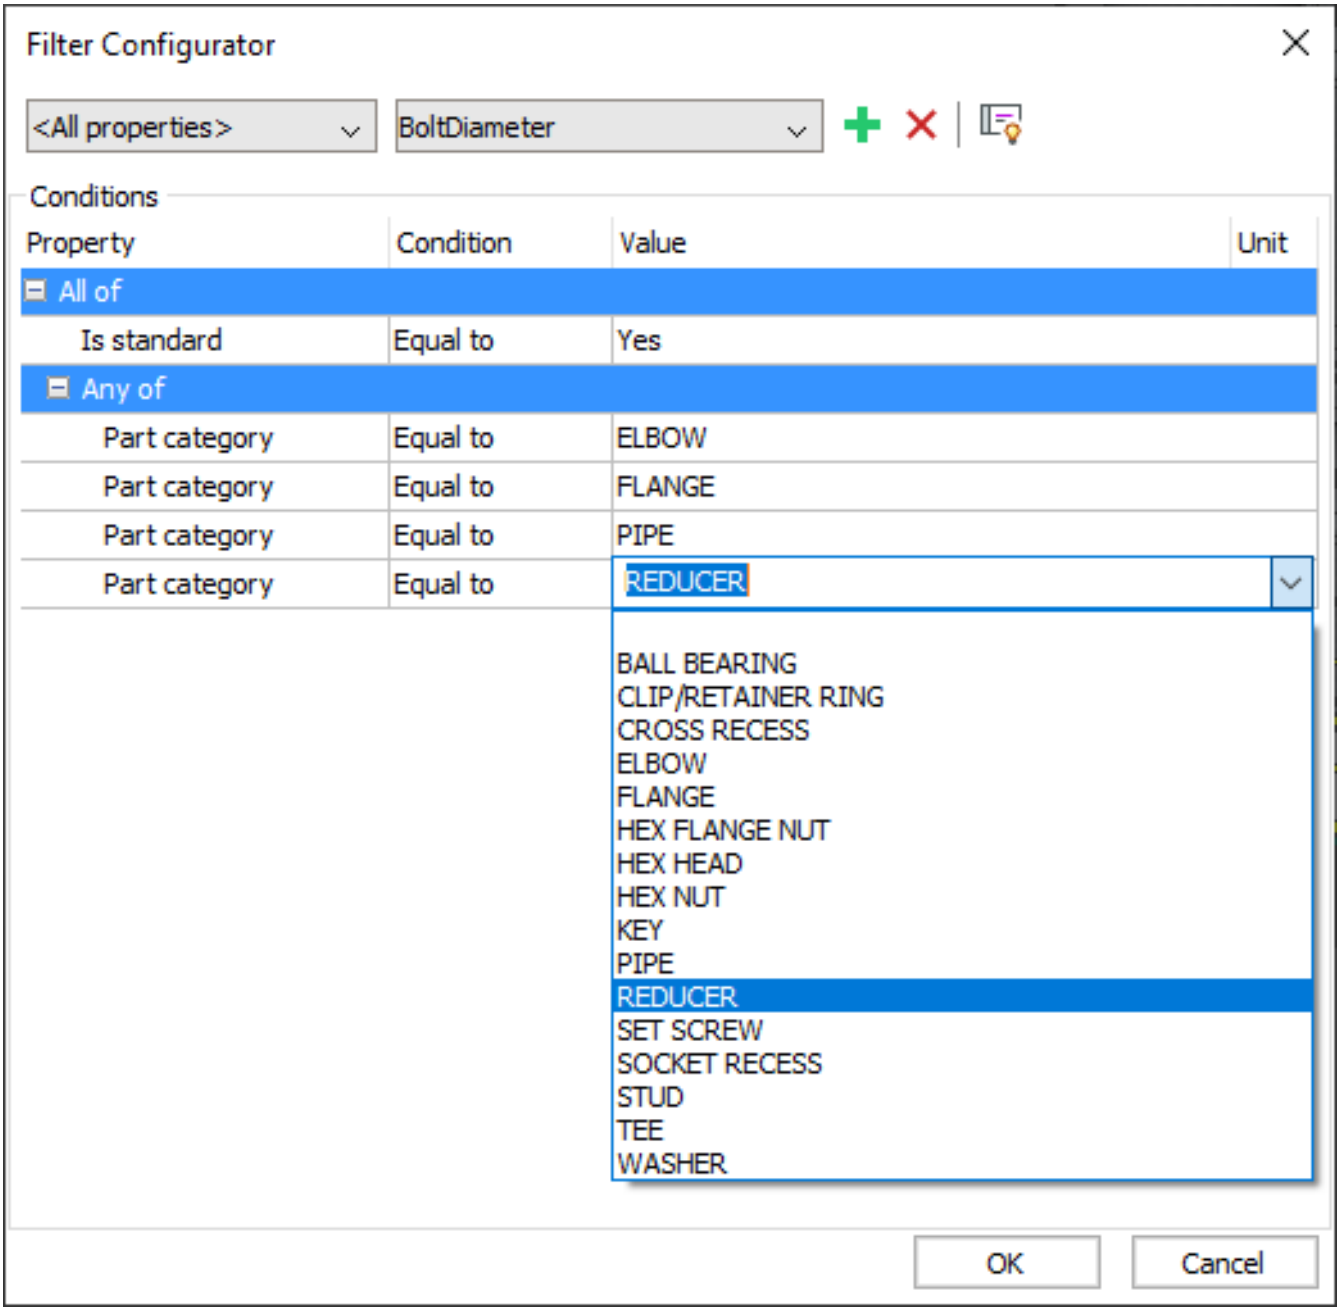

Figure 3.298

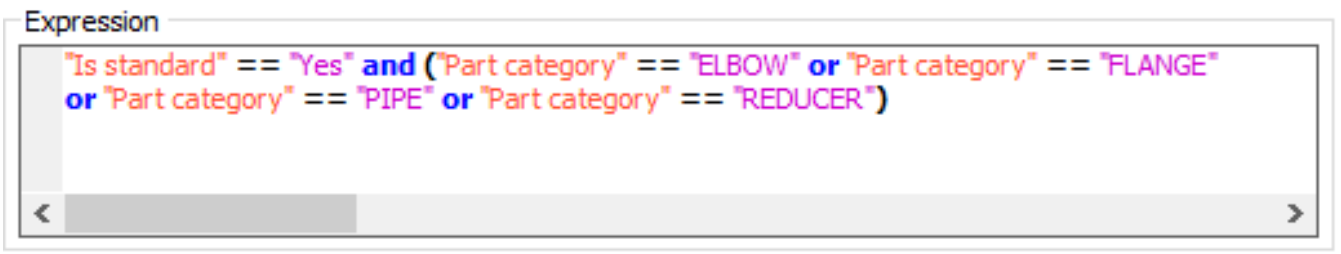


- Relational operators can be combined using "and" and "or" operators. Operator "and" will result in "true" if both sides of the operator are true. Operator "or" will result in "false" if either left or right side of the operator is true.
- Logical operators "and" and "or" are case sensitive.
- Use "(" and ")" to combine two operators into one.
- String values are enclosed in double quotation marks ""
- Relational operators for strings are case sensitive.
- "==" and "!=" operators support wildcard templates.

For example, to get a BOM of all standard parts, use the following expression:

```
"Is standard"=="Yes"
```

To get a BOM of all ISO standard parts, use the following expression:

```
"Is standard"=="Yes" and "Part standard"=="ISO"
```

To get a BOM of all ISO or DIN standard parts, use the following expression:

```
"Is standard"=="Yes" and ("Part standard"=="ISO" or "Part standard"=="DIN")
```

Wildcard characters Wildcard characters allow you to match property values against a specific template. For example, if you want to find all components containing "nozzle" in their names, a following expression could be used:

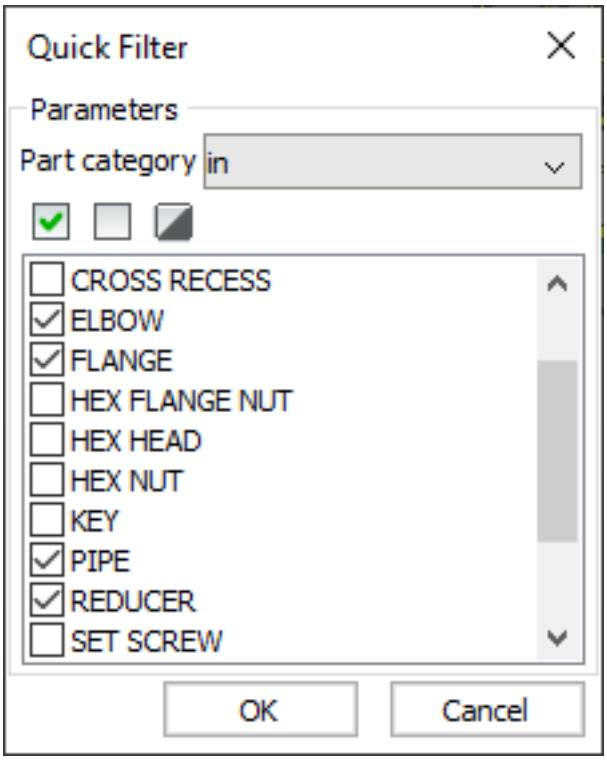
```
"Component name"=="*nozzle*"
```

Wildcard characters can be also used as target values in the Filter Configurator. Only "Equal to" and "Not equal to" relational operators support wildcard characters. Note that wildcard characters in the main filter are case-sensitive. For Column filters, you can specify if you need case-sensitive or case-insensitive matching. The following special symbols are supported:

Name	Character	Description
Back quote	‘	Escapes the next character (takes it literally).
Comma	,	Separates patterns.
Asterisk	*	Matches any character sequence, including a null sequence, anywhere.
Question Mark	?	Matches a single character.
Period	.	Matches a single non-alphanumeric character.
At sign	@	Matches a single alphabetic character.
Hash tag	#	Matches a single numeric character.
Tilda	~	If the first character in a pattern matches anything but the pattern.
Brackets	[...]	Matches a single enclosed character.
Tilda brackets	[~...]	Matches a single non-enclosed character.
Hyphen	-	In brackets, matches a single character in the specified range.

Column filter Column filters have been introduced in BricsCAD V21. This allows you to quickly set the conditions which rows display, depending on the column content (somewhat similar to filters in some spreadsheet processors). Unlike the main filter, they are applied after the BOM table has been generated. Therefore, it is possible to use column filters for columns with aggregated content, such as quantities. Each column can have one filter only; however, you can add column filters to as many columns as you need. Only rows that pass all column filters display in the final BOM. You can configure column filters using the **Column Filter** dialog in the BOM manager (3.7.9): (3.299 on the next page) In this dialog, you can select the type of filter from the list and configure it accordingly. The list of possible filters depends on the column content type, as shown in the table below:

Figure 3.299



Filter type	Column type	Description
always accepted	any	all column values are accepted
equal to	numerical	value should be equal to the target one
not equal to	numerical	value should be not equal to the target one
less than	numerical	value should be less than the target one
greater than	numerical	value should be greater than the target one
less than or equal to	numerical	value should be less than or equal to the target one
greater than or equal to	numerical	value should be greater than or equal to the target one
between	numerical	value should be in the given range, both ends included
not in range	numerical	value should be not in the given range, both ends excluded
exactly matches	text	value should exactly match the target one
does not match	text	value should be different from the target one
starts with	text	value should start with the given text
does not start with	text	value should not start with the given text
ends with	text	value should end with the given text
does not end with	text	value should not end with the given text
contains	text	value should contain the given text
does not contain	text	value should not contain the given text
matches pattern	text	value should match the given wildcard template
does not match pattern	text	value should not match the given wildcard template
in	text and numerical	value should be in the given set of values

not in	text and numerical	value should be not in the given set of values

For all text filters, you can also specify whether they should be case-sensitive or case-insensitive.

Sort a BOM table

There are three sorting modes for BOM tables:

- **Automatic order** - the table content is sorted as follows: component name, physical material name, thickness (if applicable), parameters (in alphabetic order) and finally, quantity.
- **Natural order** - the table content is not sorted. Instead, all components are in the order of their appearance in the document. In most cases, parts added earlier will precede parts added later.
- **Custom order** - the table content is sorted according to the columns you select. If no columns are specified, the natural order is used.

Starting from BricsCAD V21, BOM tables use so-called "natural sorting" of text. It means that if text contains a mix of letters and numbers, it will be sorted with respect to those numbers. For example, strings "N1", "M2", "N11", "N2", "AA1" will be sorted as "M2", "N1", "N2", "N11", "AA1." Therefore, it is possible to assign custom numbers with various prefixes to components using custom parameters, and then sort the BOM tables by those numbers in the correct order.

Evaluated columns

Evaluated columns are special columns, of which results are depending on other columns using user-defined expressions. Since BricsCAD V21, two kinds of evaluated columns are supported: **formula** and **template** columns.

Formula columns A Bill of Materials supports formula fields. The same syntax is used in the DataExtraction (6.10.4) command. **FormulaExpression** is the expression in the format of **\AcExpr** formula fields. This can contain constants such as PI or functions such as SIN (see Use Expressions (1.21.7)). An operand in an expression can be a **ColumnTitle** enclosed in arrow brackets (<>). For example, formula **=<Mass>/<Volume>** calculates the average density of the component. If a row does not contain a value, a default value will be used instead. It is possible to specify the default value for an operand using the following syntax:

```
<"ColumnTitle",DefaultValue>
```

where **ColumnTitle** is the title of the required column, and **DefaultValue** is the default value. **ColumnTitle** must be between double quotes ("). If no default value is specified, an empty value will be used, which in most cases results in an empty output. A formula column can contain multiple expressions. Each expression should be enclosed by sum brackets ({}). These expressions will be evaluated from first to last, and the first one yielding a non-empty output will be used. Starting from V21, a formula can refer to other formula columns, provided that they do not form a loop. In a hierarchical BOM, a formula can also refer to values of the parent row by adding **Parent:** before the column name. It also can refer to properties that are not explicitly added to the table, but all other formula columns referred to in the formula must exist in the table. You can still such columns displayed as invisible in the BOM table in formula expressions. For distance, area, volume and mass properties, the values will be converted to the **user-defined** unit before using them in the formula expression. If the **user-defined** unit is not set, the document unit will be used. For the mass property, kilogram will be used in metric documents and lbs (pound) in imperial documents.

Template columns Template columns allow you to combine several properties, as well as a custom text, into a single column. A special syntax, based on Diesel expressions, is used to define template columns. Expressions for template columns must start with the **$** sign. An operand in an expression can be a **ColumnTitle** enclosed in arrow brackets (<>). It is also possible to use special functions:

$(+, arg1, arg2[, ... , arg9])	Adds the provided arguments to the first one
$(-, arg1, arg2[, ... , arg9])	Subtracts the provided arguments from the first one.
$(*, arg1 , arg2[, ... , arg9])	Multiplies the first argument by the provided arguments.
$(/, arg1, arg2[, ..., arg9])	Divides the first argument by the provided arguments.
$(=, arg1, arg2)	Returns 1 if arg1 is equal to arg2; otherwise, returns 0. Both arg1 and arg2 must be numbers.

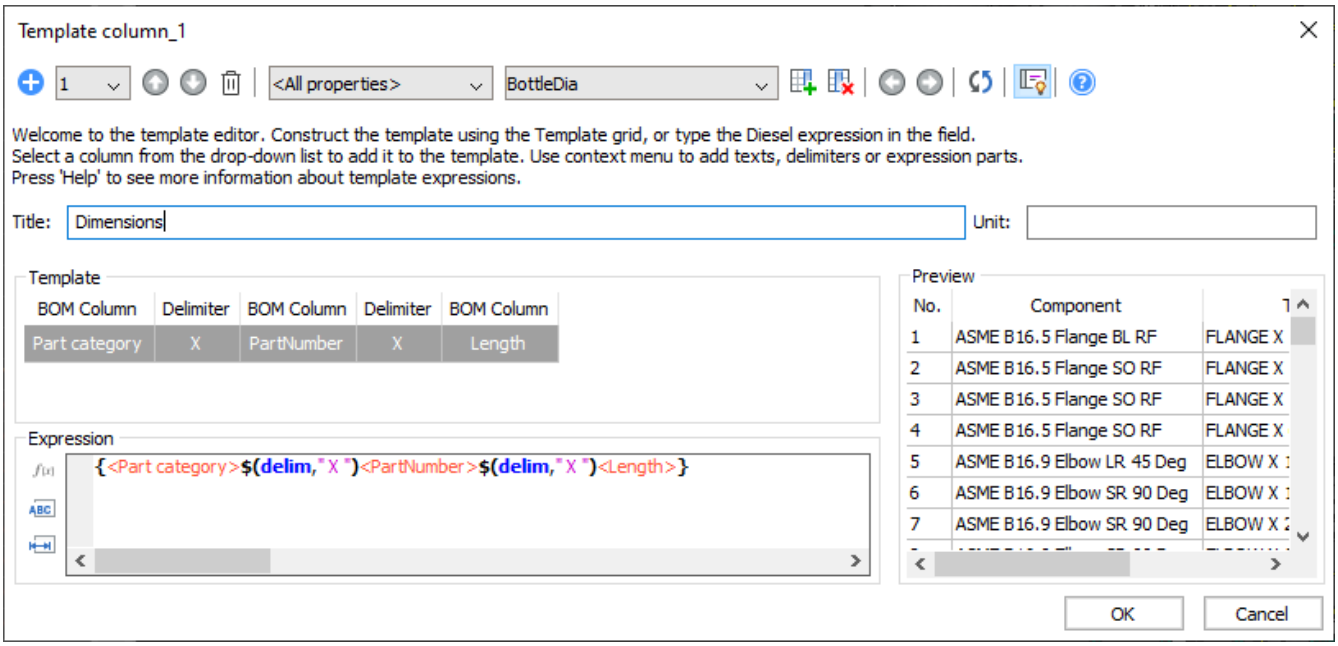
$(<, arg1, arg2)	Returns 1 if arg1 is less than arg2; otherwise, returns 0. Both arg1 and arg2 must be numbers.
$(>, arg1, arg2)	Returns 1 if arg1 is greater than arg2; otherwise, returns 0. Both arg1 and arg2 must be numbers.
$(!=, arg1, arg2)	Returns 1 if arg1 is not equal to arg2; otherwise, returns 0. Both arg1 and arg2 must be numbers.
$(<=, arg1, arg2)	Returns 1 if arg1 is less than or equal to arg2; otherwise, returns 0. Both arg1 and arg2 must be numbers.
$(>=, arg1, arg2)	Returns 1 if arg1 is greater than or equal to arg2; otherwise, returns 0. Both arg1 and arg2 must be numbers.
$(and, arg1, arg2[, ... , arg9])	Applies bitwise AND operation to arguments
$(angtos, angle[, mode, precision])	Converts the angle to string with respect to given mode (0 - degrees, 1 - d/m/s, 2 - grads, 3 - radians) and precision.
$(delim, delimiter_string)	Inserts a smart delimiter. The delimiter string will be added to the output only if the output before and after this delimiter is not empty.
$(edtime, time, format)	Formats the date according to the given format string.
$(eq, arg1, arg2)	Returns 1 if arg1 is equal to arg2; otherwise, returns 0. Both arg1 and arg2 must be text.
$(eval, expression)	Evaluates the given expression as a Diesel expression.
$(fix, value)	Truncates the real value to the integer one.
$(getvar, variable)	Returns the value of the given system variable.
$(if, arg, then[, else])	Returns 'then' if 'arg' is not 0; otherwise, returns 'else' or empty string if 'else' is not provided.
$(index, position, comma_separated_string)	Returns the substring at the given position in the given comma-separated string.
$(nth, position, arg1[, arg2, ... , arg9])	Returns the argument at the given position.
$(or, arg1, arg2[, ..., arg9])	Applies bitwise OR operation to arguments.
$(rtos, value[, mode, precision])	Formats the given value with respect to the required mode and precision.
$(strlen, string)	Returns the length of the given string.
$(substr, string, start[, length])	Returns the substring of the 'string' from 'start' of the given 'length'. Numeration starts from 1.
$(upper, string)	Converts 'string' to uppercase.
$(xor, arg1, arg2[, ... , arg9])	Applies bitwise XOR to all arguments.

One template column can contain multiple expressions. Each expression should be enclosed by sum brackets ({}). These expressions will be evaluated from first to last, and the first one yielding a non-empty output will be used. Starting from V21, a template column can refer to other evaluated columns, provided that they do not form a loop. In a hierarchical BOM, a template column can also refer to values in the parent row by adding **Parent:** before the column name. It can also refer to properties that are not explicitly added to the table, but all other evaluated columns referred to in any of the expressions must be present in the table. You can still use columns displayed as invisible in the BOM table in template expressions. You can use **"\n"** string to add a line break. For example, the following expression combines PartNumber, Width, Height and Length properties:

```
${<PartNumber>$(delim," X ")<Width>$(delim," X ")<Height>$(delim," X ")<Lenght>}
```

Expression configurator You can use the **Expression configurator** dialog to configure an evaluated column. This dialog is available in Bill of Materials Manager. (3.7.9) (3.300 on the following page) This dialog allows you to set the title and unit for the column, edit the expression using an editor with syntax highlight and autocompletion, and see a of the BOM table with the evaluated column. For a template column, the **Template** section allows you to easily insert, move and delete properties, as well as delimiters and custom texts.

Figure 3.300



Column units

You can adjust the **units placement** mode for columns that have associated units. The following options are available:

- **Don't show units** - the BOM table will not display units for this column.
- **In column title** - if all values in the table use the same unit or can be converted to a common unit, all values are converted to that common unit. The unit name will be added to the column title. You can configure the position of the title and the unit using the **Title format** property. Use **<Title>** to denote the title, and **<Unit>** to denote the unit. For example, the default title format is "**<Title>,** <Unit>**.**" You can use "\n" to add a line break. The common unit will be picked in the following order:
  1. A unit set by you.
  2. If the property is a distance, an area, a volume or a mass, and the unit mode is **Best for all values**, the best representation for the majority of the values is used.
  3. If all values have the same unit, this will be used.
- **In cell** - the unit name will be added to the value. Value and unit display in the same cell.
- **In additional column** - the unit name will are placed in a separate column.

You can set the **Unit mode** for distance, area, volume and mass values to define the units used to display a particular value. For example, if there are masses going from 1 gram to several tons, choose **Best for each value** to display each mass converted to the most suitable mass unit. To see all masses in kilograms, set kilograms as the **user-defined** unit for the column. **Best for all values** is the default. **Units mode** options:

- **Don't show units** - units are not displayed.
- **Best for all values** - the unit with the best representation for the majority of the values is displayed. Only dimensions, area, volume and mass properties are supported.
- **User-defined** - you choose the unit to display. In addition to dimensions, area, volume and mass properties, it is also possible to select a required unit for material properties, such as density, thermal conductivity and specific heat.
- **Best for each value** - the unit that is most suitable for each value is used. The **In column title** mode of the **Unit placement** automatically switches to the **In additional column** mode. Only dimensions, area, volume and mass properties are supported.

NOTE	If a user-defined unit is set for a column and this column is used in a formula field, the values converted to that unit will be substituted in the formula. Otherwise, the document unit will be used.

Footer

The BOM/Materials table supports a footer. To define which columns will form the footer, set the **Footer type** for the required columns:

Templates

You can save a BOM configuration as a template and use it to create new BOM tables. The template file contains all necessary data. It includes table type, title, filter and set of columns with all the associated properties. You can use <NAME> in the title as a placeholder for the actual name of the assembly. For example, if your assembly name is 'My Assembly' and the title of the BOM is specified as Bill of Materials for <NAME>, the the BOM title will be 'Bill of Materials for My Assembly', because 'My Assembly' replaces <NAME>. By default, BOM template files have a .BOM extension. A BOM template file is an extension of the Data Extraction Definition file (.dxd). (2.13.9) However, you cannot use a .dxd file as a BOM template, because some BOM-specific data will be missing. You can not use a .BOM file to define a DataExtraction (6.10.4) template. You can edit template files in any text editor. However, Bricsys recommends that to use the BMBOM (6.8.3) command or the BOM manager (3.7.9) to create and edit template files.

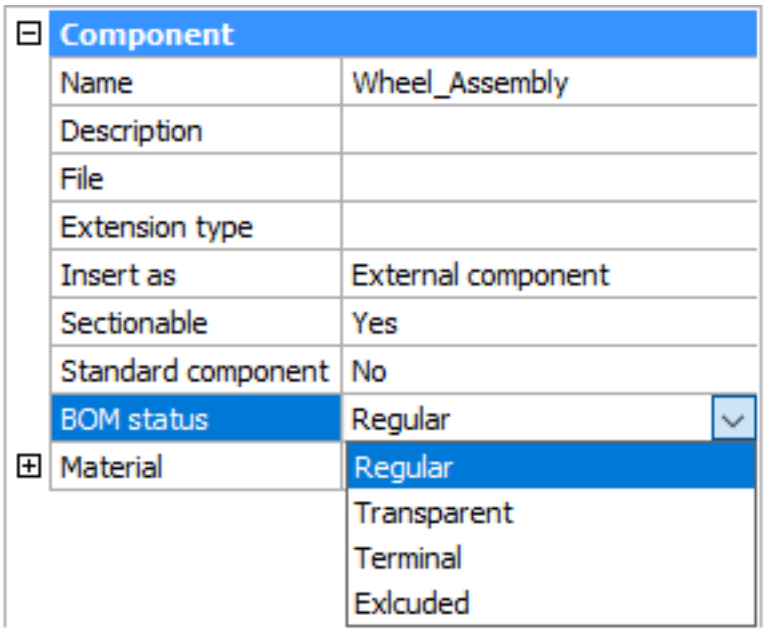
BOM status

(3.301 on the next page)

Each component has a **BOM status** property. You can use this to control the behavior of the component in **Bill of Materials** tables. This property can have one of the following values:

- **Regular** - the component appears in a Bill of Materials at the same position as the assembly structure and the default value of the selected mode for a Bill of Materials.
- **Transparent** - the component acts as a transparent container for its subcomponents. The component does not appear in the Bill of Material but subcomponents can appear in the BOM, depending on their BOM status, position in the assembly structure and the mode of the BOM table.
- **Terminal** - the component is treated as a leaf component (has no subcomponents). This is useful for complex parts or standard components.
- **Excluded** - the component and its subcomponents do not appear in the Bill of Materials.

Figure 3.301



To set the BOM Status of an external or root component

1. Open the file that contains the component.
2. Select the root component in the Mechanical Browser (6.8.32).
3. Set the **BOM status** property.

To set the BOM Status of a local component

1. Select the component in the Mechanical Browser (6.8.32).
2. Right-click on the selected node to open the context menu.
3. Select a BOM status from the BOM Status submenu. (3.302 on the facing page)

NOTE	It is not possible to set the BOM status via the context menu for local components that are inserted into an external component. To do this, you must open the component that contains the local component.

Fixed corners

Starting from BricsCAD V21, it is possible to set any corner of the table as fixed. The fixed corner will always keep its initial position during BOM update. When the table has been moved manually, the new position of this corner will be kept. Fixed corners allow to align BOM tables with other objects. You may choose which corner to fix during the table placement by either the BmBom (6.8.3) command or the BOM manager (3.7.9); use the Tab key to cycle the corners. You can change the fixed corner of a BOM table in the BOM manager (3.7.9).

3.7.12 Array Properties

Component array is an associative array made of a parametric component. Component arrays have special representation in the Mechanical Browser. (6.8.32) Component array have two main subnodes:

- Source - node that contains source object and its parameters. Source object can be presented as a component or subassembly with their own properties (3.7.3).
- Elements - node that contains all instances of source object

(3.306 on the next page) Component array context menu displayed by right mouse click on the array node while array (6.4.19) properties displayed automatically when selecting an array in the Mechanical Browser.

Context Menu

Component array context menu

Right click an array: (3.307 on page 2935)

- Dissolve: Dissolves an array created in the current drawing (See the BmDissolve (6.8.8) command).
- Unlink: Unlinks an array from 3D solid by dissolving the underlying component-based feature.
- Hide ( ) / Show ( ): Hides or shows the selected array.
- Exclude all inserts from section: Sets the **Sectionable** property of all similar inserts to **NO**. Defines whether an insert is affected by the ViewSection (6.31.12) command.
- Visual Style: Displays the **Visual Style** menu. Visual Styles (6.31.15) that are saved in the current drawing are available.

(3.308 on page 2935)

- By Viewport: Renders the selected array according to the current viewport shademode (see the ShadeMode (6.27.31) command).
- All by Viewport: Renders all arrays according to the current viewport shademode (see the ShadeMode (6.27.31) command).
- Zoom to: Zooms to the selection set.
- Select: Selects the array.
- Delete: Removes the selected array from the assembly.
- Collapse all: collapses the main component and all components and subcomponents.
- Expand all: expands the main component and all components and subcomponents.

Related Commands

3dArray (6.3.2) - creates 3D arrays. -Array (6.4.20) - creates a polar or rectangular array of entities; displays prompts at the command bar. ArrayClassic (6.4.22) - creates a static polar or rectangular array of entities through a dialog box. ArrayEdit (6.4.25) - allows editing associative array entities and their source entities. ArrayPath (6.4.26) - associatively distributes entity copies evenly along a path into multiple rows, and levels. ArrayPolar (6.4.41) - associatively distributes entity copies evenly in a circular pattern about a center point or axis of rotation, using multiple rows, and levels. ArrayRect (6.4.28) - associatively distributes entity copies into any number of rows, columns, and levels. MInsert (6.21.15) - inserts arrays of blocks.

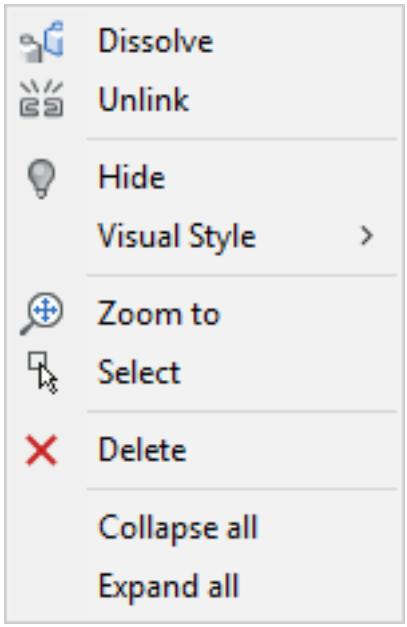

Figure 3.308

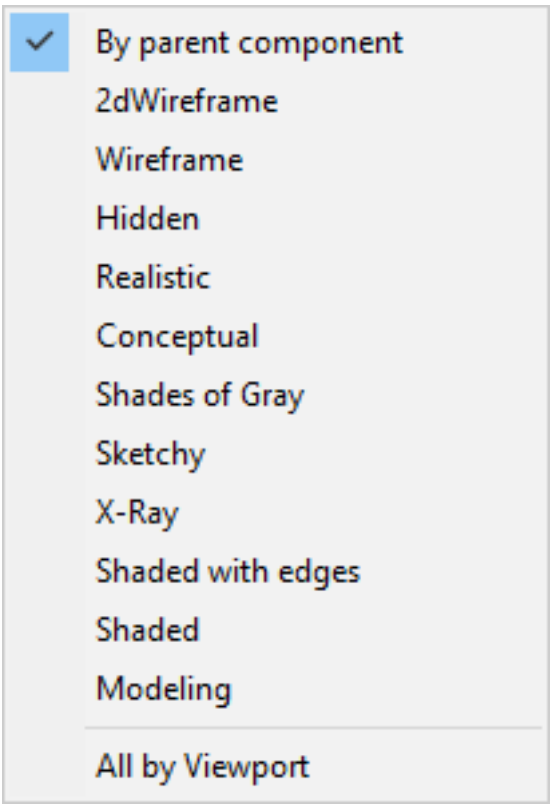


3.8 Sheet Metal - Workflows

3.8.1 Feature coloring in BricsCAD Sheet Metal

Youtube With feature coloring you can easily distinguish one sheet metal feature from another and visually validate your sheet metal parts. Each of the sheet metal features – flanges, bends, junctions and reliefs – has its own assigned color. You can easily re-set colors in the settings menu. Back to Tutorial Overview

3.8.2 Split thickness faces into regions

https://www.youtube-nocookie.com/embed/G5Q80Li-7-w When using junction features in your designs, Sheet Metal for BricsCAD will allow you to split thickness faces into regions. Thus enhancing your ability to work with junction features. Back to Tutorial Overview

3.8.3 Making a parametric workbench - Part 1

https://www.youtube-nocookie.com/embed/Lw98FrIc6D0 In this tutorial series we're going to demonstrate how you can create a parametric workbench in sheet metal. Back to Tutorial Overview

3.8.4 Making a parametric workbench - Part 2

https://www.youtube-nocookie.com/embed/DRcDVhHsxpg Starting with the completed model of the sheet metal bench from Part 1 we now add the parameters and constraints, which will allow us to drive our model. Back to Tutorial Overview

3.8.5 Parametrizing sheet metal parts

https://www.youtube-nocookie.com/embed/uK90ff5Ha64 Sheet Metal for BricsCAD adds new design intelligence by automatically placing 3D constraints within your model as you work. The result? Better dimensional control over your designs with the automated creation of these constraints. Back to Tutorial Overview

3.8.6 Batch processing in BricsCAD Sheet Metal

https://www.youtube-nocookie.com/embed/1fjMsqGpmbk Batch processes of sheet metal parts and assemblies can be **automated in large numbers** using a **dedicated LISP API.** This automation feature accomplishes tasks, such as producing families of sheet metal parts of different sizes. Example LISP scripts are included with BricsCAD. Back to Tutorial Overview

3.8.7 Working with lofted bends of an imported model

https://www.youtube-nocookie.com/embed/cnnop3X3PqU In this tutorial, we will show how an airconditioning system is manufactured using assembly modeling and lofted bends. Back to Tutorial Overview

3.8.8 Rework an imported model in BricsCAD Sheet Metal

https://www.youtube-nocookie.com/embed/WA7cfBKKJas In this tutorial, we'll investigate the creation of a sheet metal air box from an existing solid model. Back to Tutorial Overview

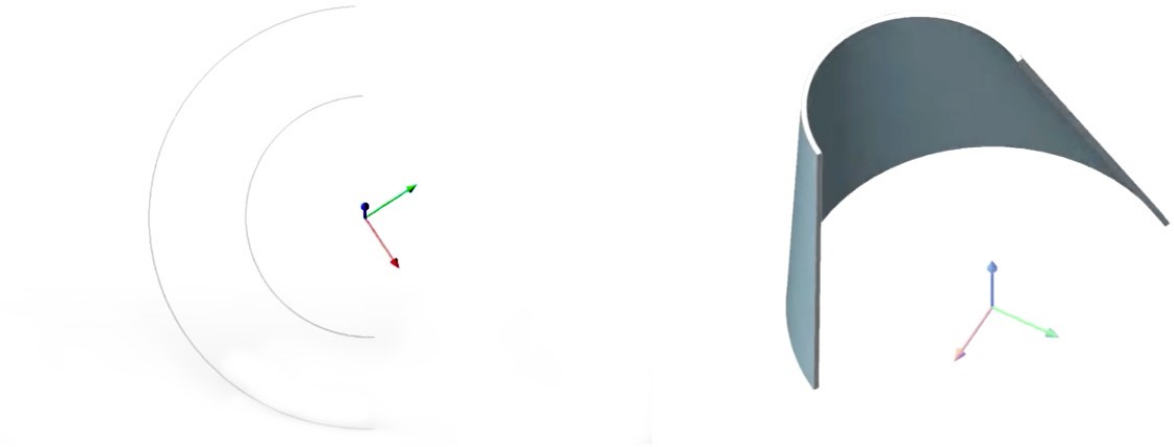
3.8.9 Lofted bends in BricsCAD Sheet Metal

Youtube BricsCAD creates sheet metal parts with lofted surfaces representing smooth transitions between two profiles, such as between lines, arcs, circles, rectangles, polylines, and splines. Imported sheet metal parts with lofted bends can be edited and unfolded. BricsCAD supports sheet metal parts with lofted bends, which are manufactured by a series of regular bends. Supported profiles include lines, arcs, circles, rectangles, polylines and splines.

A lofted bend can be created from two curves

(3.309 on the facing page)

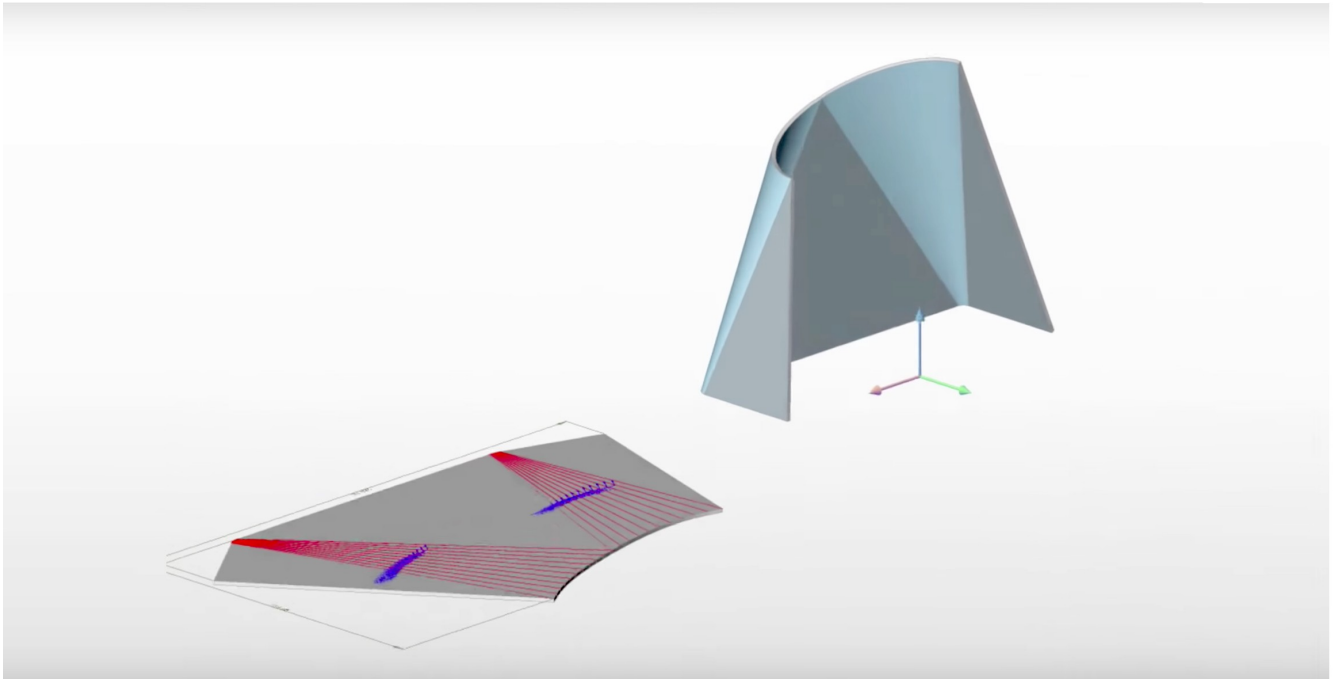
Figure 3.309



Imported sheet metal parts with lofted bends can be edited and unfolded

(3.310 on the next page) Back to Tutorial Overview

Figure 3.310



3.8.10 Making a parametric workbench - Part 3

https://www.youtube-nocookie.com/embed/El4bOrCaM7w In the third part of this tutorial series we demonstrate how an Architectural Designer can make use of our bench to complete their design. Back to Tutorial Overview

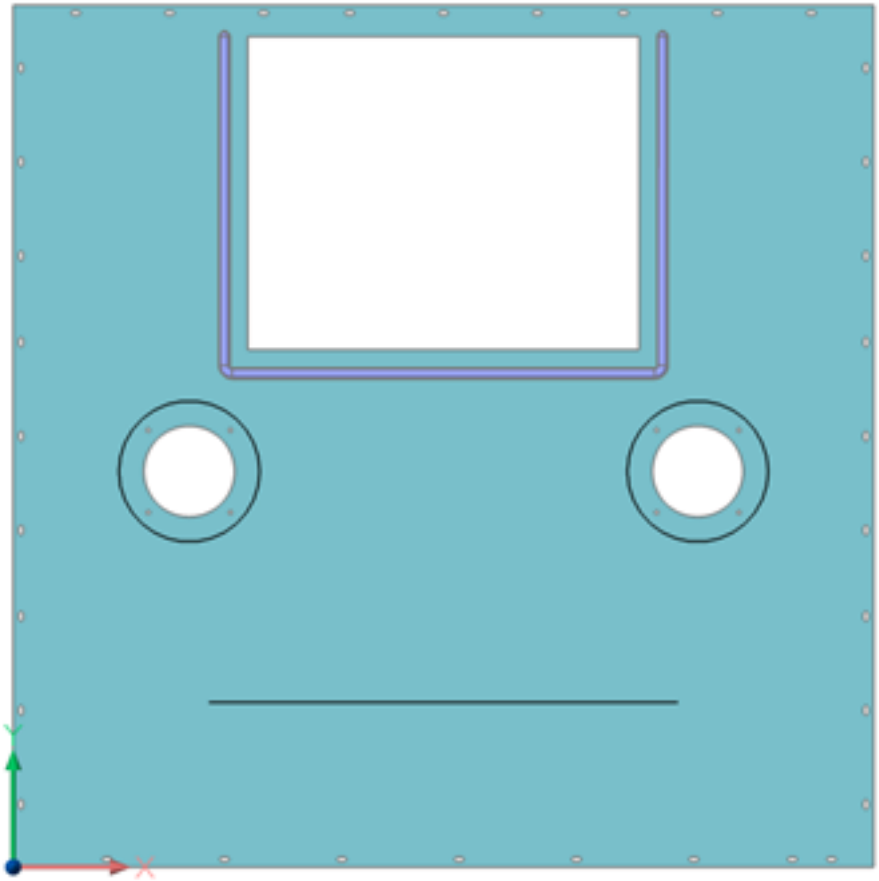
3.8.11 Making a parametric workbench - Part 4

https://www.youtube-nocookie.com/embed/u2skl7fx4f8 In the final part of this series, we take on the role of a sheet metal fabricator to prepare our workbench for unfolding, then generate the flattened profiles. Back to Tutorial Overview

3.8.12 Start from an imported model in BricsCAD Sheet Metal

Youtube Combining the simplicity of direct modeling with the power of parametric features, sheet metal parts are generated by applying direct editing operations to the geometry. Edit feature parameters in the browser. Go beyond the limits imposed by traditional history-based modeling systems with BricsCAD's interactive sheet metal toolset. Back to Tutorial Overview

Figure 3.311



3.8.13 Sheet metal ribs

https://www.youtube-nocookie.com/embed/nYxZotLlZ7Y You need a **BricsCAD Platinum** and **Mechanical** licenses for this tutorial.

1. Open the **Roof.dwg** file.
2. Click the **Create Rib Features (6.28.27)** ( ) tool button, in the **Modify** section of the **Sheet Metal** tab on the **Ribbon (1.17.6)**.
3. Select the flange face.
4. Select the U-shaped profile.
5. Hit **Enter** to complete the command. (3.311)
6. Click the **Create Rib Features (6.28.27)** ( ) button, in the **Modify** section of the **Sheet Metal** tab on the **Ribbon (1.17.6)**.
7. Select the flange face.
8. Click the **Profile radius** option on **SmRibCreate** menu.
9. Enter **6** as the new profile radius.
10. Select the two circles and the spline using a Blue Window-Inside Selection Box (1.32.7). **(3.312 on the next page)**
11. Hit **Enter** to complete the command.
12. In the Mechanical Browser (3.9.6) select **rib by spline (Rib_2)**.
13. Change the **Round radius** in the Mechanical Browser (3.9.6) to **4 mm**.
14. Select the spline using a **Blue Selection window**.
15. Click the **Midpoint** of the spline and STRETCH (1.32.3) down 100. (3.313 on the facing page)
16. Hover over the top flange face.
17. Click the **Unfold body (6.28.31)** ( ) button on the **Sheet Metal** section of the **Quad (2.3.3)**.
18. Choose the position for the unfolded body.
19. Hit **Enter** to complete the command.

3.8.14 Sheet metal parametrize

https://www.youtube-nocookie.com/embed/XZDs2m1M1WE You need **BricsCAD Platinum** and **Mechanical** licenses for this tutorial.

1. Open the **Cabin_assembly.dwg** file from SmParametrize_files.zip.
2. Select **Wall_1:1** in the Mechanical Browser (3.9.6).
3. Click **Open (6.23.8)** ( ) on the right-click menu.
4. Click the **Parametrize (6.28.23)** ( ) button in the **Sheet Metal | 3D Constraints** panel on the **Ribbon (1.17.6)**.
5. Hit **Enter**. The following 71 constraints are created: (3.315)
6. Save the file as **Wall_1_parameter.dwg.**
7. Close the **Wall_1_parameter.dwg** file.
8. Switch to the **Cabin_assembly.dwg** file.
9. Select **Wall_1** in the Mechanical Browser (3.9.6).
10. Click **Replace all insert... (6.8.31)** ( ) on the right-click menu.
11. Select the **Wall_1_parameter.dwg** file in the **Select file for component** menu, click **Open**.

12. Select **Wall_R** in the Mechanical Browser (3.9.6).
13. Click **Open (6.23.8)** () on the right-click menu.
14. Click the **Parametrize (6.28.23)** () tool button in the **Sheet Metal | 3D Constraints** panel of the **Ribbon (1.17.6)**.
15. Select the wall.
16. Click **Enter**. The following 39 constraints are created: (3.316 on the next page)
17. Save the file as **Wall_R_parameter.dwg.**
18. Close the **Wall_R_parameter.dwg** file.
19. Switch to the **Cabin_assembly.dwg** file.
20. Select **Wall_R** on the Mechanical Browser (3.9.6).
21. Click **Replace** () on the right-click menu.
22. Select the **Wall_R_parameter.dwg** file in the **Select file for component** menu, click **Open**.
23. Select the following parameters in the Mechanical Browser (3.9.6):
    - **Wall_1:1|CZ_OverallLength_Body_1**
    - **Wall_1:2|CZ_OverallLength_Body_1**
    - **Wall_1:3|CZ_OverallLength_Body_1**
    - **Wall_1:4|CZ_OverallLength_Body_1**
    - **Wall_1:5|CZ_OverallLength_Body_1**
    - **Wall_1:6|CZ_OverallLength_Body_1**
    - **Wall_1:7|CZ_OverallLength_Body_1**
    - **Wall_R:1|CZ_OverallLength_Body_1**
24. Click **Link to parameter** on the right click menu. (3.317 on the facing page)
25. Change the expression of the **CZ_OverallLength_Body_1** parameter to **2400**. (3.318 on page 2956)

(3.319 on page 2956)

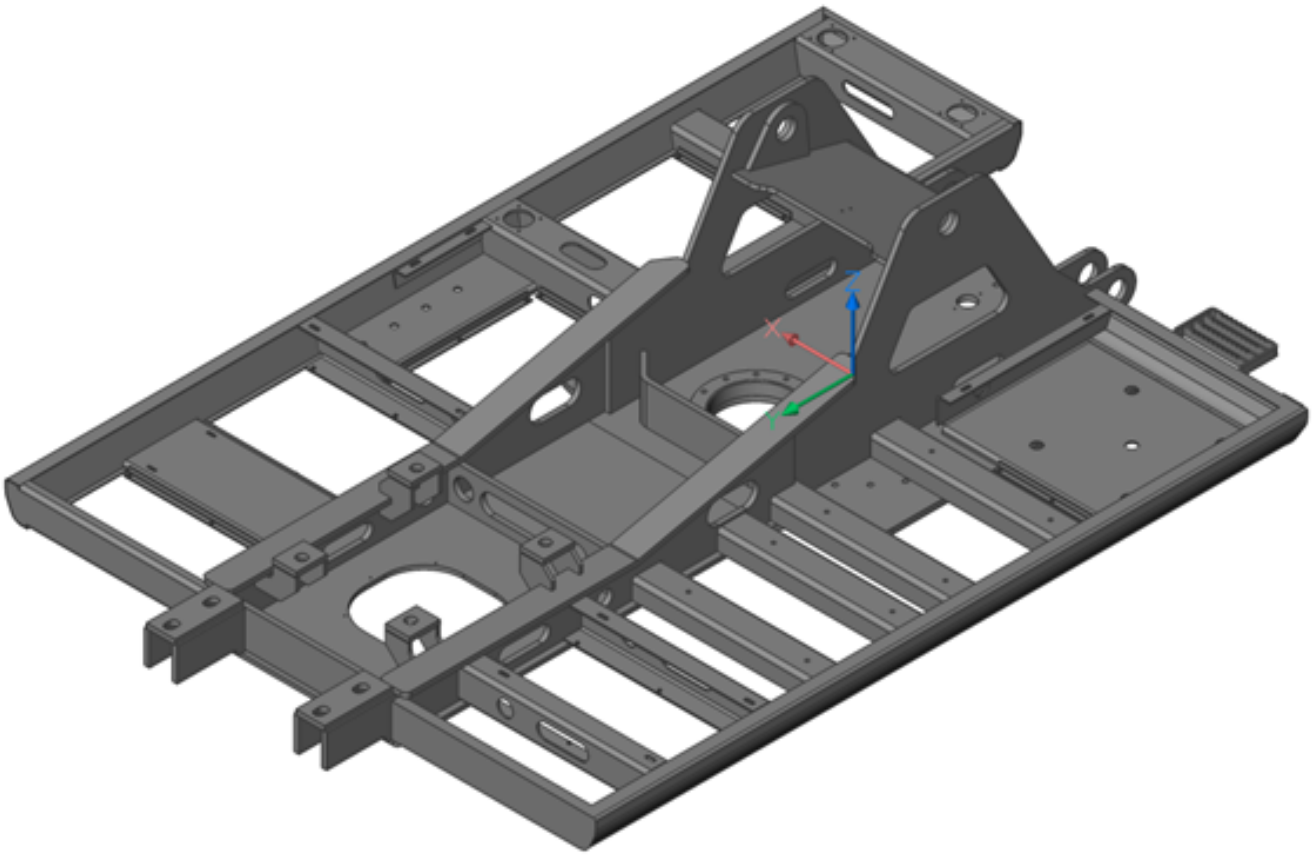
3.8.15 Designing from scratch in BricsCAD Sheet Metal

https://www.youtube-nocookie.com/embed/zPTzEKV5IrI This video demonstrates how to create a sheet metal part from scratch and then unfold it to export it to a CAM system. Creating new sheet metal parts or reworking existing ones? BricsCAD is your best choice. It is free of conceptual mistakes of history-based MCAD software. You will never need to restart your design from scratch, because we guarantee maximum flexibility for changing your models by combining the freedom of direct modeling with the power of feature-based design. Back to Tutorial Overview

Figure 3.320



3.8.16 Poor sheet metal rework

https://www.youtube-nocookie.com/embed/aPTzN1vxL_4 A Mechanical or Ultimate license level is required for this tutorial.

1. Open the **Upper_Frame_Assembly.dwg** file from Poor_Sheet_metal_rework_files.zip.
   (3.320)
2. Hover over **Border_3**, click the **Open (6.23.8)** ( ) tool button on the Quad (2.3.3) | **Model**.

1. Rework the left side of the border

(3.321 on the facing page)

1. Click the **Convert to Sheet Metal (6.28.4)** ( ) tool button on the **Sheet Metal / Create** Ribbon panel. Prompts you: Select 3D solids or seed faces or [Entire model/selection options (?)] <Entire model>:
2. Right click or press Enter.
3. Click the **Smart (6.28.30) Split** ( ) tool button on the **Sheet Metal / Modify** ribbon panel. Prompts you: Select point on flange or lofted bend border for smart split or [Propagate] <Propagate>:
4. Select the top flange and the endpoint in the corner. Hit the CTRL key twice to cycle through the options, then press Enter to accept the split.
   (3.322 on the next page)
5. Repeat the previous step on the bottom flange.
6. Click the **Create Bend (6.28.3)** ( ) tool button on the **Sheet Metal / Modify** ribbon panel. Prompts you: Select hard edges or junctions or flanges or 3D solids or [Entire model/selection options (?)] <Entire model>:
7. Select the top and bottom left edges. (3.323 on page 2960)
8. Click the **Create Junction (6.28.21)** ( ) tool button on the **Sheet Metal / Modify** ribbon panel. Prompts you: Select hard edges or bends or flanges or 3D solids [Entire model/selection options (?)] <Entire model>:
9. Select the left vertical face to create the curved junction: (3.324 on page 2960)

Figure 3.321

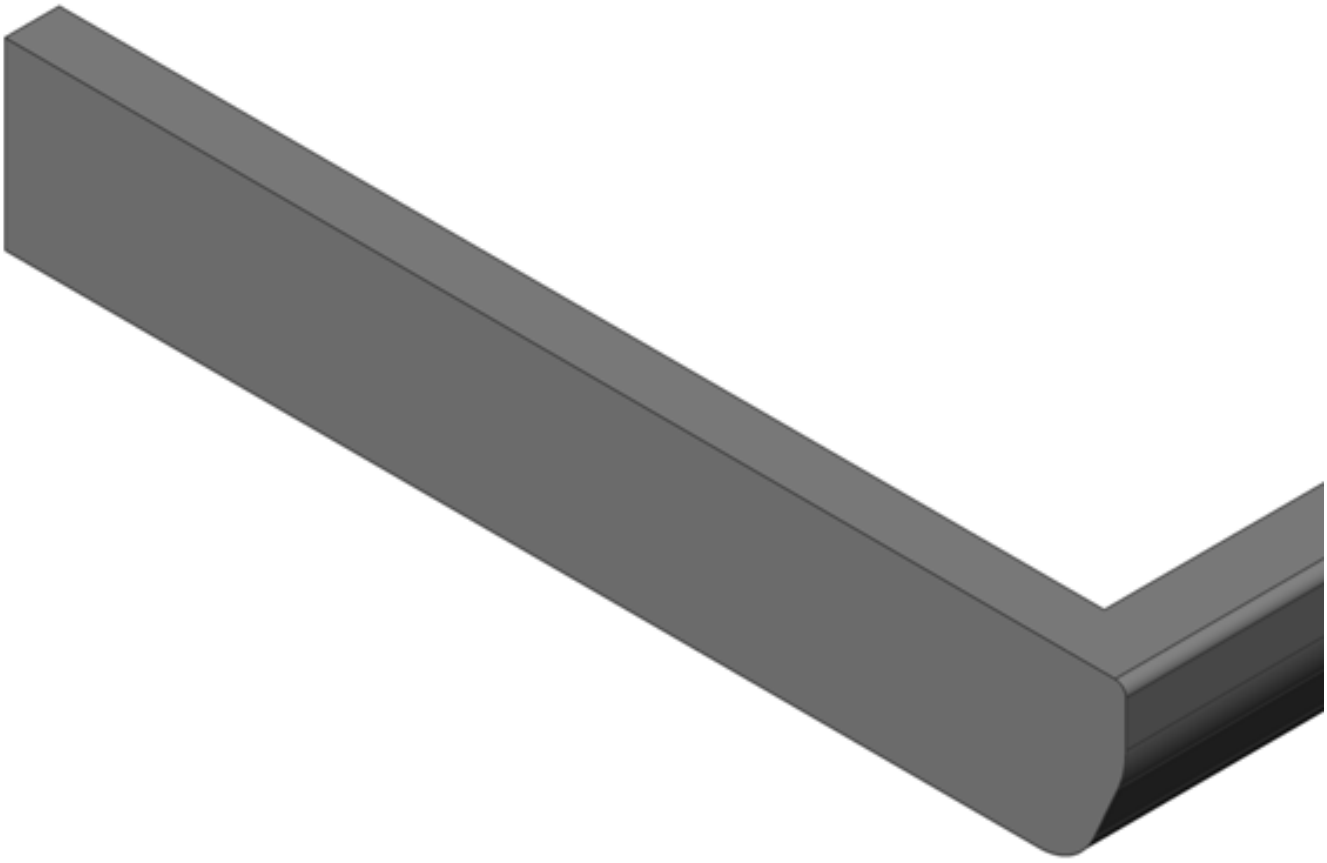


Figure 3.322

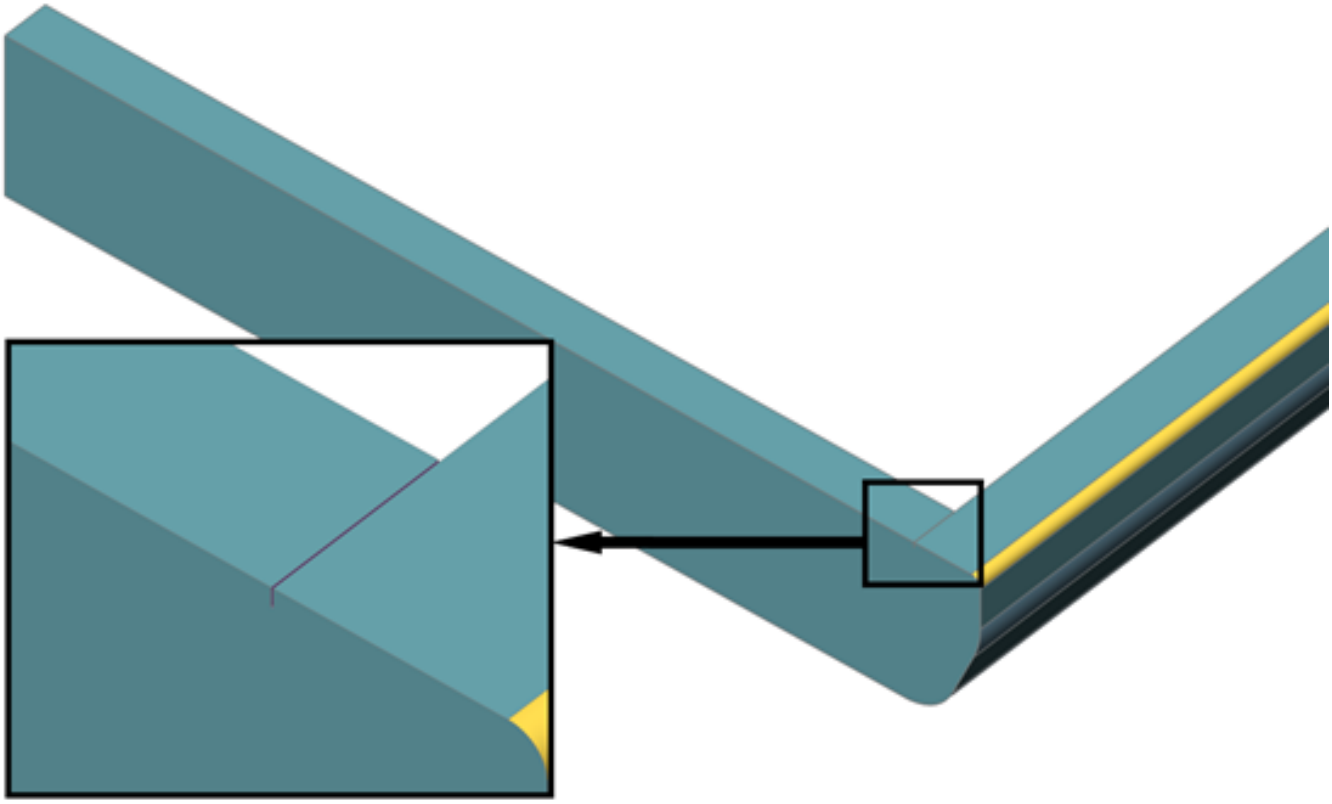

Figure 3.323

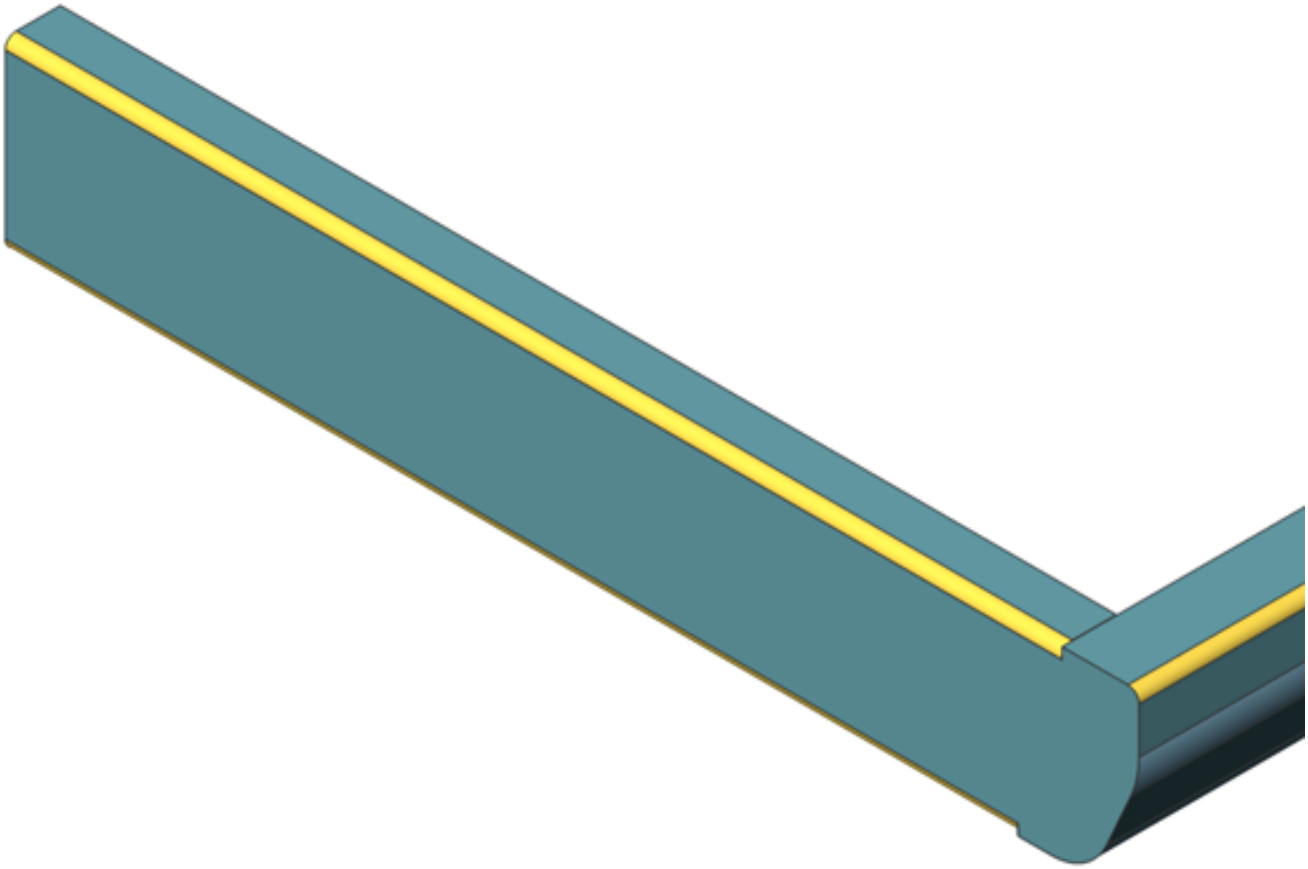

Figure 3.324

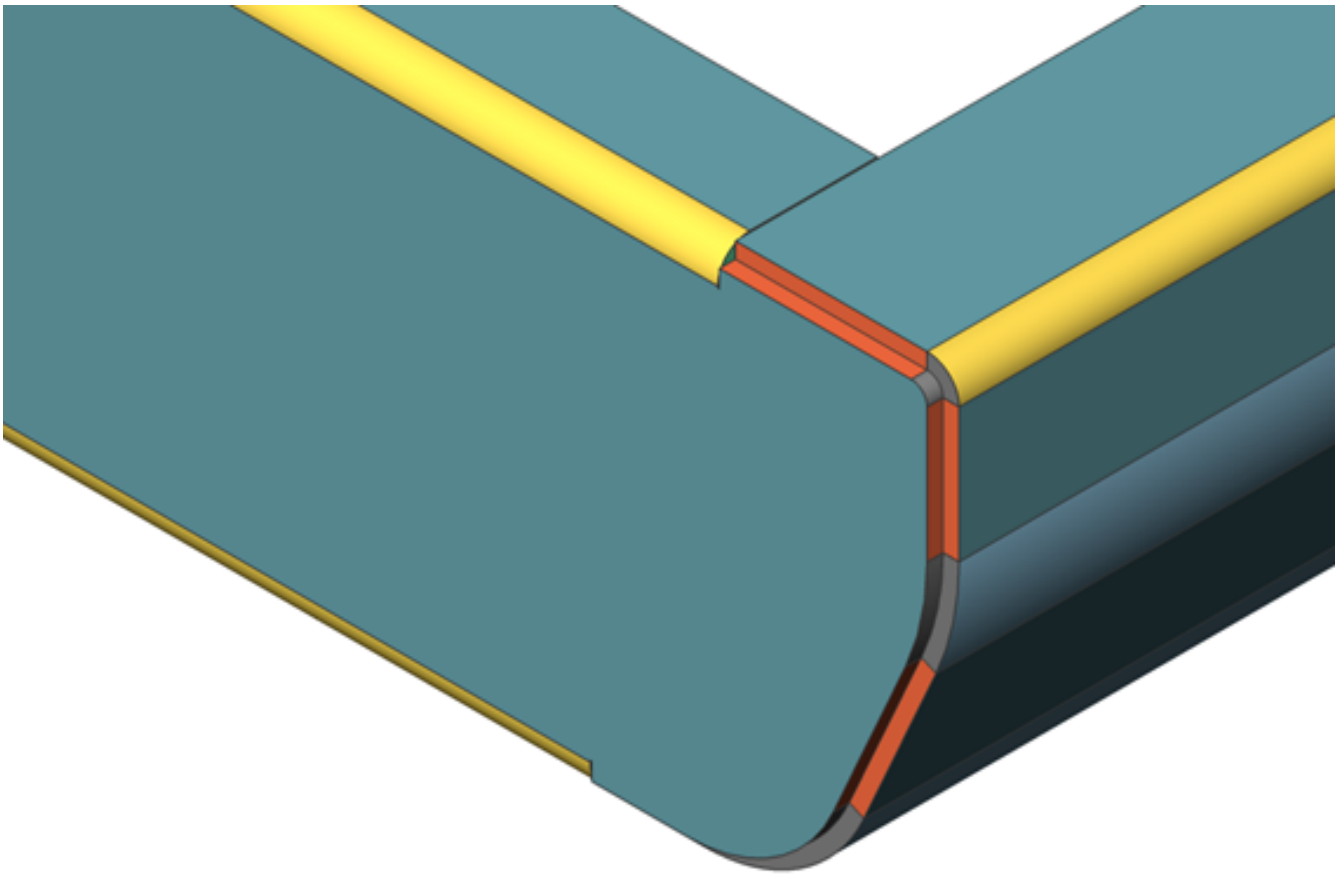

Figure 3.325

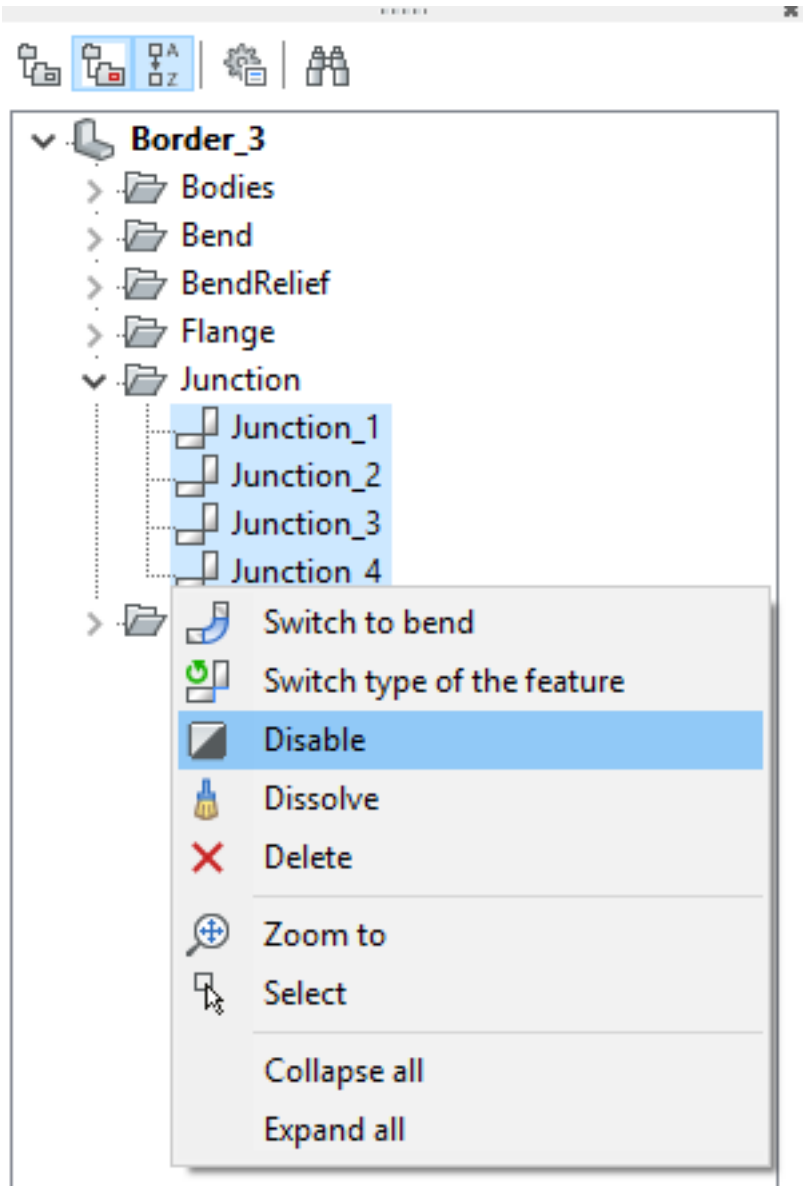

10. In the Mechanical Browser (3.9.6), select the 4 junctions then right click and choose **Disable** ( ) in the context menu. (3.325)
11. Hover over the right vertical junction face, click the **Smooth faces (6.12.28)** ( ) tool button, on the **Select** tab in the Quad (2.3.3). (3.326 on the next page)
12. Hover over the vertical junction face, click the **Push/Pull (6.12.25)** ( ) tool button, on the **Model** tab of the Quad (2.3.3) and move the cursor to the endpoint (5 mm) of the left vertical face.

(3.327 on the following page)

Figure 3.326

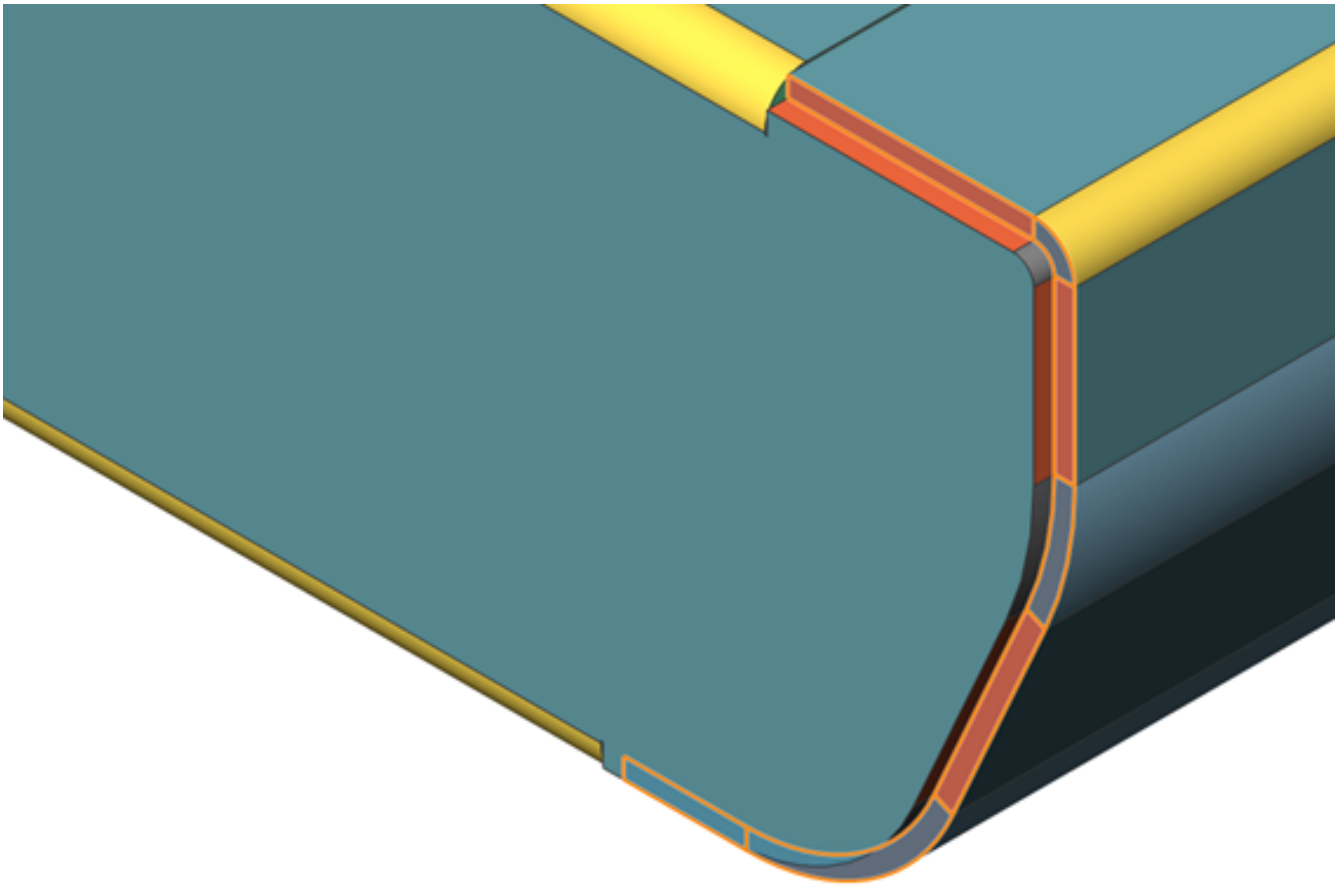

Figure 3.327

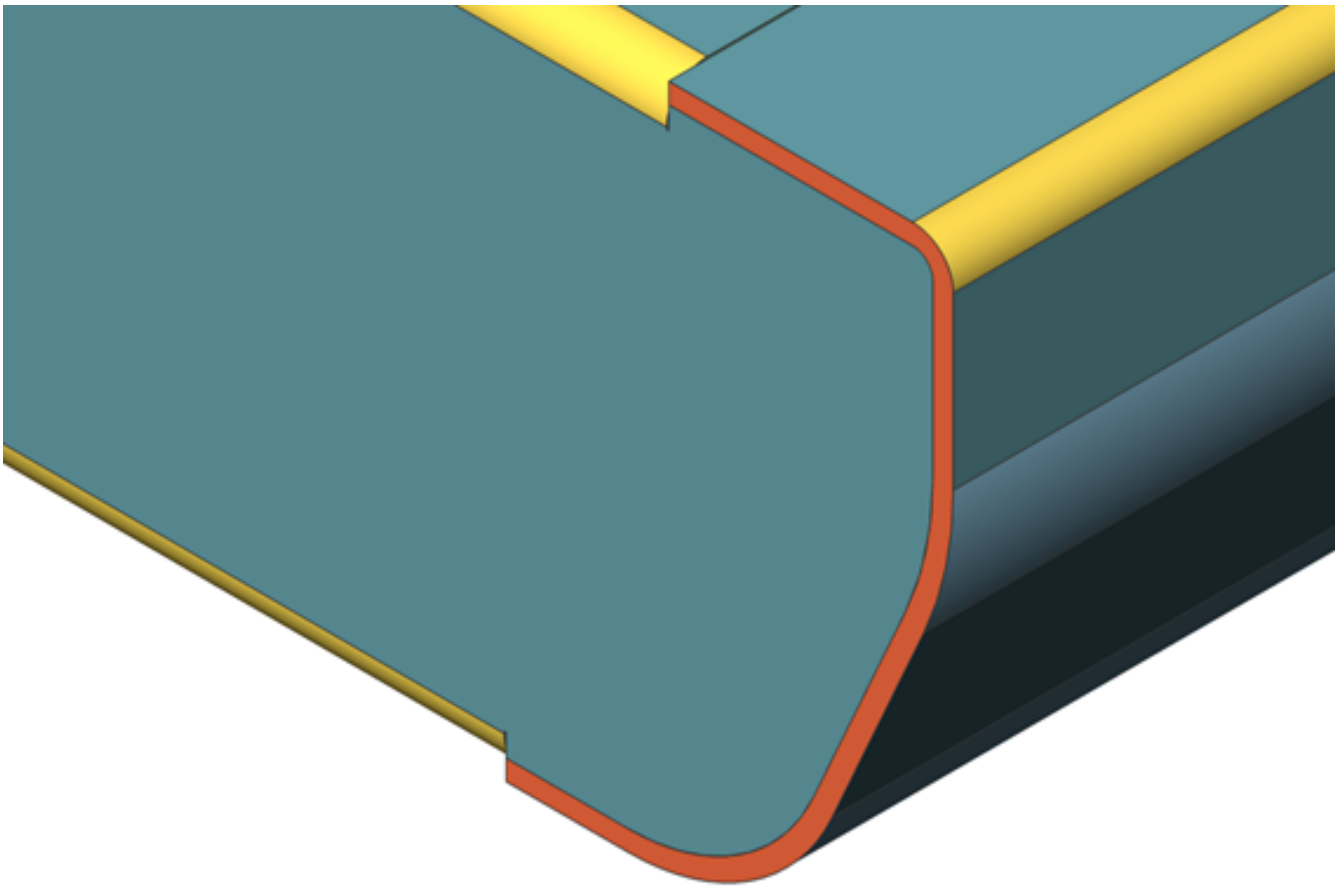
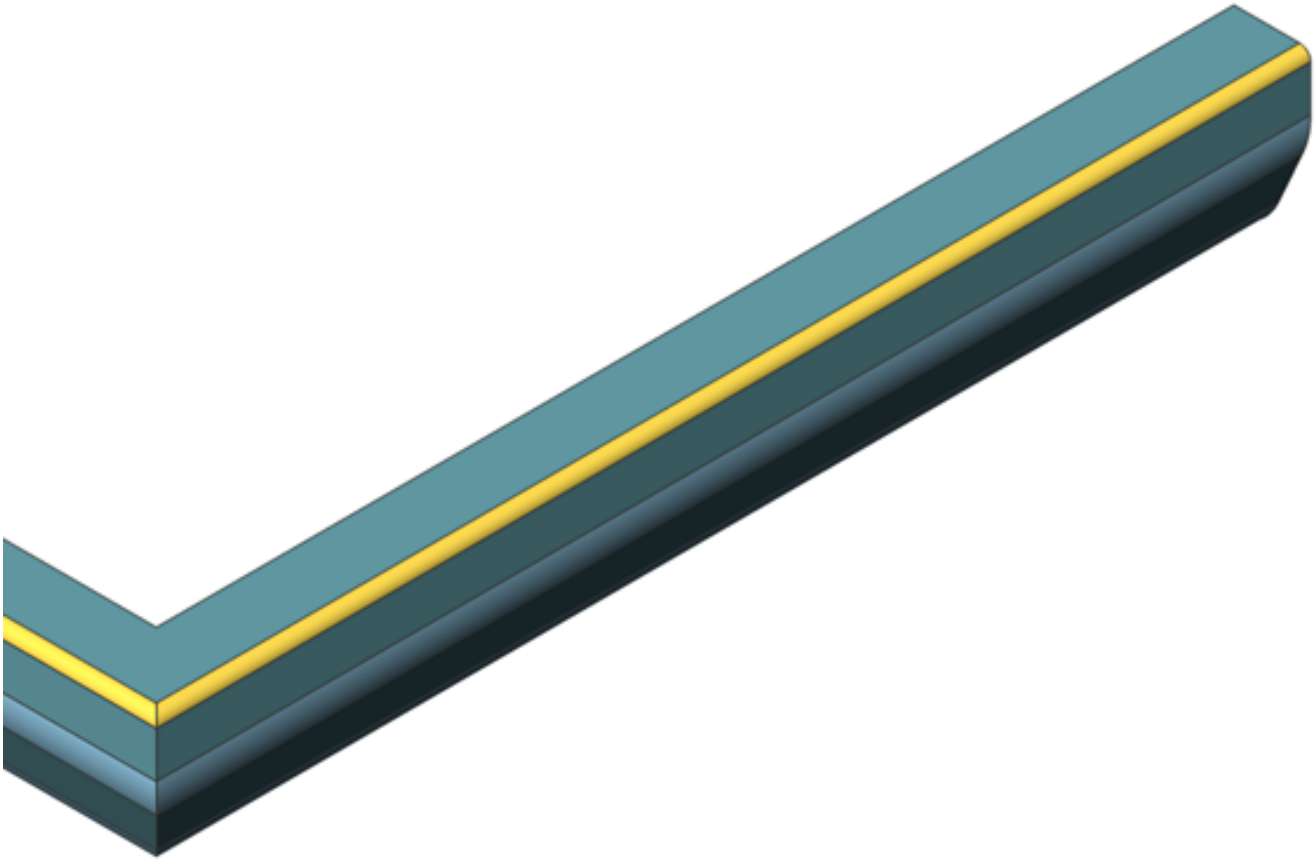


2. Rework the right side of the border

(3.328 on the next page)

1. Click the **Dissolve (6.28.7)** () tool button on the **Sheet Metal / Modify** ribbon panel. Prompts you: Select faces on models or [Entire model/selection options (?)] <Entire model>:
2. Right click or press Enter.
3. Click the **Slice (6.27.40)** () tool button on the **Solid / Edit** ribbon panel. Prompts you: Select entities [selection options (?)]:
4. Select the body, then press Enter. Prompts you: Specify first point on slicing plane or [Object/Surface/Zaxis/View/XY/YZ point/3points/Multislice] <3points>:
5. Right click or press Enter. Prompts you: Specify first point on plane:
6. Click 3 endpoints in the corner to define a slicing plane. Prompts you: Specify a point on desired side of the plane or [Both] <Both>:
7. Right click or press Enter to keep both parts. (3.329 on page 2965)

Figure 3.328



8. Click the **Convert to Sheet Metal (6.28.4)** ( ) tool button on the **Sheet Metal / Create** Ribbon panel. Prompts you: Select 3D solids or seed faces or [Entire model/selection options (?)] <Entire model>:
9. Right click or press Enter
10. Click the **Repair (6.28.29)** ( ) tool button on the **Sheet metal / Heal** Ribbon panel. Prompts you: Select flange face or lofted bend face to repair or [switch on Local repairing/Scan for lost details/selection options (?)]:
11. Select the inner vertical face of the right Sheet metal solid.
12. Repeat steps 8 to 11 on the middle part of the border. (3.330 on page 2966)
13. Save the **Border_3.dwg** file.
14. Switch to the **Upper_Frame_Assembly.dwg** file.
15. Hover over **Border_3**, click the **Update (6.8.29)** ( ) tool button on the **Model** section of the Quad (2.3.3).

(3.331 on page 2967)

Figure 3.329

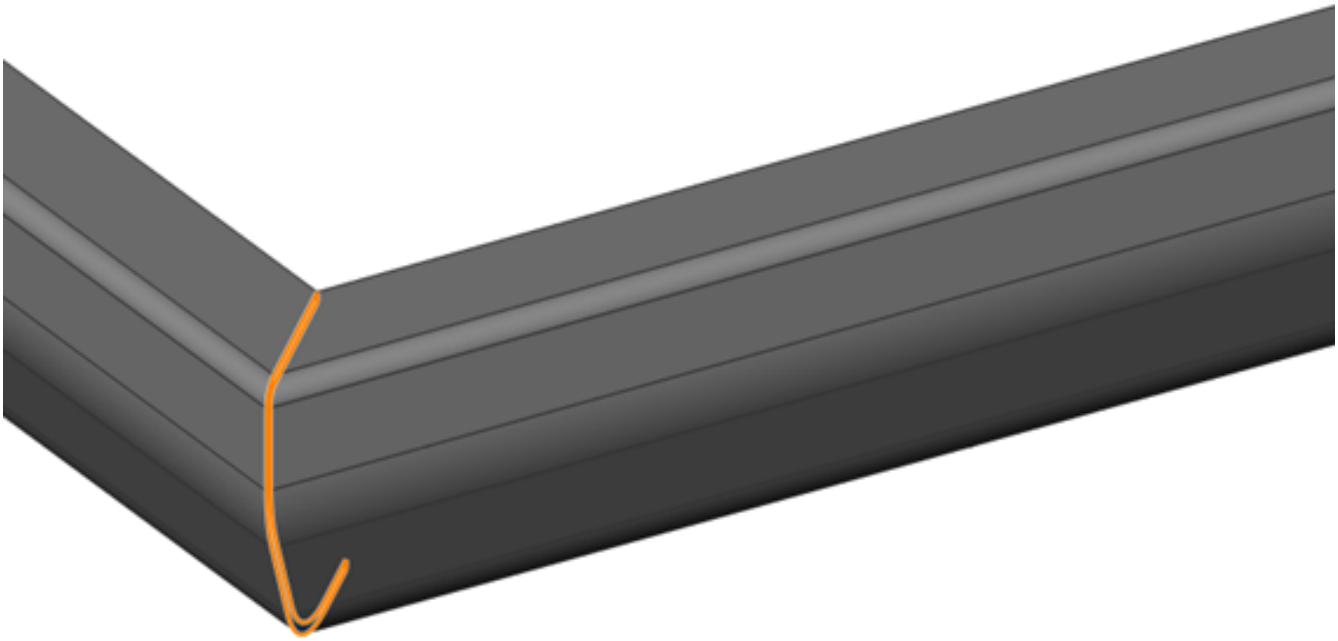


Figure 3.330

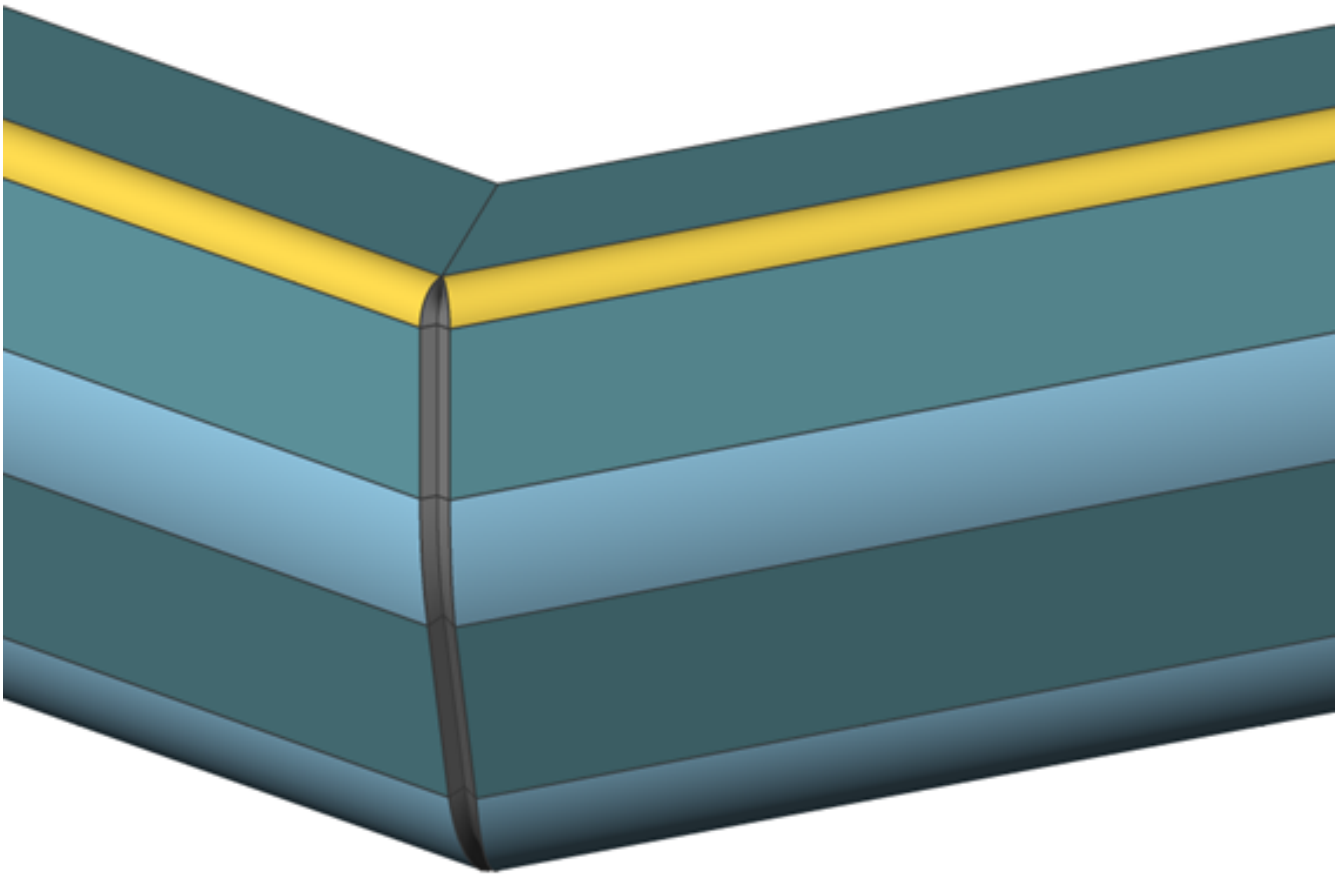

Figure 3.331

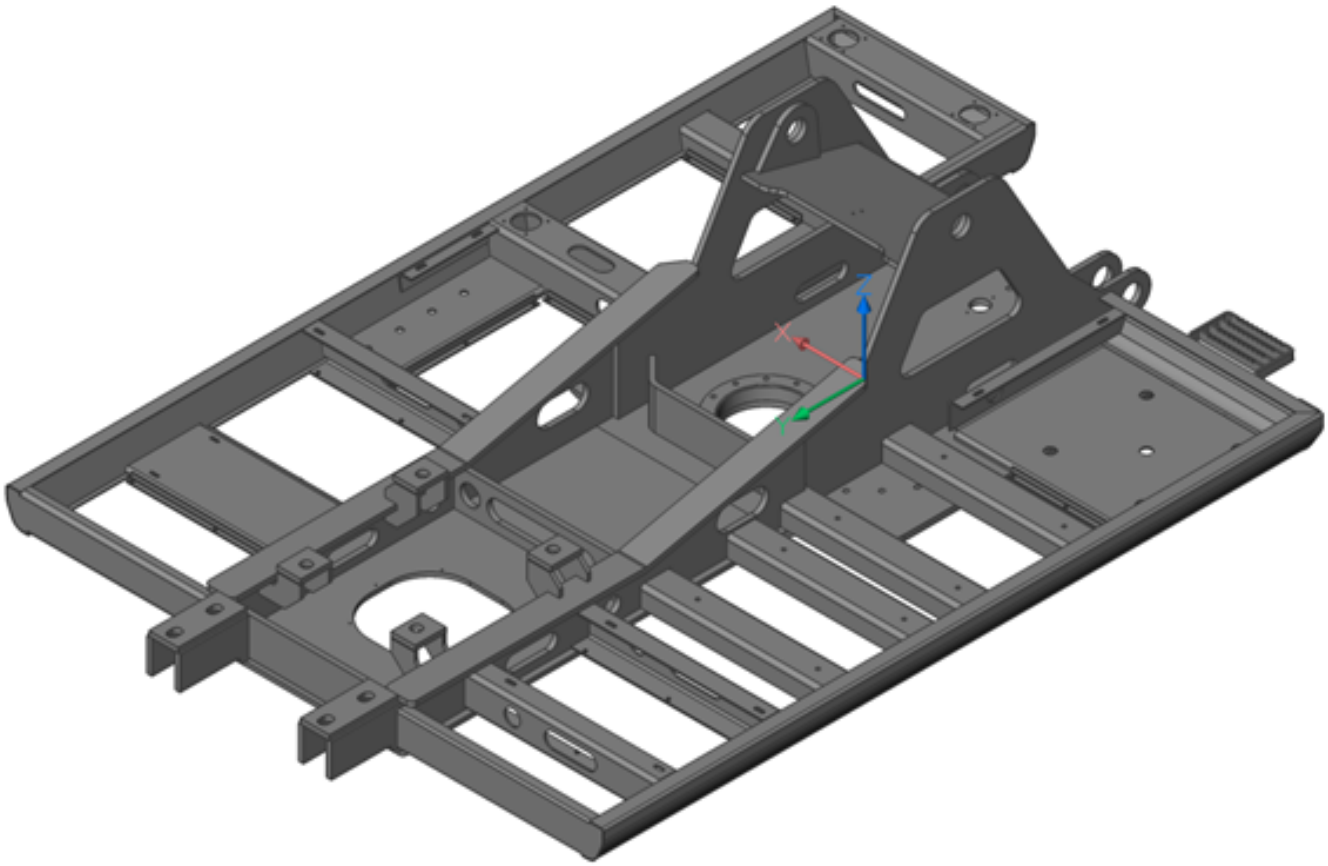

3.8.17 Sheet metal from solid

https://www.youtube-nocookie.com/embed/DpOfOc84lls You need **BricsCAD Platinum** and **Mechanical** licenses for this tutorial.

3.8.18 1. Solid creation

1. Open the **Geared_Traction_Machine_assembly.dwg** file: Sheet_metal_from_solid_files.zip. (3.332 on the next page)
2. Make sure that the **UCS orthographic** option in the Settings (6.27.25) dialog is switched on (the UCSORTHO system variable is 1). (3.333 on the facing page)
3. Switch off **SmSmartFeatures** variable on the Settings (6.27.25) dialog.
4. Switch to **Back** view on the LookFrom (6.20.41) widget.

5. Click the **Polyline (6.24.27)** ( ) tool button on **Solid | Draw** panel of the Ribbon (1.17.6). Draw a polyline that covers everything on the back view. Start from the left bottom Endpoint of the support plate of **Shaft_support** (use snap to Endpoint (6.13.7) ( )). Draw **45** back along the x-axis, **700** on the y-axis, **700** on the x-axis, **450** at an angle of **55** on the x-axis, down to the intersection with the frame (use snap to Perpendicular (6.24.25) ( )), to close the polyline. (3.334 on page 2970)
6. Switch to the **Right** view on the LookFrom (6.20.41) widget.

7. Hover over the new polyline, select **Move (6.12.16)** ( ) from the **Model** section of the Quad (2.3.3). Enter **0,0,0** as the base point, and **1000,0,0** as the second point. (3.335 on page 2971)
8. Click the **Polyline (6.24.27)** ( ) tool button on **Solid | Draw** panel of the Ribbon (1.17.6) to draw a polyline that covers everything on the right view. Start from the left bottom Endpoint of the frame (use snap to Endpoint (6.13.7) ( )). Draw **250** on the y-axis, **450** at an angle of **55** on the x-axis, **1000** at an angle of **10** on the x-axis, **700** at an angle of **80** on the x-axis, down to the intersection with the frame (use snap to Perpendicular (6.24.25) ( )), to close the polyline. (3.336 on page 2972)
9. Switch to the **Top** view on the LookFrom (6.20.41) widget to activate **World UCS**.

10. Select both polylines. Select **Extrude (2.5.10)** ( ) from the **Model** section of the Quad (2.3.3). Create two intersecting solids from the two profiles with the **Create** option. (3.337 on page 2973)
11. Select both intersecting solids. Click the **Intersect (6.17.20)** ( ) tool button on **Solid | Edit** panel of the Ribbon (1.17.6). **(3.338 on page 2974)**
12. Hover over the new solid. Select **Isolate (6.17.22)** ( ) from the **Select** section of the Quad (2.3.3).

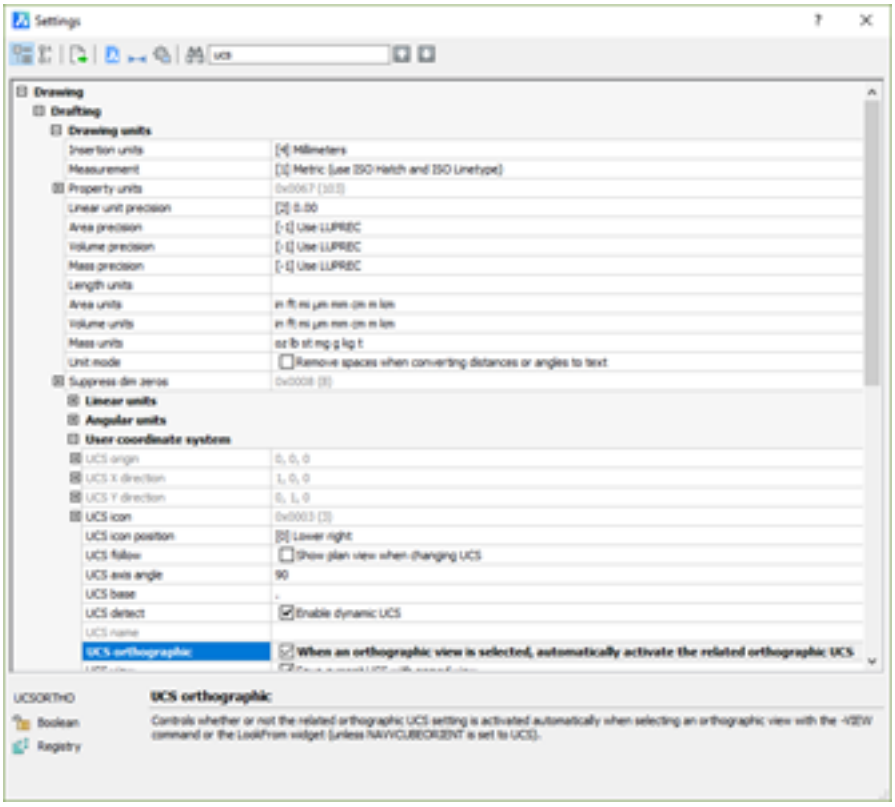

Figure 3.334

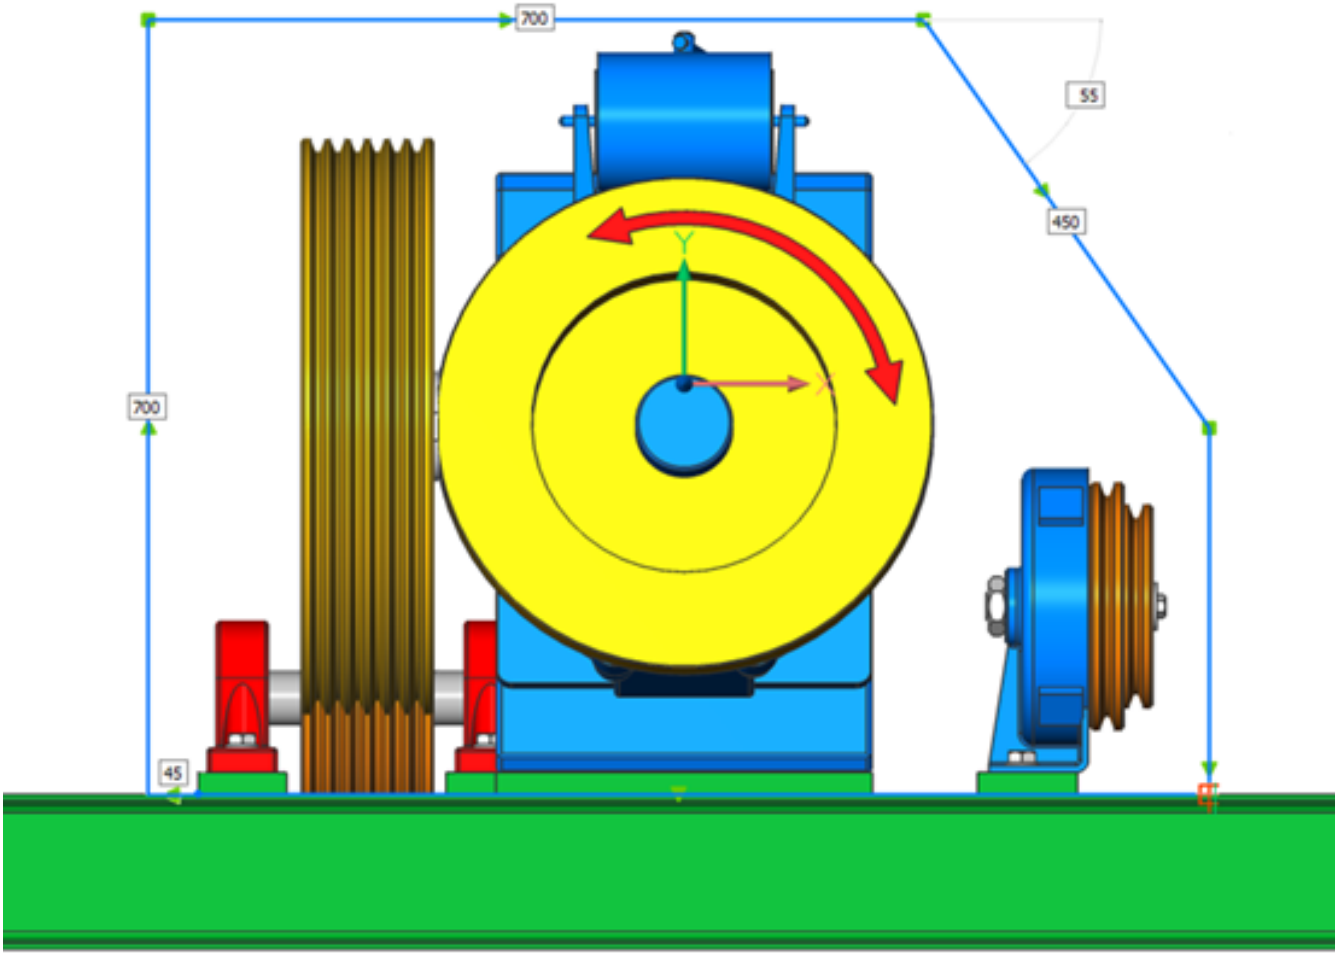

Figure 3.335

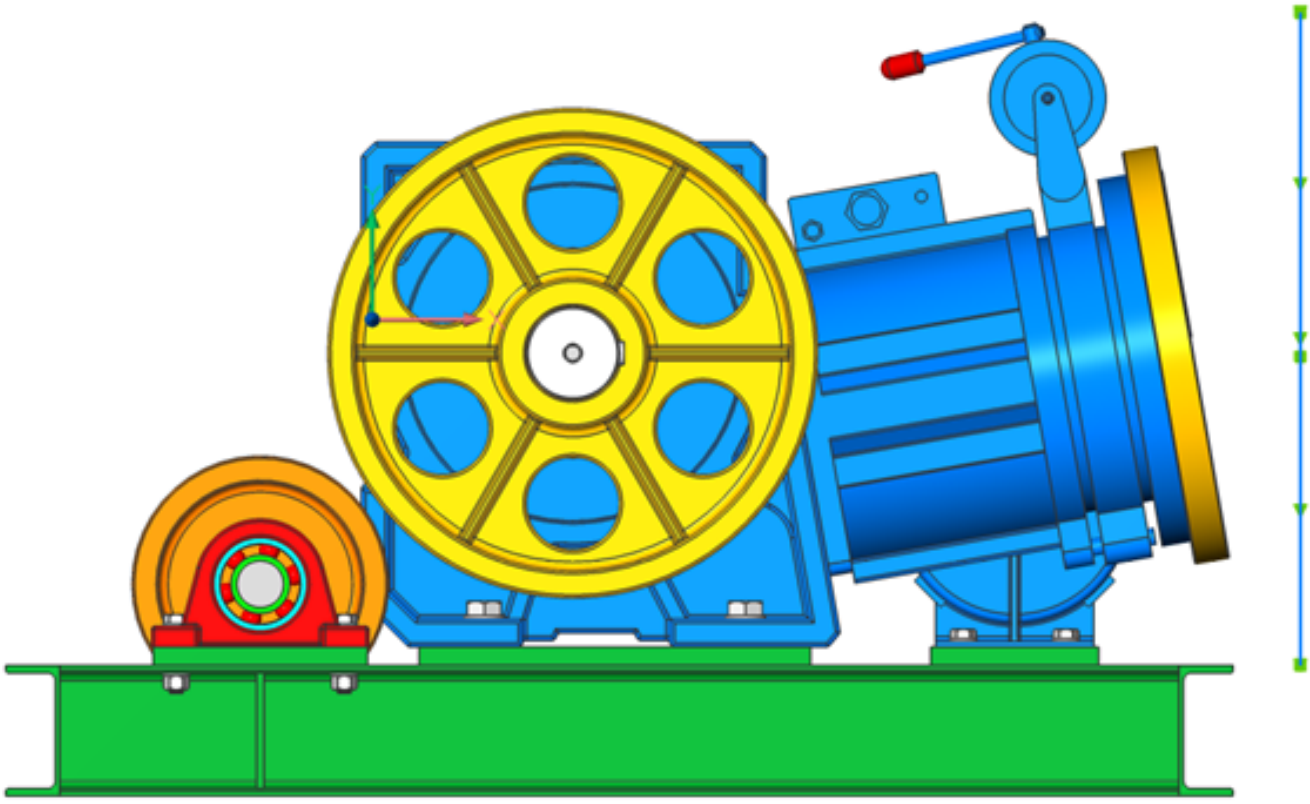

Figure 3.336

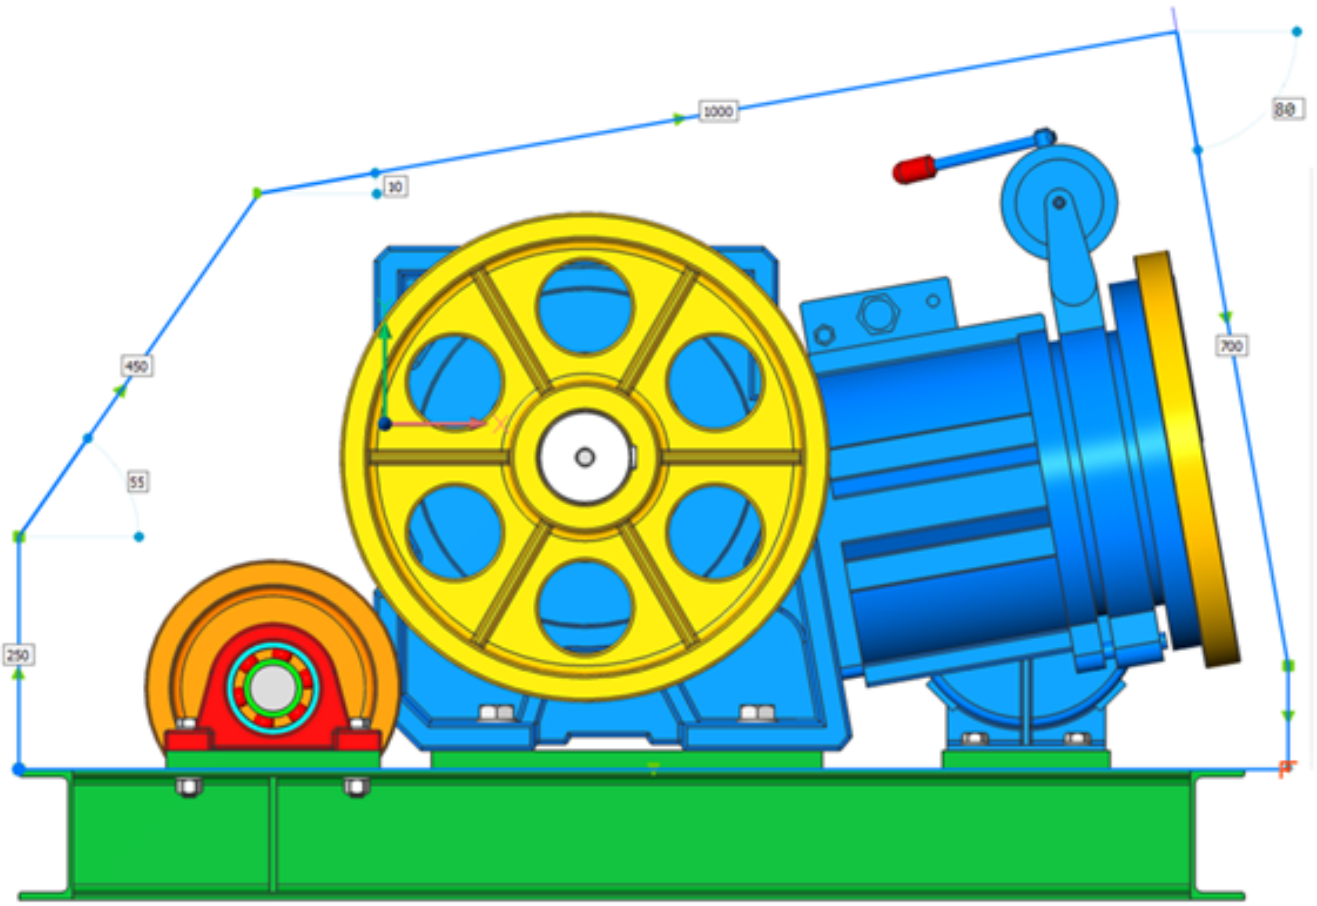

Figure 3.337

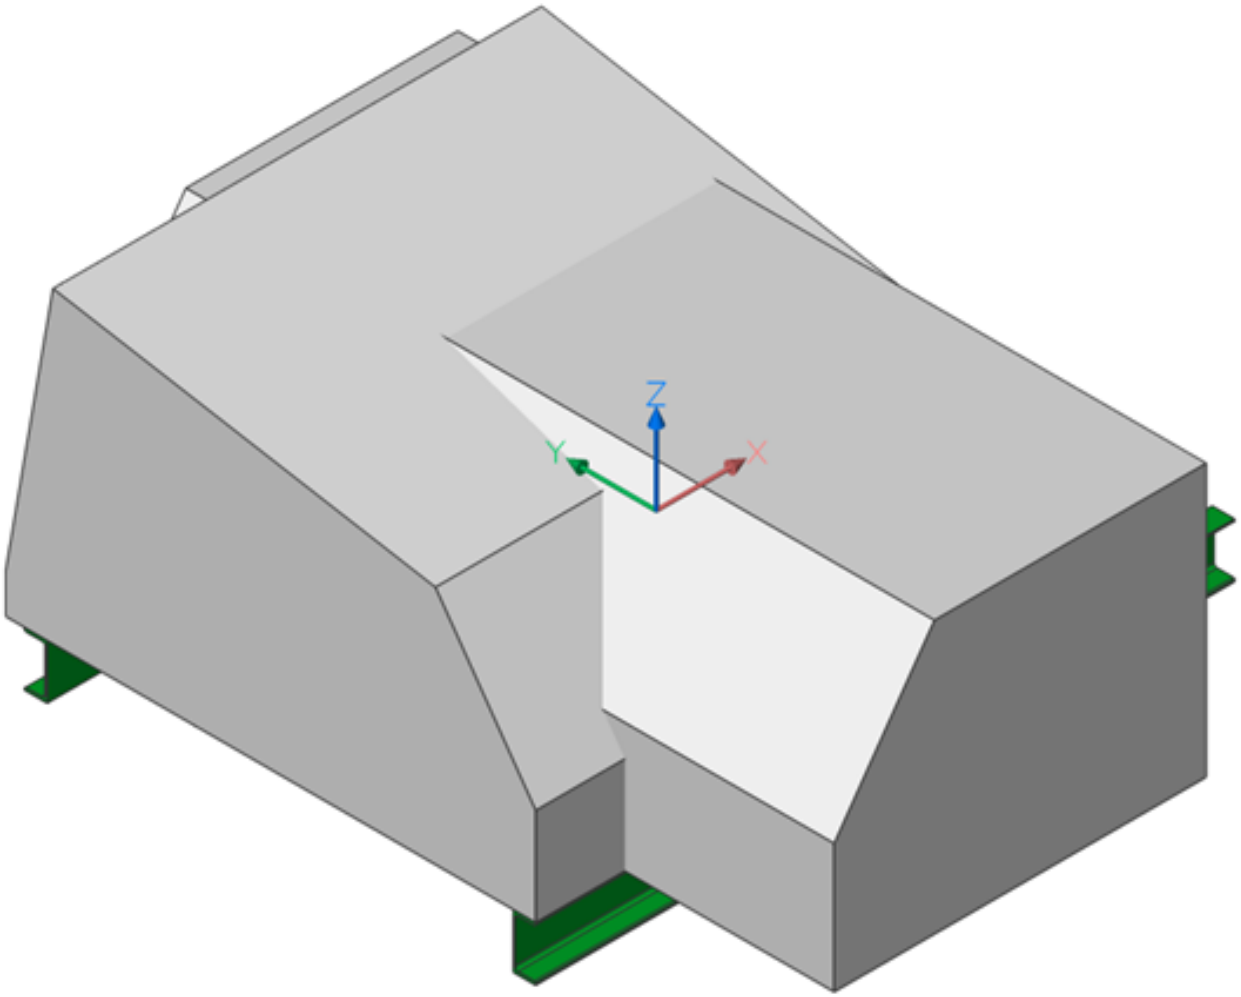

Figure 3.338

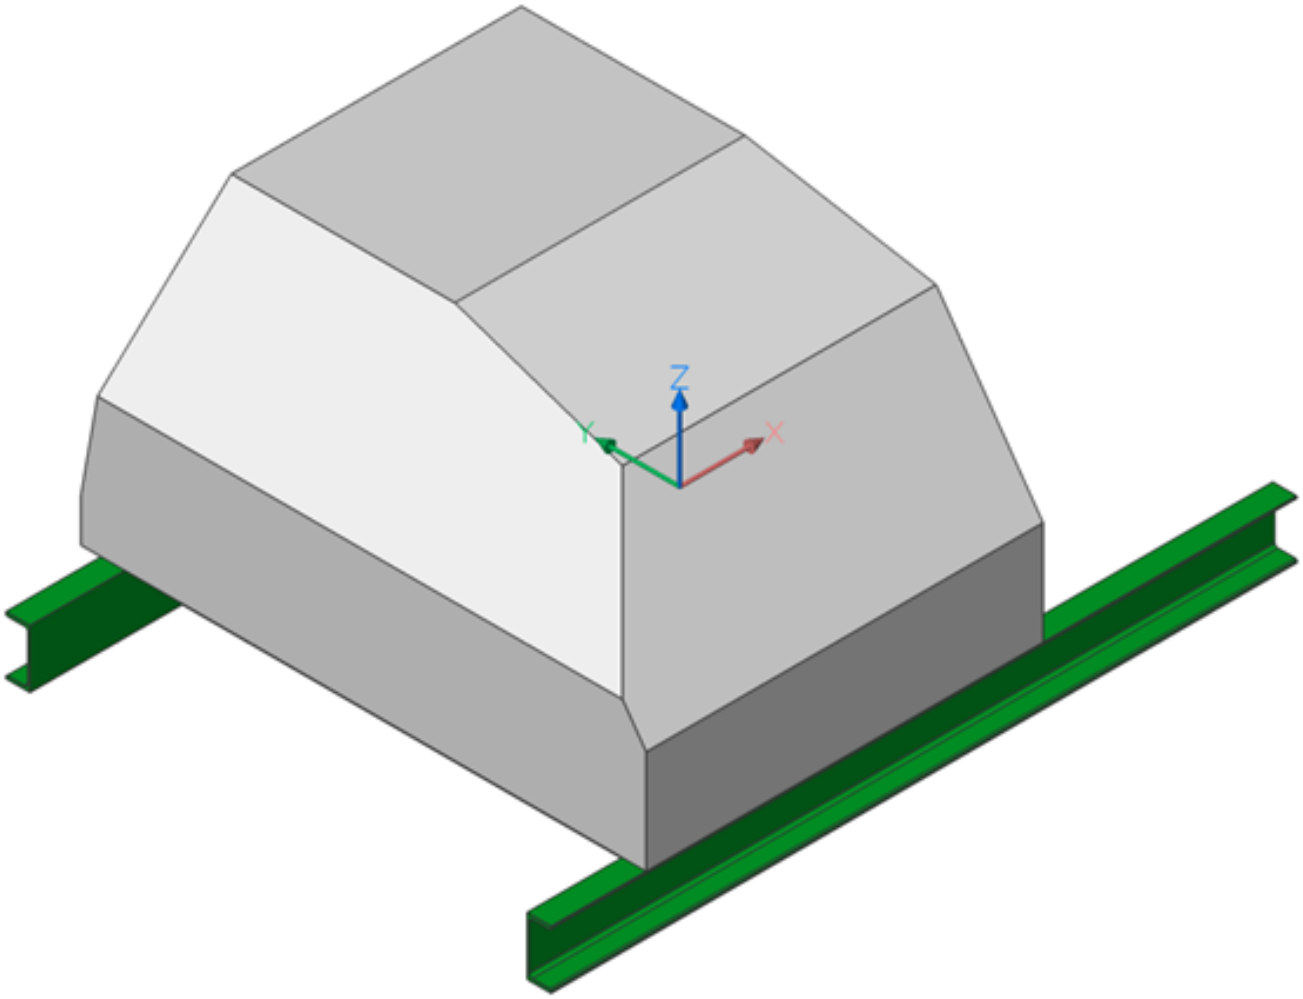

3.8.19 2. Solid to Sheet Metal conversion

1. Click the **Shell (6.27.42)** ( ) tool button on **Solid | Edit** panel of the Ribbon (1.17.6). Select the solid. Select the bottom face (to remove). Enter a shell offset distance of **2**. **Enter**. **Enter**. (3.339 on the following page)
2. Hover over the right vertical face and select **Offset (2.5.15)** ( ) from the **Draw** section of the Quad (2.3.3). Enter a distance of **100**. (3.340 on page 2977)
3. Hover over the polyline. Select **Extrude (2.5.10)** ( ) from the **Model** section of the Quad (2.3.3). Use the **Subtract** option to create an opening.
4. Select the horizontal face of the bottom opening (3.341 on page 2979)

Figure 3.339

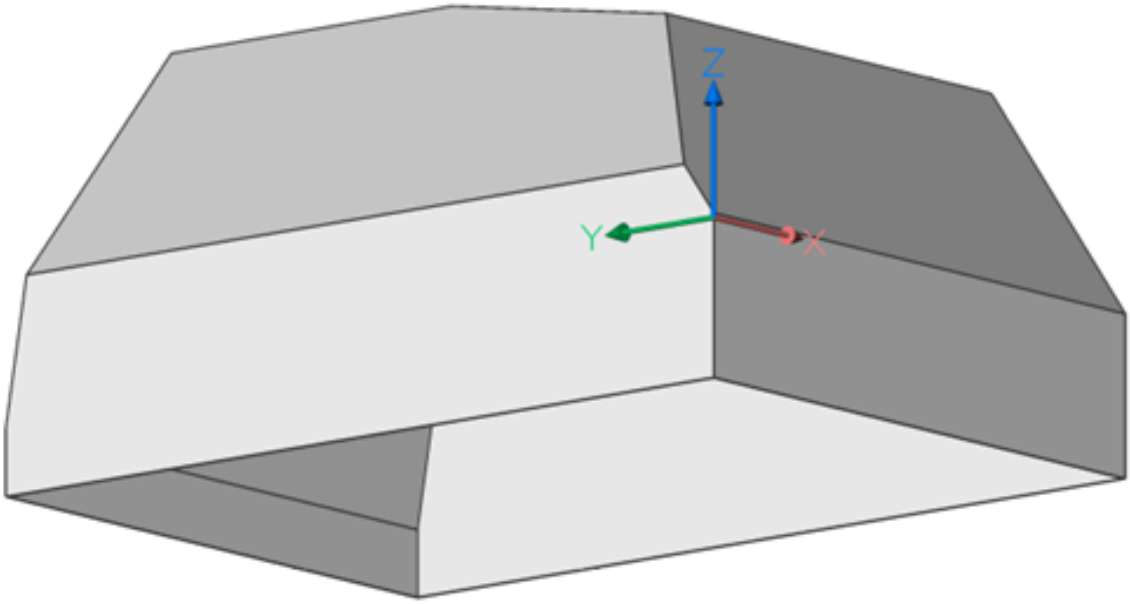

Figure 3.340

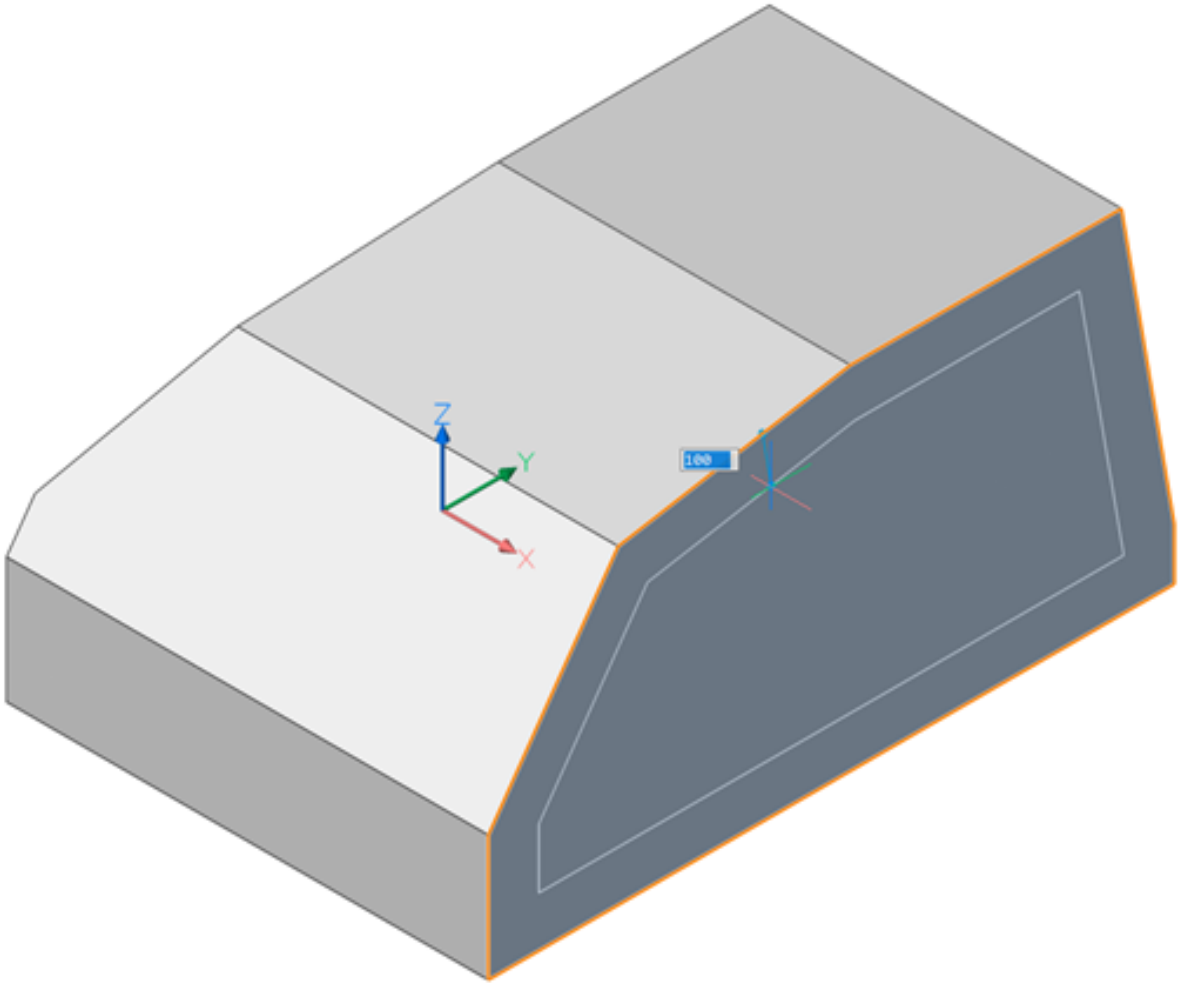

5. Select **Extrude (2.5.10)** ( ) from the **Model** section of the Quad (2.3.3). Use the **Subtract** option. Move the cursor down to increase the size of the opening. (3.342 on page 2980)
6. Click the **Convert to Sheet Metal (6.28.4)** ( ) tool button on the **Sheet Metal | Create** panel of the Ribbon (1.17.6). Hit **Enter**.
7. Click the **Create Relief (6.28.22)** ( ) tool button on the **Sheet Metal | Modify** panel of the Ribbon (1.17.6). Hit **Enter**.
8. Select edges as shown below. (3.343 on page 2981)
9. Click the **Create Junction (6.28.21)** ( ) tool button on the **Sheet Metal | Modify** panel of the Ribbon (1.17.6).
10. Click the **Create (6.28.3) Bend (6.28.3)** ( ) tool button on the **Sheet Metal | Modify** panel of the Ribbon (1.17.6). Hit **Enter**.
11. Switch to the **Right** view on the LookFrom (6.20.41) widget.
12. Use the **Smart Split (6.28.30)** ( ) tool from the **Sheet Metal | Modify** panel of the Ribbon (1.17.6) to create miters on all the corners of the opening: (3.344 on page 2982)

Figure 3.341

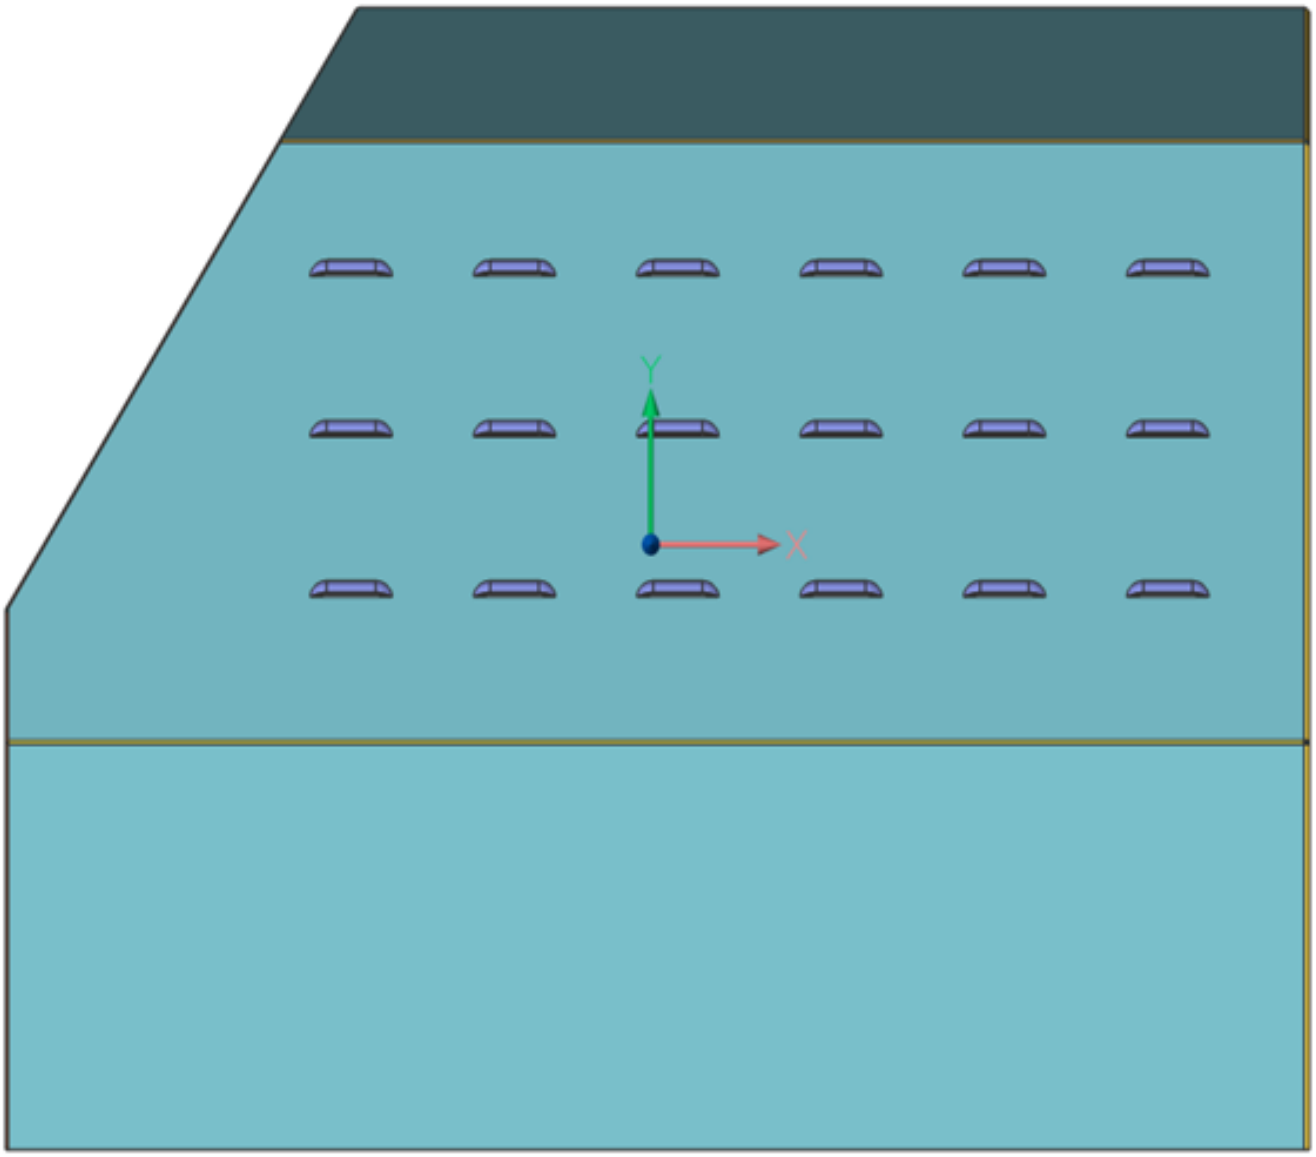
3.8.20 3. Insert an array of Form Features

1. Switch to **Front** view on the LookFrom (6.20.41) widget.
2. On the Components panel (6.9.26) select **Louver** from **Sheet Metal | Form Features** folder.
3. On **BmInsert** Prompt menu choose the **Multiple | Array** option.
4. Enter **100,100** from the top right corner as a Basepoint, **120** as the distance between columns; **120** as the distance between rows; placement **18.** Hit **Enter** to complete the command. (3.345 on the following page)

Figure 3.345



3.8.21 3. Creating flanges

1. Switch to the **Top** view on the LookFrom (6.20.41) widget to activate **World UCS**.
2. Hover over the bottom inner edge along the x-axis.
3. Select **Create Flange Edge (6.28.14)** () from the **Sheet Metal** section of the Quad (2.3.3).
4. Enter **90** as the bend angle and **100** as the length of the flange. Hit **Enter** to complete the command. (3.346 on the next page)
5. Repeat steps 3.1-3.4 to create a symmetrical bottom flange: (3.347 on page 2987)

Figure 3.346

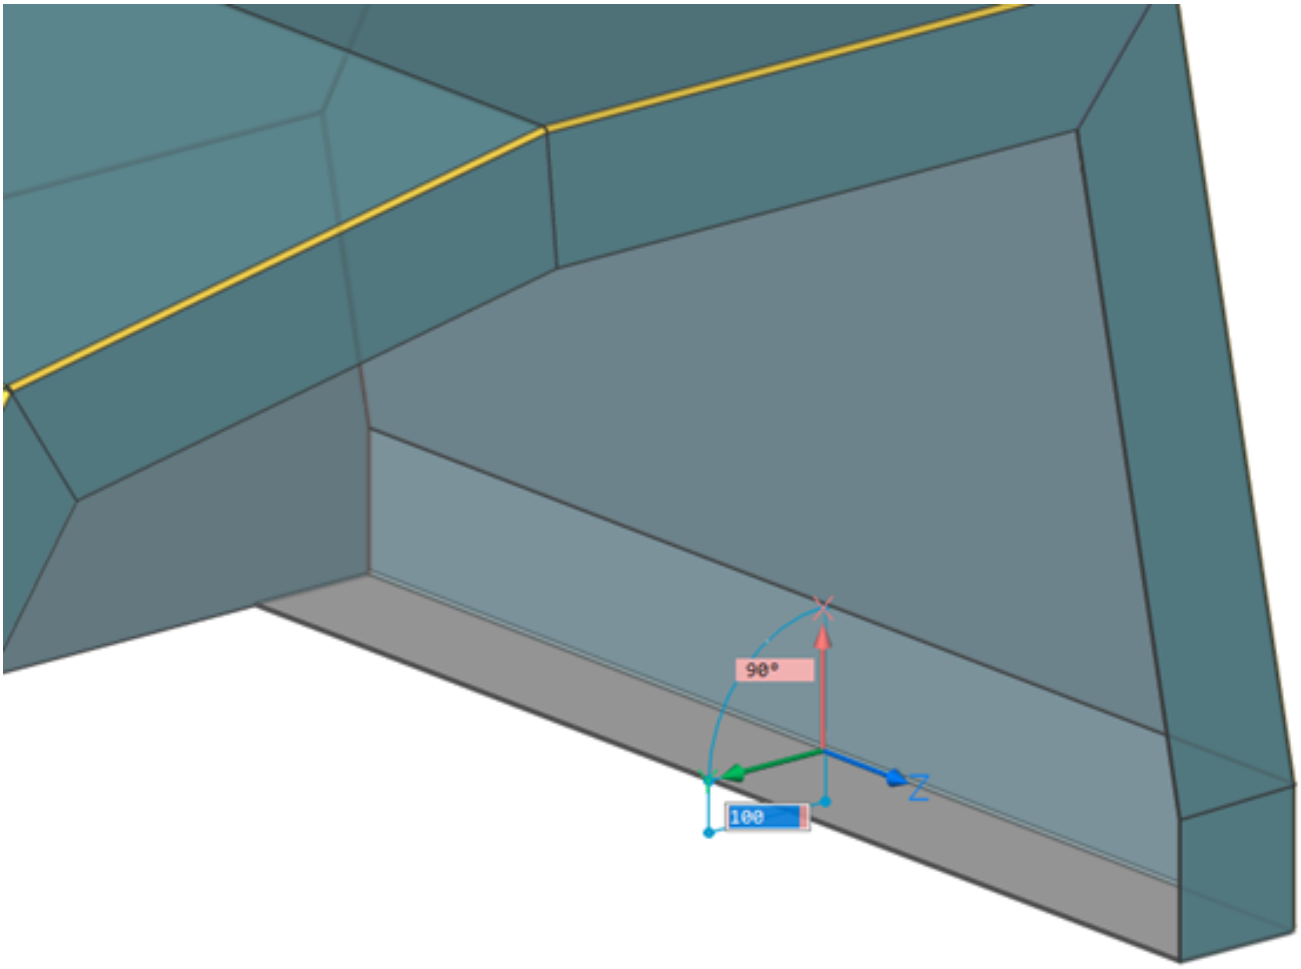


Figure 3.347

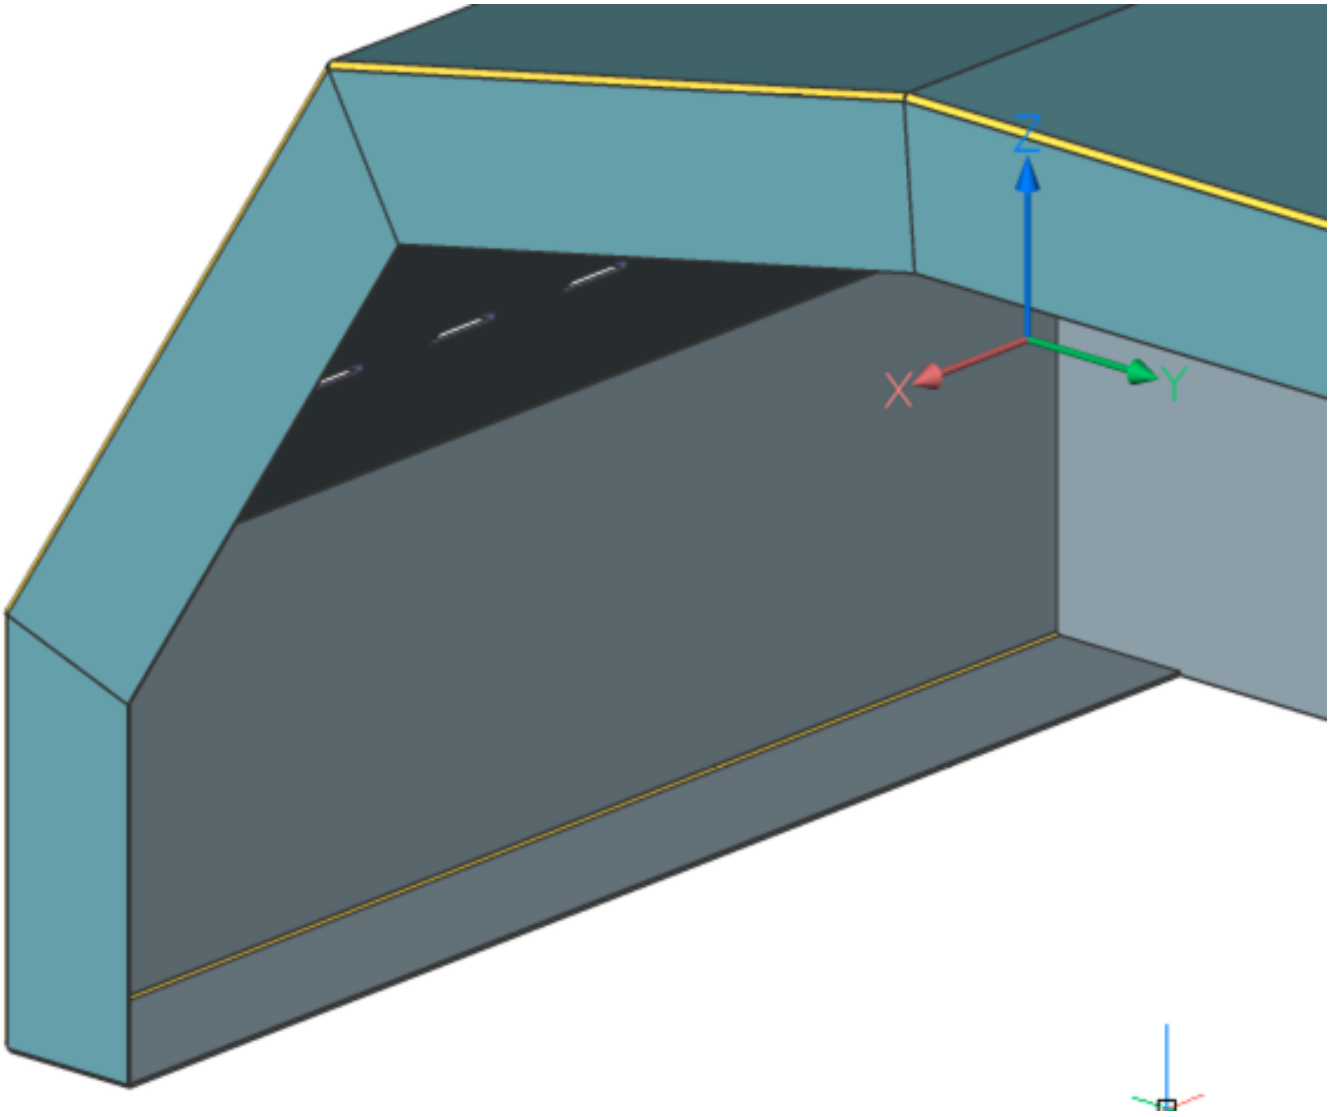

3.8.22 4. Finished sheet metal model

1. With nothing selected, right-click to call the Quad (2.3.3). Select **Show Entities (6.30.7)** () from the **General** section of the Quad (2.3.3).
2. Select the Sheet metal entity.
3. In the Properties Panel (1.15.4) click the **Transparency** field. Change the value to **90.** **(3.348 on the next page)**
4. Hover over the top flange face. Select **Unfold body (6.28.31)** () from the **Sheet Metal** section of the Quad (2.3.3).
5. Choose the position for the unfolded body. Hit **Enter** to complete the command. (3.349 on the facing page)

3.9 Sheet Metal

3.9.1 Sheet Metal Design Methods

Sheet metal design allows you to model sheet metal parts and generate their unfolded representations with manufacturing information. You can create complex sheet metal parts with BricsCAD easily and rapidly because the design process is different from a manufacturing process. Do not think in terms of a planar sheet that should be cut and bent, but model your part directly as you create solid bodies with Direct Modeling tools.

Tutorial: Introducing BricsCAD Sheet Metal Click here (**??**) to watch

Tutorial: Designing from scratch in BricsCAD Sheet Metal Click here (3.8.15) to watch You can create sheet metal parts in BricsCAD in four different ways (or in any combination of them):

1. Create a base flange from a closed planar profile, then add flanges:
   - Pull its edges to create additional edge flanges with bends.
   - Create partial flanges with automatic creation of the corresponding bend reliefs.
   - Pull several adjacent edges to create several flanges at once with automatic creation of corner reliefs and junctions between them.
   - Bend a flange to create a new flange with a bend from its portion.
2. Create a combination of flanges and lofted bends connecting two 3D profiles Using Sheet Metal Loft (6.28.20) tool.
3. Create a combination of flanges and bends from a planar profile Using Sheet Metal Extrude (6.28.9) tool.
4. Create a shelled body from a 3D solid Using **Shell**option of the SolidEdit (6.27.42) command with the desired thickness, then convert it to a sheet metal part with SmConvert (6.28.4) command, and create bends and junctions from its hard edges.
   - Make holes by drawing closed profiles on faces of the flanges and pushing them through the flanges.
   - Adjust material thickness and bend radius using pre-defined parameters.
   - Apply Direct Modeling operations and 3D constraints (1.27.3) to further adjust your design while always maintaining the design intent in terms of sheet metal features.
   - Automatically generate unfolded representation of your part and send it to a CAM system by exporting the corresponding 2D drawing with bend annotations in a .dwg or .dxf file.

You can further detail your sheet metal part using the following operations:

- Make holes by drawing closed profiles on faces of the flanges and pushing them through the flanges.
- Insert Form Features (3.9.25) from a library. A library of parametric form features is installed with BricsCAD Sheet Metal and you can create your own form features.
- Create rib form features from a 2D curve lying on the flange by the SmRibCreate (6.28.27) command.
- Adjust material thickness and bend radius using pre-defined parameters.
- Apply Direct Modeling operations and 3D constraints (1.27.3) to further adjust your design while always maintaining the design intent in terms of sheet metal features.

When your sheet metal part is ready, you can automatically unfold it and send the result to a manufacturing engineer by exporting the corresponding 2D drawing. (3.350 on the next page) (3.351 on the facing page)

Figure 3.350

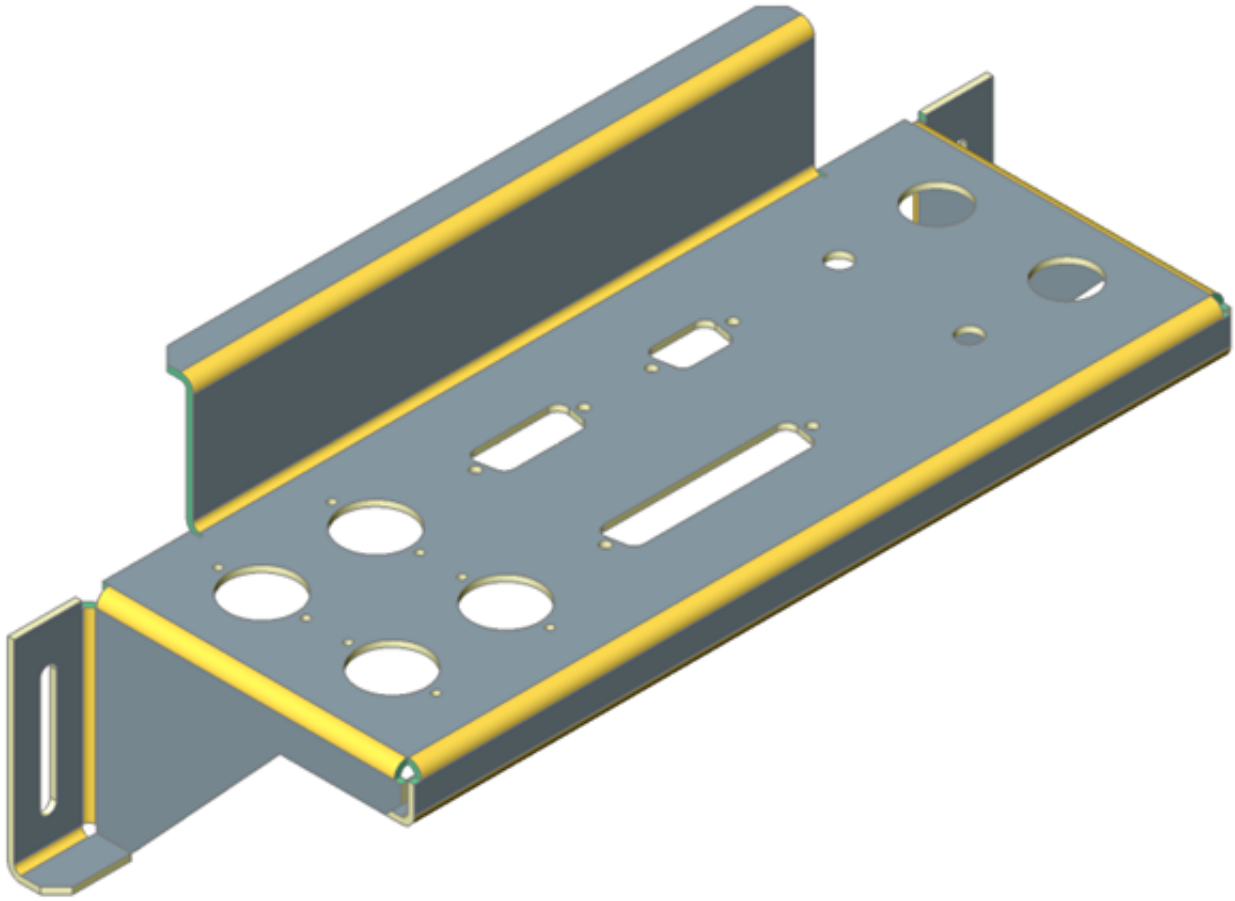

Figure 3.351

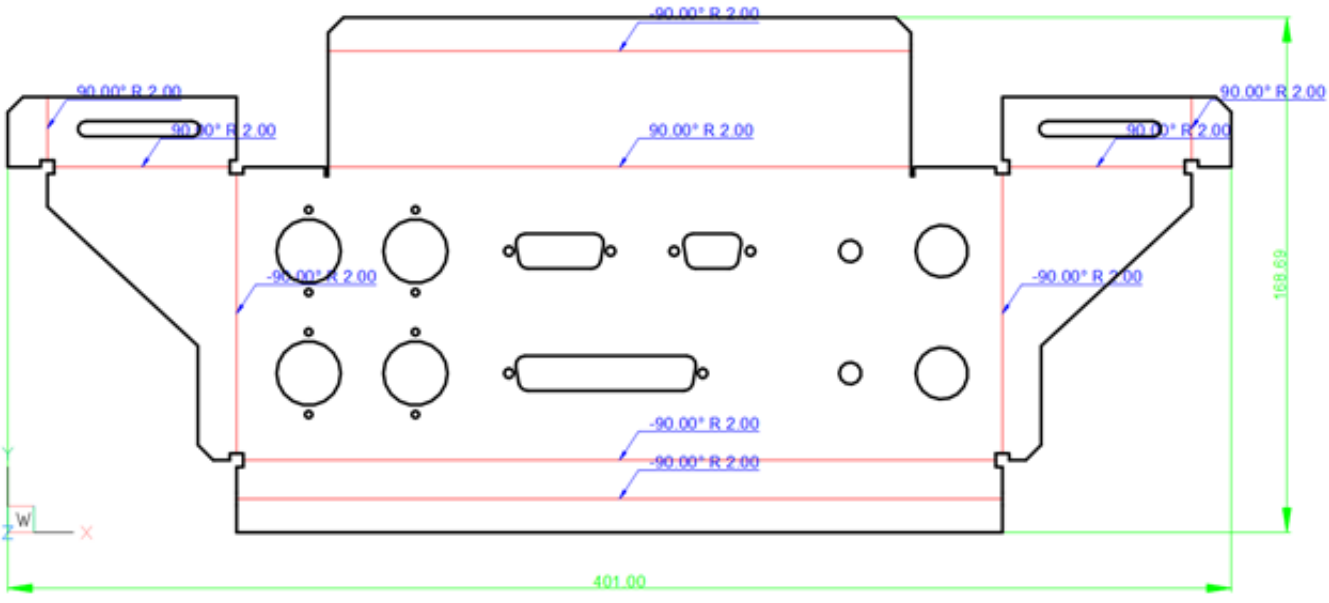

3.9.2 Sheet Metal Commands and Toolbars

Sheet Metal Toolbar Icon	Flyout Toolbar Icon	Command	Description
		SmFlangeBase (6.28.10)	Creates a base (initial) flange of a sheet metal part from a closed planar profile.
		SmExtrude (6.28.9)	Creates a sheet metal part by extruding a polyline in the direction of the normal of the curve plane. Thickness is assigned with respect to the external dimensions of the polyline.
		SmLoft (6.28.20)	Creates sheet metal part with lofted bends and flanges from two non-coplanar curves.
		SmConvert (6.28.4)	Automatically recognizes flanges, bends and lofted bends in a 3D solid.
		SmFlangeEdge (6.28.14)	Creates one or more flanges on a sheet metal part by pulling one or more edges of an existing flange.
		SmFlangeContour (6.28.13)	Creates a new flange from a closed contour and attaches it to an existing sheet metal part.
		SmFlip (6.28.25)	Changes the reference side for selected flanges with an optional shift of the flange geometry by thickness.
		SmFlangeRotate (6.28.15)	Rotates a flange.
		SmHemCreate (6.28.16)	Creates one or more closed hem features on a sheet metal part by pulling one or more edges of an existing flange.
		SmHemCreate (6.28.16)	Creates one or more open hem features on a sheet metal part by pulling one or more edges of an existing flange.
		SmHemCreate (6.28.16)	Creates one or more Teardrop hem features on a sheet metal part by pulling one or more edges of an existing flange.

		SmHemCreate (6.28.16)	Creates one or more Round hem features on a sheet metal part by pulling one or more edges of an existing flange.
		BmInsert (6.8.16)	Inserts form features.
		SmForm (6.28.17)	Creates form feature from given set of faces.
		SmForm (6.28.17)	Explodes form feature in flanges and bends if possible.
		SmRibCreate (6.28.27)	Creates an associative rib form feature on a flange face from a planar 2D curve.
		SmReplace (6.28.26)	Replaces form features (including recognized ones) in sheet metal parts with form features from a built-in or user library.
		SmBendCreate (6.28.3)	Converts hard edges (sharp edges between flange faces) and junctions into bends.
		SmBendSwitch (6.28.2)	Converts bends to lofted bends
		SmFlangeBend (6.28.11)	Bends an existing flange along a line, obeying k-factor for given bend radius.
		SmJunctionCreate (6.28.21)	Converts hard edges into junctions.
		SmJunctionSwitch (6.28.19)	Changes a symmetrical junction feature to one with overlapping faces.
		SmFlangeConnect (6.28.12)	Closes gaps between two arbitrarily oriented flanges.
		SmTabCreate (6.28.28)	Creates single tab feature to a sheet metal part by switching existing junction into the tab.
		SmTabCreate (6.28.28)	Creates array tab feature to a sheet metal part by switching existing junction into the tab.
		SmReliefCreate (6.28.22)	Makes proper corner and bend reliefs. Corner reliefs are built on corners which have three or more adjacent flanges. Bend reliefs are built on the start and end of a flange edge.
		SmReliefSwitch (6.28.24)	Converts a corner relief to a circular relief.

		SmReliefSwitch (6.28.24)	Converts corner reliefs to a rectangular relief.
		SmReliefSwitch (6.28.24)	Converts corner reliefs to a VType relief.
		SmReliefSwitch (6.28.24)	Converts corner reliefs to a Smooth relief.
		SmReliefSwitch (6.28.24)	Converts corner reliefs to a Round relief.
		SmReliefSwitch (6.28.24)	Converts corner reliefs to a Rip relief.
		SmSplit (6.28.30)	Splits a flange along a line drawn on its face.
		SmSplit (6.28.30)	Splits a flange by a single vertex in the corner.
		SmSplit (6.28.30)	Splits a flange by a single vertex in the corner and automatically suggests multiple splits of a similar type.
		SmImprint (6.28.18)	Splits thickness faces of a sheet metal part by imprinted edges, according to adjacent flanges and bends.
		SmDissolve (6.28.7)	Removes sheet metal data from the selected faces or entities.
		SmDelete (6.28.5)	Removes a bend or a junction by restoring a hard edge between two flanges; removes a flange with all the bends adjacent to it. The adjacent flanges are extended up to a junction configuration with the flange being deleted. Removes miter by restoring geometry being cut by the feature.
		SmRepair (6.28.29)	Fixes problems specific to Sheet Metal parts, both global and local workflows are supported. Optionally heals lofted bend features: merges adjacent bends and provides tangential connection with flanges.
		SmRepair (6.28.29)	Fixes problems specific to Sheet Metal parts. Only selected flange or wrong bend will be repaired.
		SmSelect (6.28.32) Same Form Features	Selects all identical form features in the sheet metal model

		SmSelect (6.28.32) Hard Edges	Selects all hard edges on sheet metal parts.
		SmSelect (6.28.32) Non-orthogonal Thickness Edges	Selects all non-orthogonal thickness edges on the sheet metal part.
		SmSelect (6.28.32) Flat Edges	Selects flat edges on the sheet metal part.
		SmSelect (6.28.32) side of the sheet metal part.	Selects side of the sheet metal part.
		SmParametrize (6.28.23)	Creates a consistent set of 3D constraints for the selected sheet metal part.
		SmUnfold (6.28.31)	Unfolds the sheet metal body.
		Associatively SmUnfold (6.28.31)	Opens an additional window with model's unfolded representation.
	OSM	SmExportOSM (6.28.8)	Exports a sheet metal solid to the .osm (Open Sheet Metal) file format.
	DXF	SmExport2d (6.28.6)	Exports the unfolded representation of a sheet metal body as a 2D profile in .dxf / .dwg file format.
	DXF	SmAssemblyExport (6.28.1)	Performs a batch export of assembly components to unfolding, creating a .dxf per each 3D solid recognized as sheet metal part.
		FEATURECOLORS (1.17.10)	Toggles the **FEATURECOLORS** system variable.

The Sheet Metal tools are available:

- In the Quad (2.3.3) cursor menu (depending on the feature under the cursor): (3.352 on the next page)
- On the **Sheet Metal** toolbars:
  - **Sheet Metal** (3.353 on the following page) (3.354 on the next page)
  - **SM Bend** (3.355 on the following page)
  - **SM Flange** (3.356 on the next page)
  - **SM Form** (3.357 on page 2997)
  - **Sm Hem** (3.358 on page 2997)
  - **SM Junction** (3.359 on page 2997)
  - **SM Relief** (3.360 on page 2997)
  - **SM Repair** 
  - **SM Split** (3.361 on page 2998)

3.9.3 Sheet Metal Features

In BricsCAD features are smart groups of faces in a 3D part. Each feature maintains a specific spatial and parametric relationship between its faces and some adjacent faces. The features allow you to embed design intent into your model. The features are created automatically by a particular geometric operation you apply. Images below show the sheet metal features in BricsCAD: (3.366) (3.367 on the facing page)

Flange The main feature of all sheet metal parts is a flange, which consists of two parallel planar faces located in front of each other (with some solid volume between them) on the distance, which is significantly smaller than the linear size of the faces. This distance is equal to the material thickness. When you modify the model, this distance relation is always maintained automatically. Other faces, which are adjacent to flange faces and do not belong to bends are called thickness faces. They are always perpendicular to the flange faces. Flange features are created by the following commands: SmFlangeBase (6.28.10), SmExtrude (6.28.9), SmLoft (6.28.20), SmFlangeEdge (6.28.14), SmFlangeBend (6.28.11) and SmConvert (6.28.4). If the FEATURECOLORS (1.17.10) system variable is ON, the display color distinguishes between the reference face of a flange and its opposite side. Parametric modifications of a sheet metal part, such as thickness change, do not move reference faces, if possible. The SmFlip (6.28.25) command swaps sides of a selected flange so that reference faces are on the other geometric side of the flange; optionally the command shifts the flange over the thickness of the sheet metal part. The images below illustrate the color legend for the flange faces of the same part.

(3.374 on page 3004)	(3.375 on page 3004)
Reference Faces	Other Faces

Bend Two flanges are connected by a bend. A bend consists of two coaxial cylindrical faces, which are always tangent to the adjacent planar faces of the flanges. Bend features are created by SmFlangeBase (6.28.10), SmExtrude (6.28.9), SmFlangeEdge (6.28.14), SmFlangeBend (6.28.11) and SmConvert (6.28.4) commands.

Zero Bend This is a design concept of bend, but geometry has a cylindrical face for the external side of the bend with a radius equal to thickness. Instead of an internal face, there is an edge. So effectively geometry represents a bend of zero radii, which is used for design purposes. SmUnfold (6.28.31) operation supports bends of this kind and generates dimensions as if these bends were regular bends with a radius equal to thickness.

Wrong Bend Wrong bend features are recognized by the SmConvert (6.28.4) command and reflect assumptions on the user's design intent. Like regular bends, wrong bends connect flanges, but their faces can be non-coaxial, or they can have non-tangent connections with adjacent flange faces, which prevent using the geometry ~~as regular bend features. Before unfolding the part, all wrong bends must either be repaired by SmRepair (6.28.29)~~ or deleted by SmDelete (6.28.5) and then recreated by SmBendCreate (6.28.3).

Figure 3.367

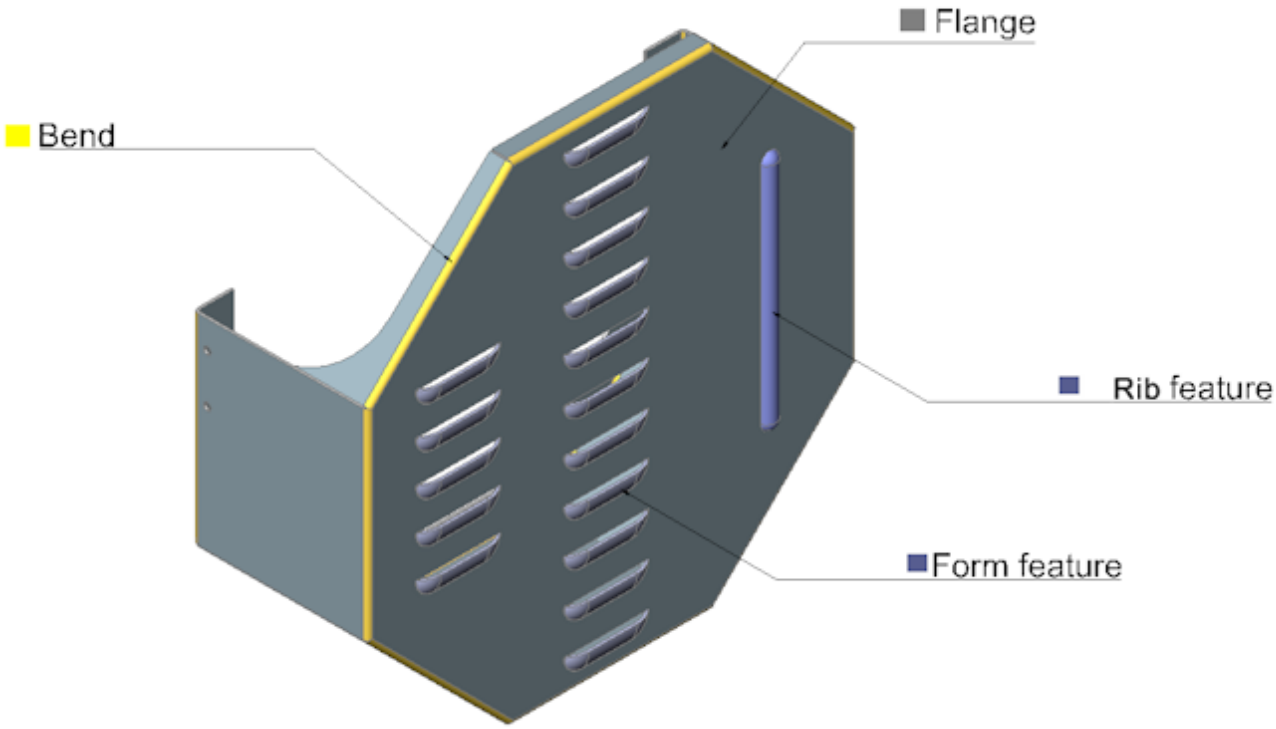

Figure 3.368

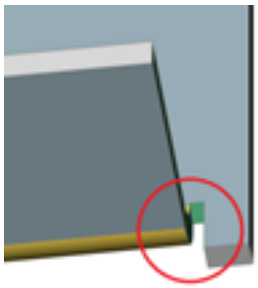

Lofted bend features are created by the SmLoft (6.28.20) and SmConvert (6.28.4) commands.

Bend Relief A group of faces representing a technological cut between two flanges of different width connected with a bend. The bend relief feature maintains the distance between two opposite faces of the cut. (3.368) Bend relief features are created by SmFlangeEdge (6.28.14), SmBendCreate (6.28.3) and SmReliefCreate (6.28.22) commands.

Corner Relief A group of faces representing a cut in the corner where three or more flanges meet together. This cut is needed to prevent unwanted material deformation during bending of the sheet metal part. A corner relief feature maintains the form and size of this cut. (3.369 on the following page) Corner relief features are created by SmFlangeEdge (6.28.14), SmBendCreate (6.28.3) and SmReliefCreate (6.28.22) commands.

Junction and T-Junction A junction feature consists of two thickness faces of adjacent flanges, which are not connected by a bend. A junction can be symmetric or overlapping. Junction features maintain the minimal distance between the flanges: the junction gap. (3.370 on the next page) A T-junction feature consists of a thickness face of a single flange, which is located near a face of another flange,. Usually, a T-Junction precedes creation of a T-Tab. For clarity, the junction gap in the image below is intentionally rather large. (3.371 on the following page) Junction features are created by SmFlangeEdge (6.28.14), SmJunctionCreate (6.28.21) and SmFlangeConnect (6.28.12) commands. T-junction features are created by SmJunctionCreate (6.28.21) and SmFlangeConnect (6.28.12) commands.

Figure 3.369

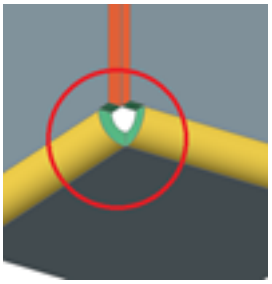

Figure 3.370

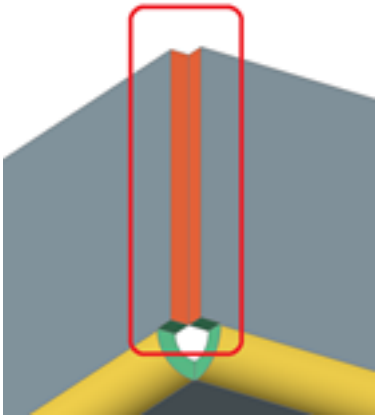

Figure 3.371

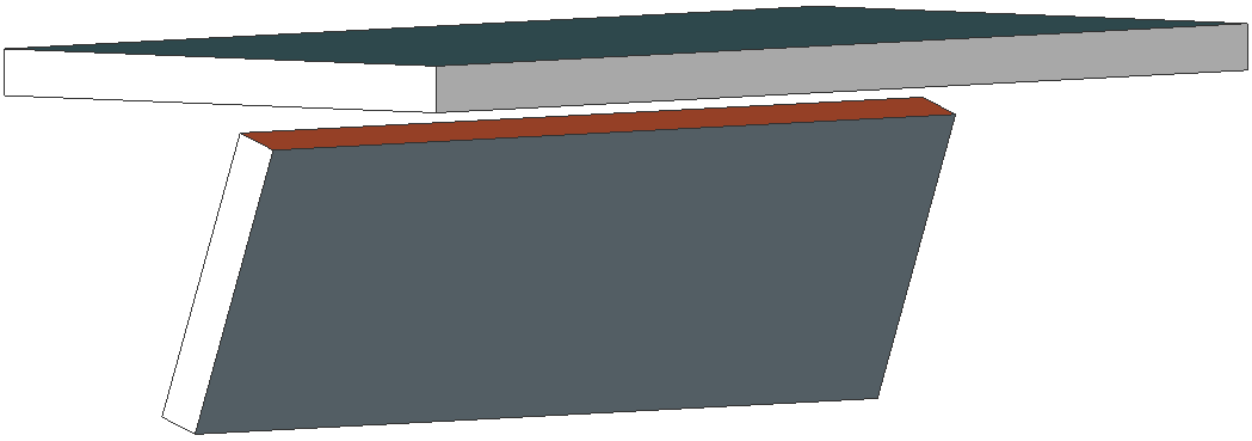

Figure 3.372

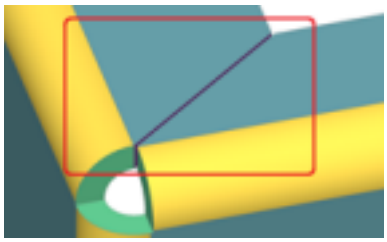

Miter Feature A miter feature represents a split between coplanar flanges created by the SmFlangeEdge (6.28.14) and SmSplit (6.28.30) commands. A miter feature maintains the miter gap. (3.372)

Form and Rib Features Form and rib features represent a rich variety of shapes which are produced by punching and wheeling. Two representations of the form features are important: one in 3D and a 2D symbol in the unfolded geometry. In case of imported geometry the symbol is obtained by the projection of the 3D faces of the form feature In case the form feature was inserted/replaced from the Form Feature Library, the unfolding symbol is taken from the library file. Rib features represent the imprint on a flange made by a wheel following an arbitrary trajectory. Form and rib features are created by BmInsert (6.8.16), SmRibCreate (6.28.27) and SmConvert (6.28.4) commands.

Tab and T-Tab Both features are used to connect two flanges, restricting their mutual displacement. Tab and T-tab features are created by the SmTabCreate (6.28.28) command.

(3.376 on page 3005)	(3.377 on page 3006)
Tab feature	T-Tab feature

Bevel Bevel features represent chamfers on thickness faces of Sheet Metal parts. Both sloped and orthogonal faces define a chamfer feature. Bevel features must be shared strictly by a single flange and can not be adjacent to bend features. Bevel features can be recognized or erased by the SmConvert (6.28.4) command, and are supported by the SmUnfold (6.28.31) command. (3.373 on the following page)

3.9.4 Feature Coloring

For better experience and easy distinguishing between the features, different colors are applied to the various types of features in the geometry. These colors are for visualization only and will never show in generated documents, paper space views, block inserts, etc. The display of feature colors is controlled through the FEATURECOLORS (1.17.10) system variable and a series of system variables, one for each feature color. Although the default feature colors are selected carefully to combine with each other, you can set them differently in the **Sheet Metal** settings group on the Settings dialog (1.17.10). (3.378) To toggle the display of feature colors:

- Click the **Color Features** tool button ( ) on the **Sheet Metal** toolbar.
- Click the **Color Features** tool button ( ) on the **Sheet Metal** ribbon bar.
- Choose **Color Features** in the **Sheet Metal** menu.

Tutorial: Feature coloring in BricsCAD Sheet Metal Click here (3.8.1) to watch

3.9.5 Sheet Metal Global and Feature Properties

Sheet metal features and context menus sit in the Mechanical Browser (6.8.32). See Mechanical Browser for Sheet Metal (3.9.6) to understand the general principles. This article describes the particular properties and context menus for each node type in the Mechanical Browser. When working with sheet metal parts, clicking the root node in **Mechanical Browser**, displays the properties of entire drawing. Sometimes these properties are referred to as the **global** Sheet Metal Context associated with the drawing: each Sheet Metal part shares this context by default. (3.379 on the facing page) Since BricsCAD V21 it is possible to assign a **local** Sheet Metal context for given solid, which allows to define Sheet Metal parts with different design parameters, and most importantly, to the change the part thickness. Before BricsCAD V21 all the parts in modelspace must have the same thickness, which forced the user to spread the parts with a different thickness to different blocks or components. Scenarios with multiple imported bodies engaging SmConvert (6.28.4) and SmAssemblyExport (6.28.1) also benefit from this new feature. Another advantage worth noticing is that the local Sheet Metal context can define its own Bend Table (3.9.7).

To switch the context of a solid to local

Do the following:

1. Select the body in **Mechanical Browser**
2. In Sheet Metal section switch **Context Type** from **Global context** to **Context for solid**

Notice that the SmConvert (6.28.4) command, in case of multiple input with different thicknesses, switches some contexts to local automatically. Sheet metal global properties sit in the bottom part of the Mechanical Browser. **Global Properties Thickness**: global sheet metal material thickness. (3.380 on page 3014) **Bend radius**: default radius of bend features; it can be changed per bend as well.

- **Type**: either thickness ratio or absolute value.
- **Value**: either ratio or value. (3.381 on page 3015)

Sharp bend radius limit: maximum bend radius to be considered a sharp (regular) bend. Used in SmConvert (6.28.4) and SmReliefCreate (6.28.22) commands to distinguish between regular and lofted bends.

- **Type**: either thickness ratio or absolute value.
- **Value**: either ratio or value.

Bend relief width: width of the cut near a single bend.

- **Type**: either thickness ratio or absolute value.
- **Value**: either ratio or value. (3.382 on page 3015)

Relief extension: size of the bend or corner relief extension.

- **Type**: either thickness ratio or absolute value.
- **Value**: either ratio or value. (3.383 on page 3015)

Corner relief diameter: default diameter of a circular corner relief.

- **Type**: minimal possible or absolute value. (3.384 on page 3016) (3.385 on page 3016)

Junction gap: gap between two adjacent flanges.

- **Type**: either thickness ratio or absolute value.
- **Value**: either ratio or value. (3.386 on page 3016) (3.387 on page 3016) (3.388 on page 3017) (3.389 on page 3017)

Junction alignment: controls the alignment of junction faces with the corresponding corner relief faces.

- **Type**: either thickness ratio or absolute value.
- **Value**: either ratio or value.
- **Junction Alignment**: either enabled (3.390 on page 3017) or disabled(3.391 on page 3018)

Flange split gap: gap between the thickness faces of a flange or the adjacent bend when splitting, see SmSplit (6.28.30).

- **Type**: either thickness ratio or absolute value.
- **Value**: either ratio or value. (3.392 on page 3018)

Flange split extension: controls the depth cut of an adjacent flange in case of a flange split.

- **Type**: either thickness ratio or absolute value.
- **Value**: either ratio or value. (3.393 on page 3018)

Rib profile radius: radius of a tool, which creates the rib.

- **Type**: either thickness ratio or absolute value.
- **Value**: either ratio or value. (3.394 on page 3018)

Rib round radius: radius of the fillet between the flange and a rib.

- **Type**: either thickness ratio or absolute value.
- **Value**: either ratio or value. (3.395 on page 3019)

Rib fillet radius: radius of the rib control curve filleting, see Working with Form and Rib Features (3.9.25).

- **Type**: either profile radius ratio or absolute value.
- **Value**: numeric value. (3.396 on page 3019)

Unfolding: parameters for the unfolded representation. **Default K-Factor**: K-Factor for the bend radius equal to the thickness, see K-Factor (3.9.8). **Bend table**: displays the Open dialog for bend tables in CSV file format. **Bend line extent**: controls how far a bend line extends beyond the unfolding boundary (zero and negative values are allowed).

- **Type**: either thickness ratio or absolute value.
- **Value**: either ratio or value.

Unfolding mode: controls the appearance of form features in the unfolded representation.

- **Keep**: keep the 3D representation of the form feature.
- **Remove**: completely remove form features from the unfolded representation.
- **Project**: project all edges of form features as 2D entities.
- **Contour**: project only the contour of form features as 2D entities.
- **Symbol**: place 2D symbols at the insertion points in unfolded representation.

Feature properties display automatically when selecting a feature in the **Mechanical Browser.** Right click a feature to display the feature context menu.

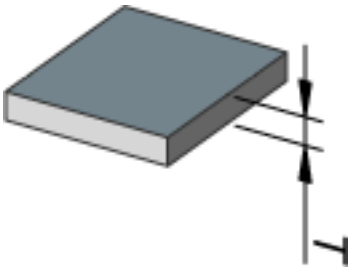
Feature Context Menus	Common tools: • **Disable**: temporarily disables a feature and skips its constraining. • **Dissolve**: removes a feature but keep its geometry. Design intent associated with the geometry of a dissolved feature will be removed. • **Delete**: See the SmDelete (6.28.5) command. Removes features from the Mechanical browser and deletes the corresponding geometry in the model. • **Zoom to**: zooms onto the selected feature. • **Collapse all**: collapses the main component including all components and subcomponents. • **Expand all**: expands the main component and all components and subcomponents.
Flange feature	Right click a flange feature:  (3.397 on page 3019) • **Flip**: swaps the sides of a selected flange so that the reference face is on the opposite geometric side of the flange. This operation shifts the flange by its thickness, in order to preserve the position of the reference face.
Bend feature	Right click on a bend feature:  (3.398 on page 3020) • **Switch to junction**: switches to a junction feature type with a gap between adjacent flanges. • **Switch to lofted bend**: switches to a lofted bend feature.

Lofted Bend feature	Right click on a lofted bend feature:  (3.399 on page 3021) • Switch to junction: switches to a junction feature type with a gap between adjacent flanges. • Switch to bend: switches to bend feature.
Wrong Bend feature	Right click on a wrong bend feature:  (3.400 on page 3021) • **Repair feature**: repairs a wrong bend feature by creating a bend feature with proper geometry, if possible.
Bend Relief feature	Right click on bend relief feature:  (3.411 on page 3025) • Switch to **smooth**, **round** or **rip**: switches a bend relief to the selected feature type.
Corner relief feature	Right click on corner relief feature:  (3.402 on page 3022) • Switch to **V-type** or **circular**: switches a corner relief feature to the selected feature type.
Junction feature	Right click on junction feature:  (3.403 on page 3022) • **Switch to bend**: switches to a bend feature. • **Switch type of the feature**: switches the alignment mode between symmetrical and aligned with one of the flanges.
Miter feature	Right click on miter feature:  (3.404 on page 3022)
Form feature	Right click on form feature:  (3.405 on page 3023) • **Select same feature**: selects all form features of the same type in the model. • **Explode to flanges and bends**: explodes a form feature into a set of flanges and bends, if possible. • Repair **feature:** recalculates the insertion point of a form feature. • **Replace...**: displays the Open dialog box in order to choose a replacement form feature.

Tab feature	Right click on tab feature:  (3.406 on page 3023) • **Switch to bend**: converts a tab feature to a bend feature • **Switch to junction**: converts a tab feature to a junction feature
T-Junction feature	Right click on T-junction feature:  (3.407 on page 3024) • **Switch to T-tab**: converts a T-junction feature to a T-tab feature.
T-Tab feature	Right click on T-tab feature:  (3.408 on page 3024) • **Switch to T-Junction**: converts a T-tab feature to a T-junction feature

Feature Properties	Common property: **Name**: the name of the selected sheet metal feature. Optionally type a name for the feature. The default name of a feature is the feature type plus an increment, e.g. Flange_1, Flange_2, ...
Flange feature	Click a flange feature: (3.409 on page 3025) **Thickness**: current thickness. The value is read-only; it equals the sheet metal component thickness property.
Bend feature	Click a bend feature: (3.410 on page 3025) • **Angle**: current angle of the bend feature; can be changed by the SmFlangeRotate command. • **Radius**: current bend radius. • **Radius type**: – Thickness ratio: ratio of thickness multiplied by a coefficient – Absolute value: the global value (main sheet metal component properties).
Bend relief	Click a bend relief feature: (3.411 on page 3025) • **Relief type**: current relief type; either rectangular, smooth, round or rip • **Width**: width of the cut near the bend; either global, thickness ratio or absolute.
Corner relief	Click a corner relief feature: (3.412 on page 3025) • **Relief type**: current relief type; either rectangular 2 bends, rectangular, v-type or circular • **Width**: width of the cut near corner.; either global, thickness ratio or absolute.

Figure 3.380



Junction feature	Click a junction feature: (3.413 on page 3025) • **Junction gap**: gap between two adjacent flanges. • **Junction gap type**: either global, thickness ratio or absolute. • **Connection type**: controls the relative position of adjacent flanges; either symmetric or adjacent to one of the flanges. • **Junction alignment**: controls the position of the faces of a junction feature; either global, enabled (aligned with the corresponding corner relief feature faces) or disabled
Miter feature	Click a miter feature: (3.414 on page 3026) • **Miter gap**: gap between the side faces of the miter. • **Type:** either thickness ratio or absolute.
Form feature	Click a form feature: (3.415 on page 3026) • **Component name**: name of form feature component definition. • **Parameters**: contains the parameters of a parametric sheet metal form feature.
Bevel feature	Click a bevel feature: (3.416 on page 3026) • **Bevel type**: defines a type of the bevel, depending on the geometry. Possible values: one-side, land, X- and K- bevel. Upon a bevel type, parameters may alter. • **Side bevel**: parameters of chamfer on one side of this bevel. • **Orhogonal bevel**: parameters of orthogonal side.

3.9.6 Mechanical Browser for Sheet Metal

The **Mechanical Browser (3.3.2)** opens automatically when switching to the **Mechanical** workspace. To open the **Mechanical Browser** manually do the following:

1. Move the cursor over a toolbar, then right click. A context menu displays: (3.417 on the following page)
2. Choose Mechanical Browser in the context menu.

Sheet Metal Context

If you work with a sheet metal part (if you created any sheet metal feature (3.9.3)), properties of the root node in **Mechanical Browser** contain "Sheet Metal" section (also called **Sheet Metal Context associated with the document**). (3.418 on the next page) Sheet Metal properties (3.9.5) are represented as grouped fields. The **Thickness** field controls the material thickness of sheet metal solids which has to be equal for all solids of the document. The **Modeling** group plays two roles:

- It provides default settings for Sheet Metal Commands, (3.9.2) such as SmFlangeBase (6.28.10), SmExtrude (6.28.9), SmFlangeEdge (6.28.14), SmFlangeBend (6.28.11), SmLoft (6.28.20), and SmConvert (6.28.4) in a newly created model. The initial parameters are saved in the drawing, which allows creating a set of .dwt template drawings for each type of sheet metal models created in a company.
- New features created by the commands usually derive their properties (3.9.5) from Sheet Metal Context. For example, the default value of **Radius Type** property for the bend feature is "Use global value". Thus when you change **Bend radius** in Sheet Metal Context, all the bend features with the derived property will change its radius. So the second application of Sheet Metal Context properties is that they allow globally change properties of sheet metal part.

The **Unfolding** group of properties in Sheet Metal Context lists some properties of SmUnfold (6.28.31), SmExport2d (6.28.6) and SmAssemblyExport (6.28.1) commands. Sheet Metal Context is created when first sheet metal part appears in the document and is initialized from settings listed in Initial Parameters (3.9.9). Typical workflows for creating sheet metal part are listed in Sheet Metal Design Methods (3.9.1). Sheet Metal Context is removed when all the features in the document are dissolved by SmDissolve (6.28.7) command. Note that if you just select all sheet metal parts in the document and Erase (6.13.8) them, Sheet Metal Context is kept, despite there are no sheet metal solids and no sheet metal features.

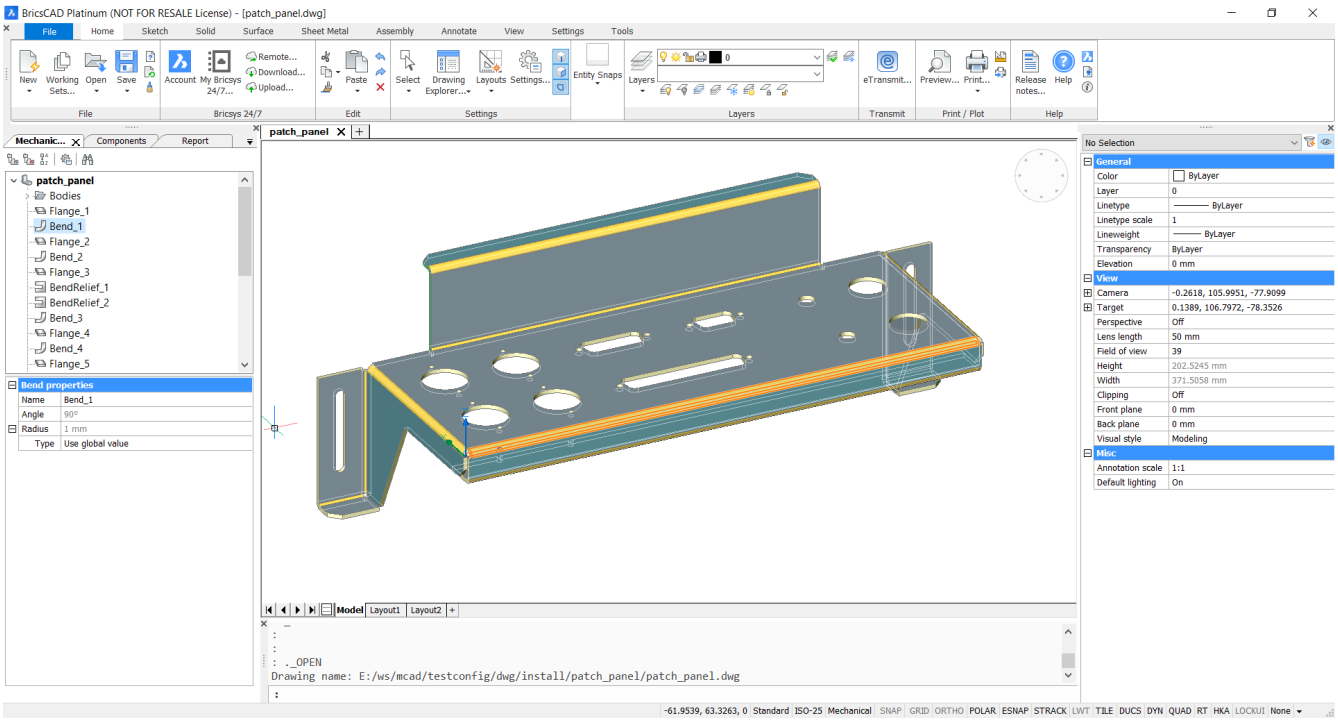
Working with Features

All features of a sheet metal part are listed in the **Mechanical Browser**. When you select a feature in the **Mechanical Browser**, its faces are highlighted in the model area: (3.419 on the following page) Note that **Sheet Metal** group of properties has changed to **Bend properties**. Thus clicking on feature in Mechanical Browser allows:

- locate feature on the part by highlighting its geometry
- see properties of given feature

Figure 3.419



Changing the Thickness

To change the thickness of a sheet metal part:

1. Select the root node in the Mechanical Browser (3.3.2).
2. Type a value in the **Thickness** field. (3.420 on the next page)

Feature Operations

Mechanical Browser provides fast access to operations over given sheet metal feature, list depend upon the feature type. List of operations depends upon selected features and contains operations available for the selection. Selecting two bends results in operations for bend feature: (3.421 on the facing page) Selecting flange and bend limits list to operations available for both features: (3.422 on the next page)

Figure 3.421

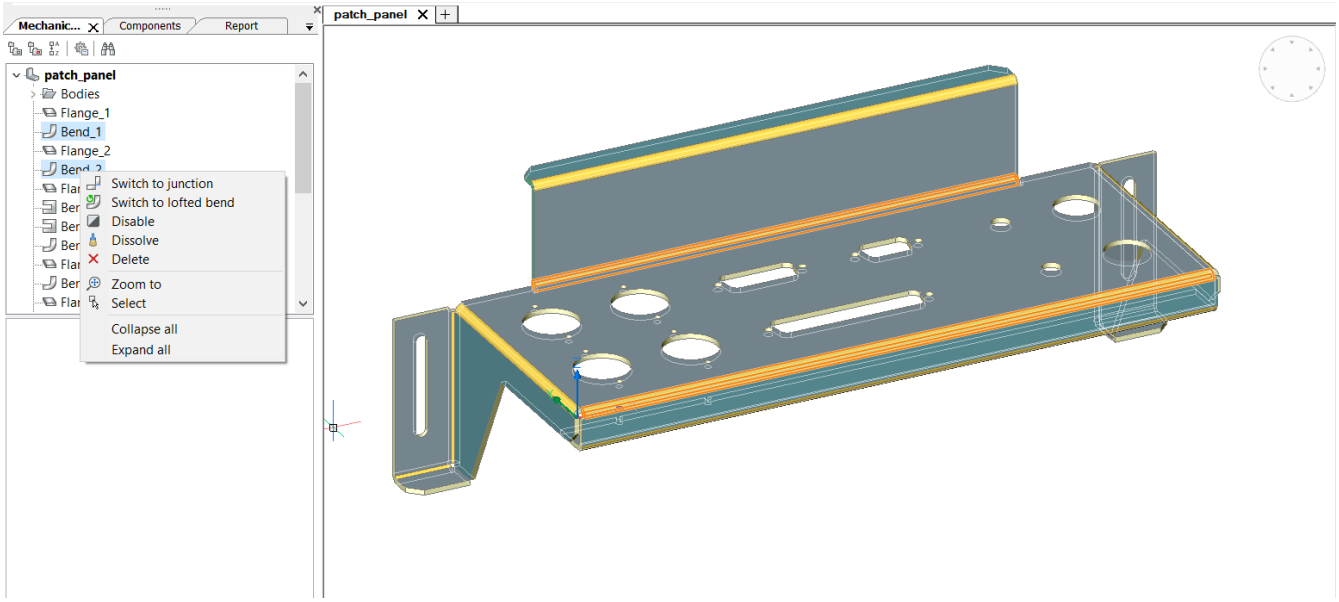

Figure 3.422

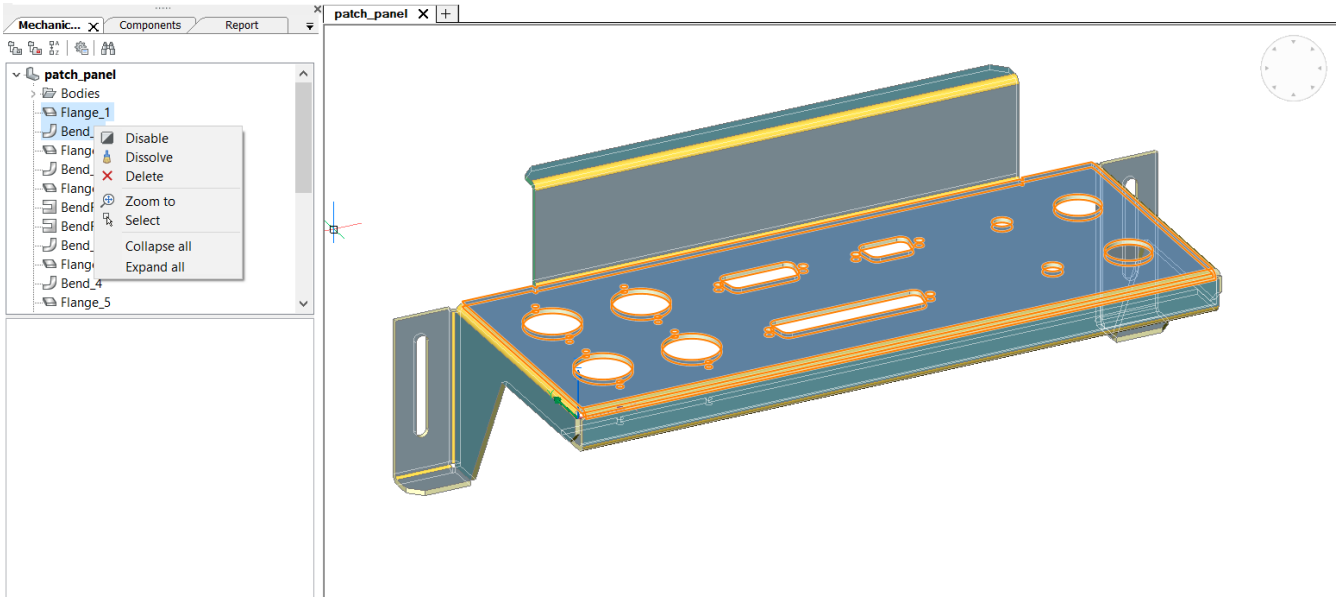

Understanding the Difference Between Disable, Dissolve and Delete

When you right click a feature in the **Mechanical Browser**, then select **Dissolve** from the context menu the selected feature is removed from the part, but it will keep its geometry. However, design intent (spatial and parametric relationships between the feature's faces) associated with the geometry of a dissolved feature is removed If your intent is temporary forget about given feature, you can choose **Disable** option. The feature will remain in the **Mechanical Browser**, but the part will behave like the feature was dissolved. It is beneficial in contrast with dissolve, that feature still updates on geometry changes and you can turn it on when you want, avoiding recreating it or recognizing by SmConvert (6.28.4). Some of Sheet Metal features support **Delete** operation in the **Mechanical Browser** which is the analogue of SmDelete (6.28.5) command. In this case the feature is removed from the browser and geometry is changed depending upon the type of the feature.

3.9.7 Bend Table

Bend tables are a more reliable way to express material deformation properties than K-Factor (3.9.8). When you physically bend a flat sheet of a particular material, you can measure its length before and after this process. You can repeat this procedure for different bend angles, bend radius, and sheet thickness and save the measurements in a bend table. Then these measurements can be taken into account to compute the correct unfolded length for all parts made of the same material. In a bend table, you can add the measurements for as many different bend angles as you want. However, in most cases it suffices to measure the length for a 90 degrees angle. BricsCAD will automatically compute the length for other bend angles using a reliable interpolation technique. Bend tables are stored in a *.csv (comma separated values) file format. You can create such a table in an ASCII text editor, such as Notepad, but a more reliable and easier way is to create a table in a spreadsheet, such as Microsoft Excel or LibreOffice and then export it to .csv file format. Bend tables in BricsCAD have the following structure: (3.423) The following rules apply:

- The content of the first cell reads "BricsCAD".
- **Version**: currently supported version is 1.
- **AngleType**: Currently only internal bend angles are supported: (3.424 on the next page)
- **LengthType:** the semantics of the value in the cells of the bend table corresponding to a particular bend angle and bend radius. Now only bend deduction measured from the tangent point is supported ("BendDeductionTangent"). Bend deduction (BD) is the difference between the sum of the lengths of two flanges measured to the tangent point on a 3D model and the length of the same fragment in the unfolded state: (3.425 on the following page) In depth: methodics to compute tangential bend deduction for acute and obtuse angles. (3.426 on the next page)
- Within the defined header, several tables can exist. For each table, the first key is the thickness of the sheet metal part, the second key, **DieWidth**, is optional. The **Thickness / DieWidth** pairs must be unique. If the **DieWidth** is not defined, only one unique **Thickness** value key is allowed, but multiple thickness values can be added. When a bend table is used to control the unfolding process, the **Thickness** and **DieWidth** , defined in the sheet metal part, must exist in the bend table. If the table is not found the default K-Factor policy is used.
- Once the bend table is found in the .csv, it will be used to unfold the sheet metal part. Using the sample bend table above, let's have a look at a few cases: T = Thickness, R = Internal Bend Radius, A = Bend Angle
  - T = 1, R = 2, A = 45. Then after unfolding it will obtain the BD = 0.466, because both R and A are found in the bend table for the given thickness.

Figure 3.424

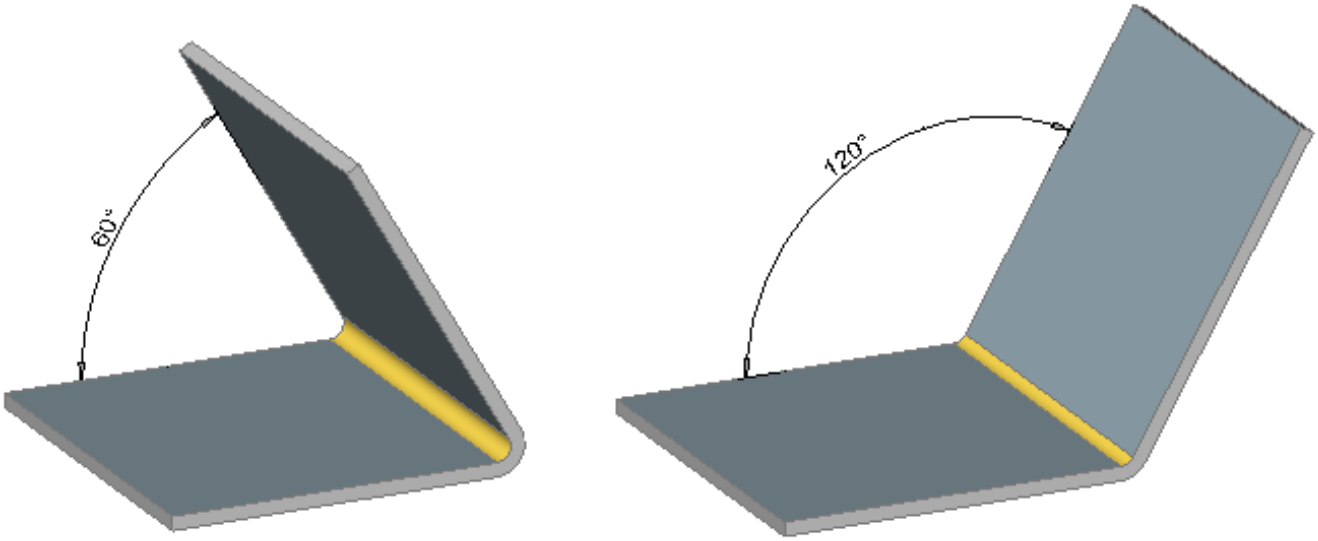

Figure 3.425

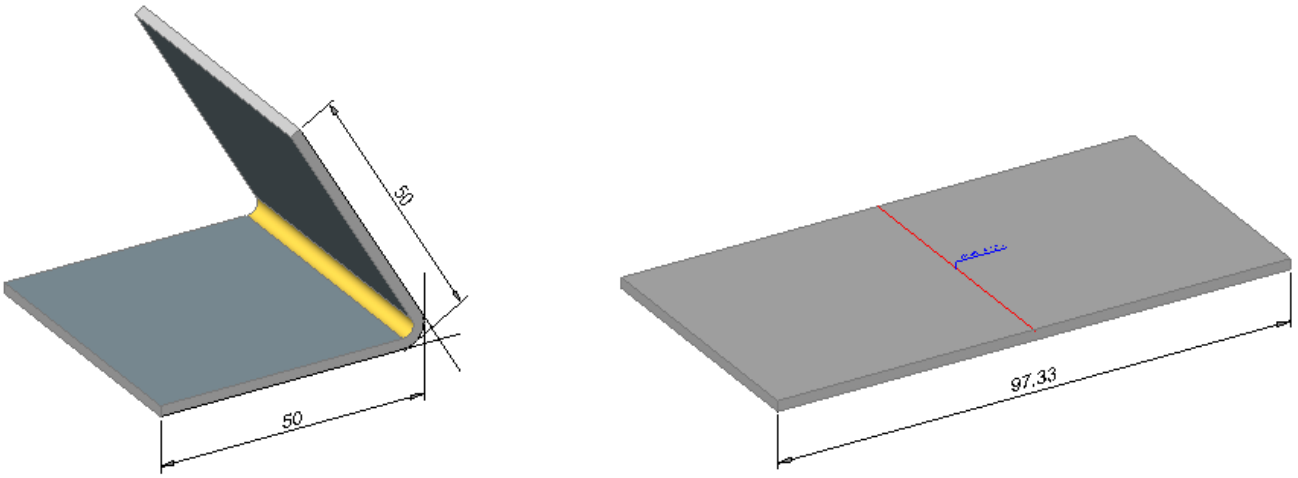

Figure 3.426

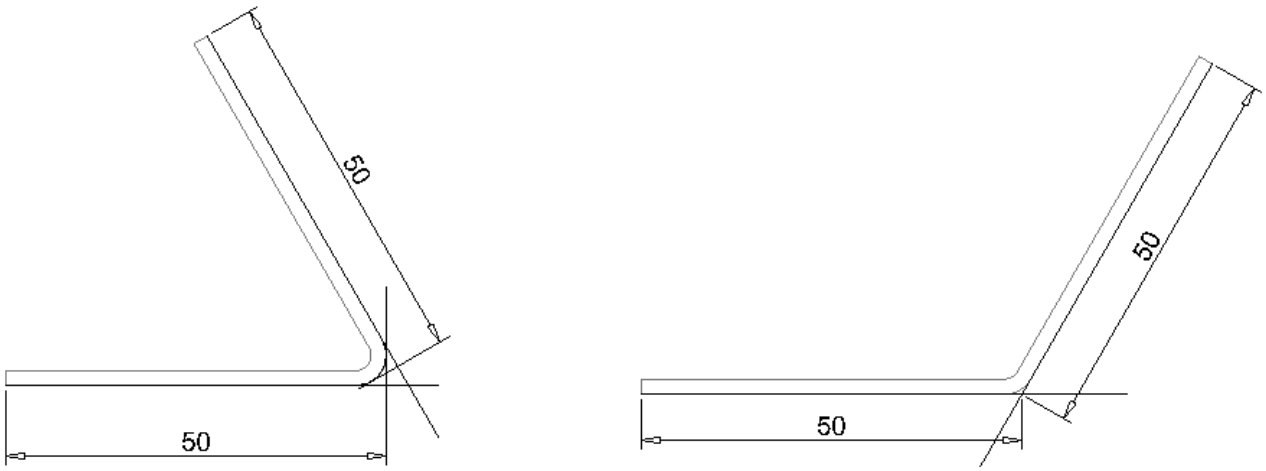

- T = 1, R = 2.5, A = 45. A = 45 is found, but R = 2.5 is missing: the interpolation of BD between R=2 and R=3 is used.
- T = 1, R = 2.5, A = 75. Neither R nor A is found in the table: the following cells are used to calculate the value of BD: (R=2, A=60), (R=3, A=60), (R=2, A=90) and (R=3, A=90).

The top-of-the-edge algorithm is used to calculate the interpolation. For example, linear interpolation on adjacent BD values render unnatural results, which will not match the real bending results. Also keep in mind that for a given T, R and A not all BD values make sense: a random one might place the neutral surface outside the sheet metal part, or expressed in K-Factor (which can be deduced from BD), the K-Factor can be out of range [0, 1]. In this case, the BD for the default K-Factor will be used.

- If you produce your sheet metal parts with different tools, you can describe them in one bend table using **DieWidth** parameter. A sample bend table is provided for your convenience in the **[BricsCAD Installation folder]\Samples\Mechanical\bend_tables**. Please notice that writing rights to this folder might be limited. In such case you need to copy the bend tables to a different folder in which you have full access rights.

To set the bend table for your sheet metal part:

1. Select the root node in the Mechanical Browser (3.3.2).
2. Select the **Bend table** field. (3.427)
3. Click the Browse button (...).
4. Select the *.csv file then double click or press the **Open** button.

Figure 3.427

To update the bend table set previously:

1. Select the root node in the Mechanical Browser (3.3.2).
2. Select the **Bend table** field.
3. Press the **Update** button ( ).

If the bend table is not assigned to the document or has no **DieWidth** secondary key, the **DieWidth** parameter can not to assigned to single bend or all the bends. In order to make the assignment, do the following steps: (3.428 on the next page)

1. Select .csv file **DieWidth** secondary keys and thickness matching the current part. On given example we assume that part has thickness of 1 mm and bend radius also equals to 1. We will vary bend deduction to different tools: the first subtable is when the tool is not specified, second subtable is for the case when tool **DieWidth** is equal to 20, and the last one is for a tool with **DieWidth** equal to 30.
2. Assign the bend table to the sheet metal part.
3. Check that in the Mechanical Browser (3.3.2) new fields appeared: (3.429 on the facing page) In this global setting we can select any default **DieWidth** value suitable for the part thickness. The value will be assigned by default to the bends in the part, which can be checked by the property of the bend (click on the bend in the Mechanical Browser (3.3.2)): (3.430 on page 3042)
4. However, we can select a specific tool which will be used for the given bend by expanding the drop-down list: (3.431 on page 3042)
5. With the given selection, an unfolding of Bend_1 will use a third subtable from our bend table for bend deduction and uses the value 1.8. For the rest of the bends, unless **DieWidth** is set for them, the default no-die-width value will be used, which will trigger first the bend table and uses value 2.1 for 90-degrees with a bend radius equal to 1.

NOTE	After assigning the **DieWidth** to the bends and saving the document, the value is saved to the bends. However, next time the drawing is opened, in order to assign the **DieWidth** value to another bend, you have to reload the bend table first (press the green arrow button), see **To update the bend table set previously**. After the reload the values from the bend table will be available.

Note : Since BricsCAD V21 you can alter bend tables for different solids in model space by defining a **local Sheet Metal Context** per each solid. For details see: Sheet Metal Global and Feature Properties (3.9.5).

3.9.8 K-Factor

When a metal sheet is bent with a press brake, its material is deformed, which is the reason for the difference in overall length of a sheet in folded and unfolded states. BricsCAD automatically takes this deformation into account when you unfold a sheet metal part. Two approaches are used to compute it: a simplified one (K-Factor) and a more advanced one (Bend Table (3.9.7)). The material deformation properties for bending is based on the assumption that there is internal surface for the sheet metal part which is not deformed when the sheet is bent. From the variety of internal surfaces, one surface is selected which is equidistant from one side of the bend. The surface is local for each bend, and for simple cases it can be propagated on entire part, like the one on the picture. We assume that this surface is not stretched stretch during bending. (3.432 on the previous page) (3.433 on the preceding page) T: thickness of the sheet metal part R: internal radius of the bend The K-factor (k) is the ratio of the location of the neutral surface to the material thickness. As a result the neutral surface lies at a distance kT from the internal surface of the bend. The bend radius of the neutral surface equals R + kT. The K-Factor is a simple geometric calculation of the location of the neutral surface. Forming stresses and other unknown (error) factors are not taken into account. The K-Factor depends on many factors, including the kind of material, bending type, tools, etc ... The K-Factor typically lies between 0.3 and 0.5. The default K-Factor for a bend radius equal to the material thickness (T) is 0.27324. (3.434 on the previous page) In the unfolded state of a sheet metal part, the flanges (L1 and L2) are not stretched. The bend part is indicated as BA: bend allowance. The BA equals the length of the unfolded neutral surface: BA = BendAngle * (R + kT) In real world practice it is hard to measure the K-Factor or the bend allowance. The following formula allows to calculate the tangential Bend Deduction (BD): BD = B1 + B2 - Unfolded Length = B1 + B2 - (L1 + L2 + BA) For simple cases the K-Factor value can be overridden in the browser, for maximal precision a bend table containing tangential bend deductions has to be provided. For each sheet metal part, you can either specify a K-factor or use the default one.

Changing the K-Factor for a Sheet Metal Part To change the K-Factor for a sheet metal part, select the root node in the Mechanical Browser (3.3.2) and type a value in the **K-Factor** field. The value must lie in the range [0, 1], since the neutral surface is located inside the sheet metal part. In BricsCAD the K-Factor is defined for bend radius equal to the material thickness (R/T = 1); to compute the value of K-Factor for an arbitrary bend radius, BricsCAD uses a special interpolation technique which is proved to be valid for industrial sheet metal applications. The image below shows the interpolation strategy: for R/T < 1 the linear interpolation is done between 0 and 0.27324, for 1 < R/T < 4 the K-Factor is linearly interpolated between 0.27324 and 0.5 and if R/T is greater than 4, the K-Factor is constant and equals 0.5. Physically it means that if the bend radius is much larger than the thickness (at least 4 times), the material stretch is can be neglected. (3.435) The only K-Factor parameter one can control in the browser is for R/T. I.e. if we set the value to 0.6, the interpolation law leads to the following result: (3.436 on the next page) Pic: the varying K-Factor in the browser leads to the following effective curve. The distinguishing feature of the curve is that varying R in range of (0, T], L1 + L2 + BA will give the same value. This is explained by the fact that for radii less than the thickness they relate to are for design convenience rather than for some physical process modeling, since during bending tool radius is usually greater or equal to thickness. Lets review the example with varying K-Factor by control curve setting (the bend radius is kept constant). T = 2, R = 2, B1 = 100, B2 = 100 (3.437 on the following page) Setting K=0 gives L1=L2=96, Unfolded Length = 195.14, thus BA is 3.14. (3.438 on the next page) This value fits the formula exactly: a straight angle in radians roughly equals 1.57 (PI/2). The default K-Factor 0.27324 gives an Unfolded Length = 196. Or: L1=L2=96 (flanges are not deformed), the BA = 4 as we can compute from the dimensions (196 - 2*96) or from the Bend Allowance formula: BA = BendAngle * (R + kT) = 1.57 * (2 + 2*0.27324) = 4 (3.439 on the following page) Finally, maximizing K-Factor results in an Unfolded Length = 198.28. This is the maximal value one can achieve in this example since the neutral surface is taken from the external side of the bend. (3.440 on page 3047) The Bend Deduction (BD) for k = 0.27324: BD = B1 + B2 - Unfolded Length = 100 + 100 - 196 = 4

3.9.9 Sheet Metal Settings

The Sheet Metal section in the Settings dialog (1.17.10) controls the different properties of Sheet Metal within BricsCAD. Properties are split into four groups: **Commands**, **Feature colors**, **Initial parameters**, and **Modeling**. (3.441) **Note:** Most of the sheet metal settings are stored in the drawing. For best results always start with one of the sheet metal template files (1.19.1) DWT or create your own.

3.9.10 Commands

The **Commands** section contains settings that control the behavior of the various Sheet Metal commands. **Note:** Before BricsCAD V19 these controls were available as options within the individual commands. They were moved to the settings dialog to simplify the command interface. (3.442 on the next page) The Layers used for Sheet Metal Unfolding determine the appearance of unfolded parts. (See Unfolding Sheet Metal Parts and Exporting to CAM (3.9.24) for more details.)

3.9.14 Creating Flanges

A flange is the main feature of most sheet metal parts. In BricsCAD you can create flanges using many different techniques:

- Create a base flange from a closed 2D profile, which defines its boundary.
- Create one or several edge flanges by pulling edges of existing flanges.
- Create several flanges at once by extruding a 2D polyline (every linear edge of the polyline becomes a flange).

These techniques are described in the article below, but there are also other techniques you can use to create flanges. These are described in other articles:

- Flanges can be created as elements of lofted sheet metal parts (3.9.21).
- Flanges can be recognized (3.9.28) in existing geometry.

In contrast to history-based MCAD, BricsCAD applies the same set of tools to modify (3.9.15) any flange - independently.

Create a Base Flange

In most cases, you create a base flange to start your sheet metal part design. To create a base flange, select a closed planar profile and call the SmFlangeBase (6.28.10) command. Do one of the following:

- Click the **Create Base Flange** tool button () on the **Sheet Metal** toolbar.
- Choose **Create Base Flange** in the **Sheet Metal** menu.
- Choose **Create Base Flange** in the **Sheet Metal** group of the Quad (2.3.3) cursor menu:

(3.447 on the facing page) (3.448 on the next page) To create a base flange the SmFlangeBase (6.28.10) command extrudes a profile. The height of the base flange is the default **Thickness** property of the sheet metal part. To change the thickness of your sheet metal part, type the appropriate value in the **Thickness** field of the Mechanical Browser (3.3.2).

Figure 3.447

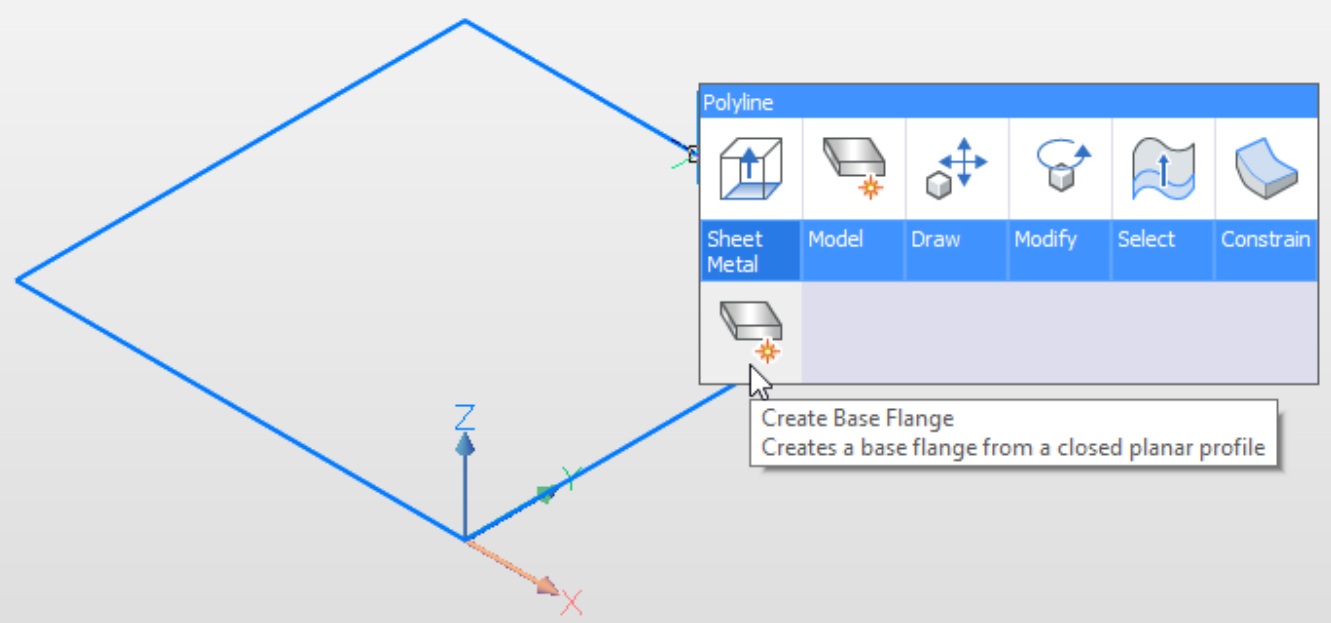

Figure 3.448

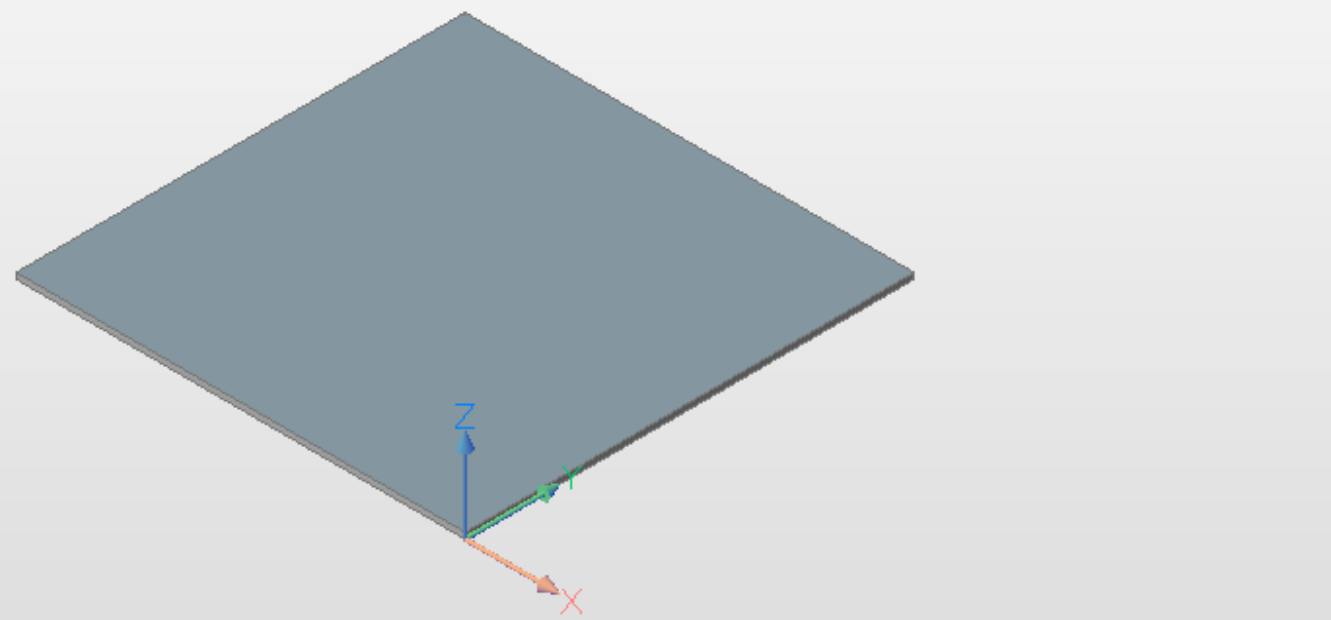

Create Edge Flanges

To add an additional flange to your sheet metal.

1. Select a linear edge.
2. Select the SmFlangeEdge (6.28.14) command in the **Sheet Metal** section of the Quad (2.3.3) cursor menu.
3. Move your mouse pointer to define the desired length of the edge flange and the angle between the two flanges. You can also use the dynamic dimensions fields to enter the required values.

(3.449 on the facing page) (3.450 on the next page) (3.451 on page 3062) To create an edge flange where the width is different to the width of the edge, select the **Width** option of SmFlangeEdge (6.28.14) command and define the offset distance from one or both sides of the edge. (3.452 on page 3062) (3.453 on page 3063) (3.454 on page 3063) **Note** when you create an edge flange of a different width to the edge, bend reliefs are created automatically.

Figure 3.449

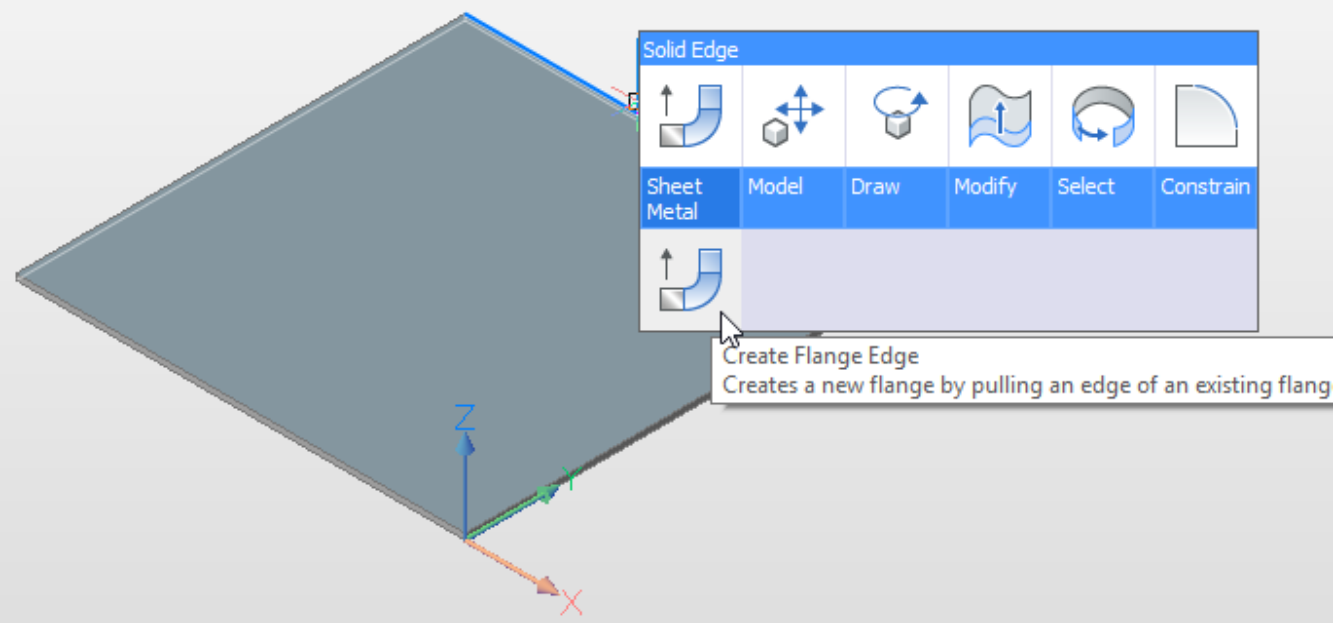

Figure 3.450

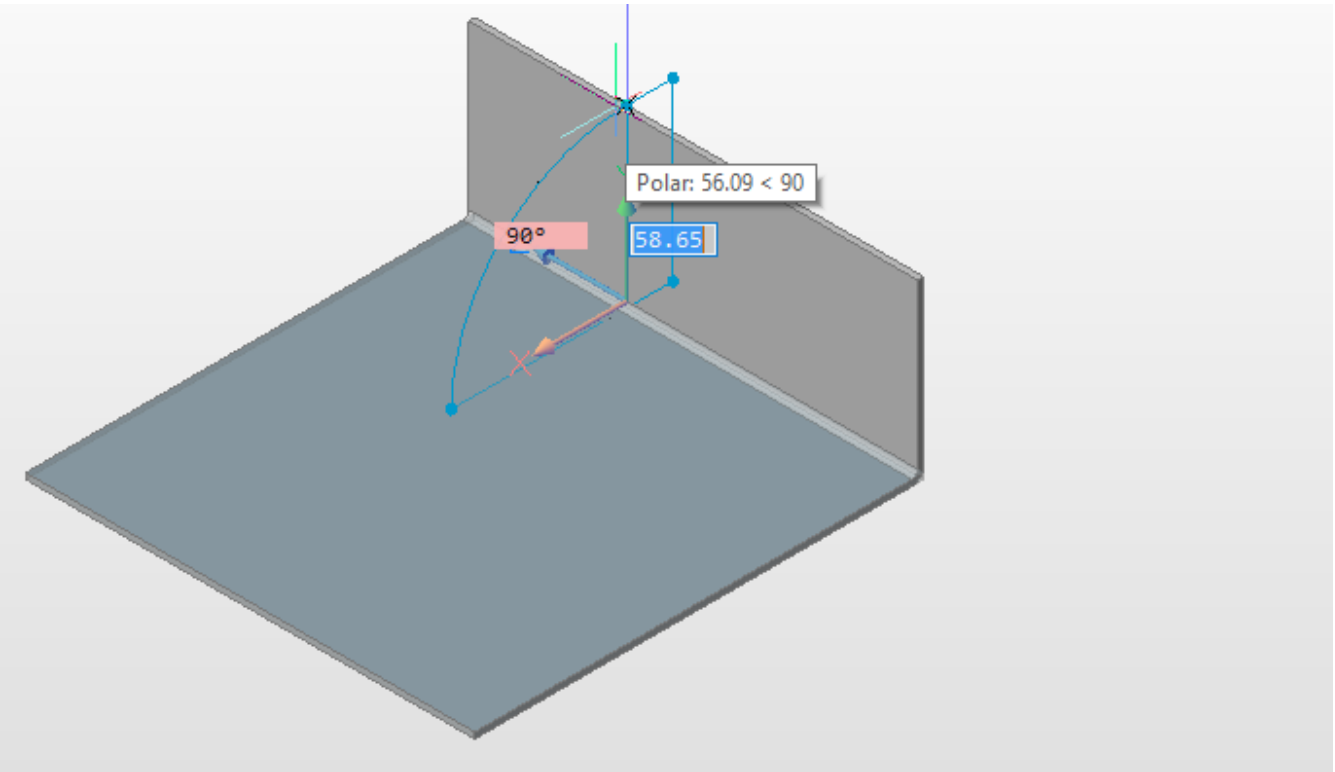

Figure 3.451

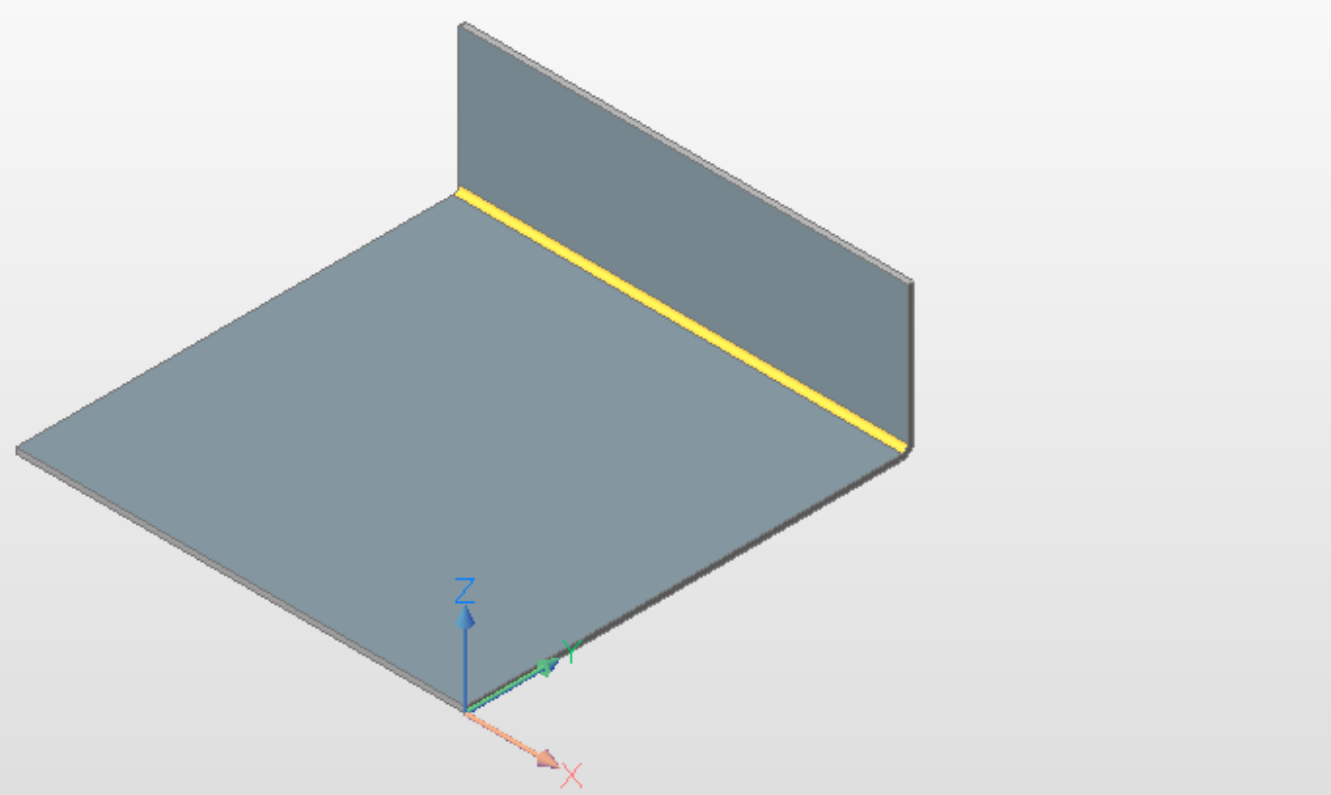

Figure 3.452

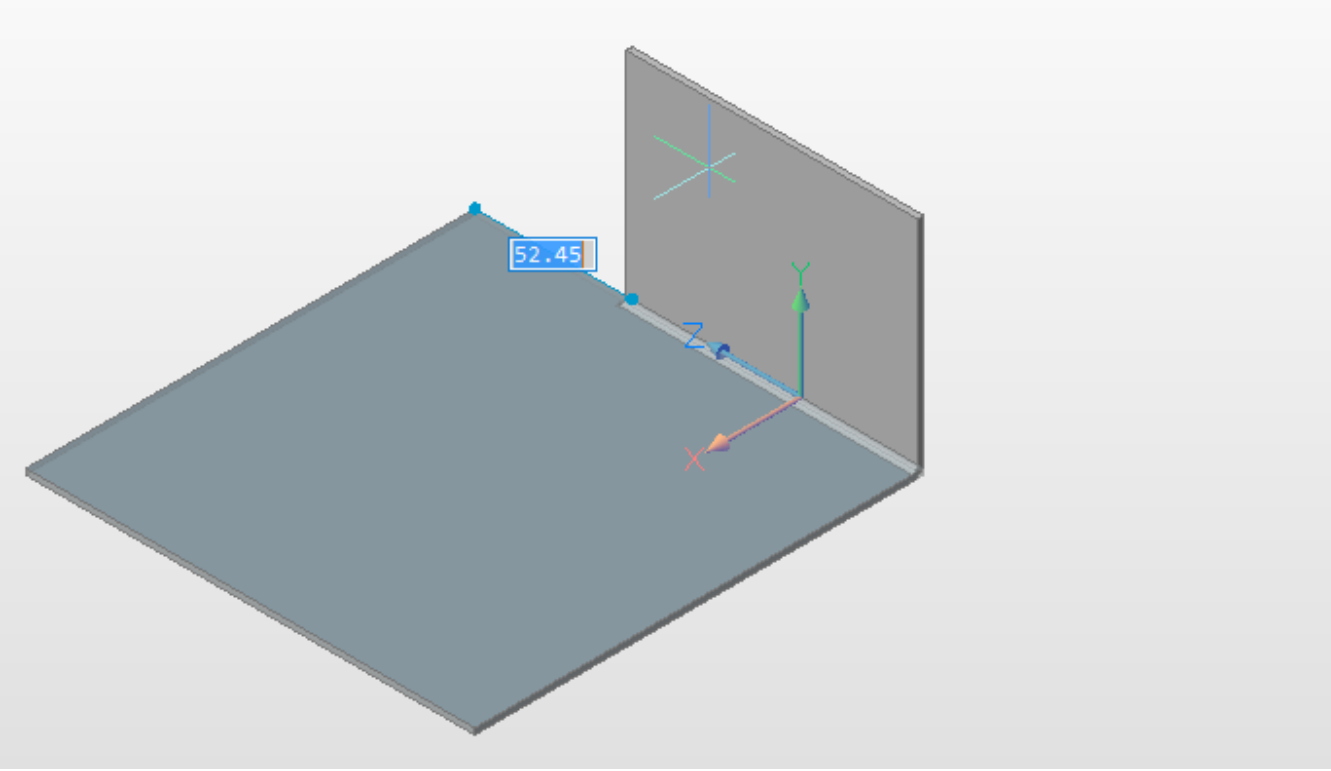

Figure 3.453

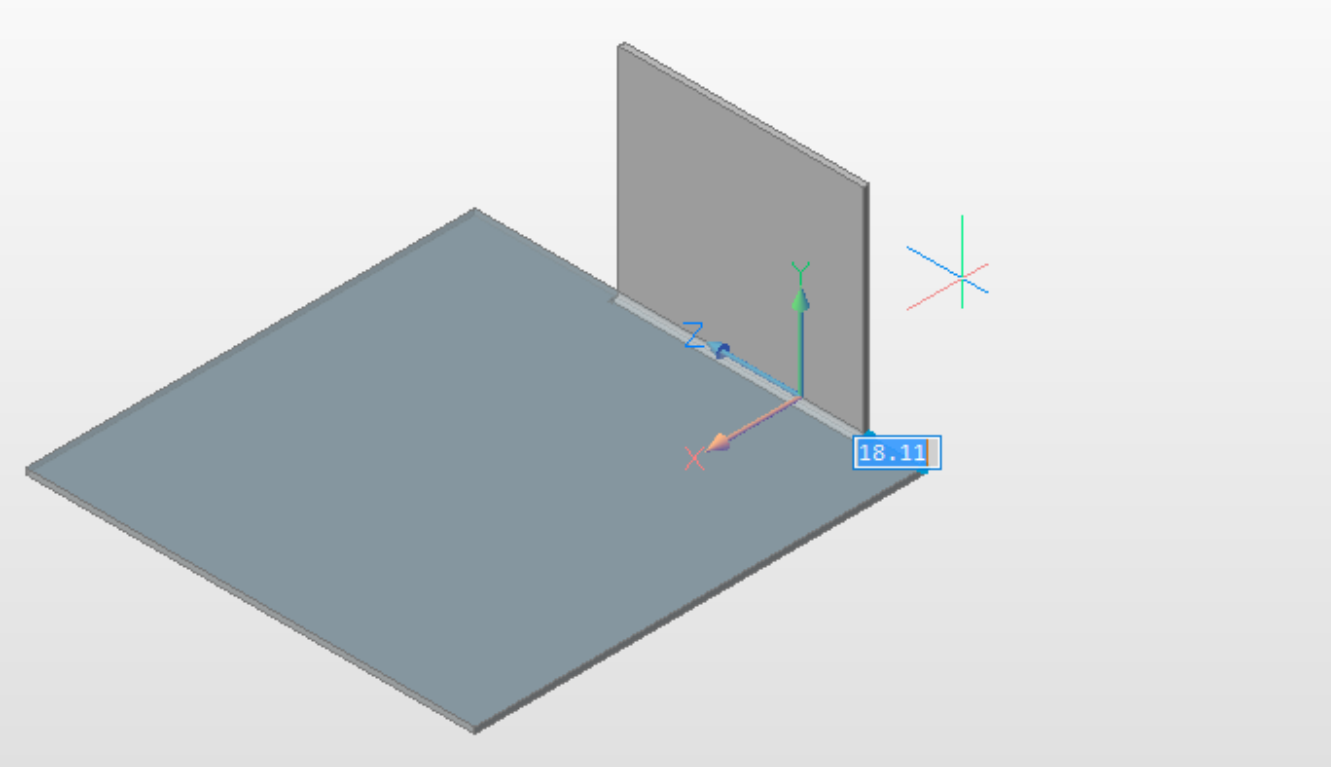

Figure 3.454

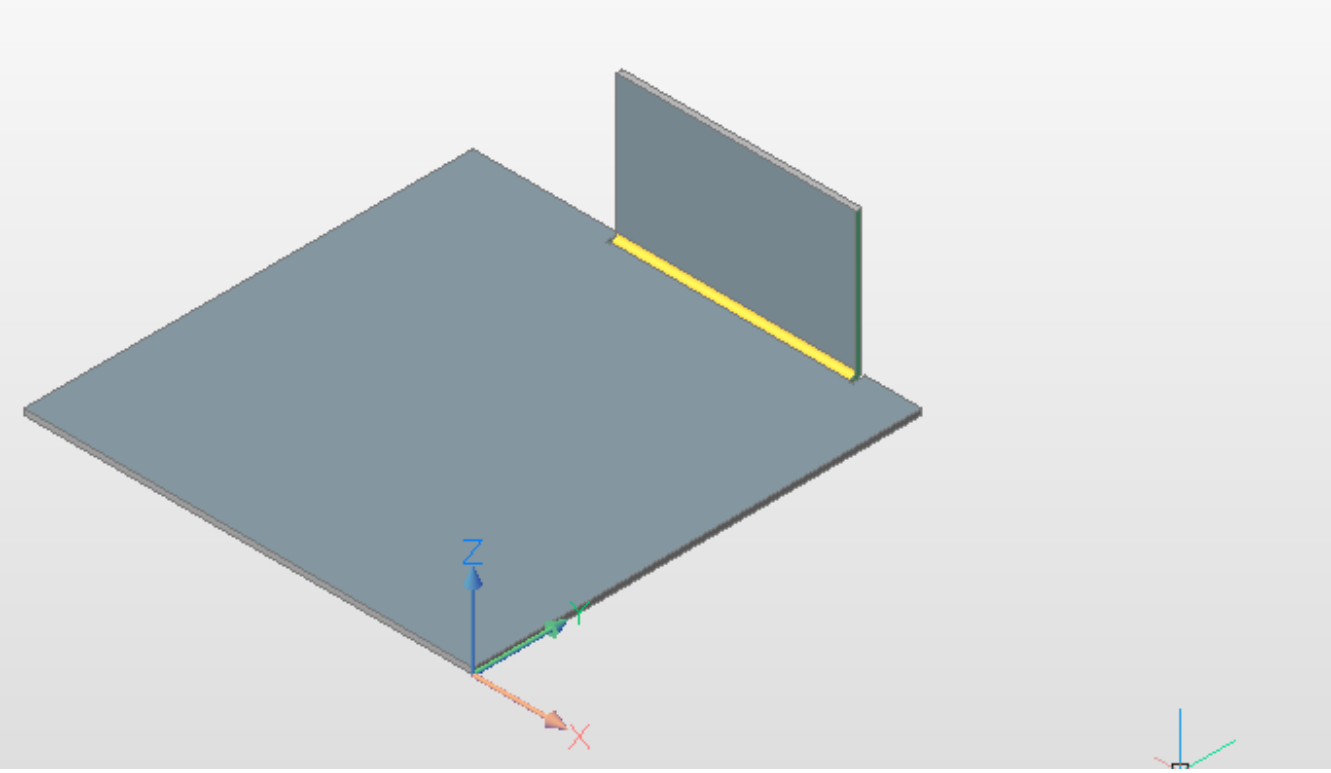
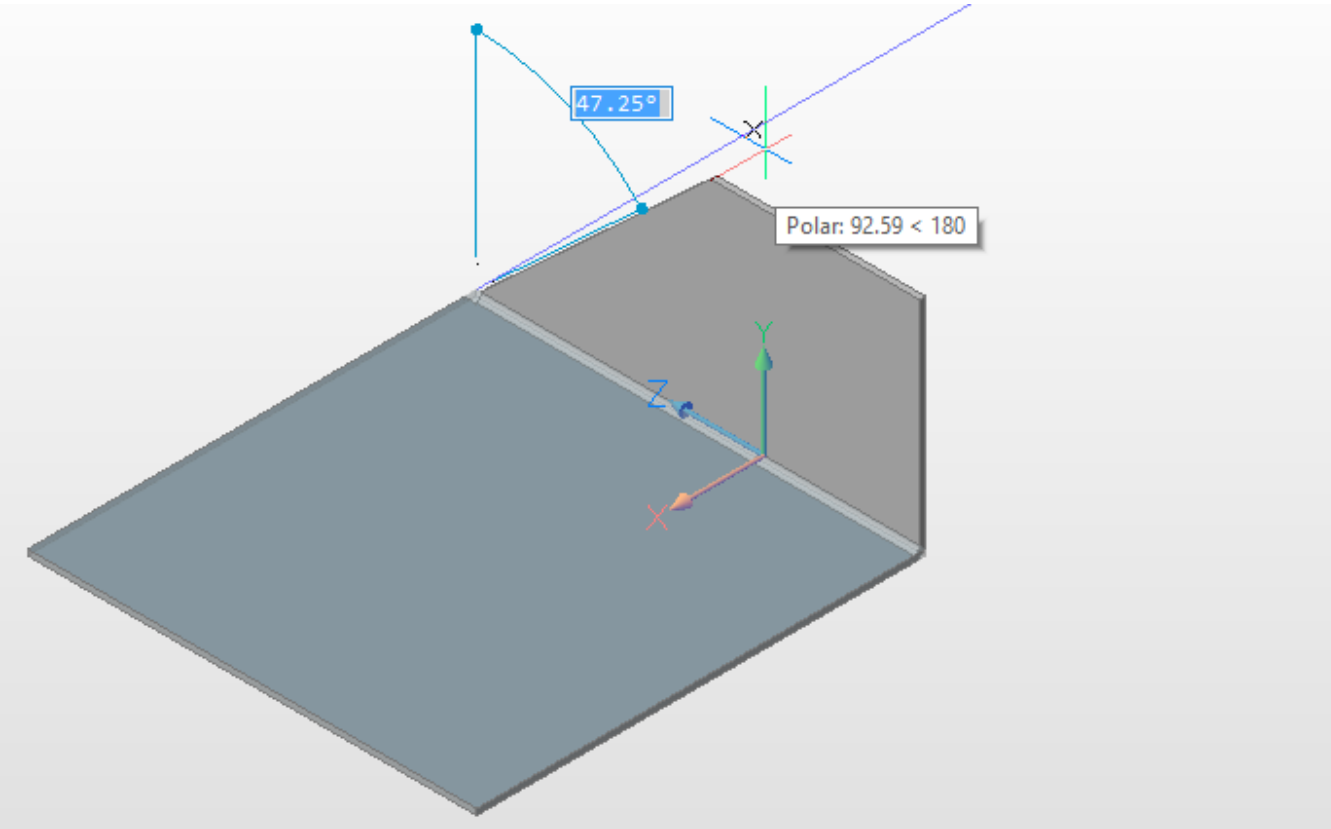


Create Edge Flange With Taper Angle(s)

You can create trapezoidal edge flanges with the **Taper angle** option of SmFlangeEdge (6.28.14) command: (3.455 on the facing page) (3.456 on page 3066)

Figure 3.455



(3.457 on the following page)

Figure 3.456

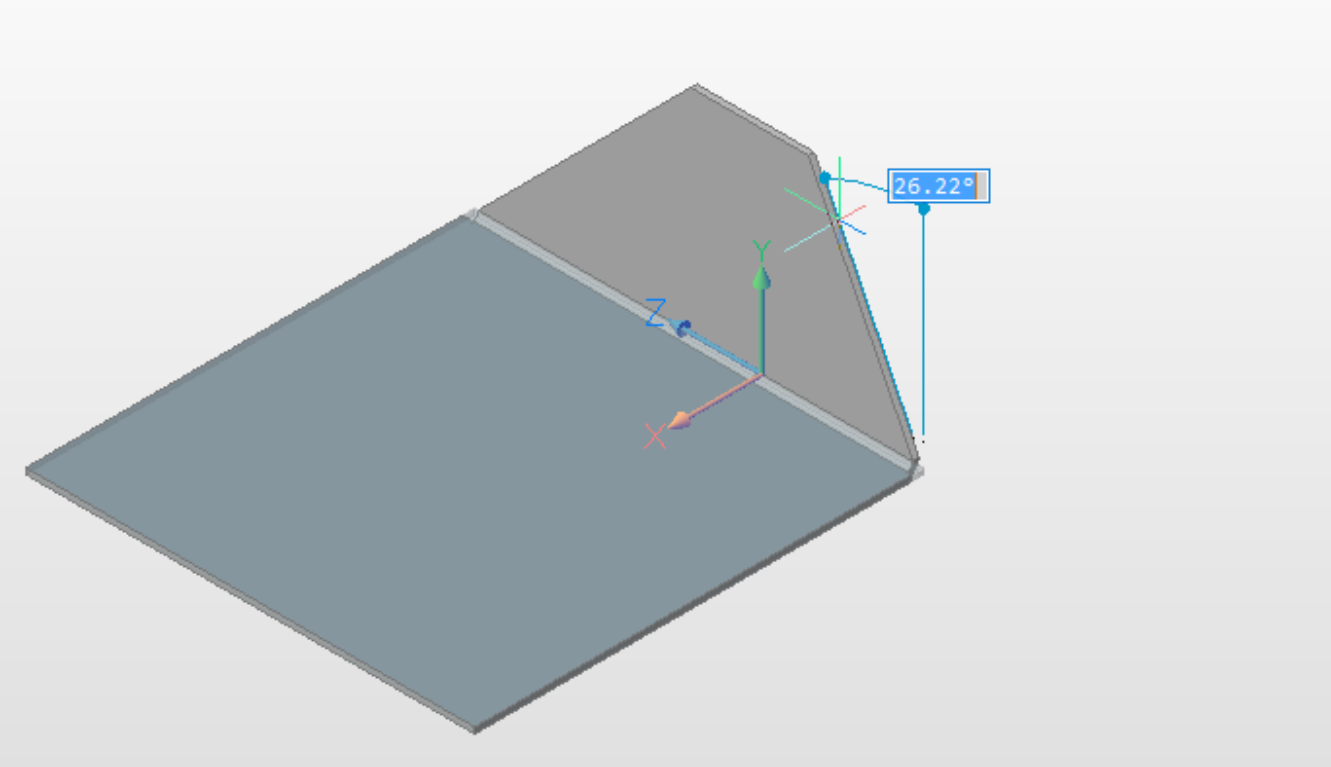


Figure 3.457

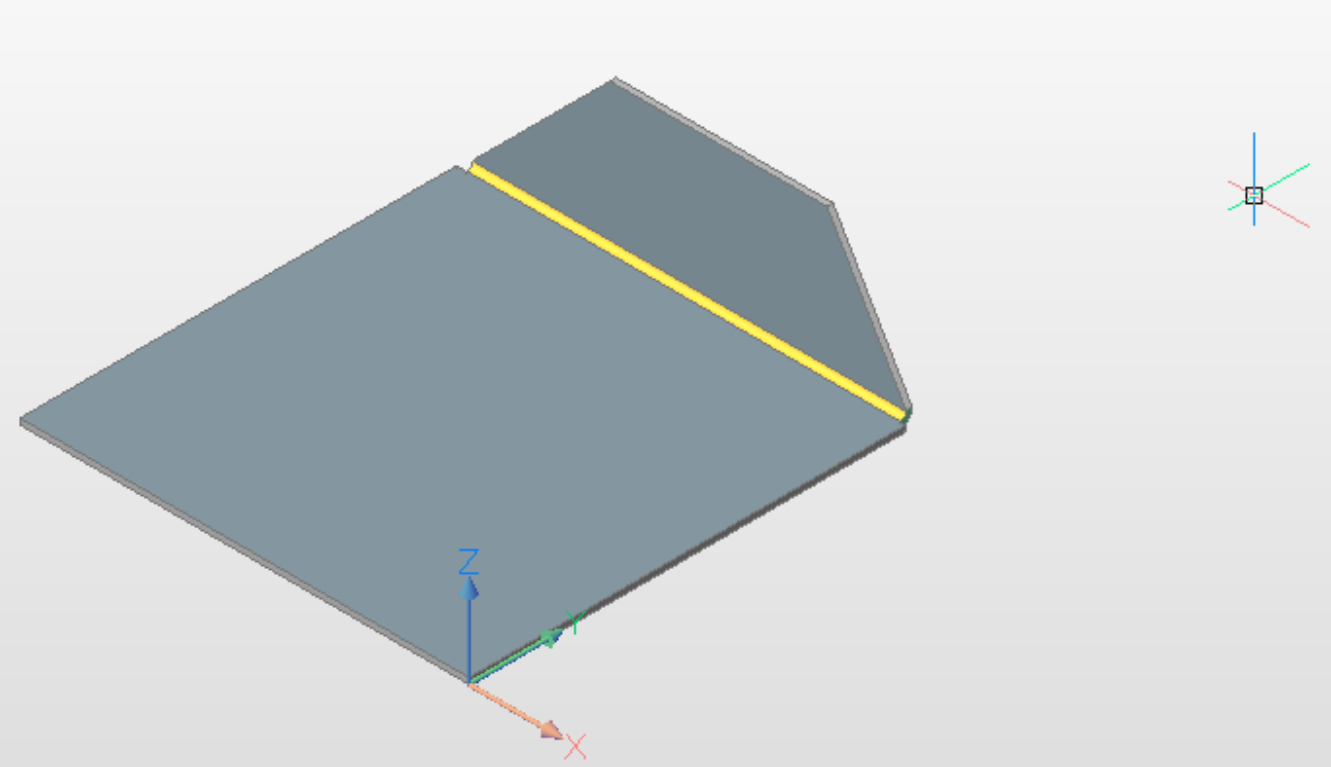

Create Multiple Flanges by Extruding a Polyline

There is a simple but important class of sheet metal parts which are seen as a thickened polyline if we view on the part from the "front" side: (3.458 on the next page) To create this part you can use sequential calls of SmFlangeEdge (6.28.14) command **OR** you can draw a polyline and use DmExtrude (6.12.14) followed by DmThicken (6.12.30), SmConvert (6.28.4), and SmBendCreate (6.28.3). However, there is a better way! BricsCAD gives you the possibility to draw a part in a complex assembly with other parts so that it does not interfere with other entities in the assembly. (3.459 on the following page) You can control the thickening direction of every line segment individually with SmExtrude (6.28.9).

1. Draw (6.24.27) a polyline that represents a sketch of the future sheet metal part: (3.460 on page 3069) Do one of the following:

   - Click the **Extrude Polyline** tool button () on the **Sheet Metal** toolbar.
   - Choose **Extrude Polyline** in the **Sheet Metal** menu.
   - Choose **Extrude Polyline** in the **Sheet Metal** group of the Quad (2.3.3) cursor menu:(3.461 on page 3070)

2. Hover mouse to select extrusion height or enter the value and press Enter to accept:(3.462 on page 3071) The body is created and the extensions are respected. The sheet metal part does not exceed the dimensions of the original polyline. The behavior is the same even with different thicknesses:

(3.477 on page 3086)	(3.478 on page 3087)	(3.479 on page 3088)
Thickness 1 mm	Thickness 2 mm	Thickness 4 mm

Note the policy of preserving external dimensions also works for sheet metal parts created by other workflows: sequential flange building with SmFlangeEdge (6.28.14), part bends with SmFlangeBend (6.28.11) and sheet metal design recognition with SmConvert (6.28.4). If you want to change the extrusion direction for a flange, apply the SmFlip (6.28.25) command to it.

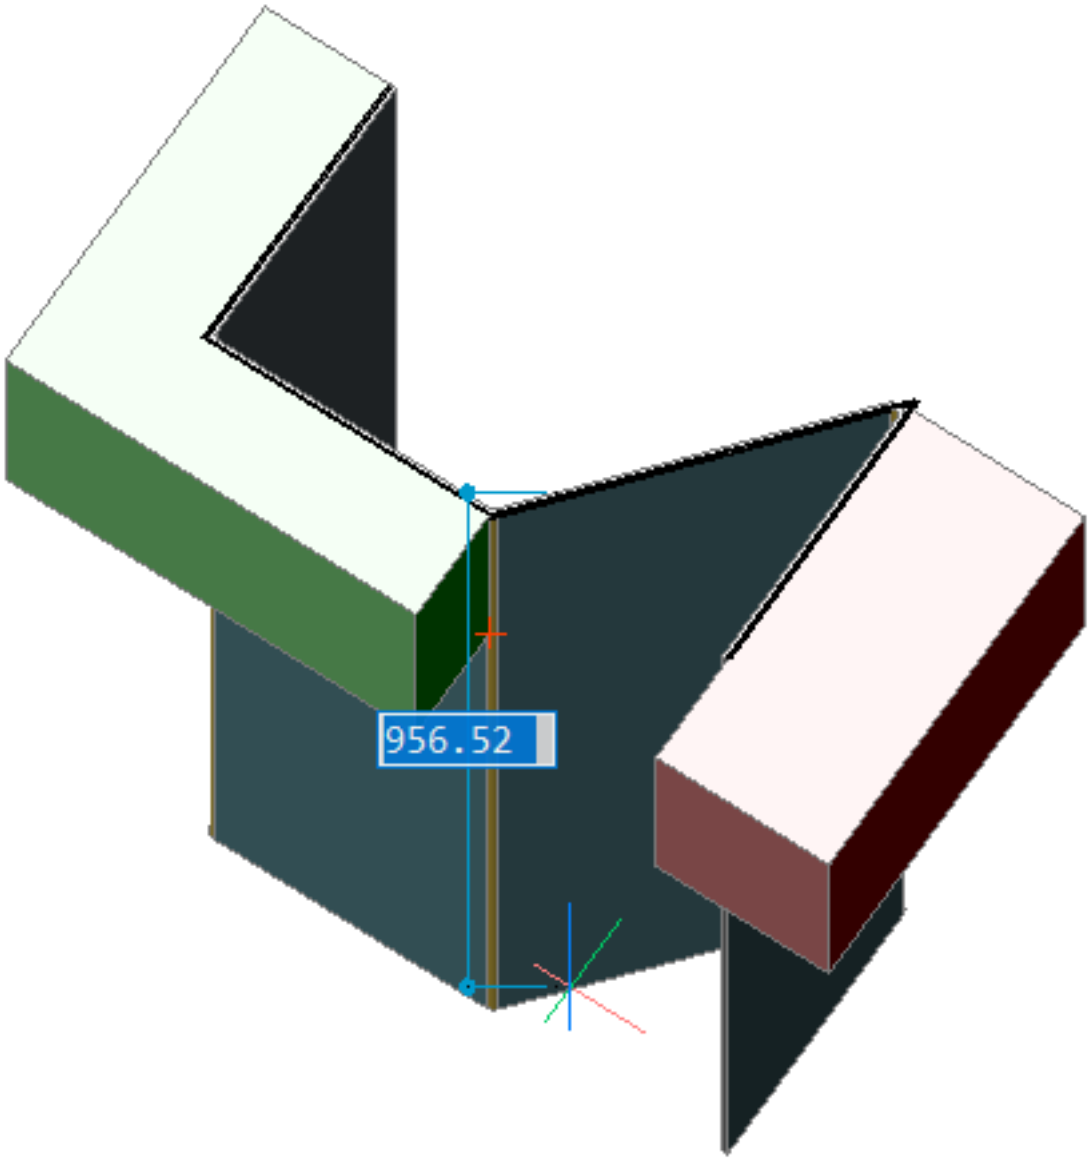
Figure 3.462



Extrude a Contour to Create a Flange

SmFlangeContour (6.28.13) command allows you to extrude a given contour to a new flange and attach it to the model. It can be thought of as a sequence of the SmFlangeBase (6.28.10), SmFlangeConnect (6.28.12), and SmBendCreate (6.28.3) commands. In reality, it intelligently chooses the thickness faces on selected flanges and connects them with the thickness faces on a new flange. Do one of the following:

- Click the **Create Flange from closed Contour** tool button () on the **Sheet Metal** toolbar.
- Choose **Create Flange from Contour** in the **Sheet Metal** menu.
- Choose **Create Flange from Contour** in the **Sheet Metal** group of the Quad (2.3.3) cursor menu:

(3.463 on the next page) Once all the required flanges are selected, click on the contour: (3.464 on page 3074) The command creates a new flange and merges it with the selected flanges on the part: (3.465 on page 3075)

Figure 3.463

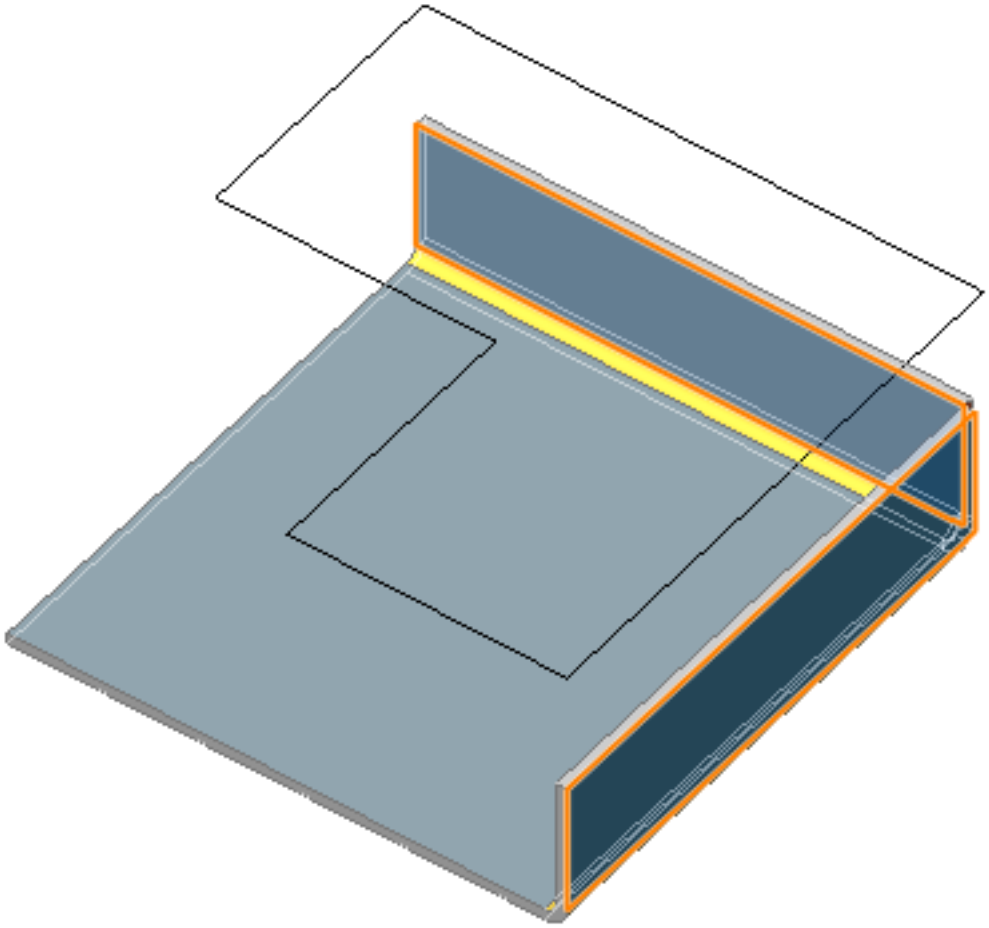


Figure 3.464

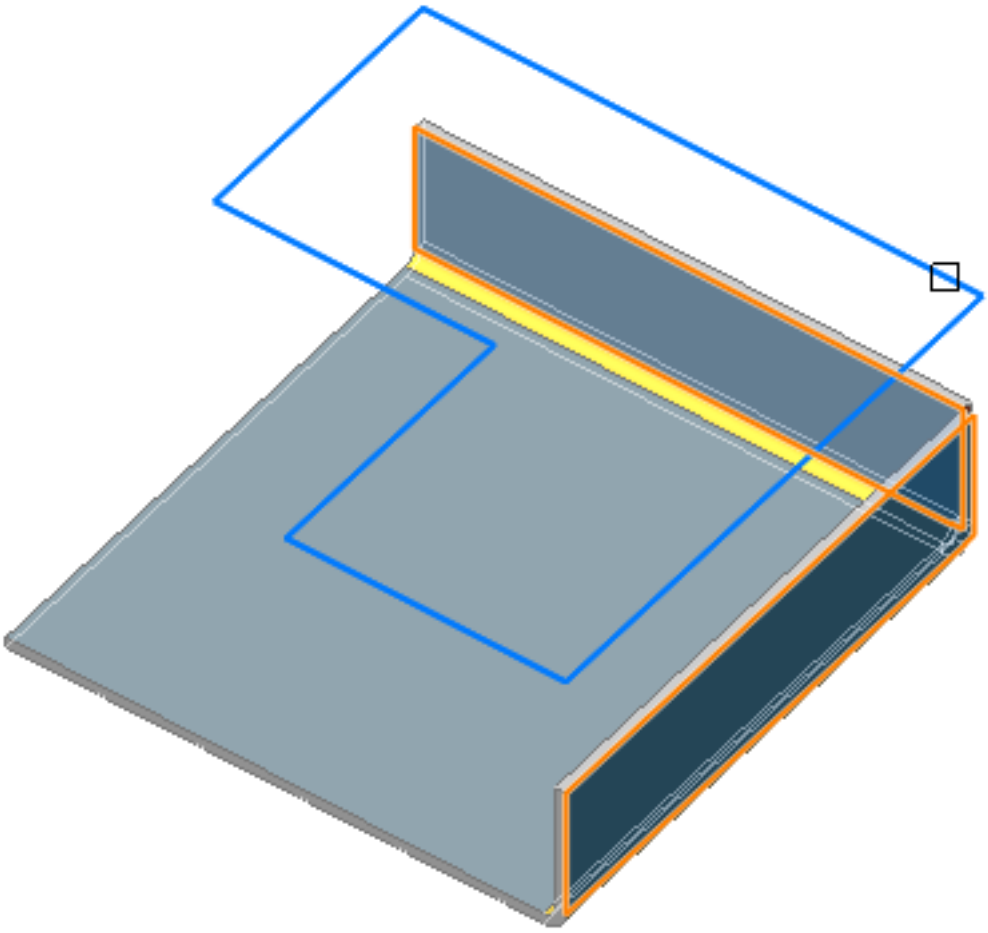

Figure 3.465

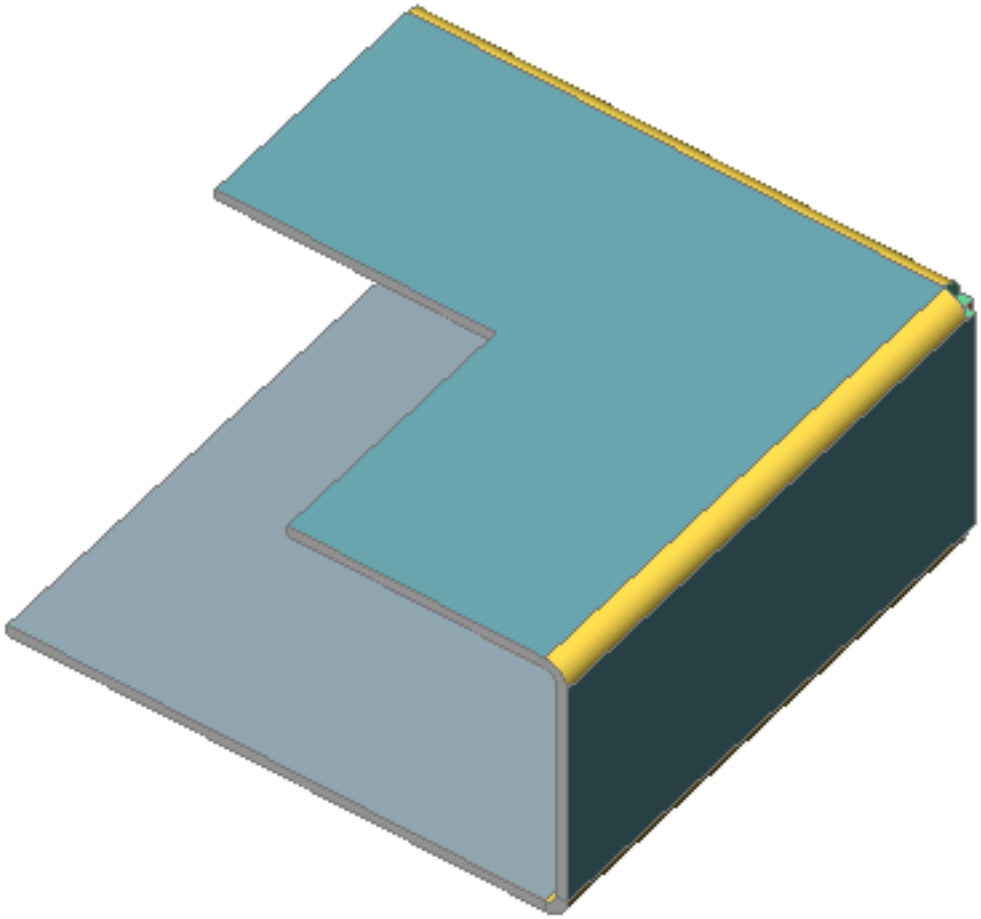


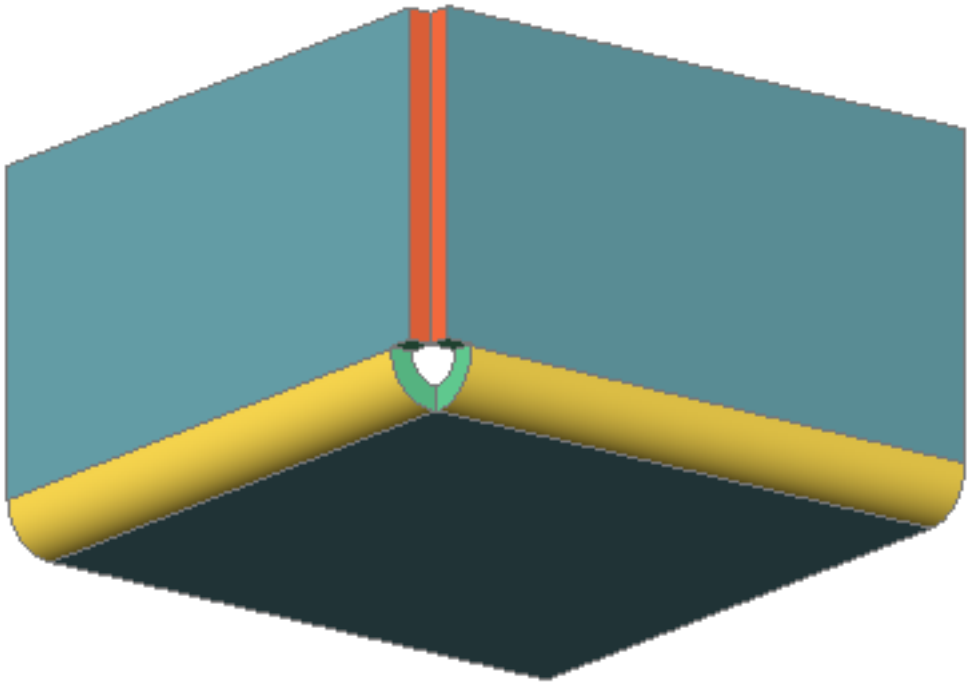
Bends, Corner Reliefs and Junctions

When you pull an edge flange with the SmFlangeEdge (6.28.14) command, a bend feature between the edge flange and the base flange is automatically created. A corner relief feature is automatically created in a corner where three flanges meet together. This operation also creates a junction between two flanges, which are not connected with a bend. (3.466 on the facing page)

Please read 'Working with Bends and Junctions (3.9.16)' to learn more about these features.

Tutorial: Design from scratch in BricsCAD Sheet Metal Click here (3.8.15) to watch

Figure 3.466



Create Multiple Flanges

You can create several flanges simultaneously. Do one of the following:

- Select multiple edges, then choose **Create Flange Edge** () in the **Sheet Metal** command group in the Quad (2.3.3).
- Launch the SmFlangeEdge (6.28.14) command and select multiple edges.

(3.467 on the next page)

- Create the edges dynamically. Define the angle and the flange height using the dynamic entry fields. Hit the **TAB** key to switch between the **Angle** and the **Distance** field. (3.468 on the following page)
- Select the inside edges of the newly created flanges: (3.469 on page 3079)
- Create the flanges. The command automatically calculates the intersection of the flanges and creates a junction or miter features. At 90 degrees miters are created: (3.470 on page 3079) For other angles junctions are created: (3.471 on page 3080) In all cases material conflicts are avoided: (3.472 on page 3081)

If the flanges are created externally, use the **Toggle** option (as well as widget control) to control the connection type for miters: (3.473 on page 3082) (3.474 on page 3083) and junctions: (3.475 on page 3084) (3.476 on page 3085)

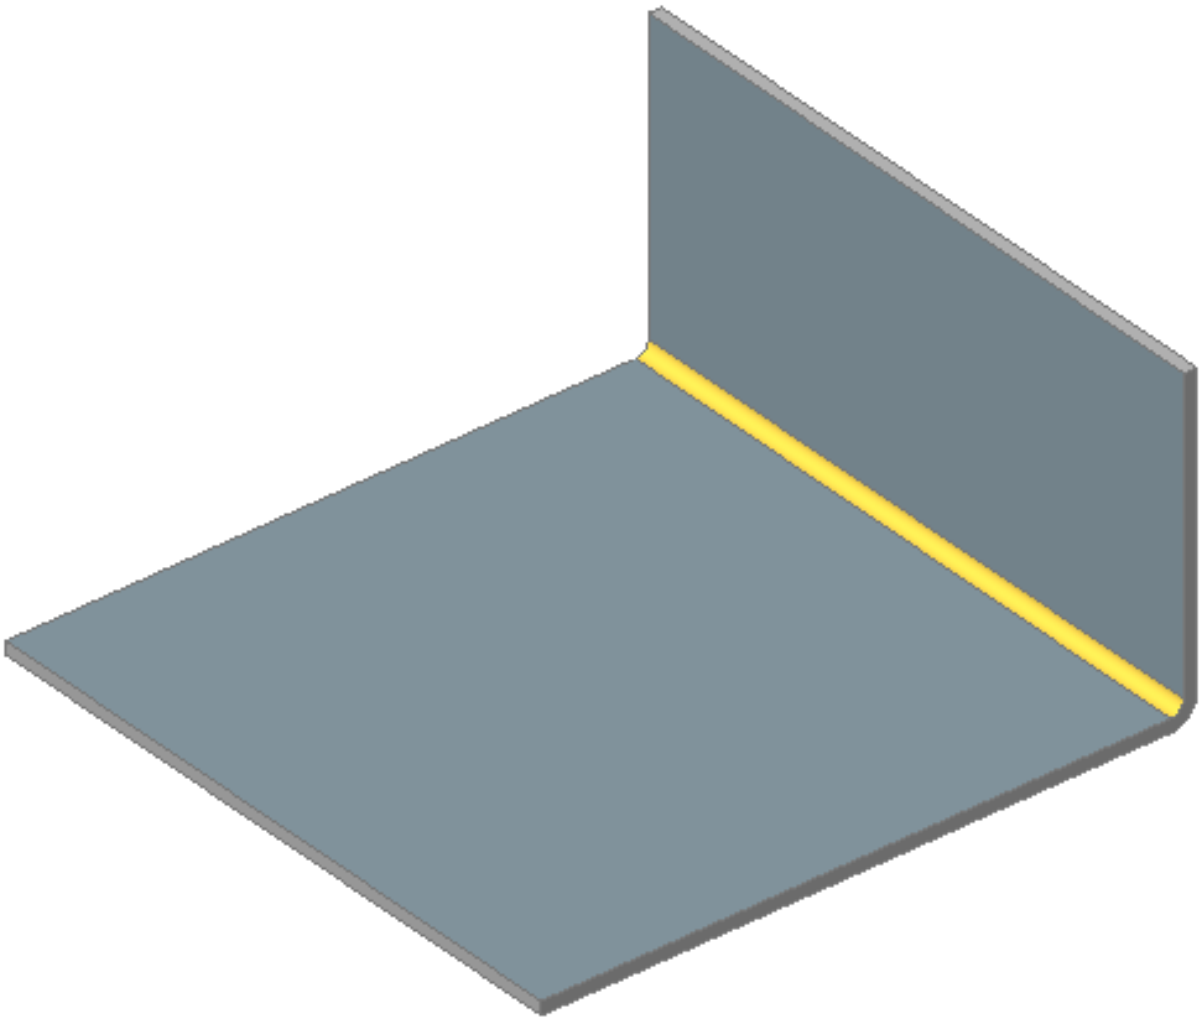
3.9.15 Modifying Flanges

BricsCAD provides several tools to modify flanges in sheet metal parts. These tools can be applied consistently to any part - independent of its design history. In this article we use Solid Modeling (3.5.4) tools and specific sheet metal tools. Almost all solid modeling tools apply to sheet metal parts, while preserving the design intelligence provided by Sheet Metal Features (3.9.3).

To change flange size and shape

On a given simple model we will apply several Solid Modeling (3.5.4) operations in order to modify the shape of its flanges. Please note that we work on thickness faces of the model only: (3.480 on the next page)

Figure 3.480



To stretch flanges

1. Hover over the thickness face, then the select PushPull (6.12.25) in the **Model** command group in the Quad. (3.481 on the following page)
2. Drag the face then right click. (3.482 on page 3093)
3. The changes will be applied to the part, the flange is stretched over the specified distance.

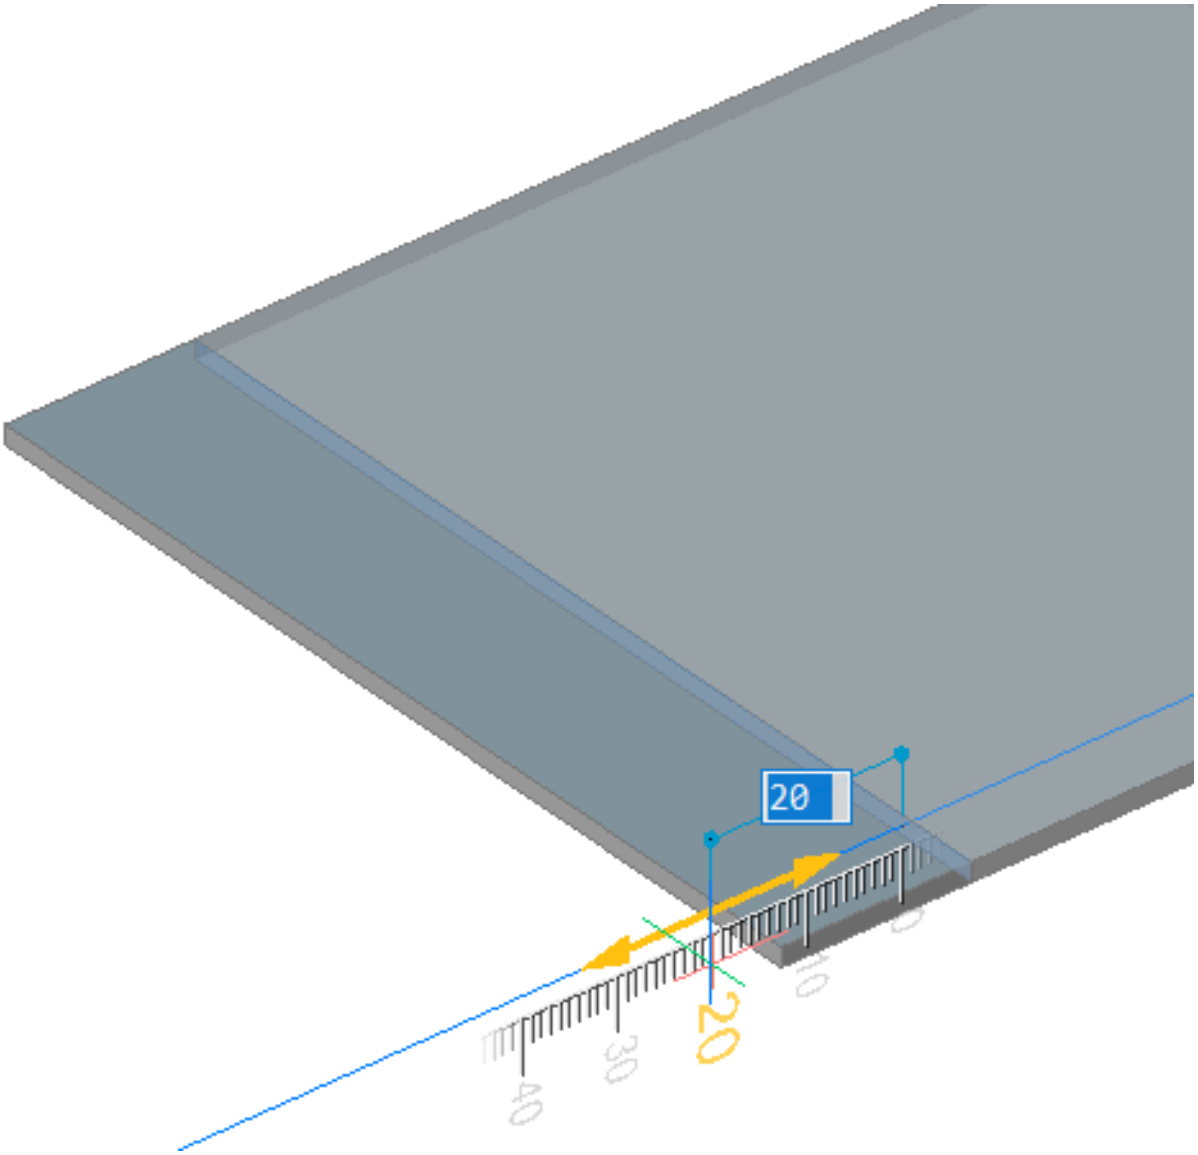
Figure 3.482



To rotate a thickness face

1. Hover over the face and choose Rotate (6.12.24) in the **Model** command group in the Quad (2.3.3). (3.483 on the facing page)
2. Specify the rotation axis, base point and angle (for more details see the DmRotate (6.12.24) article in the Command Reference): (3.484 on page 3096)
3. We will now fillet the sharp edges. Hover over a thickness edge and choose **Same Length Edges** () in the **Select** command group in the Quad (2.3.3). (3.485 on page 3097)
4. Press Enter. Edges with the same length are selected. (3.486 on page 3098)
5. Choose **Fillet** in the **Model** command group in the Quad (2.3.3).
6. Specify the desired fillet radius: (3.487 on page 3099) (3.488 on page 3100)

To make a hole in a flange

1. Create 4 circles as indicated in the image below. Use the Snap to Center entity snap to define the center points. (3.489 on the following page)
2. Select the circles.
3. Choose **Solid extrude** in the **Model** command group in the Quad (2.3.3). (3.490 on the next page)
4. Move the cursor to create the holes. (3.491 on page 3103) (3.492 on page 3103)

See also Working with Form and Rib Features (3.9.25) and Working with Hole Features (3.9.23) articles to create holes.

Figure 3.489

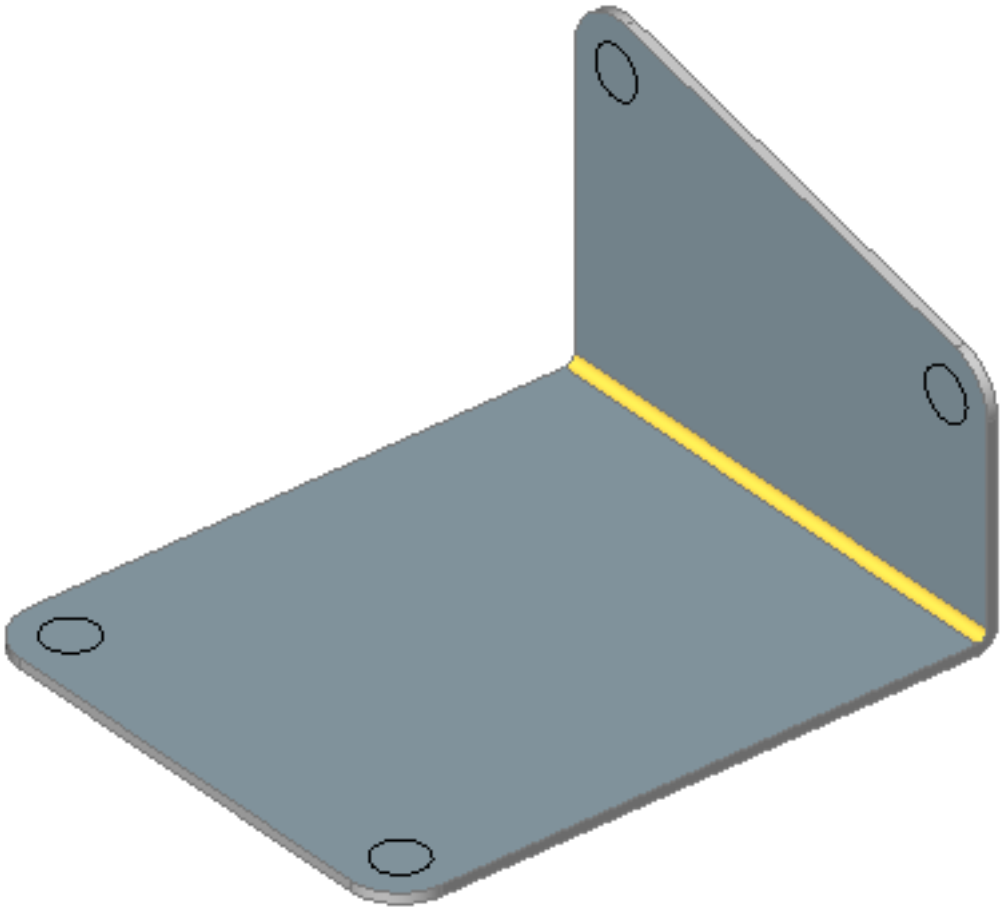

Figure 3.490

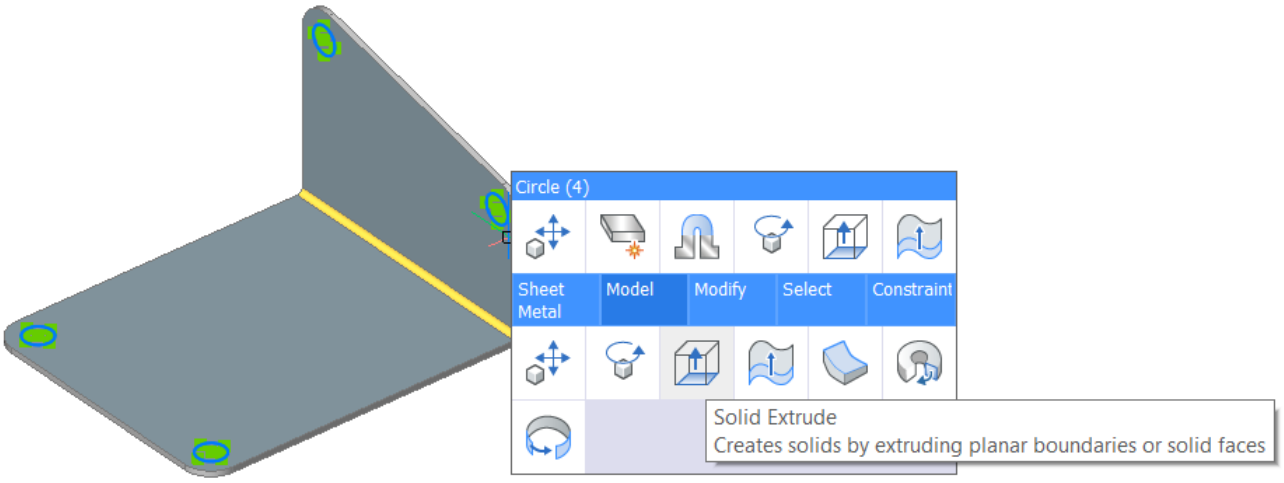

Figure 3.491

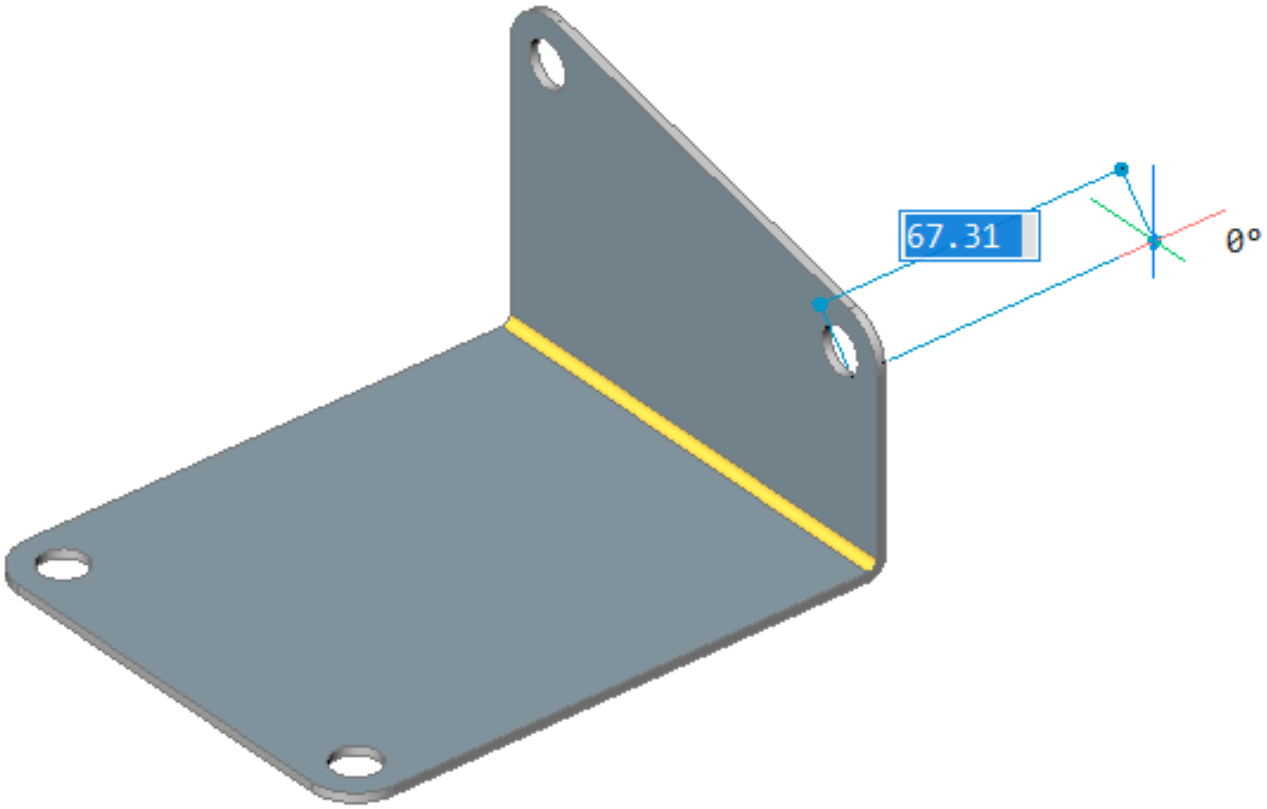

Figure 3.492

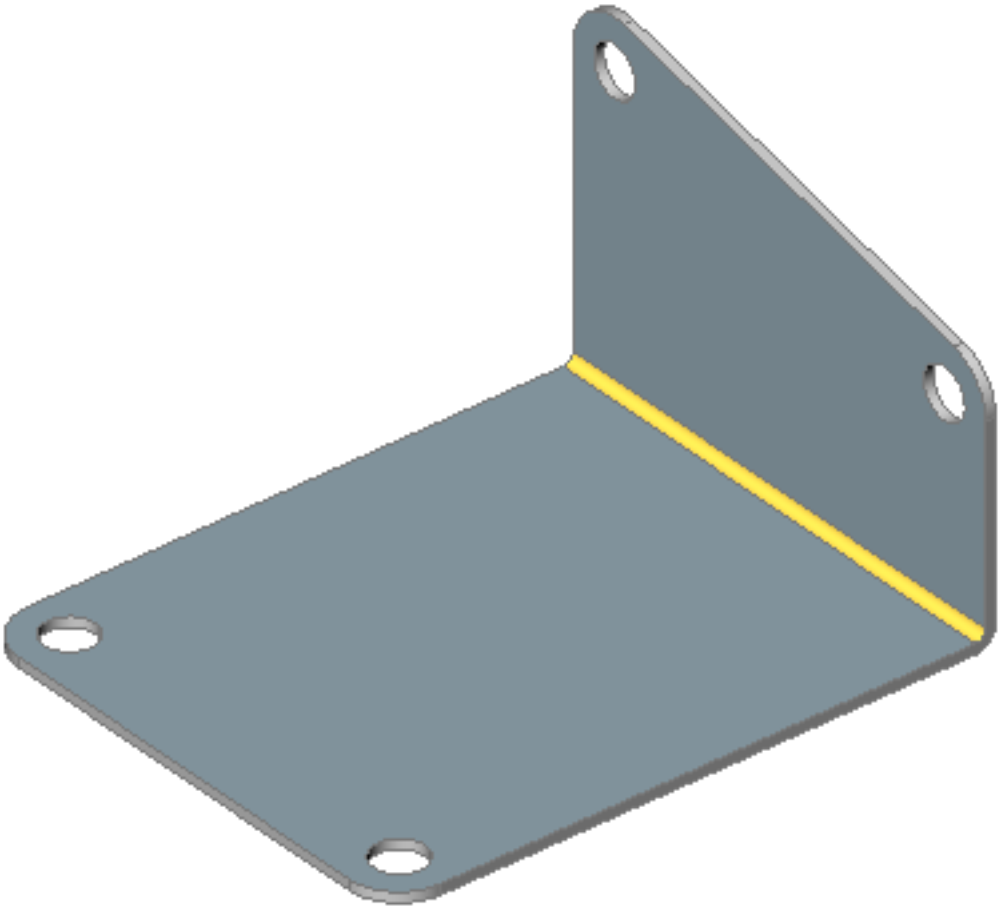

To move a flange

1. Do one of the following:

   - Click the **Push/Pull** tool button ( ) on the **Direct Modeling** toolbar.
   - Choose **Direct Modeling > Push/Pull** in the **Model** menu.
   - Choose **Push/Pull** ( ) in the **Edit** panel of the **Sheet Metal** tab in the ribbon.
   - Call DmPushPull (6.12.25) command for given face.
   - Hover over the face you want to move and choose **Push/Pull** in the **Model** command group in the Quad (2.3.3).

   (3.493 on the facing page)

2. Select new position of the flange. Note that due to presence of Sheet Metal Features (3.9.3), part thickness is preserved. (3.494 on the next page) (3.495 on page 3106)

Figure 3.493

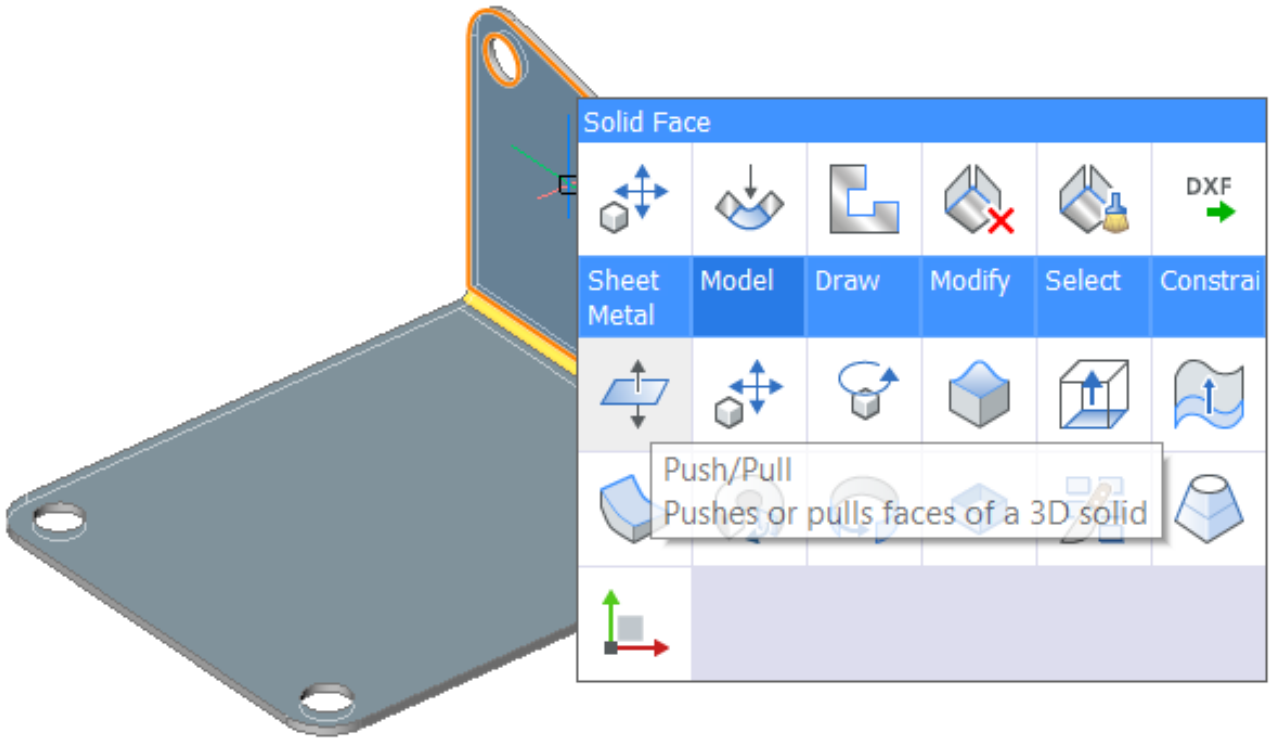

Figure 3.494

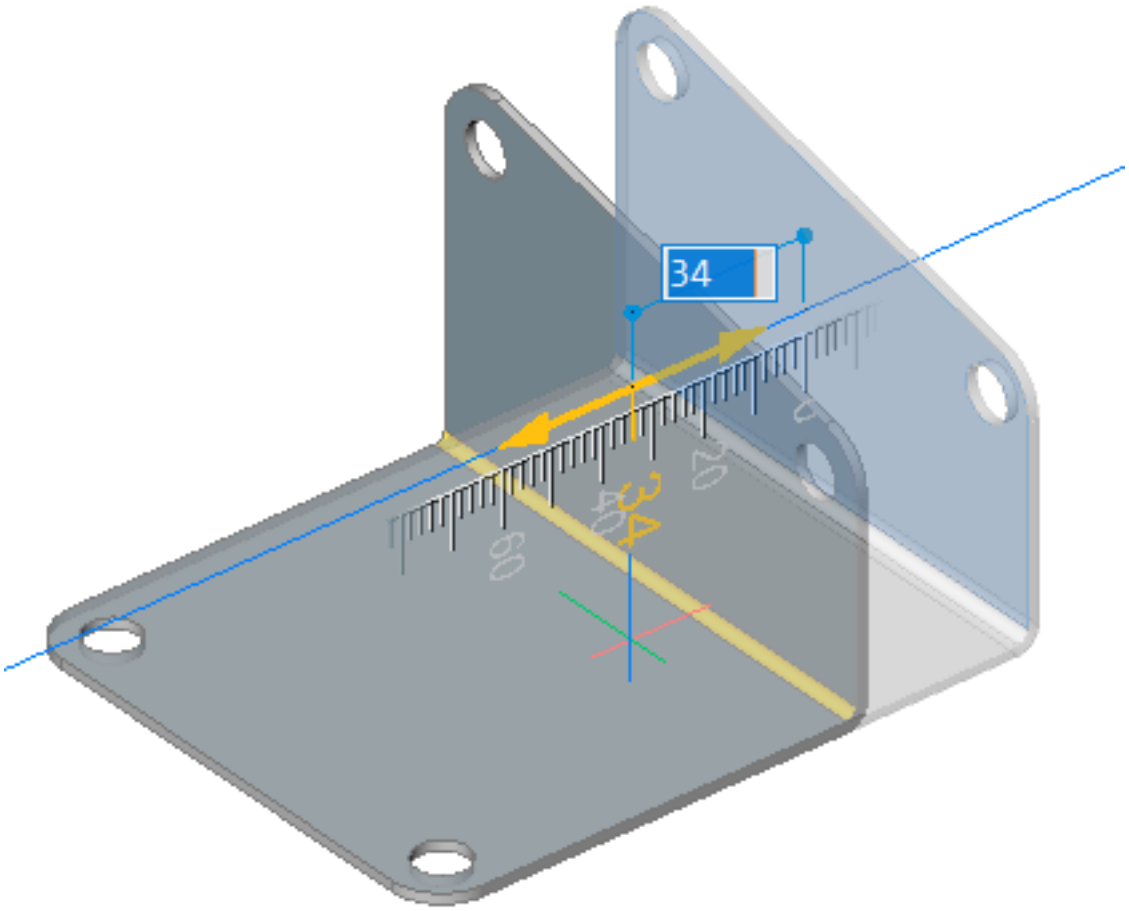

Figure 3.495

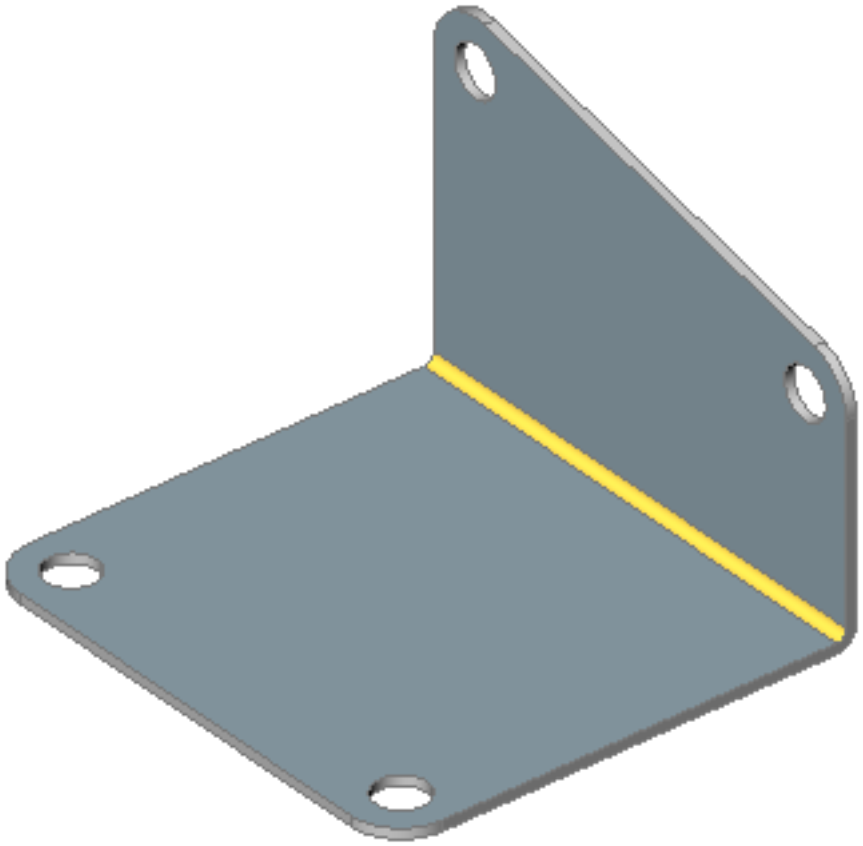

To rotate a flange

Although it is possible to rotate a flange using the DmRotate (6.12.24) command ( ), it is recommended to use SmFlangeRotate (6.28.15) ( ) instead, because this command automatically selects the rotation axis to respect the design intent of the sheet metal part.

1. Launch the SmFlangeRotate (6.28.15) ( ) command. **You are prompted: Select a flange face to rotate:** Flange faces under the cursor highlight.
2. Click to select a flange face. The flange rotates dynamically. A dynamic dimension displays the current angle with respect to the base flange.
3. Do one of the following:
   - Select a point.
   - Type a value in the dynamic dimension field.
   - Press the TAB key, then specify the absolute rotation angle in the dynamic dimension field.

NOTE	Wh the DmRotate (6.12.24) command is used to rotate a flange, which is connected to other flanges by junction features, these features are automatically dissolved before the rotation.

To split a flange

In some cases flanges are better split to minimize the material consumption, e.g. when a flange has a large hole, as shown in the image below: (3.496 on the next page)

1. Launch the SmSplit (6.28.30) ( ) command. **You are prompted:** Select flange or lofted bend face:
2. Select a flange face. **You are prompted:** Select lines or edges to split the flange or [use SMart split/draw a New line] <draw a New line>:
3. If no line exists yet on the flange face, right click. **You are prompted:** Start point of the line:
4. Specify the start point of the line. **You are prompted:** End point of the line:

Figure 3.496

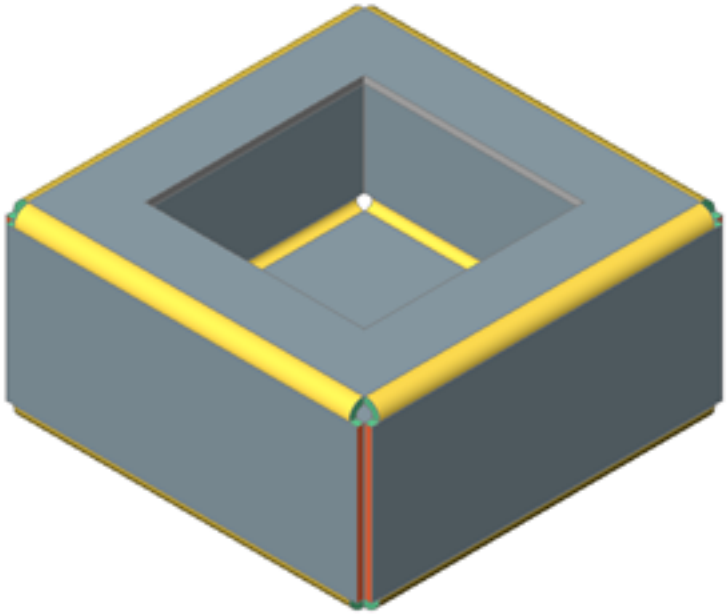

Figure 3.497

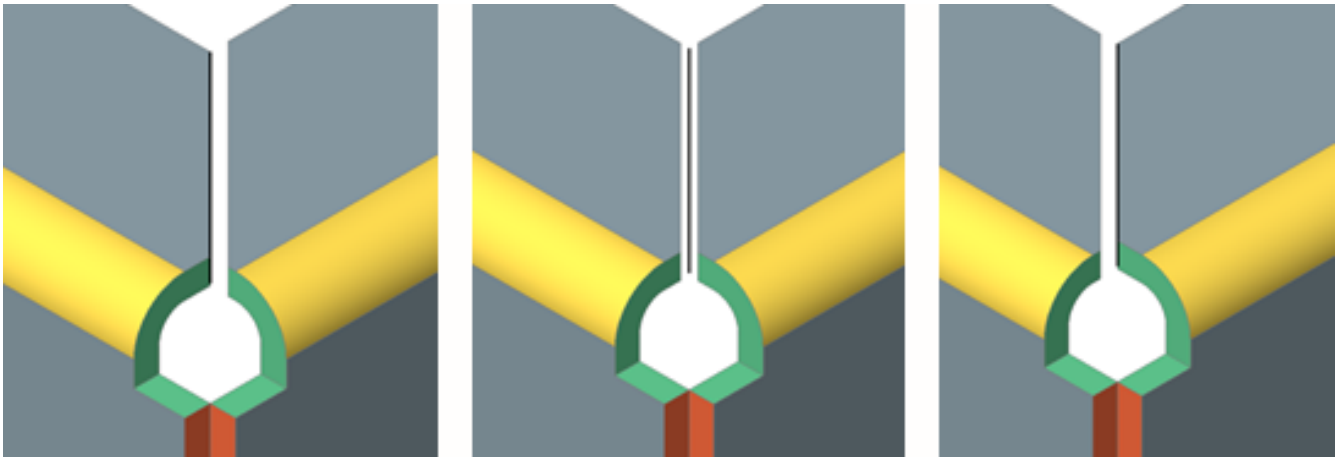


Smart tools to split a flange

The scenario below illustrates the other capabilities of the SmSplit (6.28.30) command:

- Smart split by selecting a single vertex in the corner.
- Split off the bend and convert the part adjacent to the corner into a junction. (3.498 on the next page)

1. Do one of the following:

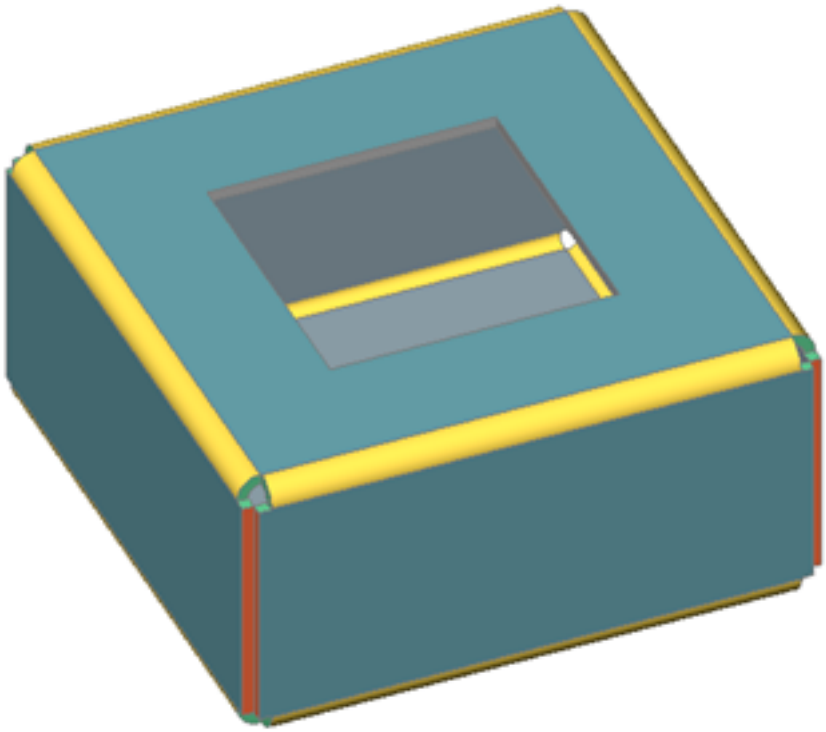
   - Click the **Use Smart Split Flange** tool () on the **Sheet Metal** ribbon tab;
   - Choose **Use Smart Split Flange** in the **Sheet Metal** menu;
   - Type **smsplit** in the command bar.

   You are prompted: Select flange or lofted bend face:

2. Select a flange face. **You are prompted:** Select lines or edges to split the flange or [use SMart split/draw a New line] <draw a New line>:

3. Select the **Use Smart split** option, then select a corner vertex: (3.499 on page 3110)

Figure 3.498



You are prompted: Make split [(6.28.30)Center/Left/Right/Accept] <Accept>: The options are: (3.500 on the next page) (3.501 on page 3111) (3.502 on page 3111) **Note:** The conversion of part of the bend into a junction is unrelated to the **Smart Split** mode.

4. To toggle the options, do one of the following:

   - Repeatedly hit the CTRL key. If TIPS (1.15.2) is ON the currently selected option is indicated in the Tips Widget.
   - Select **Center**, **Left** or **Right** in the Prompt Menu.
   - Type an option in the command bar, then press Enter.

   The flange is cut by a line, the bend is partially converted into the junction: (3.503 on page 3112)

In case of the **Center** option if Smart Features (3.9.26) are turned on, corner reliefs adjacent to the split will be converted into bend reliefs.

Figure 3.499

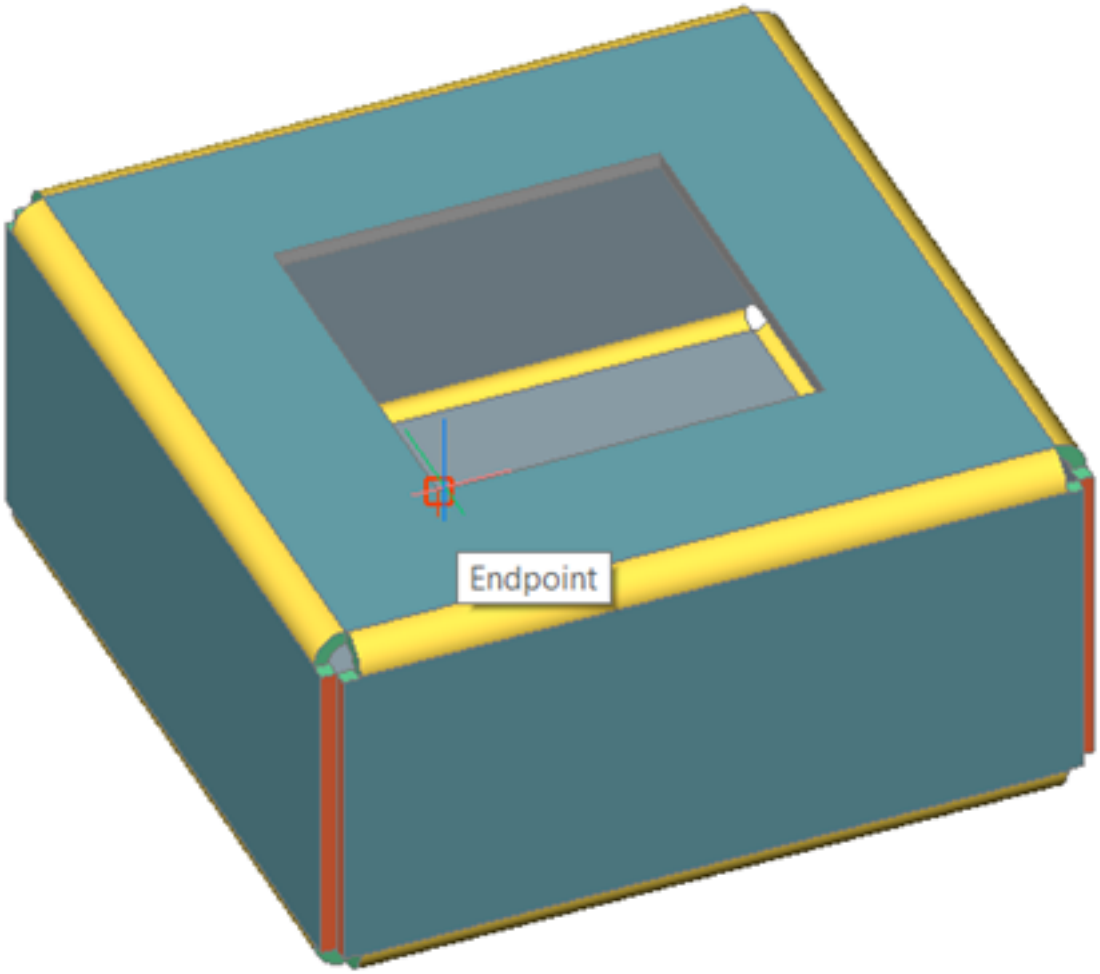


Figure 3.500

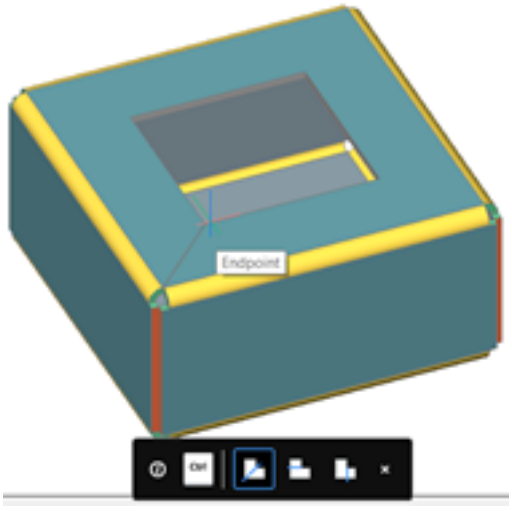

Figure 3.501

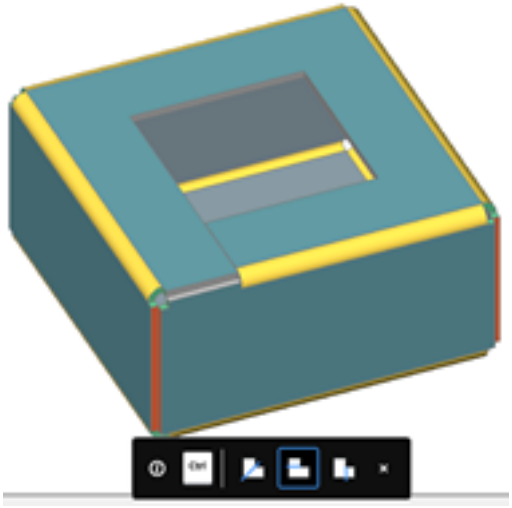

Figure 3.502

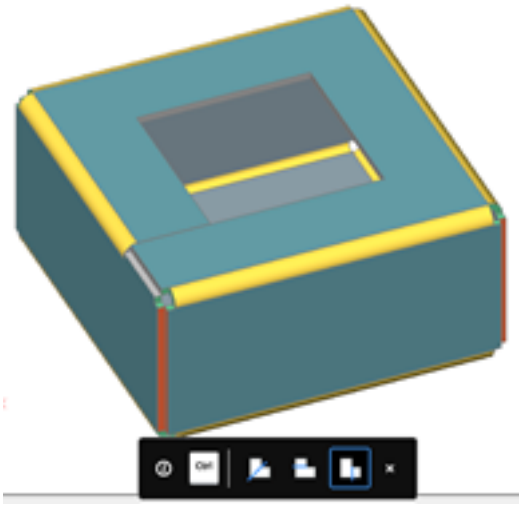

Figure 3.503

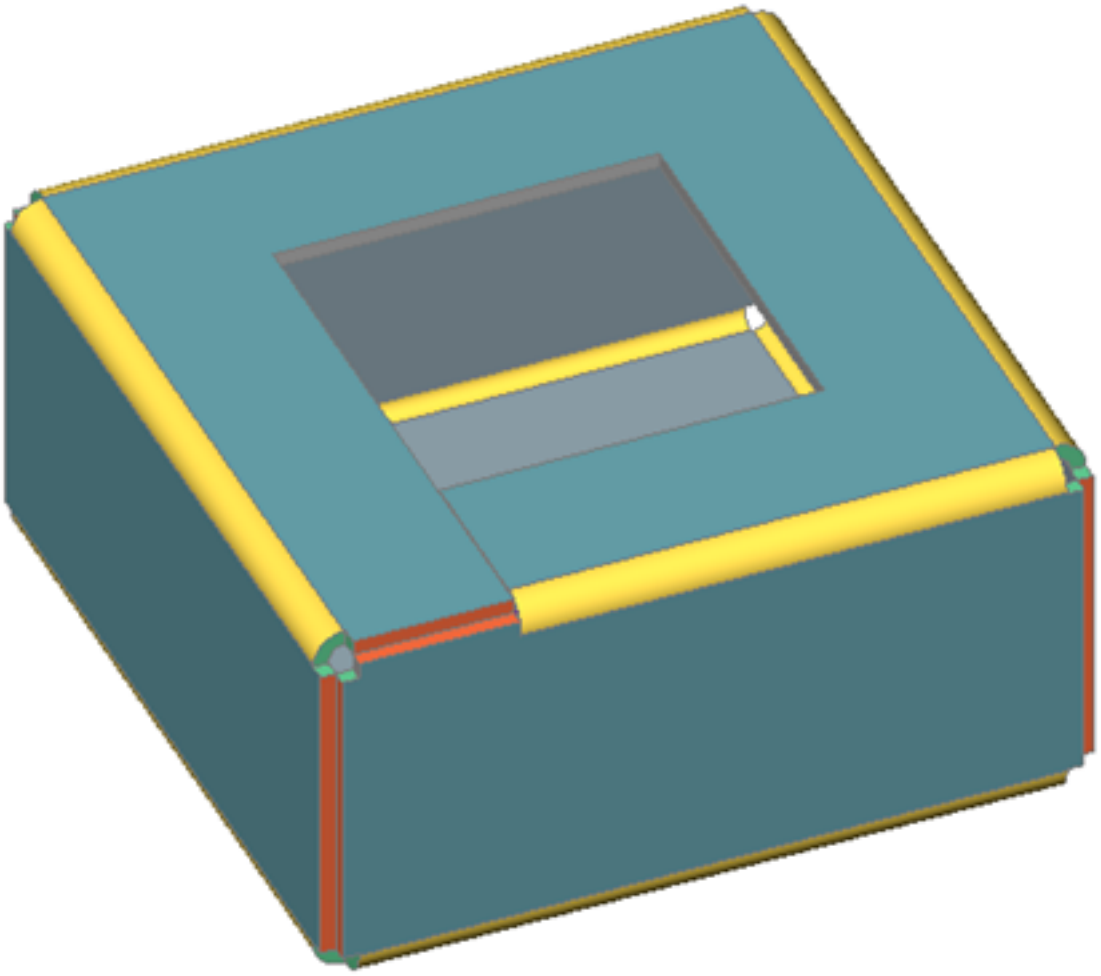

To bend a flange

The SmFlangeBend (6.28.11) command bends one or more flanges using a line. You can either draw the line first, then start the command, or use the **New Line** option of the command.

To bend multiple flanges simultaneously

1. Launch the SmFlangeBend (6.28.11) command. **You are prompted:** Select a flange face:
2. Select the flange you want to bend. **You are prompted:** Select line or edge to bend the solid or draw a [New line] <New line>:
3. Do one of the following:
   - Select a line that overlaps the flange(s) to be bent.
   - Choose the **New Line** option. **You are prompted** to draw a line on top of the flange(s) to be bent.
4. **You are prompted:** Pick a point on the side that will be moved: (3.504 on the next page) Pick a point at the side of the line you want to move. The selected part is bent dynamically. **You are prompted:**Enter bend angle or set [Radius/Switch side]:
5. (option) Type a value to define the bend angle, using the default bend radius.
6. (option) Select the **Radius** option.
   - **You are prompted:** Enter bend radius [Back] <Back>: Type a value to override the default bend radius and press Enter.
   - **You are prompted:** Enter bend angle or set [Radius/Switch side]: Type a value to define the bend angle. (3.505 on the following page)

Figure 3.504

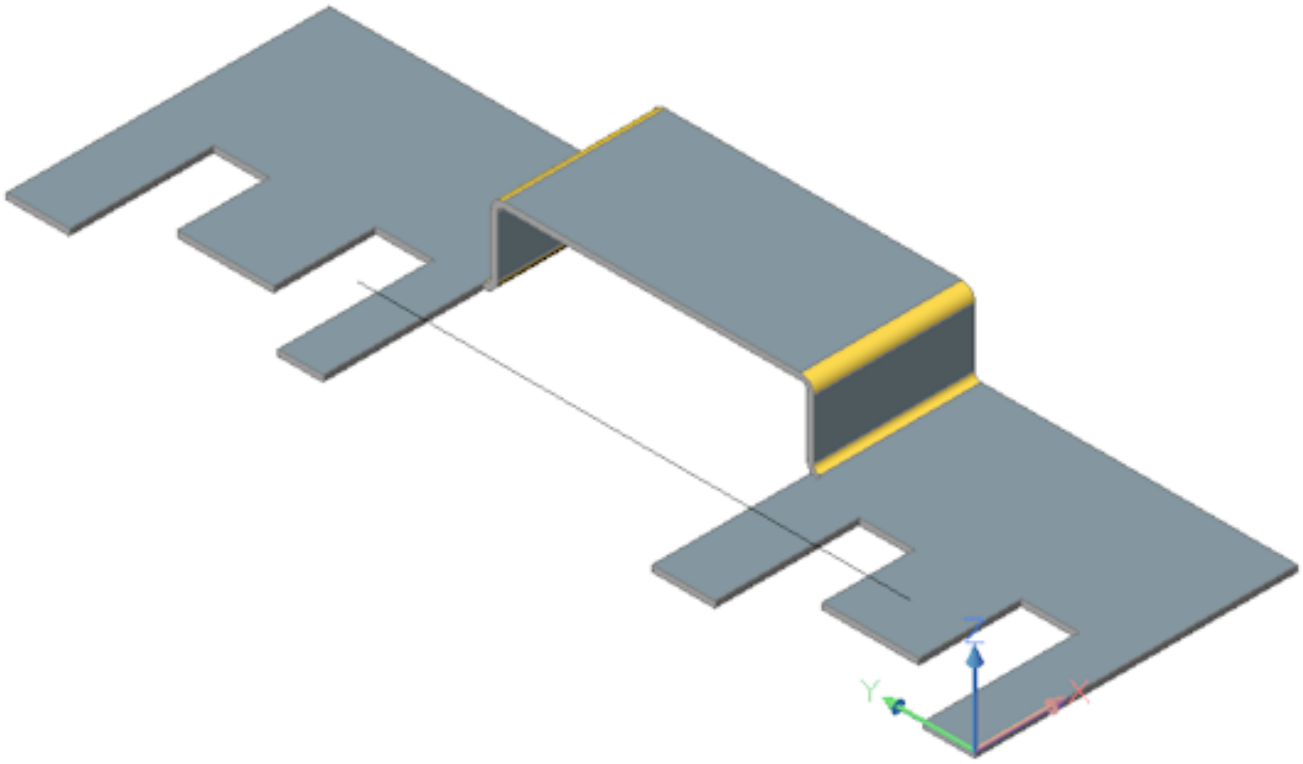

Figure 3.505

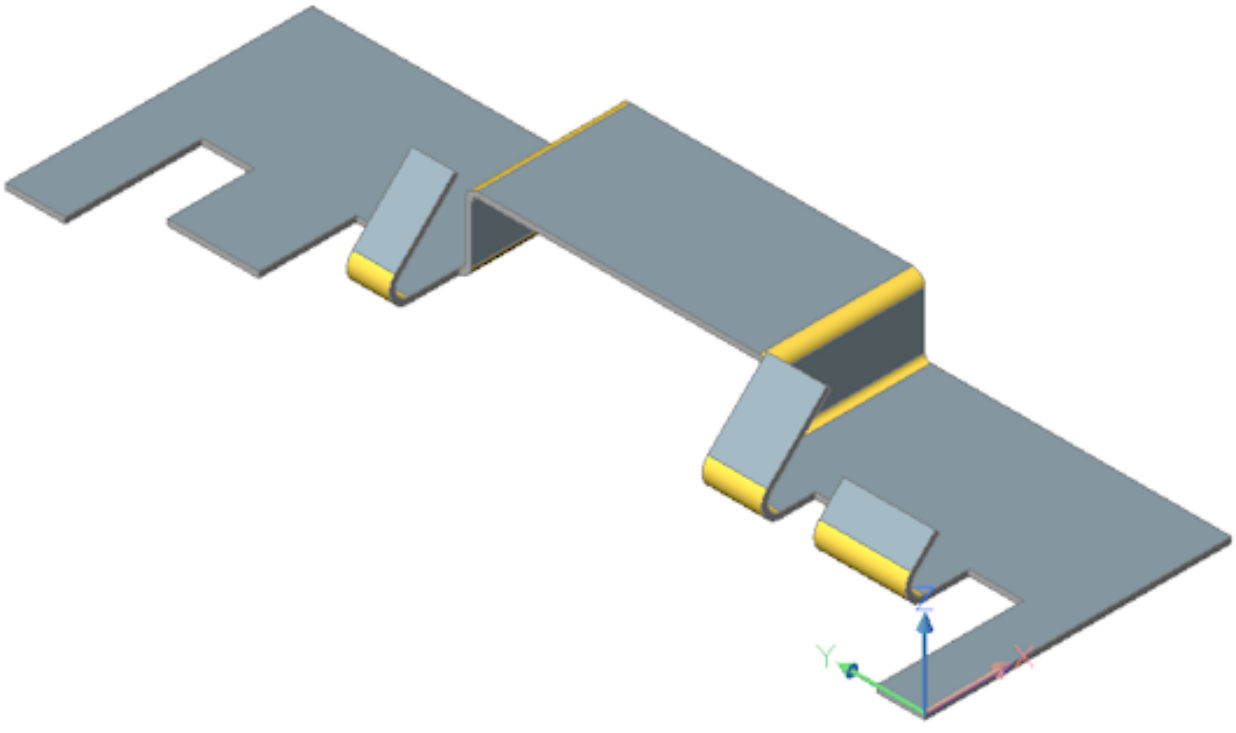


To connect flanges

The SmFlangeConnect (6.28.12) command closes gaps between two arbitrarily oriented flanges.

1. Launch the SmFlangeConnect (6.28.12) command. **You are prompted:** Select planar thickness faces of two flanges: Flange faces under the cursor highlight.
2. Select the thickness face of the first flange. **You are prompted:** Entities/subentities in set: 1 Select planar thickness faces of two flanges:
3. Select the thickness face of the second flange. The selected thickness faces are connected.

Note: After connecting two flanges, you can convert the junction feature to a bend.

3.9.16 Working with Bends and Junctions

Two adjacent flanges of sheet metal parts are connected by a bend or a junction. As different from many other mechanical CAD systems, in BricsCAD bends and junctions are separate features: a bend can be switched to a junction and vice versa, which allows you to fix or optimize the unfolded representation of a sheet metal part easily.

Converting Hard Edges to Bends or Junctions

If adjacent flanges of a sheet metal part are not connected by a bend or junction, the part cannot be unfolded or exported to a CAM system. Therefore such hard edges must be converted to bends or junctions.

Converting hard edges to bends

1. Do one of the following:
   - Hover over a hard edge and click the **Create Bend** ( ) tool in the Quad (2.3.3) menu
   - Click the **Create Bend** ( ) tool button in the **Sheet Metal** ribbon tab
   - Choose **Create Bend** in the **Sheet Metal** menu
   - Type **smbendcreate** or the command bar.

   You are prompted: Select hard edges or junctions or flanges or 3D solids or [Entire model] <Entire model>:
2. Select a flange face or a hard edge. **You are prompted:** Entities in set: 1 **Select flange faces or hard edges:**
3. Do one of the following:
   - Select more faces or hard edges.
   - Right click or press Enter to create the bends or junctions on the selected items.

(3.521 on page 3132) Selected a hard edge	(3.522 on page 3133) A bend is created

Converting Hard Edges to Junctions

1. Do one of the following:
   - Hover over a hard edge and click the **Create Junction** ( ) tool in the Quad (2.3.3) menu;
   - Click the **Create Junction** ( ) tool buttons in the **Sheet Metal** ribbon tab;
   - Choose **Create Junction** in the **Sheet Metal** menu;
   - Type **smjunctioncreate** in the command bar.

   You are prompted: Select hard edges or bends or flanges or 3D solids [Entire model] <Entire model>:
2. Select a flange face or a hard edge. **You are prompted:** Entities in set: 1 Select flange faces or hard edges:
3. Do one of the following:
   - Select more faces or hard edges.
   - Right click or press Enter to create the bends or junctions on the selected items.

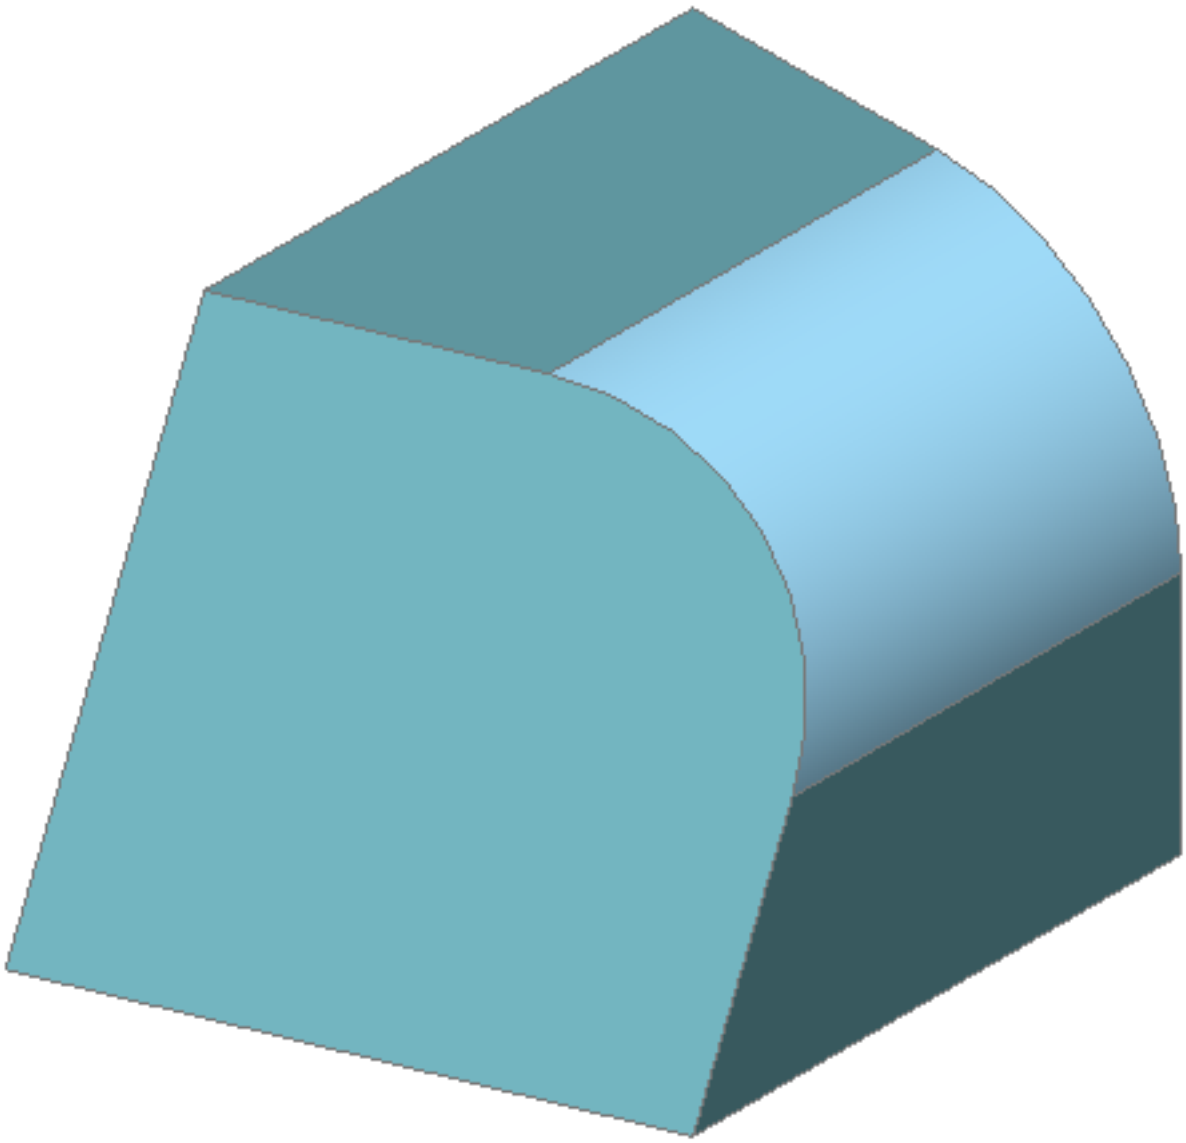
(3.523 on page 3133) Selected hard edges. Notice that a corner relief has to be created first	(3.524 on page 3134) Junctions created. Notice that unnecessary material cuts have been removed due to Smart Features (3.9.26)

Creating Curved Junctions

Lets have a look at a more complex scenario where a junction has to be cut over a non-linear edge. To make the part unfoldable, we need to:

- Cut the bend relief for one of the linear hard edges.

Figure 3.506



- Cut the junctions for the remaining linear and curved hard edges.
- Create a bend on the remaining hard edge. (3.506)

1. Create bend reliefs. Do one of the following

   - Click the **Create Relief** tool button ( ) on the **Sheet Metal** ribbon tab.
   - hoose **Create Relief** in the **Sheet Metal** menu.
   - Type **smreliefcreate** in the command bar.

2. **You are prompted:** Select a hard edge, bend face, flange face or 3D solid [Entire model]: Select a hard edge. (3.507 on the following page) **You are prompted:** Select another hard edge or bend face for the corner relief:
3. Press Enter or right click. **You are prompted:** Enter relief size by bend radius ratio or [force Bend reliefs/Auto] <Auto>:
4. Press Enter or right click. Two bend reliefs are created for the edge: (3.508 on the next page) We created two bend reliefs because: A hard edge side with a "free" vertex needs a relief in order to make orthogonal thickness face We created a bend relief on the side adjacent to the lofted bend because this feature is different from a regular bend: creating a corner relief there would be too big.
5. Create two junctions. Do one of the following:

   - Click the **Create Junction** ( ) tool buttons in the **Sheet Metal** ribbon tab;

Figure 3.507

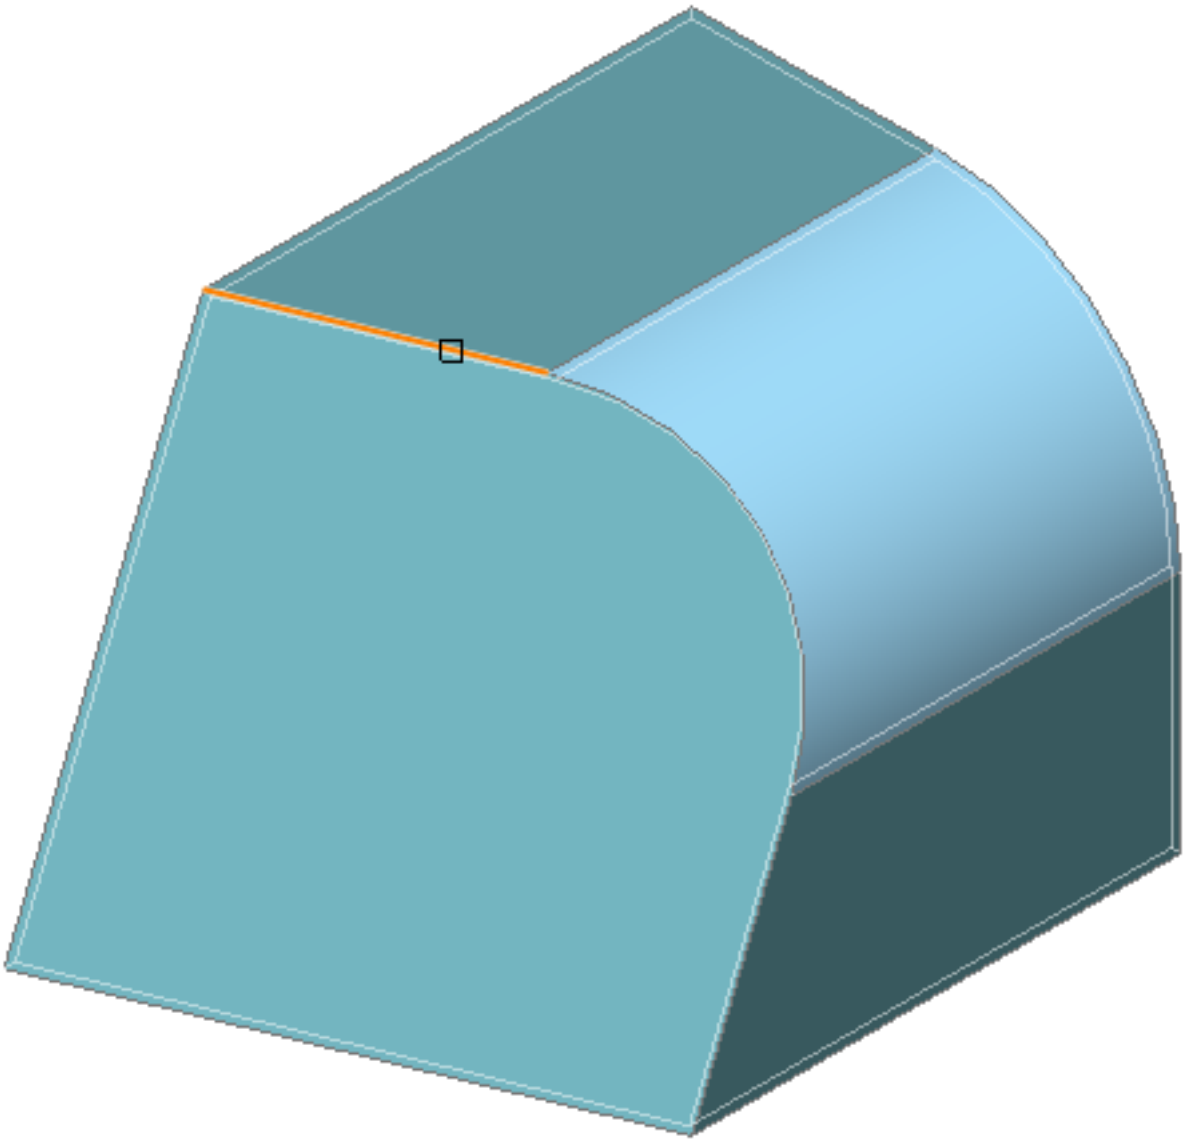


Figure 3.508

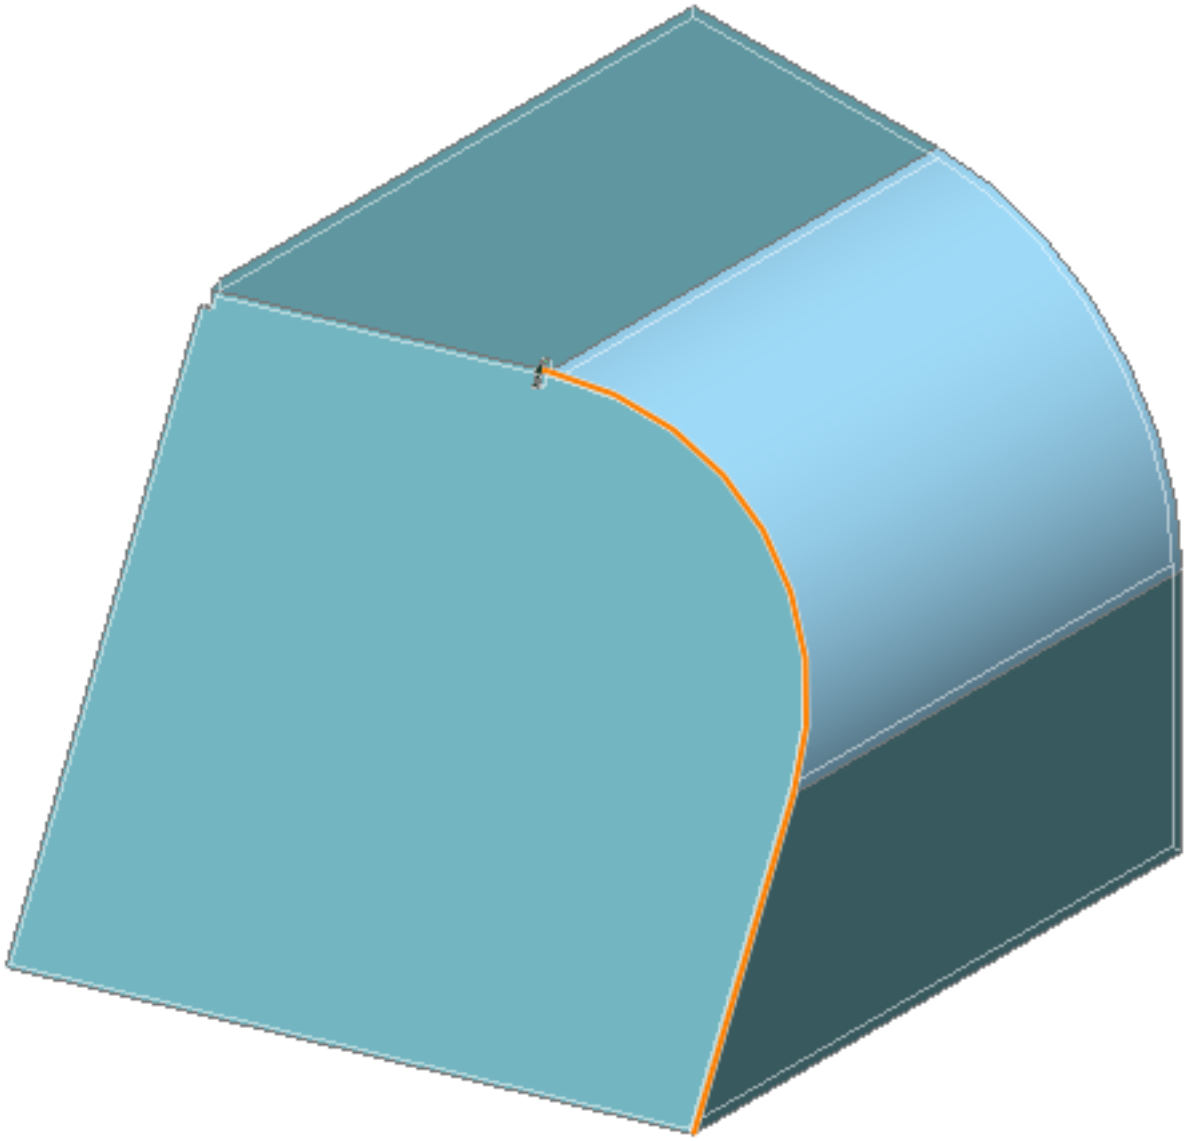
Figure 3.509



- Choose **Create Junction** in the **Sheet Metal** menu;
- Type **smjunctioncreate** in the command bar.

6. **You are prompted:** Select hard edges or bends or flanges or 3D solids [Entire model] <Entire model>: Select following three hard edges: (3.509) Don't forget about small hard edge: (3.510 on the next page) The cut is created. Parts which corresponded to linear edge get regular junction features.

7. Create bend on the hard edge. Since it is the only hard edge left on the model, we can apply the command to entire model.

   - Click the **Create Bend** ( ) tool buttons in the **Sheet Metal** ribbon tab.
   - Choose **Create Bend** in the **Sheet Metal** menu.
   - Type **smbendcreate** or the command bar.

8. **You are prompted:** Select hard edges or junctions or flanges or 3D solids or [Entire model] <Entire model>: Press Enter. Bend is created. (3.511 on page 3121)

9. Unfold the part.

   - Click the **Unfold Body** ( ) tool buttons in the **Sheet Metal** ribbon tab.
   - Choose **Unfold Body** in the **Sheet Metal** menu.
   - Type **smunfold** or the command bar.

Figure 3.510

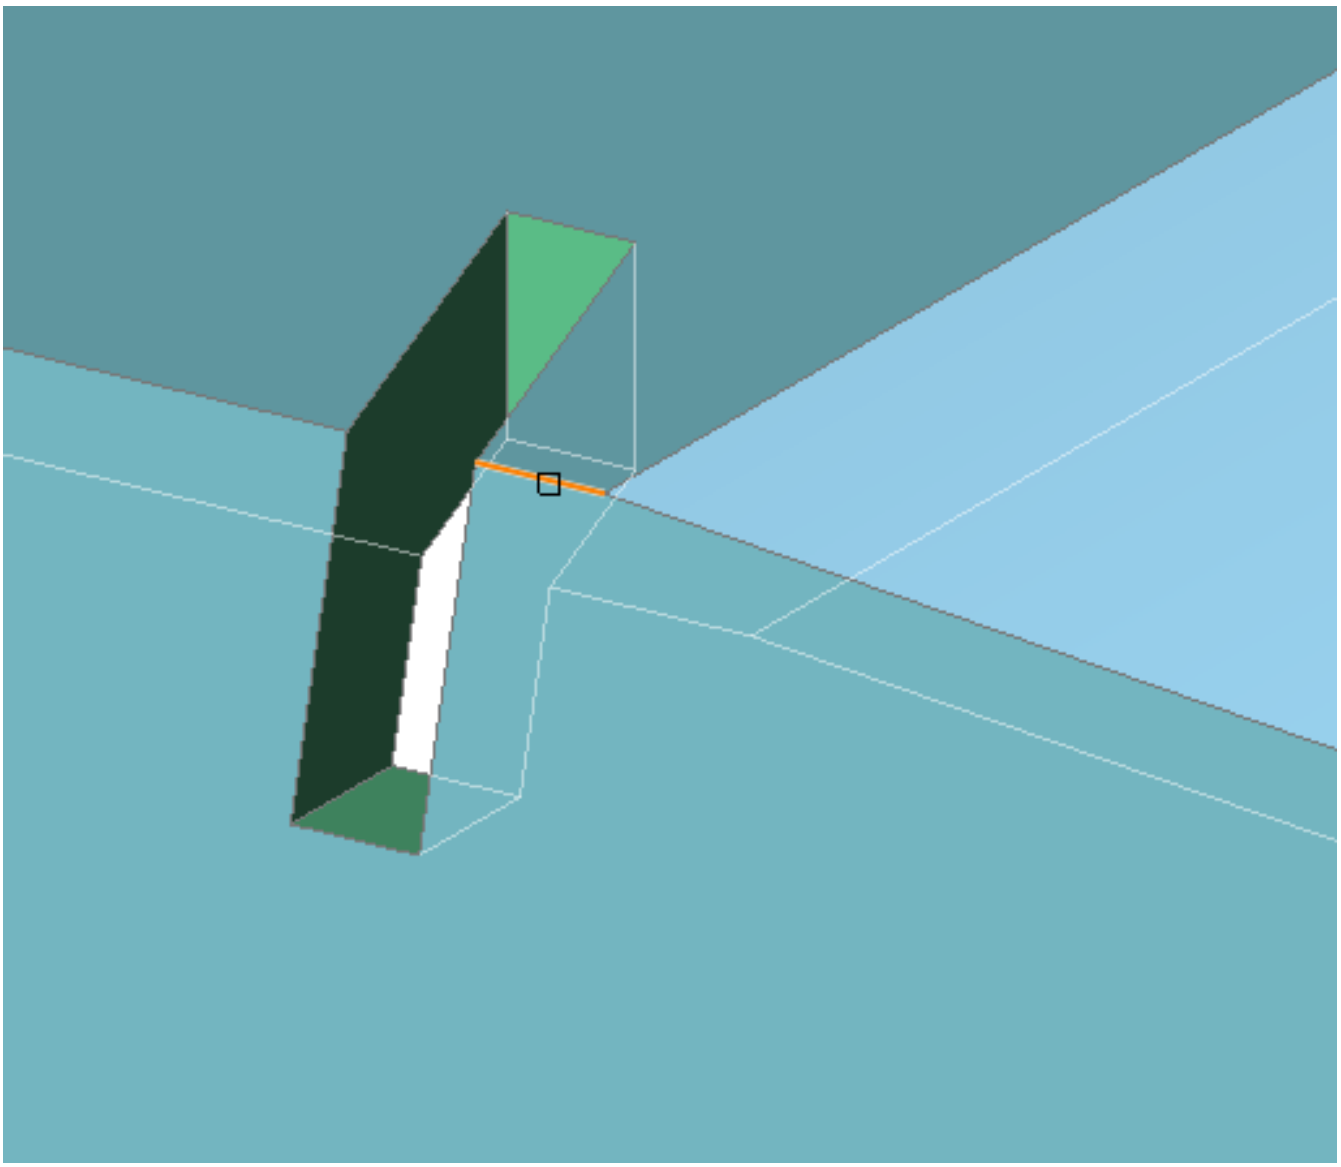


Figure 3.511

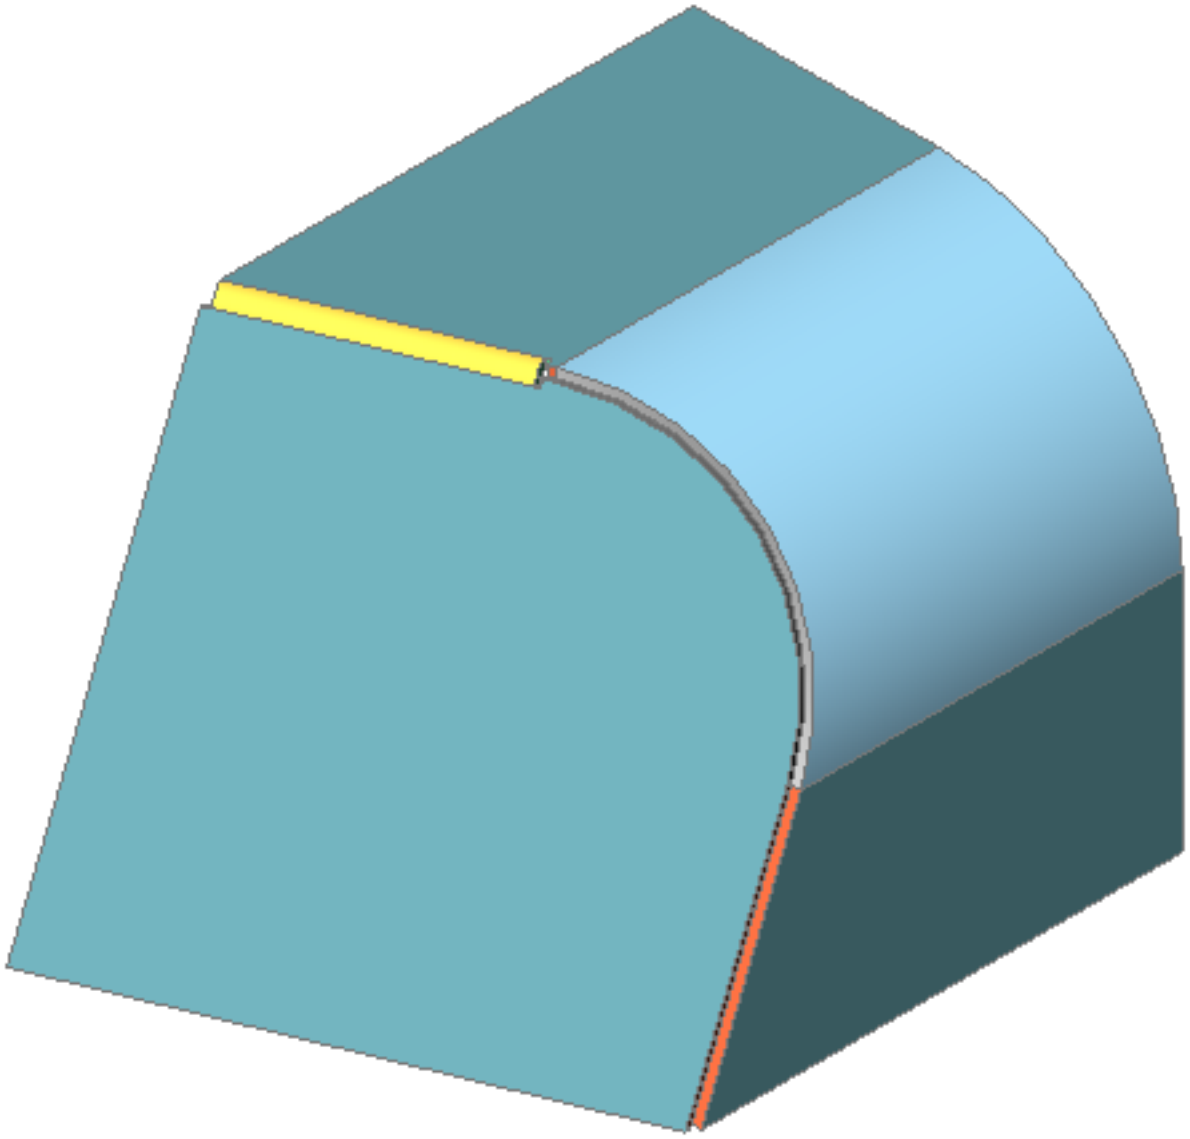

Figure 3.512

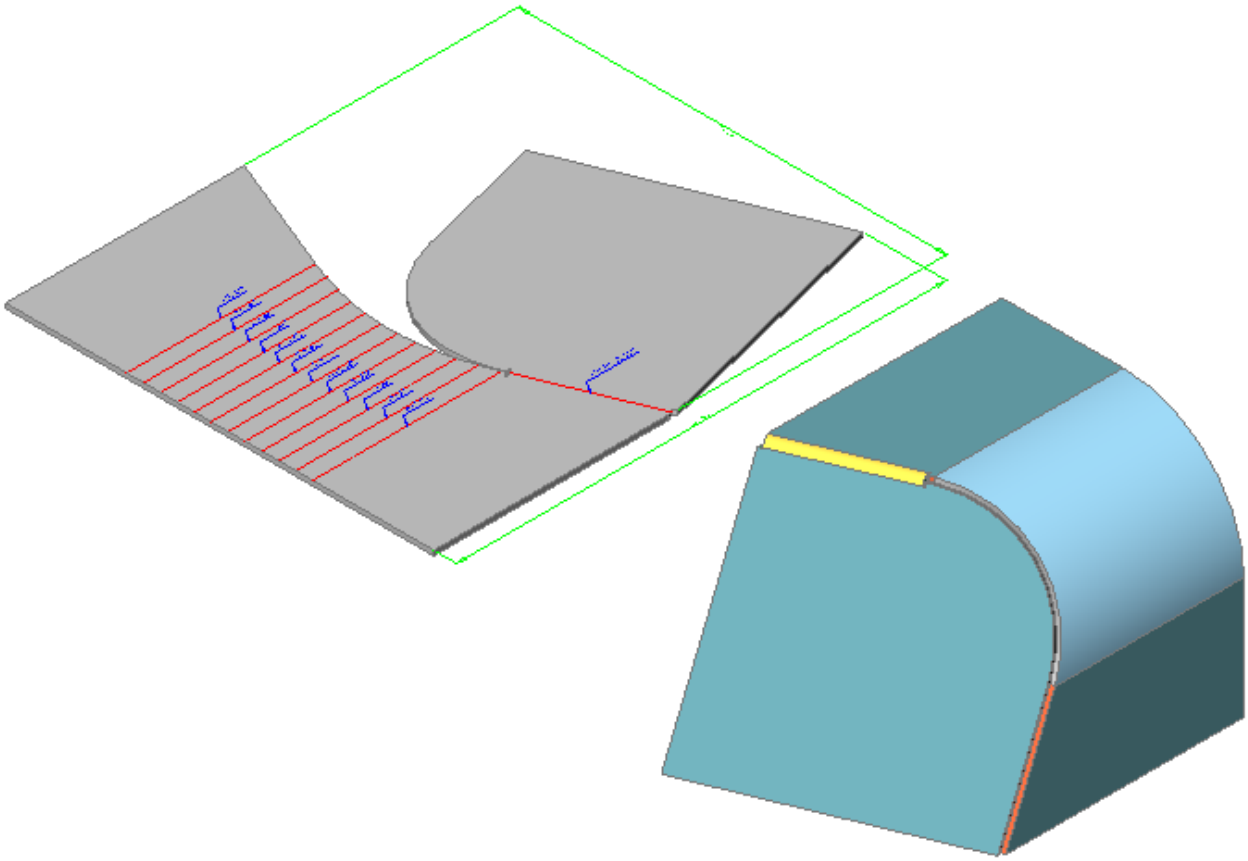

10. **You are prompted:** Select a flange or lofted bend face to start unfolding [Associative]: Select some flange face.
11. **You are prompted:** Select position of the unfolded body: Place the unfolded part.
12. **You are prompted:** Validate the unfolded body and select an option [save 2D geometry/save 3D geometry/Optimize bend annotations/Keep] <Keep>: Press Enter to keep the result. (3.512)

To Split a Thickness Face

To extend a flange which shares the same thickness face with other flanges, the thickness face needs to be split.

1. Launch the SmImprint (6.28.18) command ( ). Prompts you: **Select a thickness face:**
2. Select the shared thickness face. (3.513 on the facing page)
3. Right click or press Enter to split the face. (3.514 on page 3124)
4. The flanges can now be extended separately: (3.515 on page 3126)

Figure 3.513

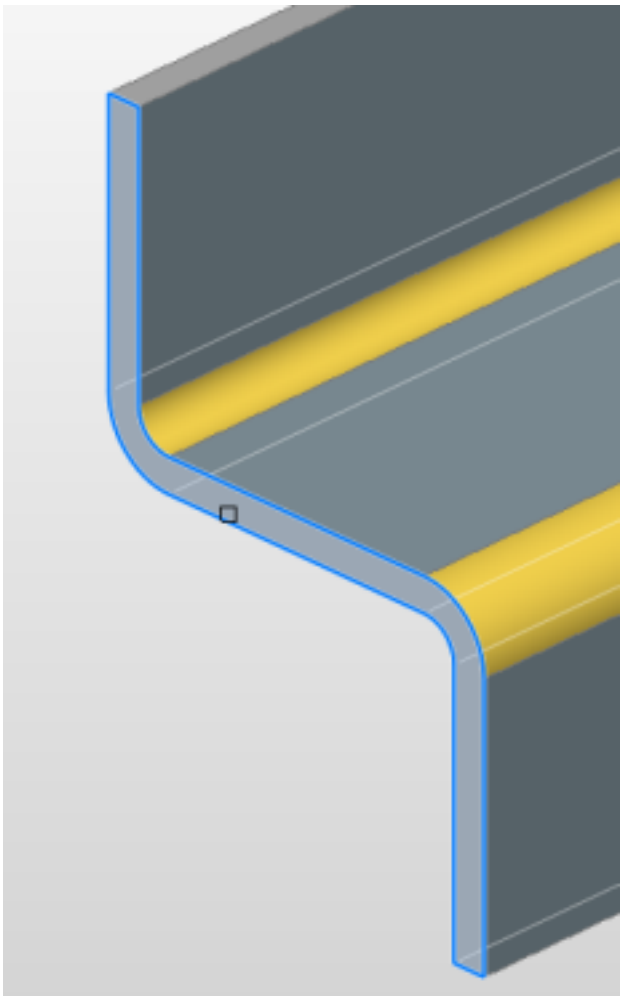

Figure 3.514

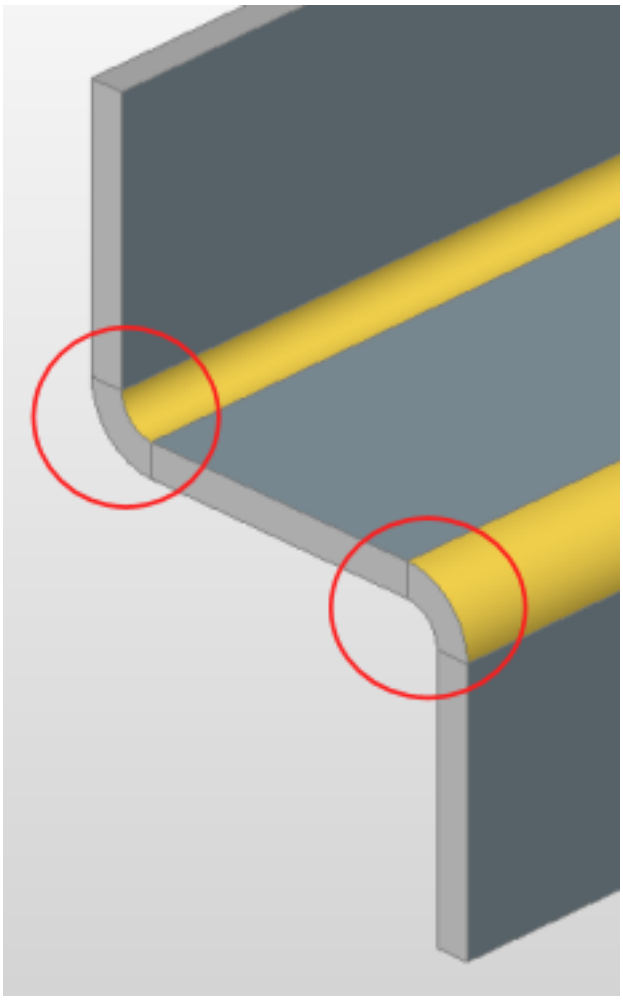
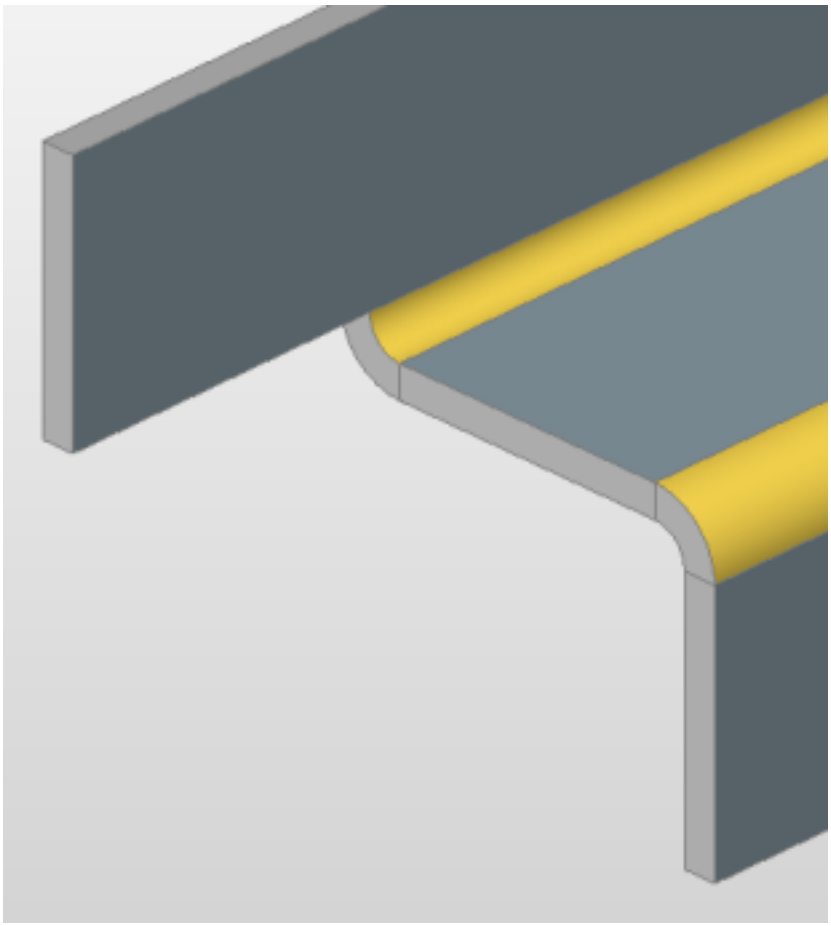


5. Execute the DmSimplify (6.12.27) command to remove the unneeded splits, thus unifying the coplanar thickness faces.

Tutorial: Split thickness faces into regions Click here (3.8.2) to watch

Figure 3.515



Changing the Bend Radius

To change the overall bend radius:

1. Select the root node in the Mechanical Browser (3.3.2)
2. Find the **Bend radius** group in the bottom part of the Mechanical Browser (3.3.2).
3. Do one of the following:
   - Set **Type** to **Absolute Value**, then type the radius value in the **Value** field. The **Bend Radius** field changes accordingly.
   - Set **Type** to **Thickness ratio**, then type a value in the **Value** field. The **Bend Radius** field is calculated as the product of the **Thickness** and the **Thickness ratio**.

To change the bend radius for a particular bend:

1. Select the bend node in the Mechanical Browser (3.3.2) The selected bend highlights in the model. The Bend Properties display in the bottom part of the Mechanical Browser (3.3.2).
2. Do one of the following:
   - Set the **Type** to **Global value.** The current global bend radius is applied to the selected bend.
   - Set the **Type** to **Absolute value,** then type the radius value in the **Value** field. The **Bend Radius** field changes accordingly.
   - Set the **Type** to **Thickness Ratio** and type a value in the value field. The **Bend Radius** field is calculated as the product of the **Thickness** and the **Thickness ratio**.

Changing the Junction Gap

To change the overall junction gap:

1. Select the root node in the Mechanical Browser (3.3.2).

2. Find the **junction gap** group in the bottom part of the Mechanical Browser (3.3.2)
3. Do one of the following:
   - Set **Type** to **Absolute Value**, then type the gap value in the **Value** field. The **junction gap** field changes accordingly.
   - Set **Type** to **Thickness ratio**, then type a value in the **Value** field. The **junction gap** field is calculated as the product of the **Thickness** and the **Thickness ratio**.

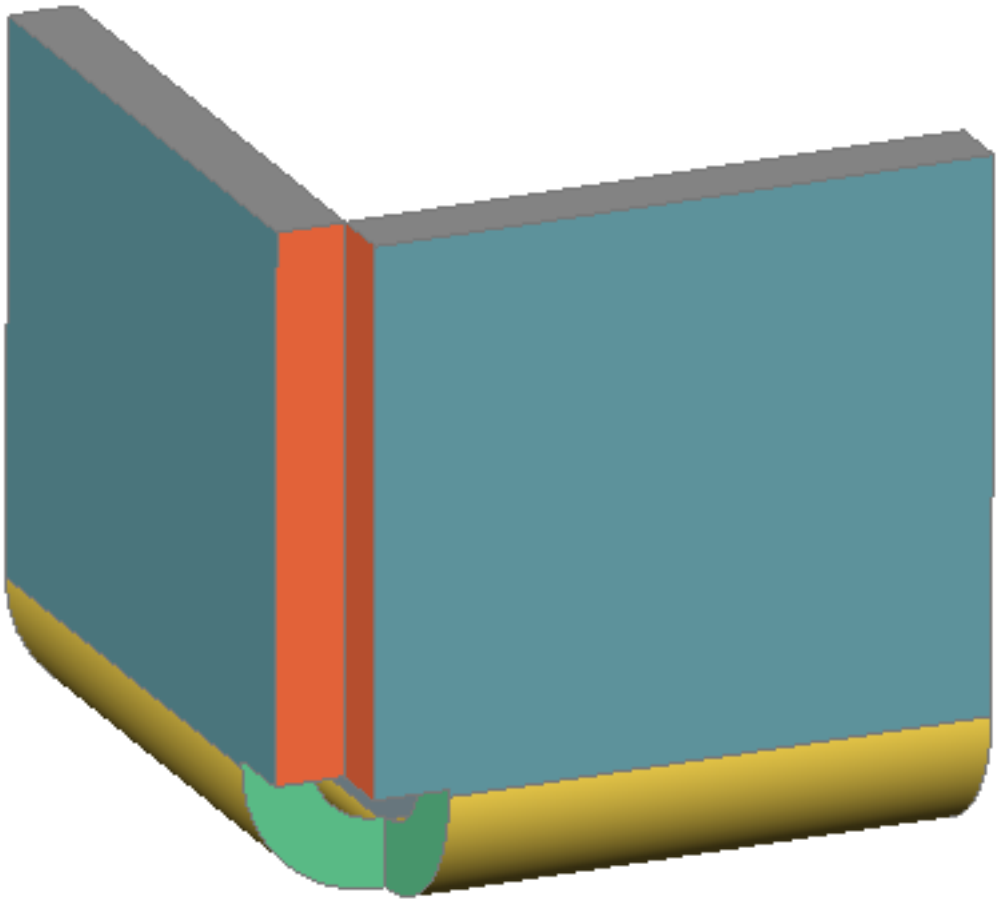
To change the junction gap for a particular bend:

1. Select the bend node in the Mechanical Browser (3.3.2) The selected bend highlights in the model. The Bend Properties display in the bottom part of the Mechanical Browser (3.3.2).
2. Do one of the following:
   - Set the **Type** to **Global value.** The current global junction gap is applied to the selected bend.
   - Set the **Type** to **Absolute value,** then type the gap value in the **Value** field. The **junction gap** field changes accordingly.
   - Set the **Type** to **Thickness Ratio** and type a value in the value field. The **junction gap** field is calculated as the product of the **Thickness** and the **Thickness ratio**.

Changing the Junction Type

By default, BricsCAD creates symmetric junctions, as shown in the image below: (3.516 on the next page) The SmJunctionSwitch (6.28.19) command allows changing a symmetrical junction feature to one with overlapping faces.

Figure 3.516



To change the junction type using the Quad:

1. Hover the cursor over one the thickness faces of this junction.
2. Select **Switch Junction Type** in the Sheet Metal command group in the Quad (2.3.3). (3.517 on the following page) The selected thickness face is aligned with the flange face. (3.518 on the next page)

Figure 3.517

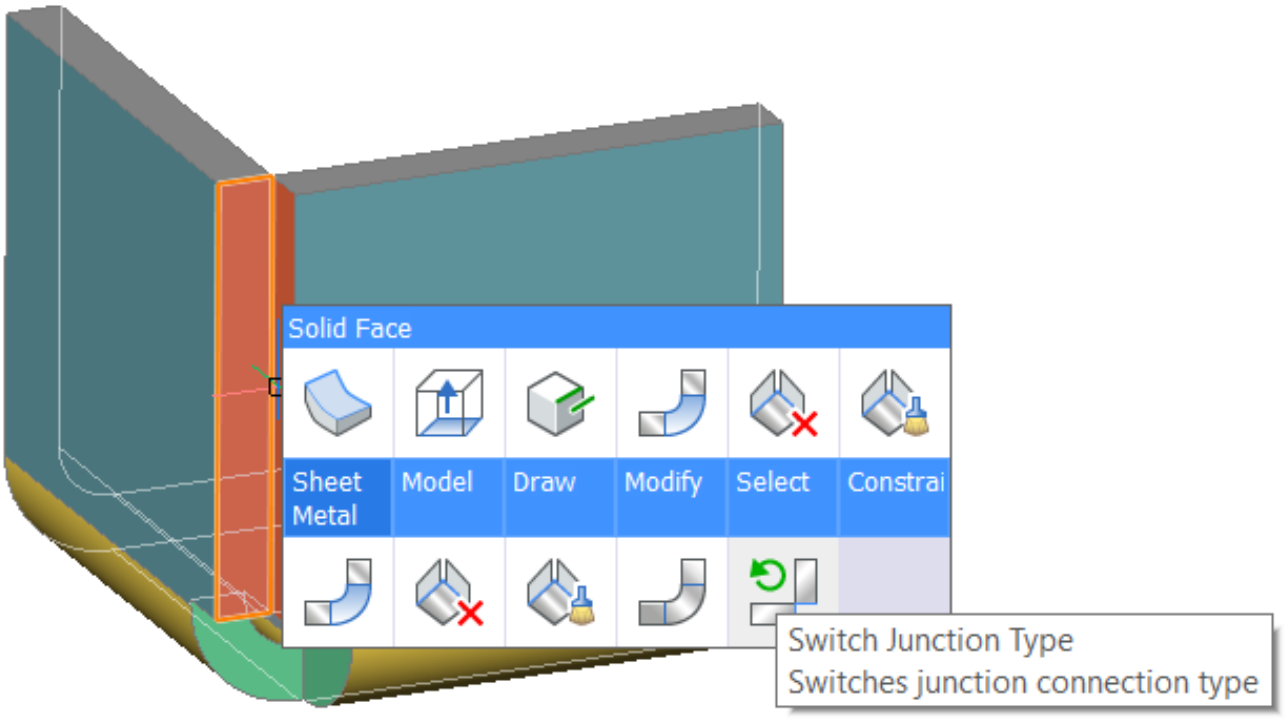


Figure 3.518

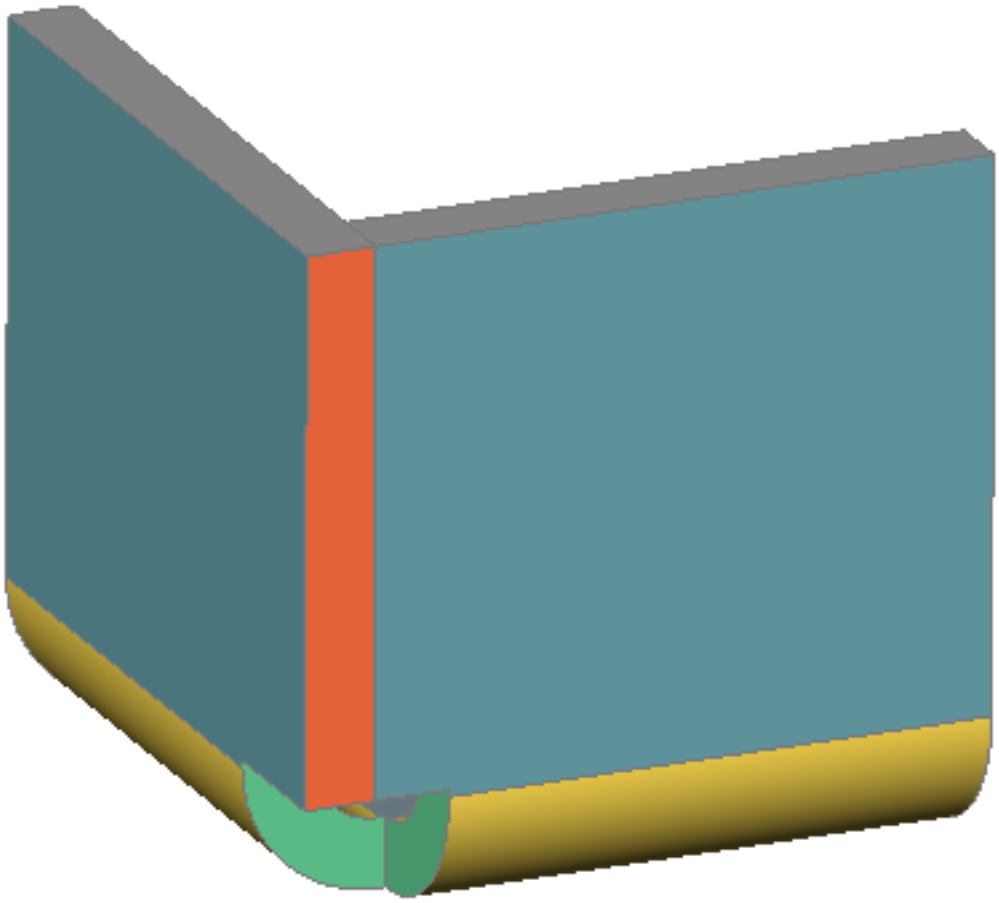

To change the junction type in the Mechanical Browser Method 1:

1. Select the corresponding junction in the tree. The junction properties display in the bottom part of the Mechanical Browser (3.3.2).
2. Select the **Connection type** property.
3. Choose the desired junction type. The options are: **Symmetric, Aligned to Flange_X** or **Aligned to Flange_ Y**. (3.519) The junction is updated accordingly.

Method 2:

1. Select the corresponding junction in the tree. A context menu displays: (3.520 on the next page)
2. Right click and choose **Switch type of feature** in the context menu.

NOTE	Both symmetric and aligned junctions maintain the same gap value between connected flanges.

Figure 3.519

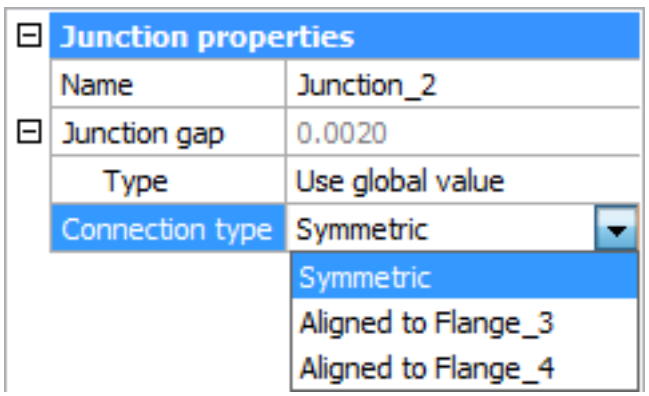

Figure 3.520

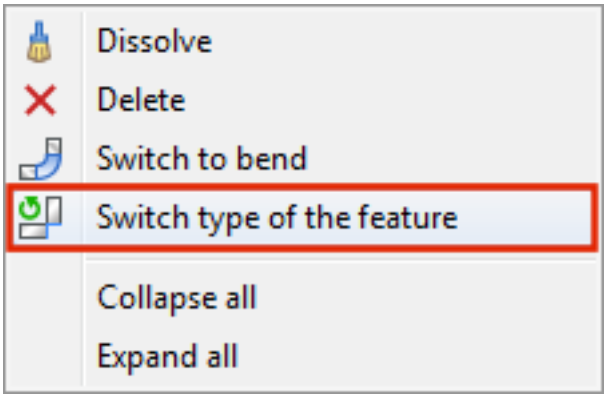

Figure 3.521

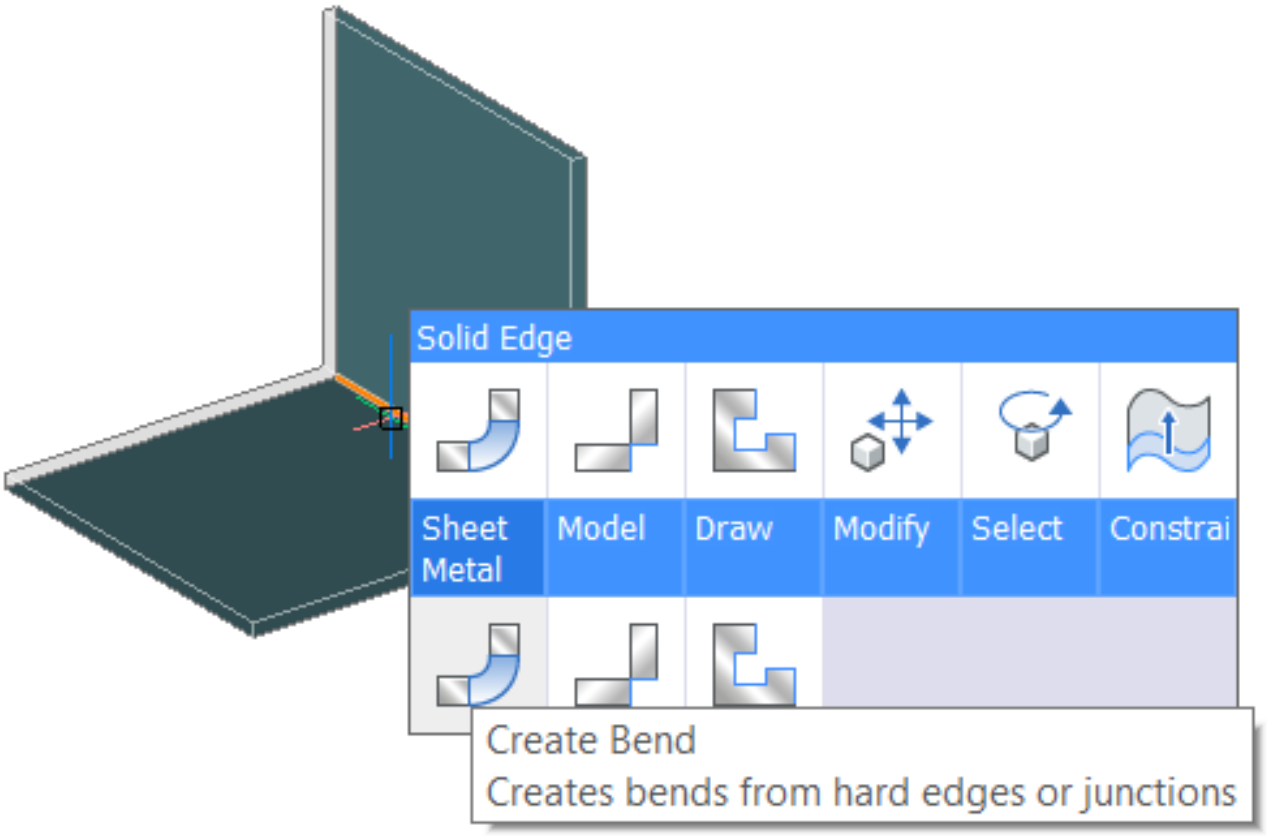

Figure 3.522

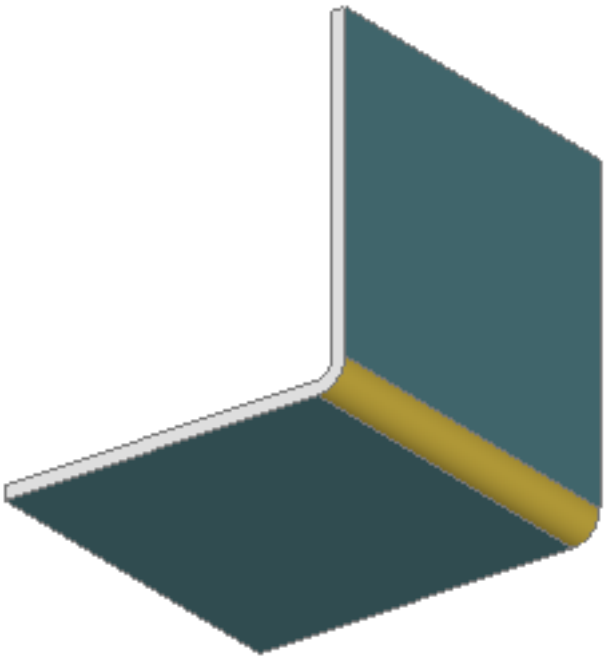

Figure 3.523

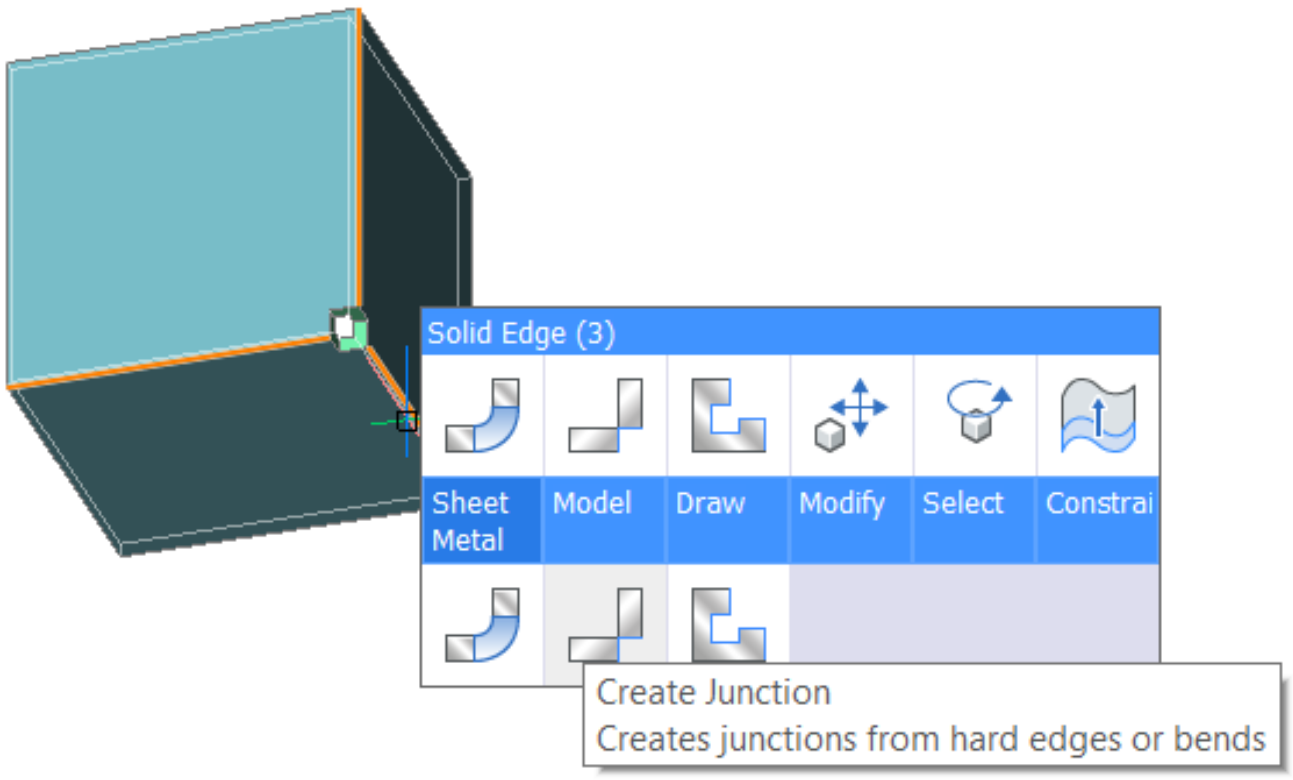

Figure 3.524

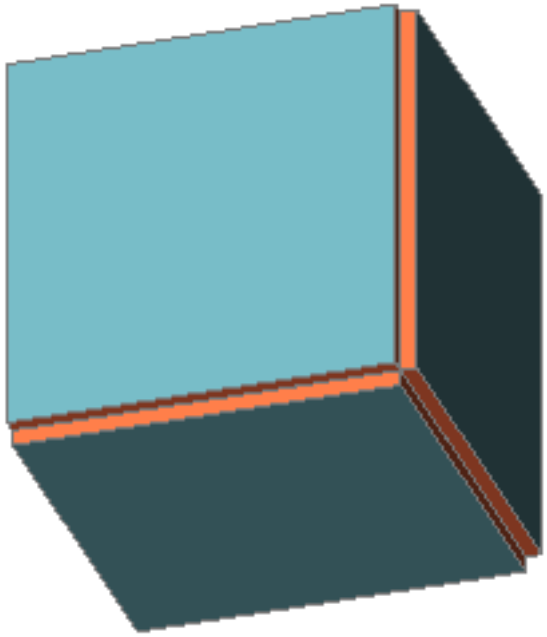

3.9.17 Working with Hems

A hem feature is produced when the edge of a sheet metal flange is folded back on itself. SmHemCreate (6.28.16) simplifies the creation of sheet metal hems. In BricsCAD hems have their own set of properties depending on the type, "flange" and "bend" type of the geometry. Hem features are recognized by the SmConvert (6.28.4) command and have a special symbol when unfolded with SmUnfold (6.28.31).

Create a Hem

1. Do one of the following:
   - Select several linear edges on the flange
   - Hover the mouse over a linear edge of the flange
2. Select **Create a Closed Hem** ( ) tool in the Quad (2.3.3) menu or
   - Click the **Create a Closed Hem** ( ) tool buttons in the **Sheet Metal** ribbon tab or
   - Choose **Create a Closed Hem** in the **Sheet Metal** menu or
   - Type **smhemcreate** in the command bar.(3.525 on the following page)
3. Hover mouse to adjust the hem length: (3.526 on the next page)
4. Use the Ctrl widget or **Toggle tapering** option to flip the adjustment of a hem to the edge: (3.527 on page 3137)
5. When finished, press **Enter**: (3.528 on page 3138)

Hems and auxiliary features (reliefs and miters) are created.

Figure 3.525

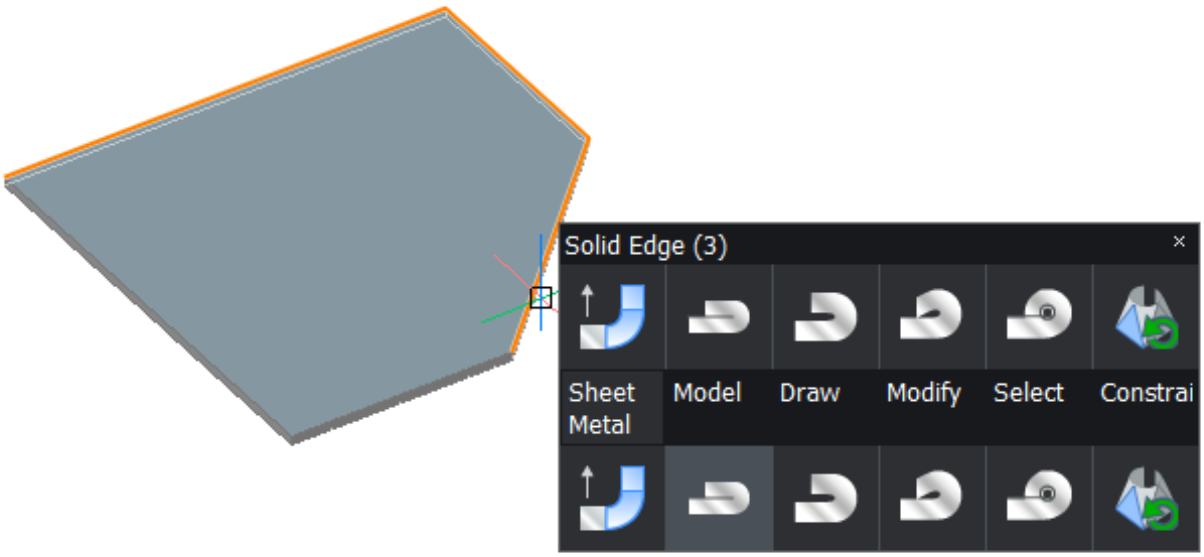

Figure 3.526

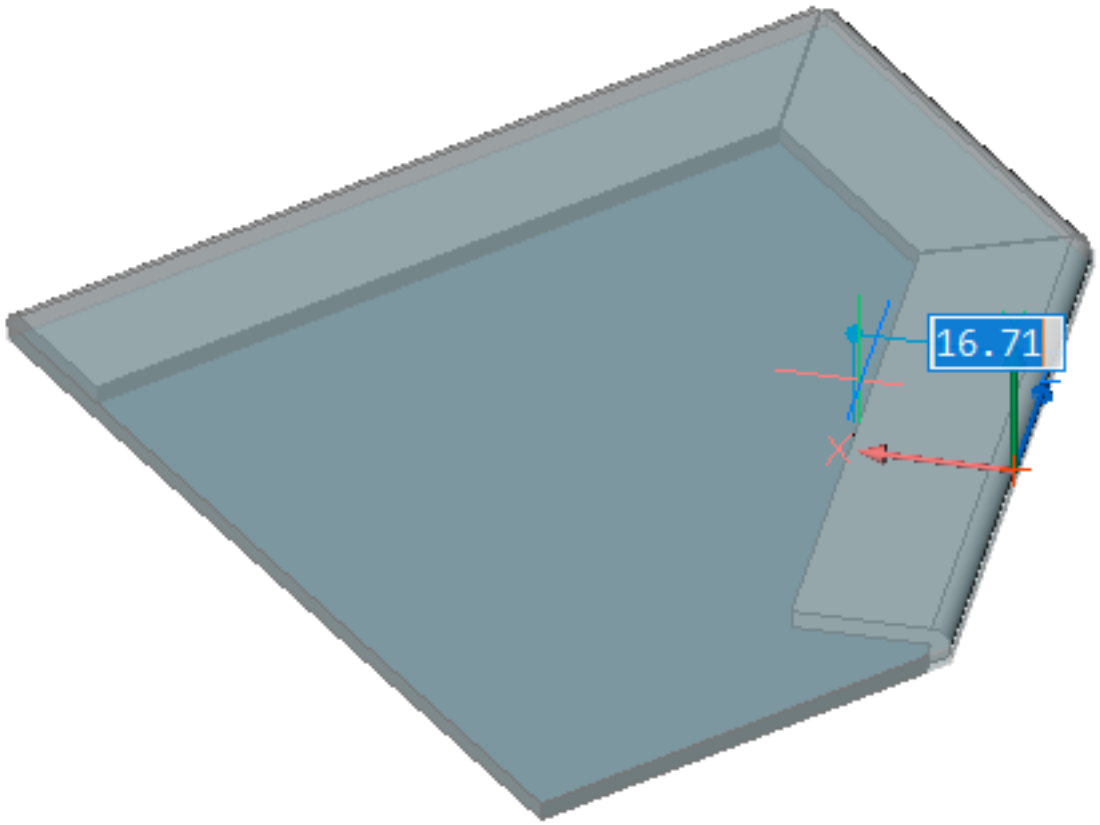

Figure 3.527

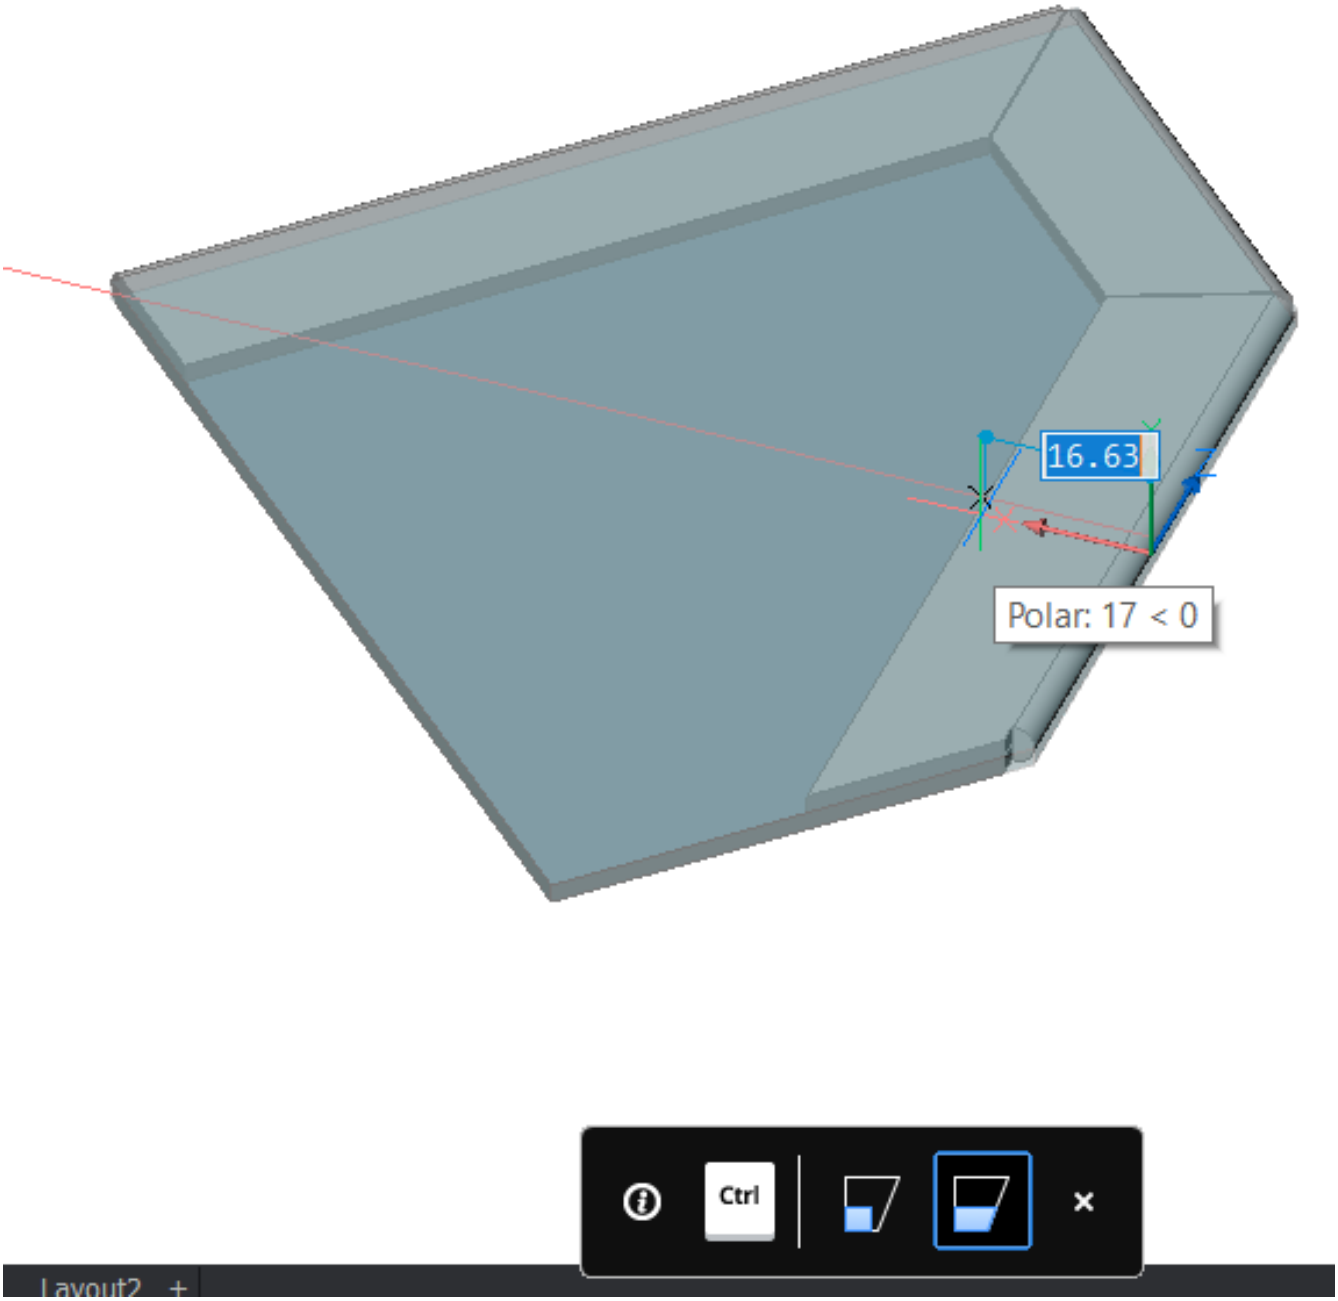

Figure 3.528

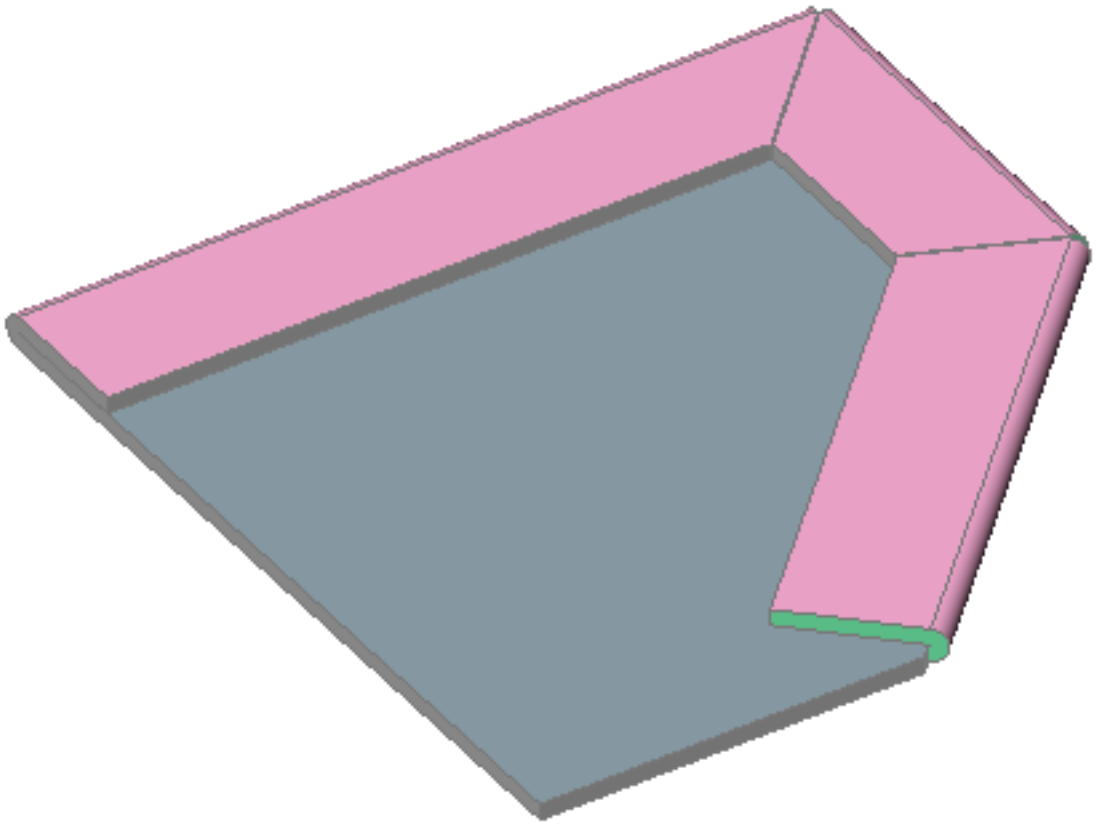

Modify Hem Parameters

To modify Hem parameters select the feature and use the Mechanical Browser. Different parameters are available, depending on the type of the hem.

Type of hem	Available parameters
Closed	Radius Length
Open	Radius Length
Teardrop	Radius - changes the angle of the hem Length - change the angle of the hem
Round	Radius - change the "planar" part of the hem

In the case of any parametric change, the hem type is preserved and the geometry is moved inside, to maintain external dimensions.

Erase a Hem

When a hem feature is erased, BricsCAD intelligently restores the geometry's dimensions and reliefs. The flange part below has external dimensions equal to 100. (3.529 on the facing page) 1. Use the Width option of SmHem-Create (6.28.16) command to create a partial hem on a single edge: (3.530 on the next page) 2. Create hems on two other edges: (3.531 on page 3140) These operations lead to the appearance of complex relief geometry: (3.532 on page 3141) **Note** the external dimensions of the part are preserved. (3.533 on page 3142) 3. Select the hem features and delete them. (3.534 on page 3143)

Figure 3.529

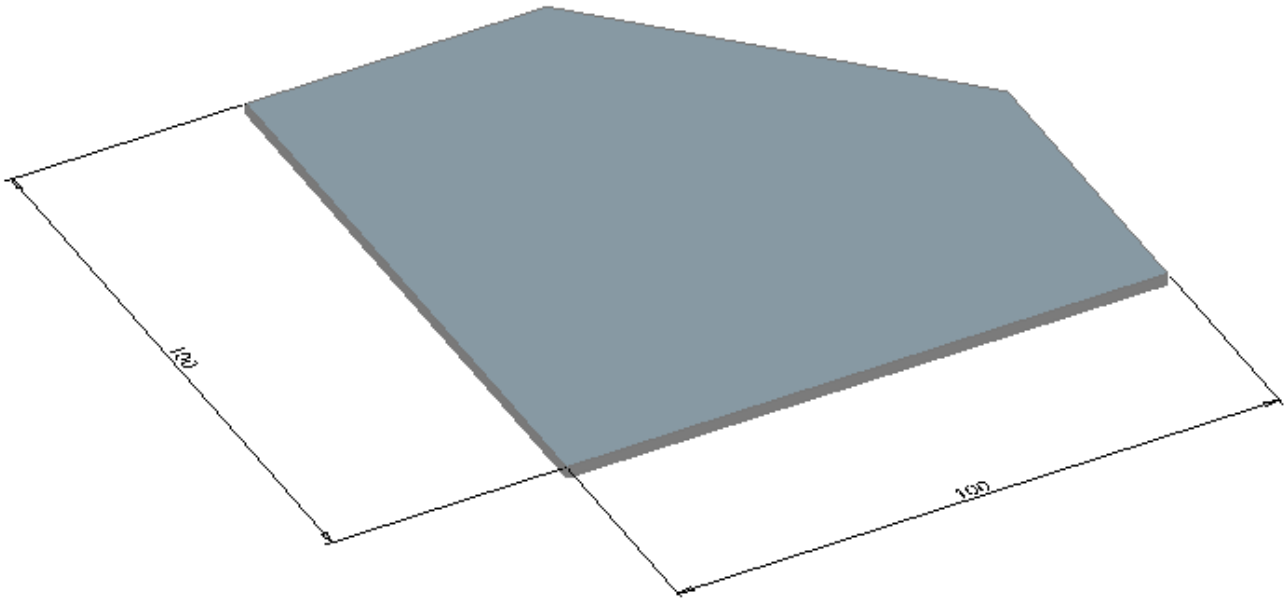

Figure 3.530

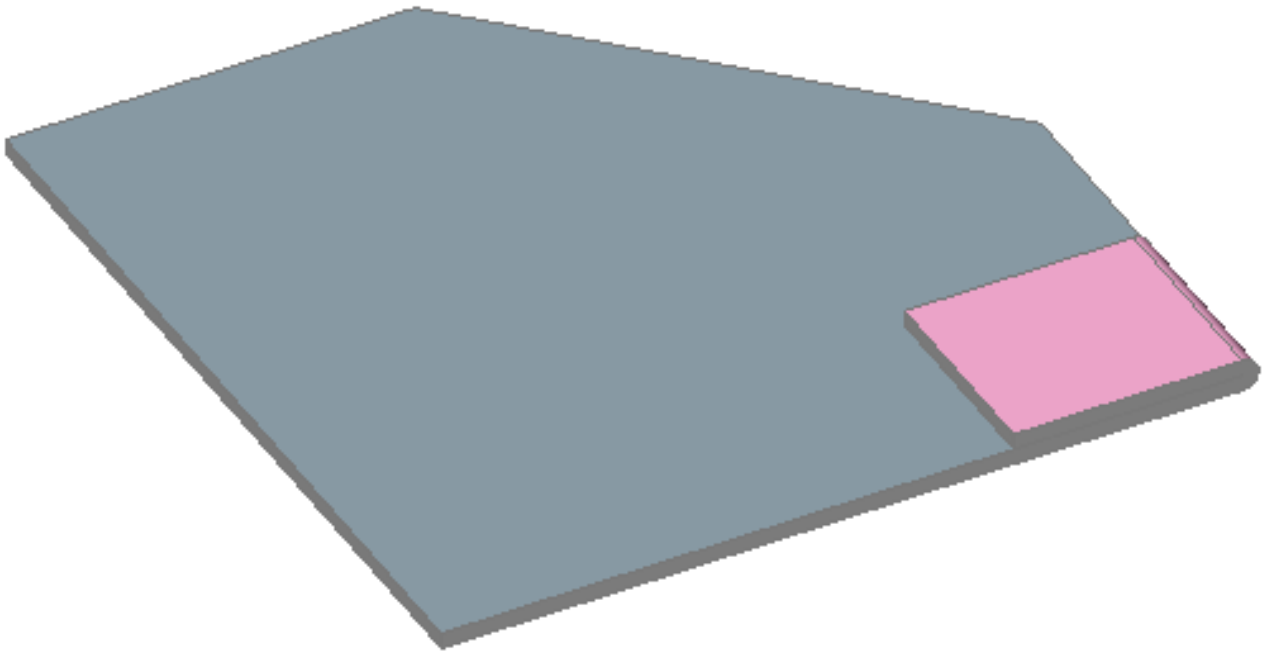

Figure 3.531

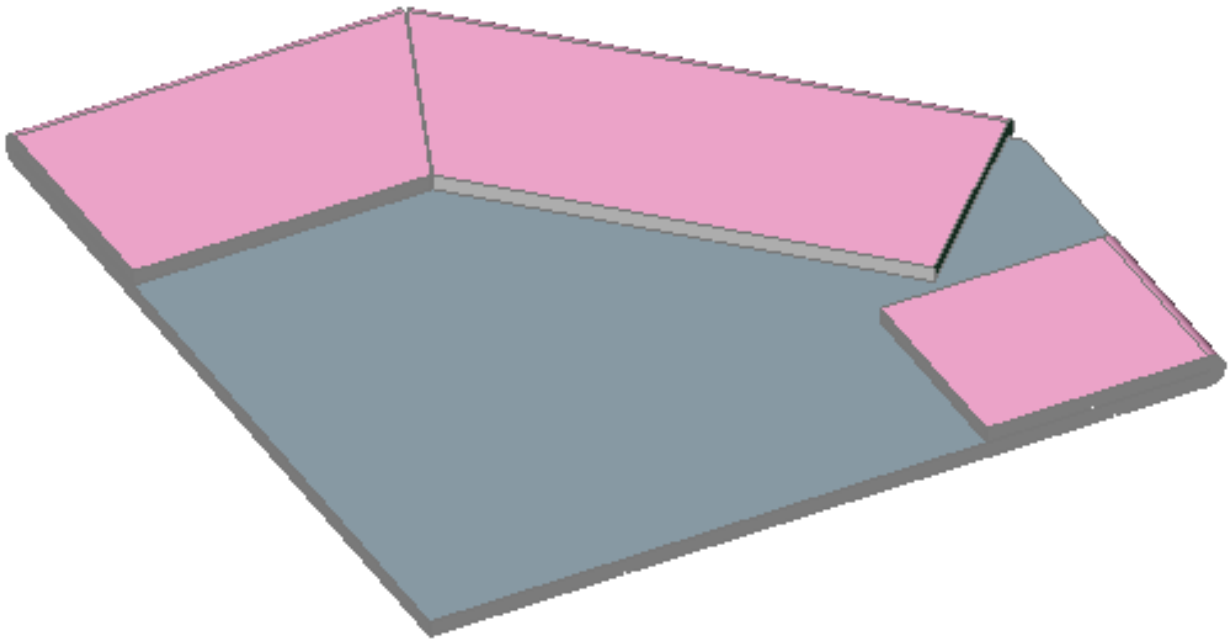

Figure 3.532

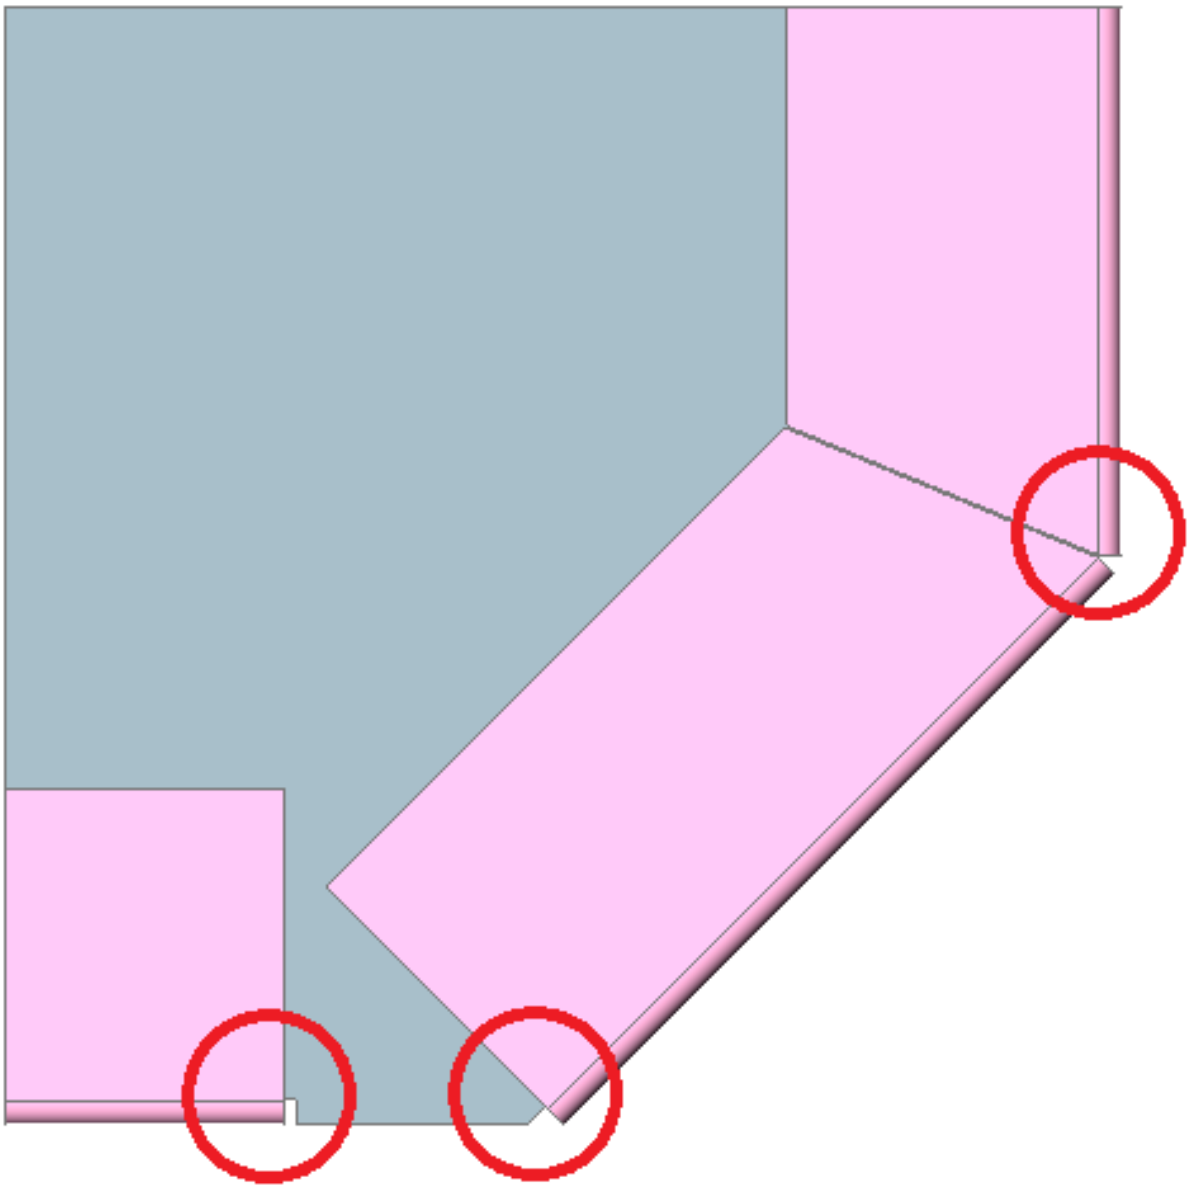

Figure 3.533

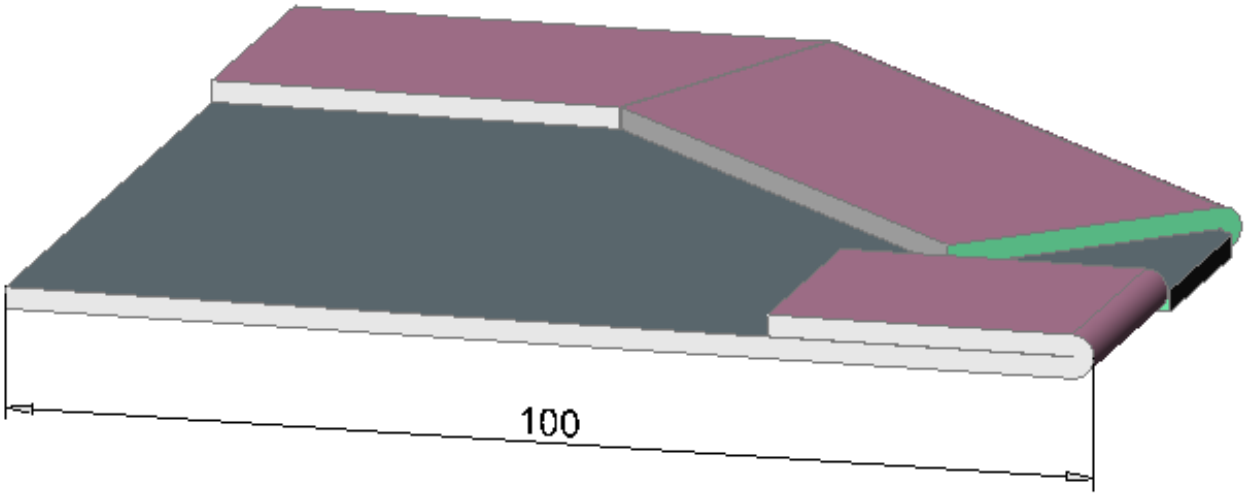

Some imperfections are left on the corner relief feature and the imprinted edge: (3.535 on the following page)
4. Delete the corner relief feature and use DmSimplify (6.12.27) to get the original part with original dimensions. (3.536 on the next page)

Figure 3.534

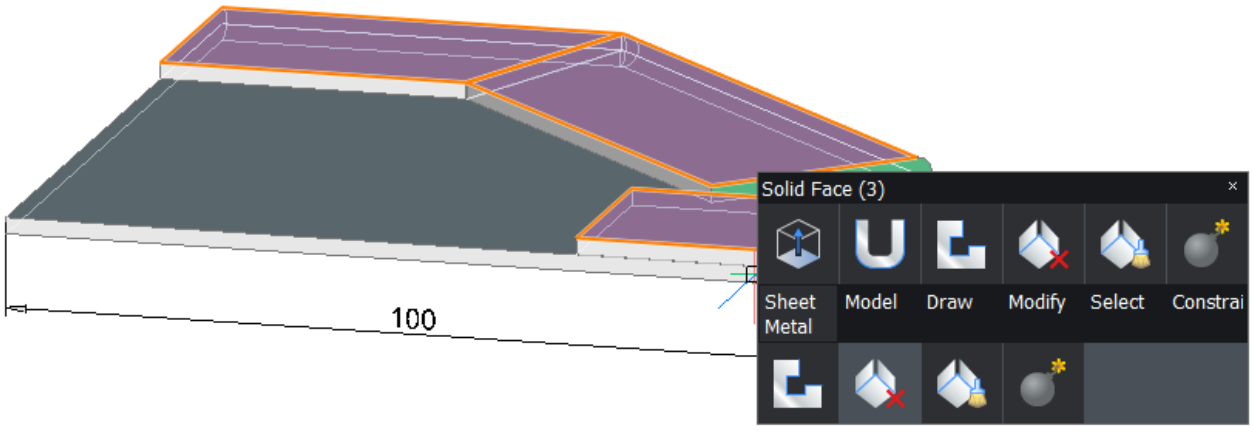

Figure 3.535

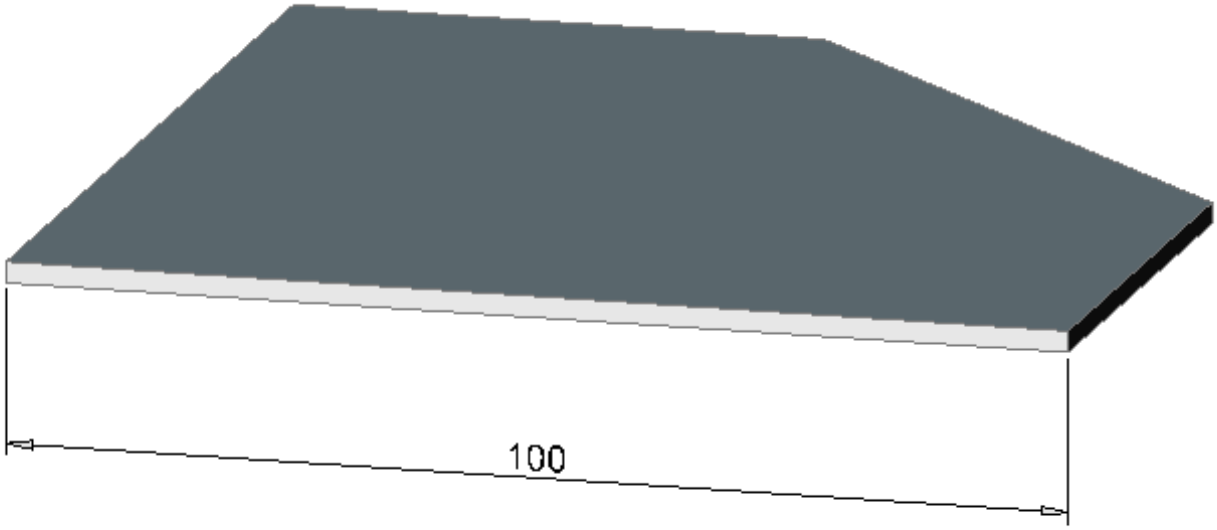
Figure 3.536



Related Commands

MechanicalBrowserOpen (6.8.32) - displays the Mechanical Browser. SmDelete (6.28.5) - restores a hard edge between two flanges to remove a bend or a junction - removes a flange and all adjacent bends. The adjacent flanges are extended up to a junction configuration and the flange is deleted. Restores geometry removed by the miter. SmHemCreate (6.28.16) - creates one or more hems to a sheet metal part by pulling one or more edges of an existing flange.

3.9.18 Working with Tabs

Tab features are used to create easy and robust connections between sheet metal parts. Tab features are created from junctions.

Creating a Single Tab

A single tab is created by default by SmTabCreate (6.28.28) command. This feature has only a single slot.

1. Do one of the following:

- – Hover over a junction face and click the **Create single Tab** () tool in the Quad (2.3.3) menu
  – Click the **Create single Tab** () tool button in the **Sheet Metal** ribbon tab
  – Choose **Create single Tab** in the **Sheet Metal** menu
  – Type **smtabcreate** in the command bar.

Prompts you: Select junction to create single tab or [Array]: Select a junction face. Prompts you: Enter the length of the tab or [Central point]: Define the length of the tab. A tab is placed symmetrically in relation to a central point. Type values in the dynamic length entry fields to define the length of a tab. (6.2567 on page 5696) Select the **Central point** option to position the tab. Prompts you: Select the central point or [Length]: Two Tab-controlled dynamic dimensions are used to create a tab relative to a junction: (6.2568 on page 5697) Select the **Length** option in order to specify the length or press Enter to finish the command.

Figure 3.537

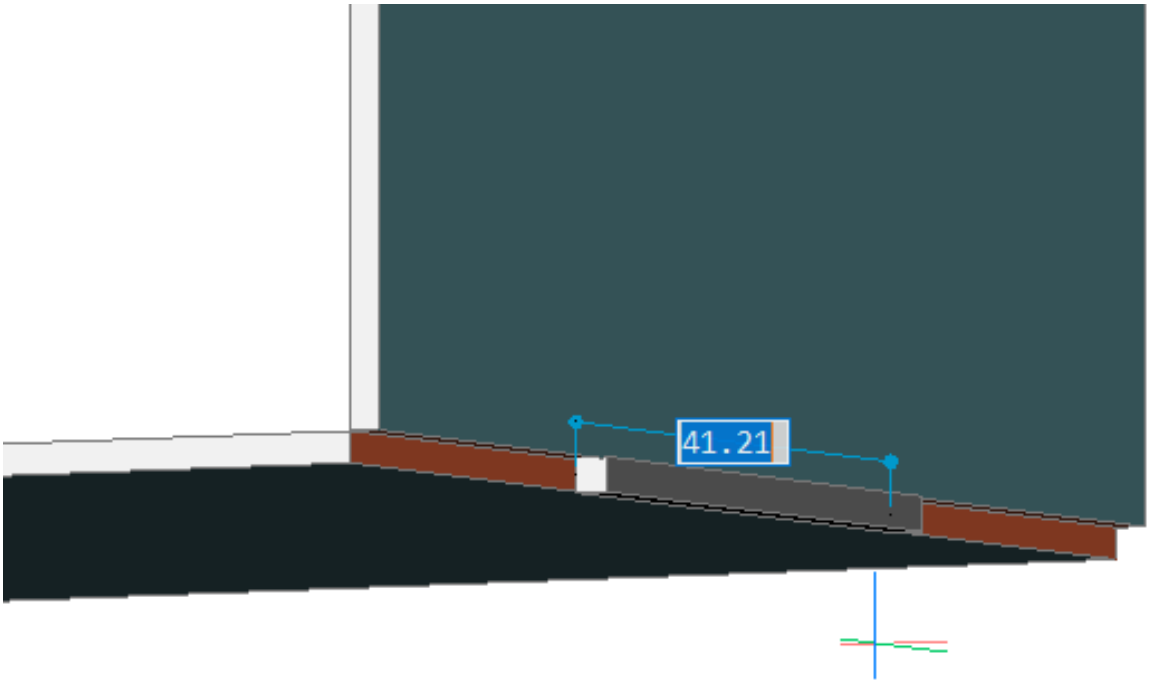


Figure 3.538

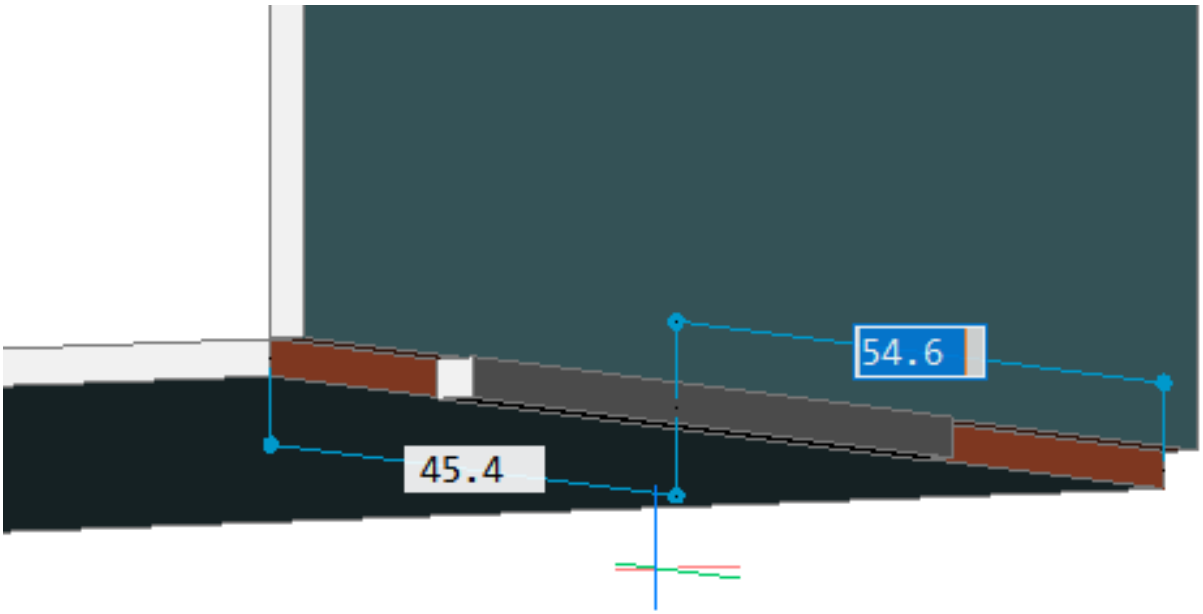


Creating an Array Tab

An array tab feature has several slots, in contrast to Single tabs.

1. To create an array tab, do one of the following:
   - Hover over a junction face and click the **Create array Tab** () tool in the Quad (2.3.3) menu
   - Click the **Create array Tab** () tool button in the **Sheet Metal** ribbon tab
   - Choose **Create array Tab** from the **Sheet Metal** menu
   - Type **smtabcreate** in the command bar.

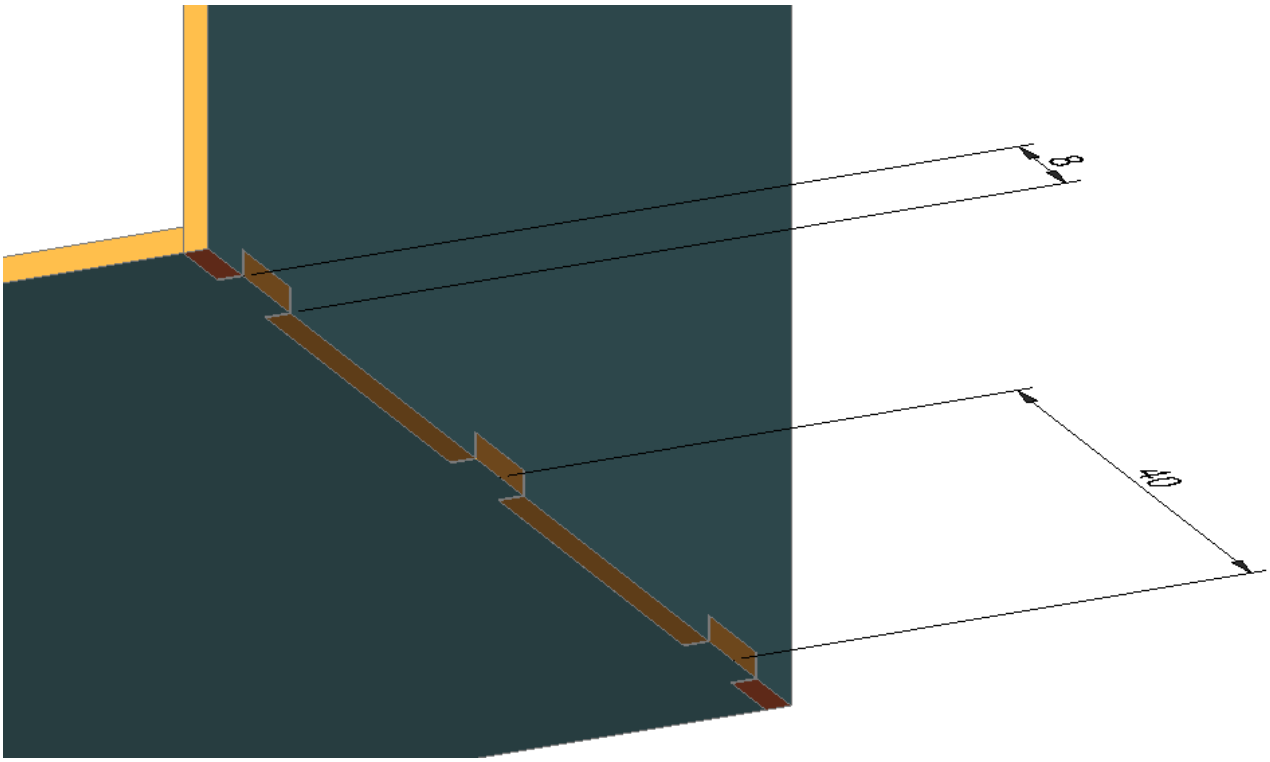
Prompts you: Select junction to create single tab or [Array]: Select the **Array** option. Prompts you: Select junction or curved hard edge to create array tab or [Single tab/selection options (?)]: Select a junction face. Prompts you: Accept tab configuration or [Flip/slot Number/Distance/Length/Round radius/CHamfer distance/Accept] <Accept>: You can use options to modify the appearance of an array tab (see the example below).

- – **slot Number = 3** - notice that the picture is not symmetric. If you click the **Flip** option, 3 slots will appear on the other side of the junction.
  – **Length = 8** - the length of the slot
  – **Distance = 40** - the dimension between slot centers (3.539 on the facing page)

Change the **Round radius** and **CHamfer distance** to define the fillets and chamfers for the edges. If you set fillets or chamfers by mistake, use zero values to turn them off. Once you have set all the options, choose **Accept** or press Enter to create the tab and finish the command.

Fillets	Chamfers
(3.542 on page 3153)	(3.543 on page 3153)

Figure 3.539

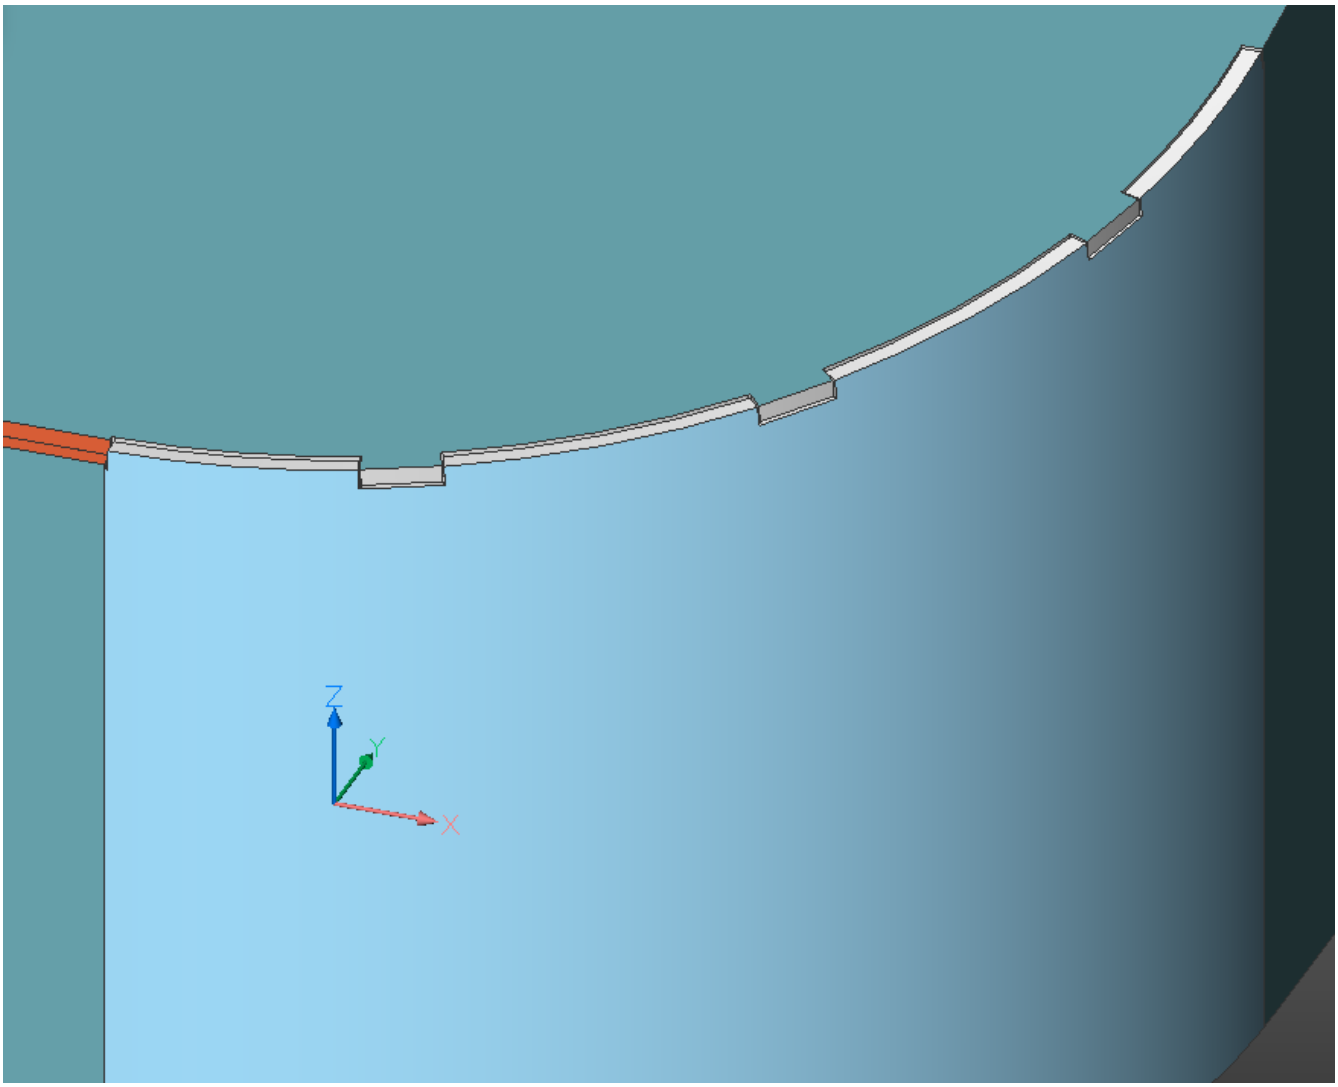


Creating a Curved Array Tab

This case is similar to creation of straight Array Tab, but the tabs are placed along a curved path.

1. To create a curved array tab, do one of the following:
   - – Hover over a curved hard edge and click the **Create array Tab** ( ) tool in the Quad (2.3.3) menu
   - – Click the **Create array Tab** ( ) tool button in the **Sheet Metal** ribbon tab
   - – Choose **Create array Tab** from the **Sheet Metal** menu
   - – Type **smtabcreate** in the command bar.
2. Prompts you: Select junction or curved hard edge to create array tab or [Single tab/selection options (?)]: Select a curved hard edge. (3.540 on the next page)

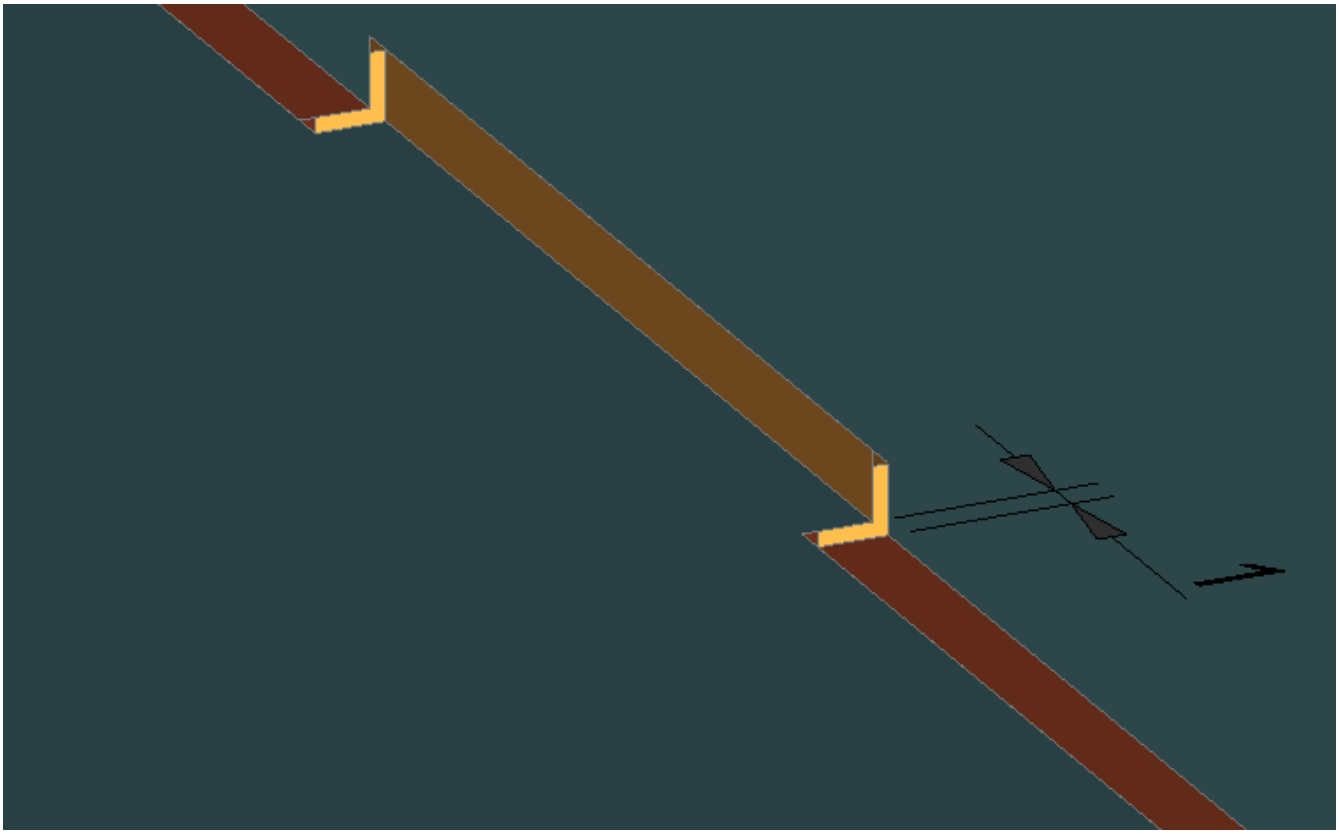
Figure 3.540



Modifying Tabs

Single and array tabs have different editable properties, which are available in the Mechanical Browser (3.3.2) Click the tab feature name to edit. A single tab has **Length**, **Clearance**, **Fillet radius,** and **Chamfer distance** parameters. **Tab clearance** defines the gap between the tab and the slot faces. (3.541 on the following page) An array tab has **Slot number**, **Distance**, **Length**, **Clearance**, **Fillet radius,** and **Chamfer distance** parameters. Note**.** Curved Array Tabs can not be modified.

Figure 3.541



Deleting Tabs

Use SmDelete (6.28.5) to delete tabs (not applicable for curved). A junction feature is created in place of the tabs.

Exploding Tabs

Use SmExplode to explode a tabbed junction to a set of tab features The tab geometry remains the same and its faces are distributed among several junction features.

Original tab feature (3.544 on page 3154)	Result of deletion (3.545 on page 3155)	Result of explode (3.546 on page 3156)

Figure 3.542

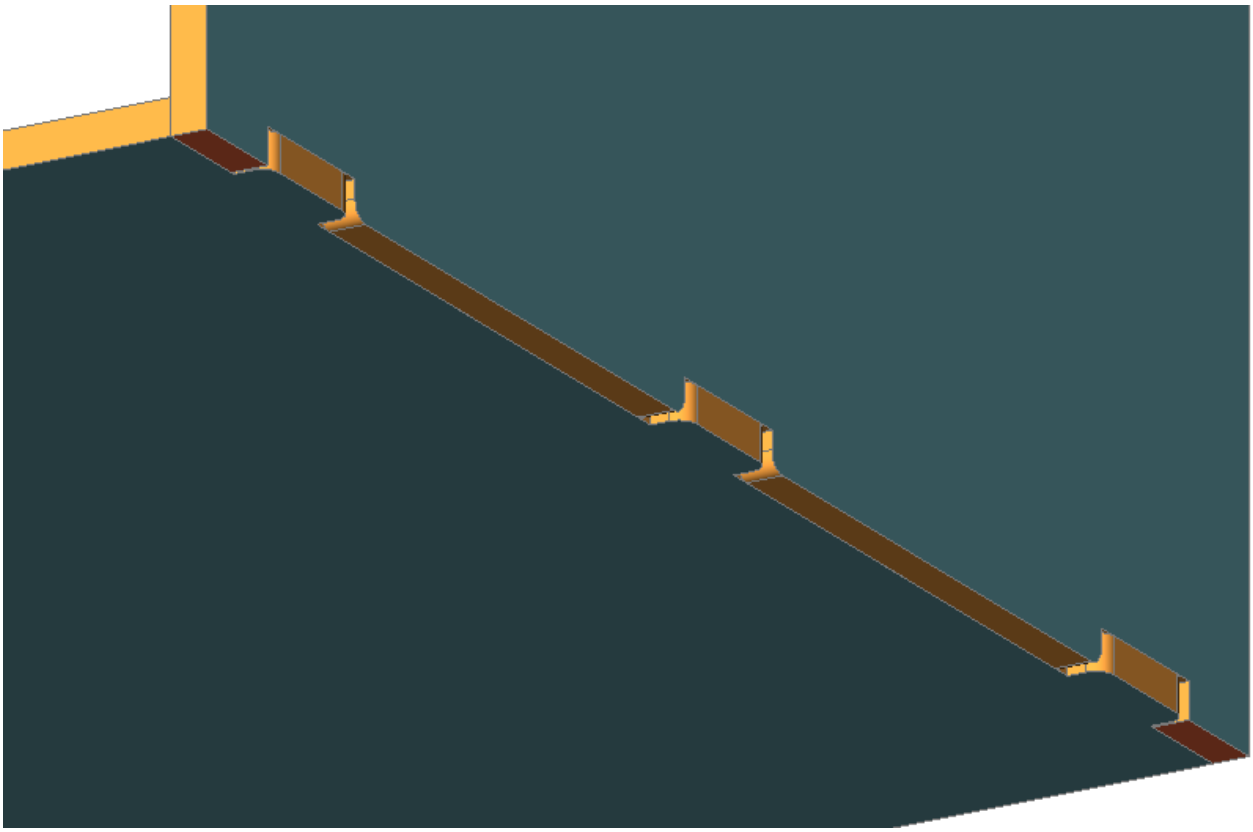


Figure 3.543

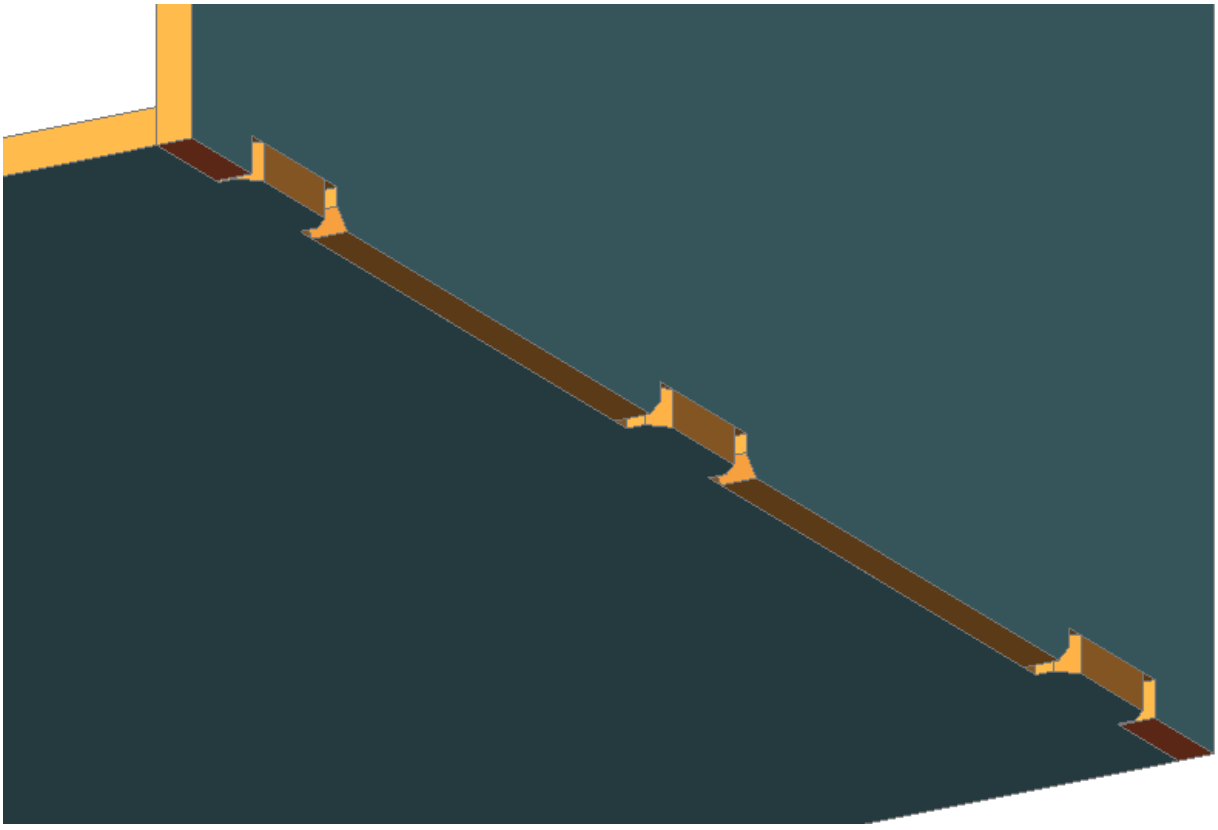

Figure 3.544

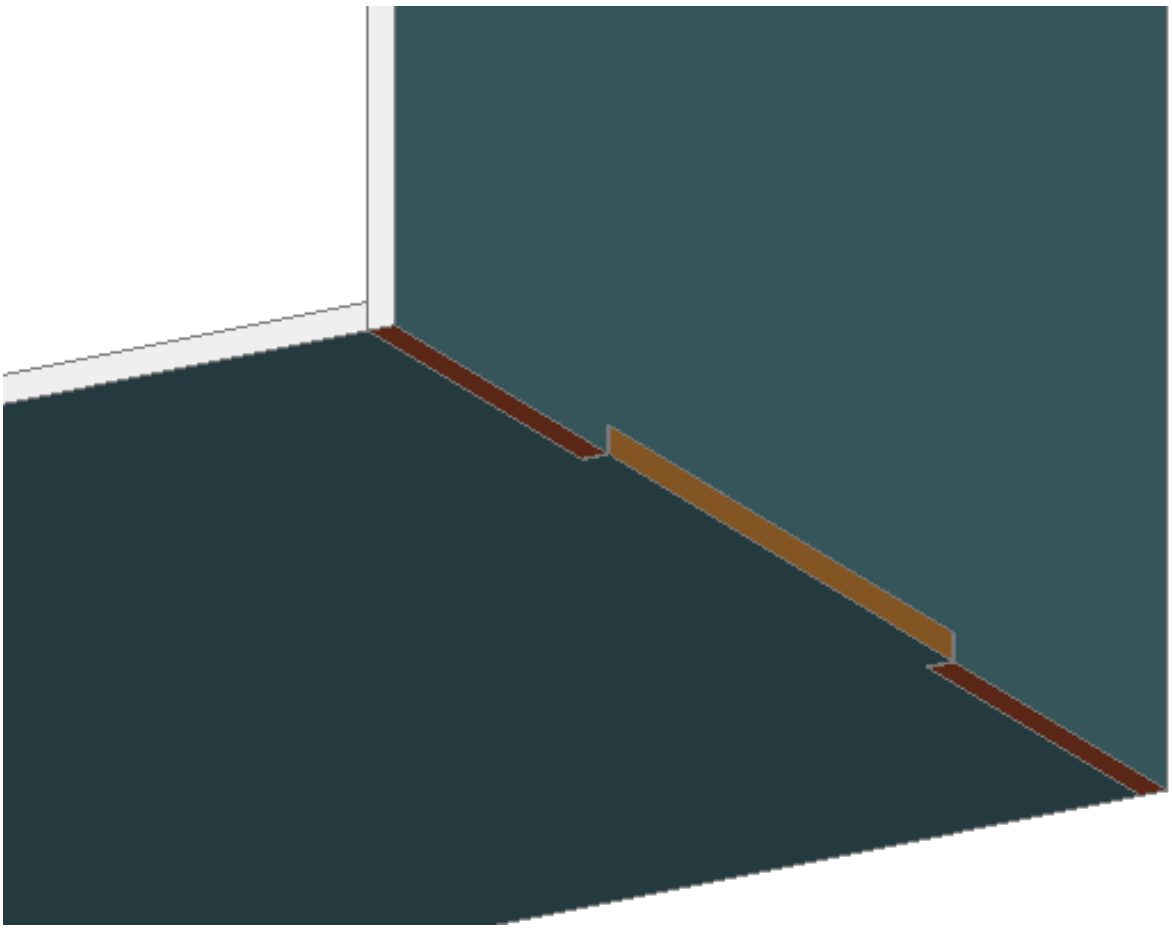

Figure 3.545

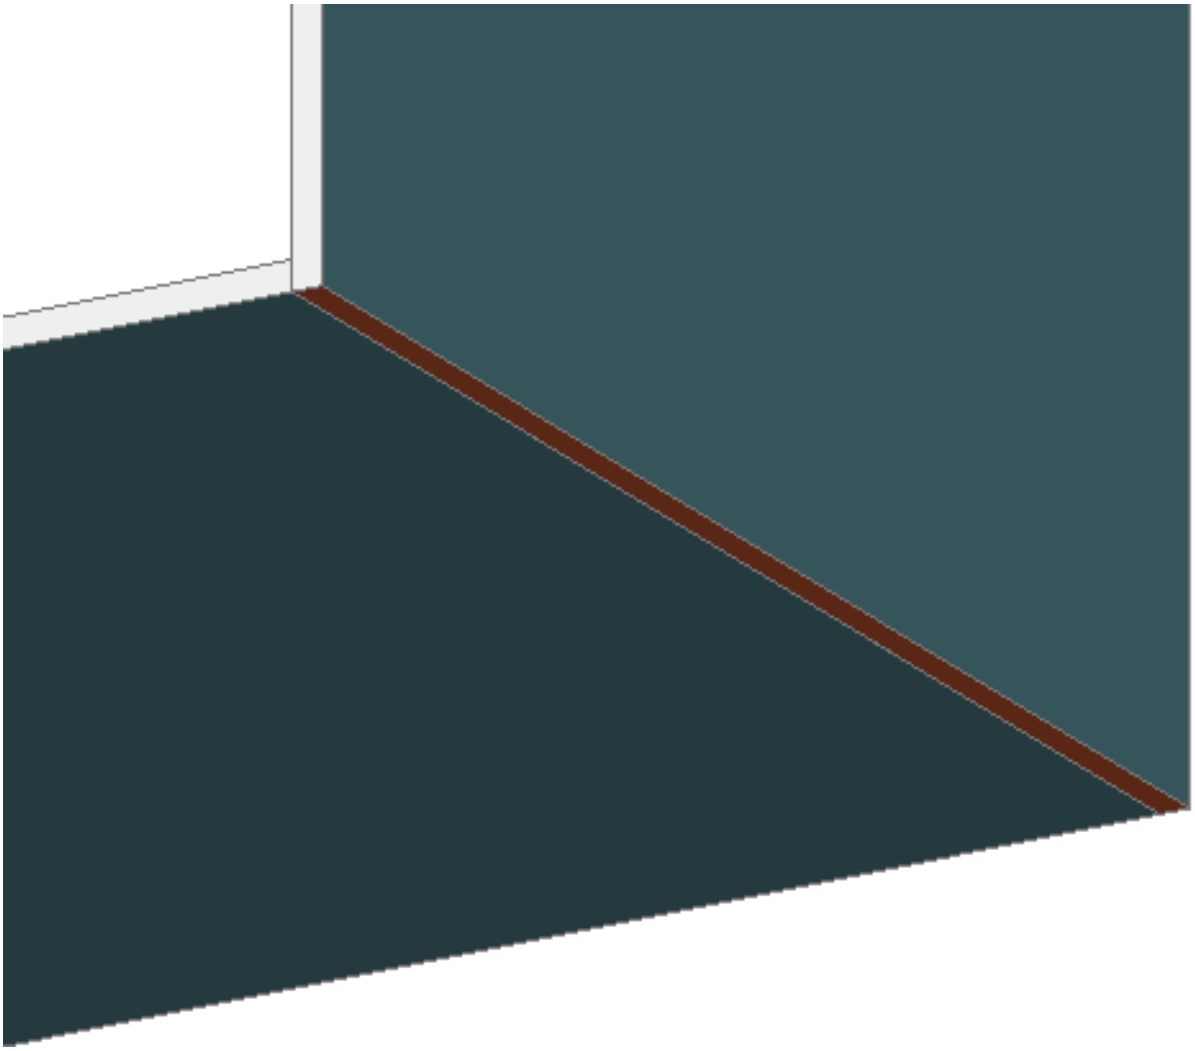

Figure 3.546

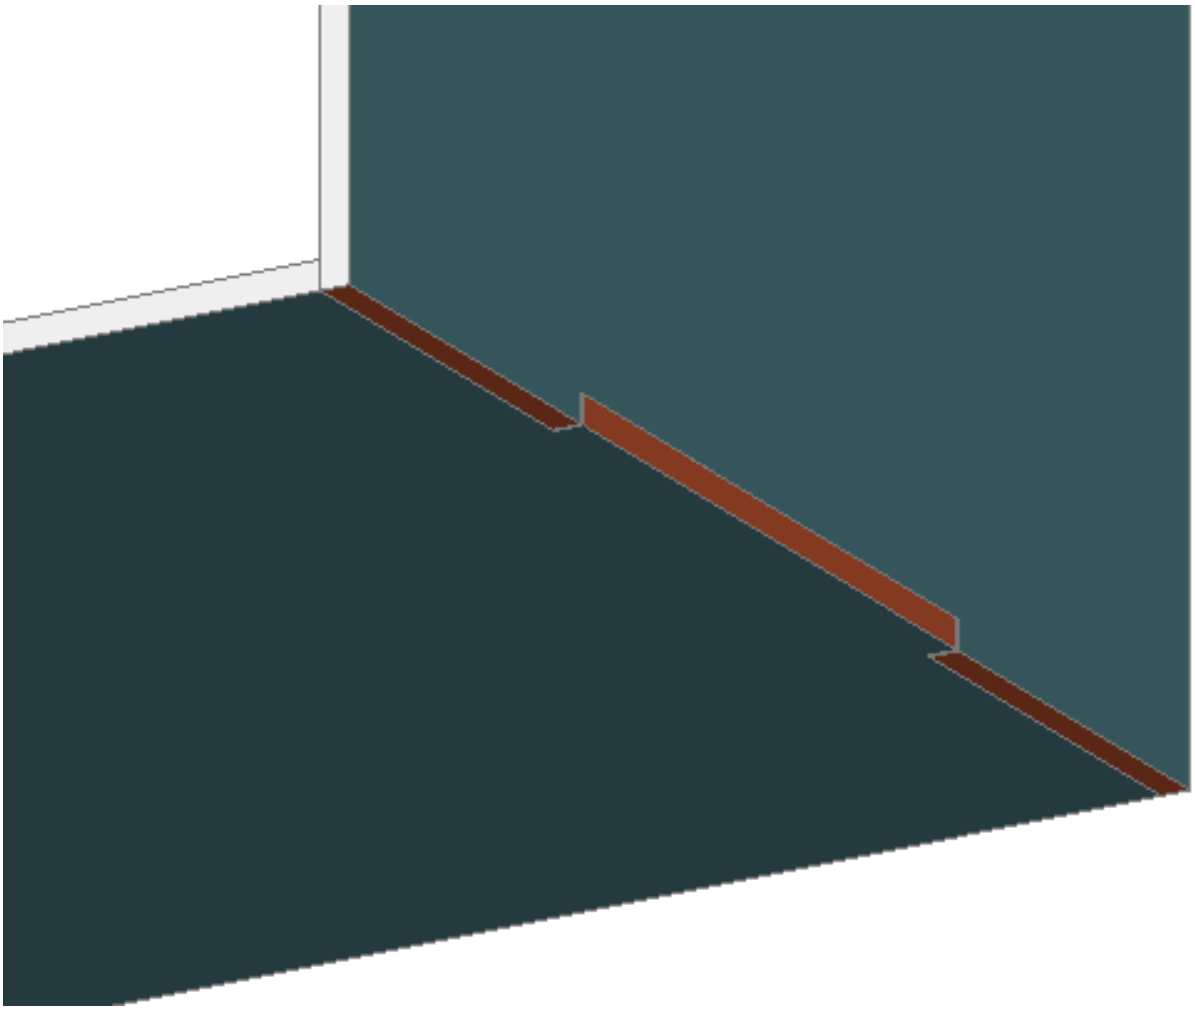

Figure 3.547

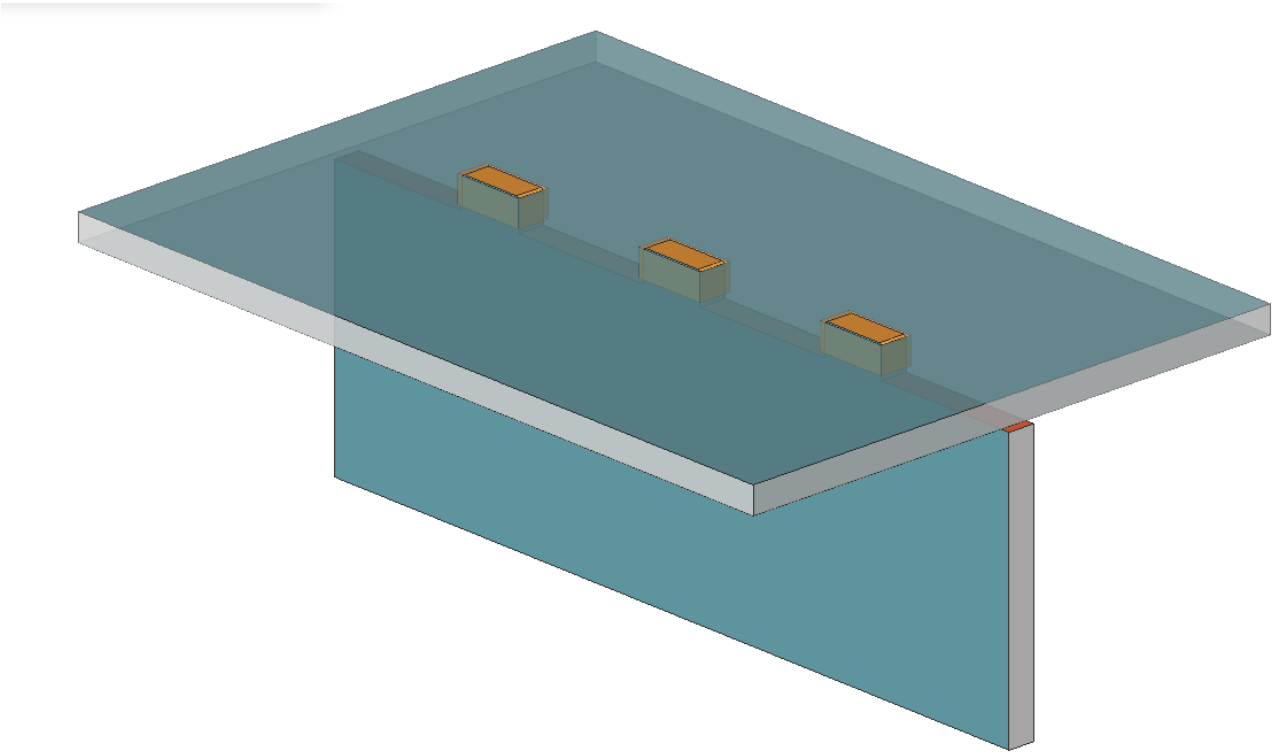


3.9.19 Working with T-Tabs and T-Junctions

T-tab features are used to create a connection with robust positioning between two sheet metal flanges. Unlike normal tabs, T-tabs form a T-like configuration, when one flange is attached to the other. (3.547) T-Tabs can be created from T-Junctions by SmTabCreate (6.28.16) command. T-junction features are often used as an intermediate stage for making T-Tabs.

Creating a T-Junction

A T-Junction can be created on existing separate flanges in the following way.

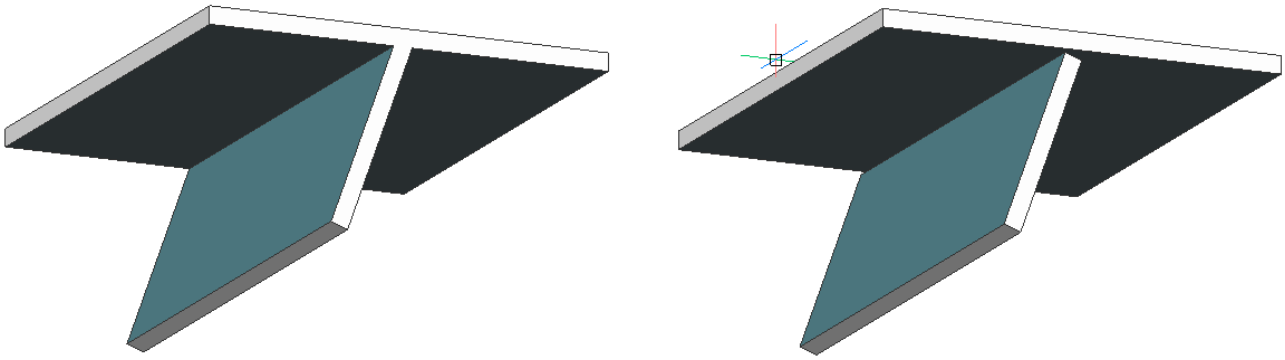
1. Select one thickness face on the flange
2. Click the **Connect Flanges** ( ) tool button in the **Sheet Metal | Junction** ribbon tab or
   - Choose **Connect Flanges** in the **Sheet Metal | Junction** menu or
   - Type **smflangeconnect** in the command bar
3. Press Enter.

Alternatively, a T-junction feature can be created in place of a T-like hard edge between two flanges (image at the left): (3.548 on the next page) Hover over a hard edge between the flanges then click the **Create Junction** ( ) tool in the Quad (2.3.3) menu or do one of the following:

- Click the **Create Junction** ( ) tool button in the **Sheet Metal** ribbon tab
- Choose **Create Junction** from the **Sheet Metal | Junction** menu
- Type **smjunctioncreate** in the command bar

Then select a hard edge.

Figure 3.548



Creating a Single T-Tab

The command SmTabCreate (6.28.28) creates a single T-tab by default. This feature has only a single slot. To create a single T-tab, hover over a T-junction face and click the **Create single Tab** ( ) tool in the Quad (2.3.3) menu or do one of the following:

- Click the **Create single Tab** ( ) tool button in the **Sheet Metal** ribbon tab
- Choose **Create single Tab** from the **Sheet Metal | Tab** menu
- Type **smtabcreate** in the command bar

Then select a T-junction face.

Creating an Array T-Tab

As different from Single T-tabs, array T-tab features have multiple slots. To create an array T-tab, hover over a T-junction face then click the **Create array Tab** ( ) tool in the Quad (2.3.3) menu or do one of the following:

- Click the **Create array Tab** ( ) tool button in the **Sheet Metal** ribbon tab
- Choose **Create array Tab** from the **Sheet Metal | Tab** menu
- Type **smtabcreate** in the command bar; **you are prompted:** Select junction to create single tab or [Array]: select **Array** option

Then select a T-junction face.

Modifying T-Junction and T-Tab Parameters

A T-Junction has only the **Junction gap** parameter. Array T-Tabs and Single T-Tabs have the following properties: **Distance**, **Length**, **Clearance**, **Fillet radius,** and **Chamfer distance.** Array T-Tabs also have the **Slot number** parameter. The value of all parameters can be set in the Mechanical Browser (3.3.2) panel.

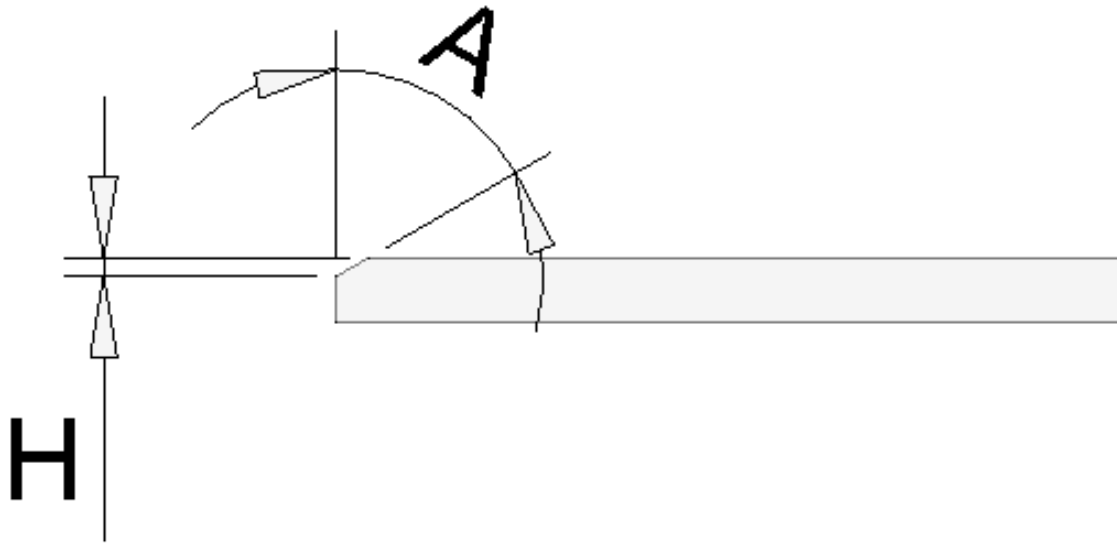
Deleting a T-Junction or T-Tab

When a T-tab feature is deleted, BricsCAD restores a T-junction feature with the corresponding geometry. Erasing a T-Junction joins the flanges and creates a T-like hard edge between them.

Related Commands

MechanicalBrowserOpen (6.8.32) - displays the Mechanical Browser. SmDelete (6.28.5) - erases a feature.

Figure 3.549



3.9.20 Working with Bevels

Bevel features represent a chamfer operation made on Sheet Metal parts. On the level of BricsCAD V21 each bevel should be exactly on a single flange. There are no specific operations to create a bevel, so the DmChamfer (6.12.4) command has to be used on an edge of a flange, and then use DmRotate (6.12.24) to adjust the bevel angle. The SmConvert (6.28.4) command recognizes the bevels and will be processed by SmUnfold (6.28.31). Bevel features are also supported by the SmDelete (6.28.5) and SmRepair (6.28.29) commands. This procedure applies to two scenarios:

- working with importing geometry, including batch export by SmAssemblyExport (6.28.1)
- modifying parts

We distinguish between the following bevel types:

(3.553 on page 3162)	One-side bevel
(3.554 on page 3163)	Land bevel
(3.555 on page 3163)	K-bevel
(3.556 on page 3163)	X-bevel

In the Mechanical Browser (3.3.2) the properties of each chamfer of a bevel feature are available separately. These properties are: (3.549) **Height (H):** the depth of the chamfer operation, much like the DmChamfer (6.12.4) command does. **Angle (A):** the slope of the chamfered face. Please notice that in the Mechanical Browser properties, Top or Bottom are not used to describe bevel features.

Recognizing bevels

Let's start with a sheet metal part with bevel geometry (chamfered flange edges). (3.550 on the next page)

1. Click the **Convert to Sheet Metal (6.28.4)** ( ) tool button on the **Sheet Metal / Create** Ribbon panel. Prompts you: Select 3D solids or seed faces or [Entire model/selection options (?)] <Entire model>::
2. Press Enter to convert the 3D solid to a sheet metal part.

The bevel features are recognized and appear in Mechanical Browser and show on the part: (3.551 on page 3161)

Figure 3.550

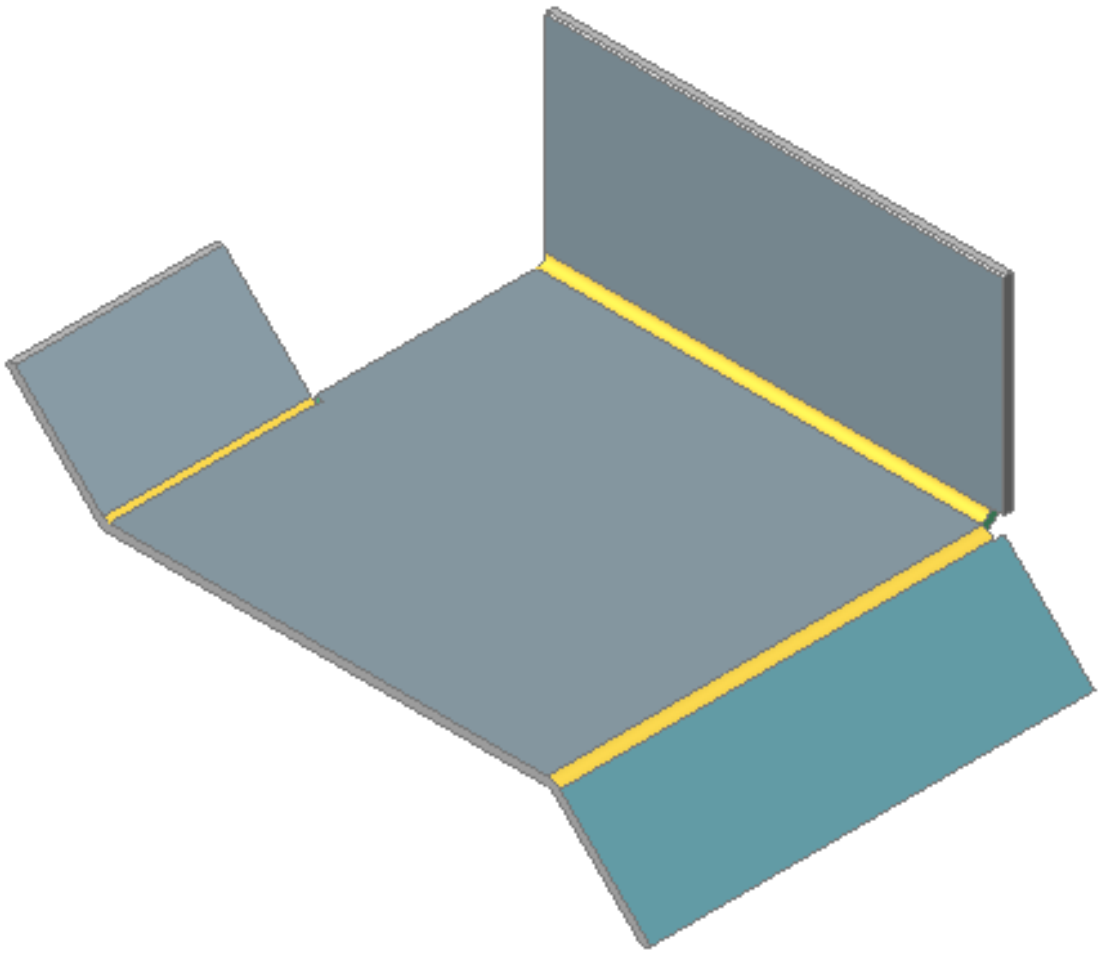


Figure 3.551

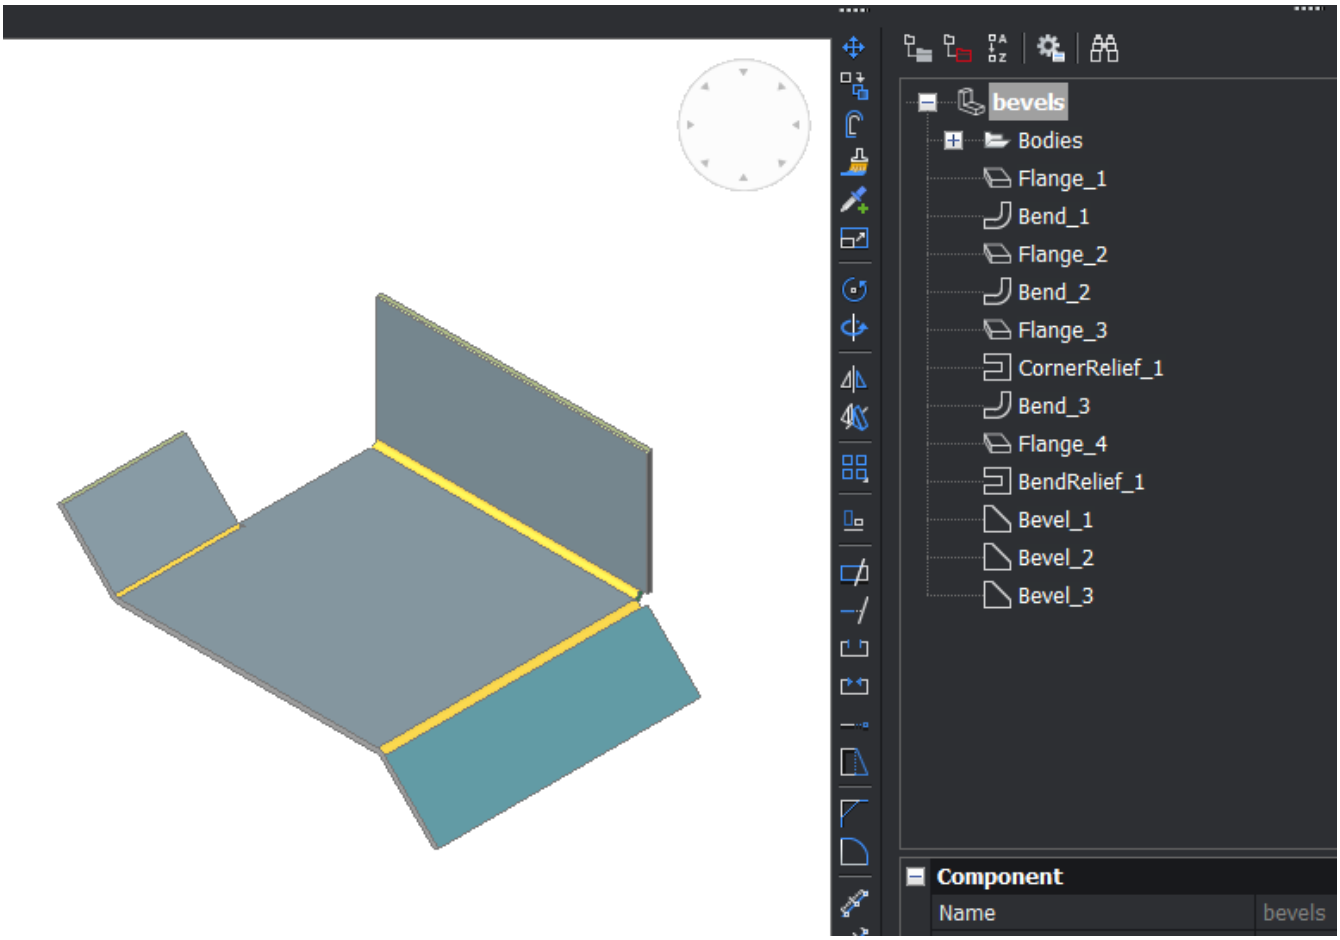

Delete and Repair

The following round trip does not change the overall dimensions of the part: Create the bevel geometry and feature using DmChamfer/SmConvert then delete the bevel using SmDelete and restart the procedure. When using SmDelete (6.28.5) to delete a bevel the volume is **always added** to the part because the dimensions of the part cannot be reduced. Support in the SmRepair (6.28.29) command is important as well, since this command is a part of the Import and Rework workflow. Note: If you apply the SmRepair (6.28.29) command to a part with chamfers but without bevel features, chamfers will be lost and dimensions will change, depending on the selected side of the part.

Unfold

Bevel features are unfolded according to the **Unfolding Mode** setting in the **Mechanical Browser**. The options are: **Keep**: does nothing with bevel geometry. resulting in a 3D solid with chamfers. These chamfered faces will likely produce artifacts in the 2D .dxf **Remove**: same result as applying SmDelete (6.28.5) on all the bevel features: all the chops are filled. **Annotate**: each bevel feature is removed and the edge is annotated. This mode is recommended. This is the result for the example part:

- Each bevel edge has been annotated with a pink text on the **Bevel Annotations** layer.
- UP and DOWN are with respect to the selected side for unfolding. when choosing the opposite side, all the UP annotations become DOWN and vice versa.
- For **One-side** and **Land** bevels a single chamfer operation is needed only: a single UP or Down annotation is created.
- For **K-** and **X-** bevels two chamfer operations are needed: UP and DOWN annotations are created.

(3.552 on the next page)

Figure 3.554

Figure 3.555

Figure 3.556

3.9.21 Creating and Splitting Lofted Bends

BricsCAD allows you to create or recognize (3.9.28) lofted sheet metal parts with curvilinear geometry, which can be manufactured using multiple bending.

General Procedure to Create a Sheet Metal Part with a Lofted Bend

1. Launch the SmLoft (6.28.20) command. Do one of the following:

   - Click the **Create Lofted Bend** tool button ( ) on the **Sheet Metal** toolbar.
   - Click the **Create Lofted Bend** tool button ( ) on the **Sheet Metal** ribbon bar.
   - Choose **Create Sheet Metal Loft** in the **Sheet Metal** menu.

   You are prompted: Select two cross sections:

2. Select two profile entities. (3.557 on the facing page) **You are prompted:** Set fillets Radius/Thickness/Single bend/<Flanges with bends>:

3. Press Enter to accept the default settings. A preview of the sheet metal part is created. **You are prompted:** Set fillets Radius/Thickness/Single bend/Flanges with bends or make thicken Both sides/Inside/<Outside>: (3.558 on the next page)

4. Hit the CTRL key to choose the position of the sheet metal part thickness with respect to the source profiles: **Left**, **Center** or **Right**. If TIPS (1.15.2) is ON the tips widget displays.

5. Press Enter to create the sheet metal part. (3.559 on page 3166) If FEATURECOLORS (1.17.10) = ON, you can distinguish between the two flanges ( ) and the lofted bend ( ).

The properties of the lofted bend display in the Mechanical Browser (3.3.2): (3.560 on page 3166) Optionally select the lofted bend feature to edit its properties:

- **Number of subdivisions**: the number of flat regions in the unfolded representation of a lofted bend feature (the greater the number, the more bend lines will be added to the unfolded view for the lofted bend).
- **Force triangulation**: most of lofted bends can be unfolded using an intelligent algorithm of quad tessellation; however sometimes it might produce non-optimal results. In such cases set this property to **Yes** to switch to more straight-forward algorithm which creates triangle-like quads.

Tutorial: Lofted bends in BricsCAD Sheet Metal Click here (3.8.9) to watch

Figure 3.557

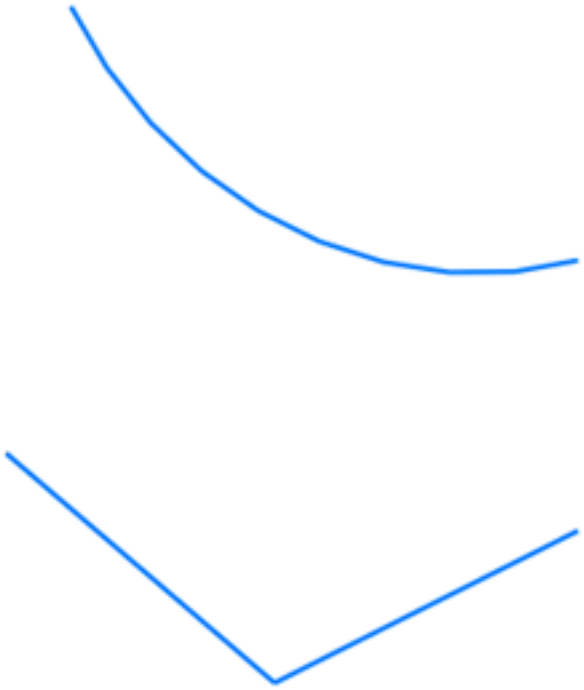

Figure 3.558

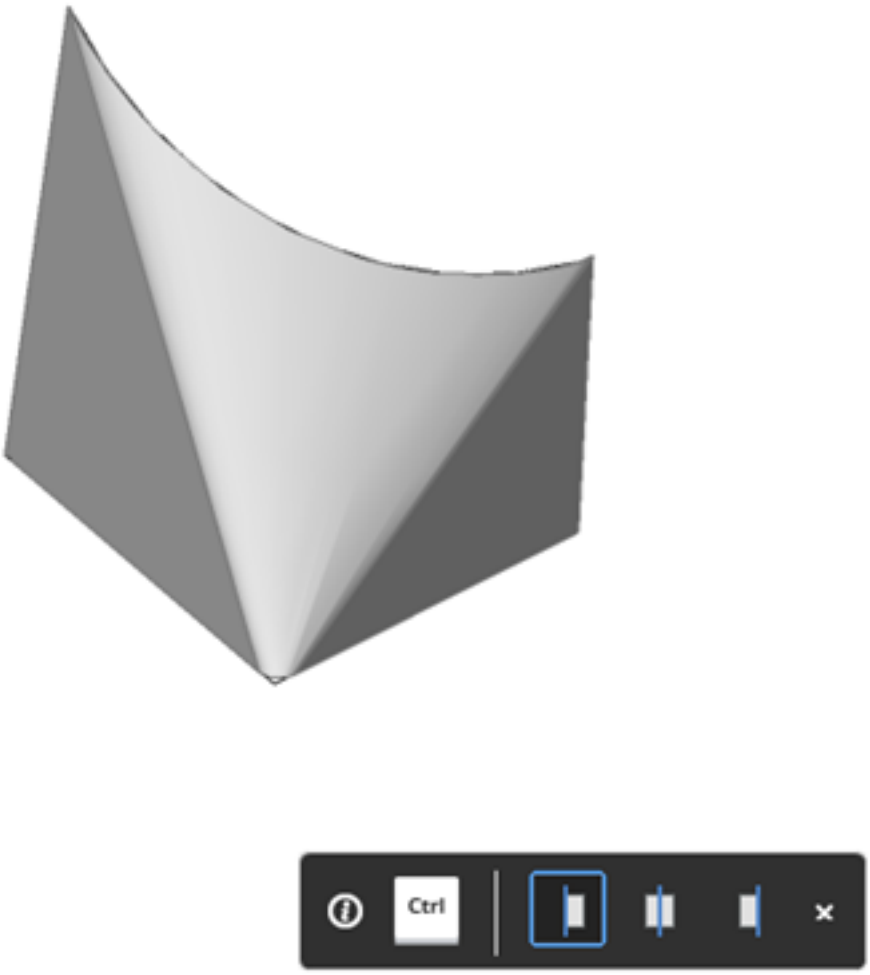

Figure 3.559

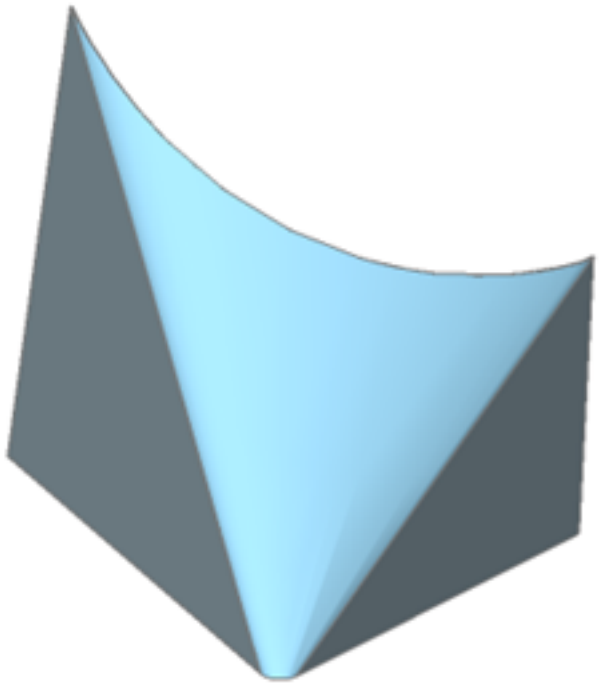

Figure 3.560

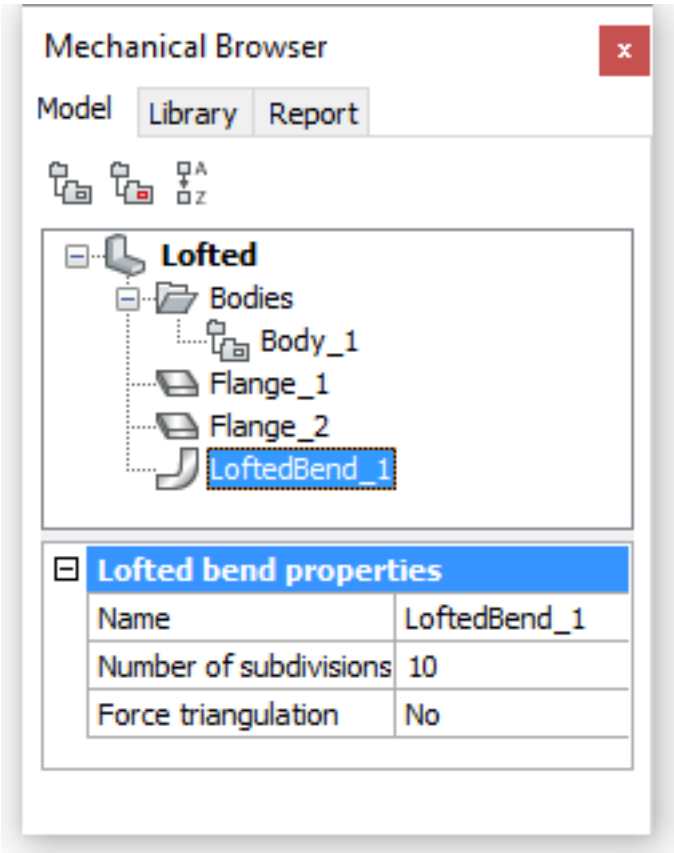

To Split a Lofted Bend

Lofted bends can split along a line on the lofted surface at an arbitrary point:

1. Do one of the following:

   - Click the **Split** tool ( ) on the **Sheet Metal** ribbon tab;
   - Choose **Split** the **Sheet Metal** menu;
   - Type **smsplit** in the command bar

   You are prompted: Select flange or lofted bend face:

2. Select a lofted bend face. **You are prompted:** Select point on lofted bend face:

3. Select a point on the lofted bend surface. (3.561 on the following page)

The lofted bend is split. If the connecting junction is dissolved, you can freely move the separated part. (3.562 on page 3169) (3.563 on page 3170)

Figure 3.561

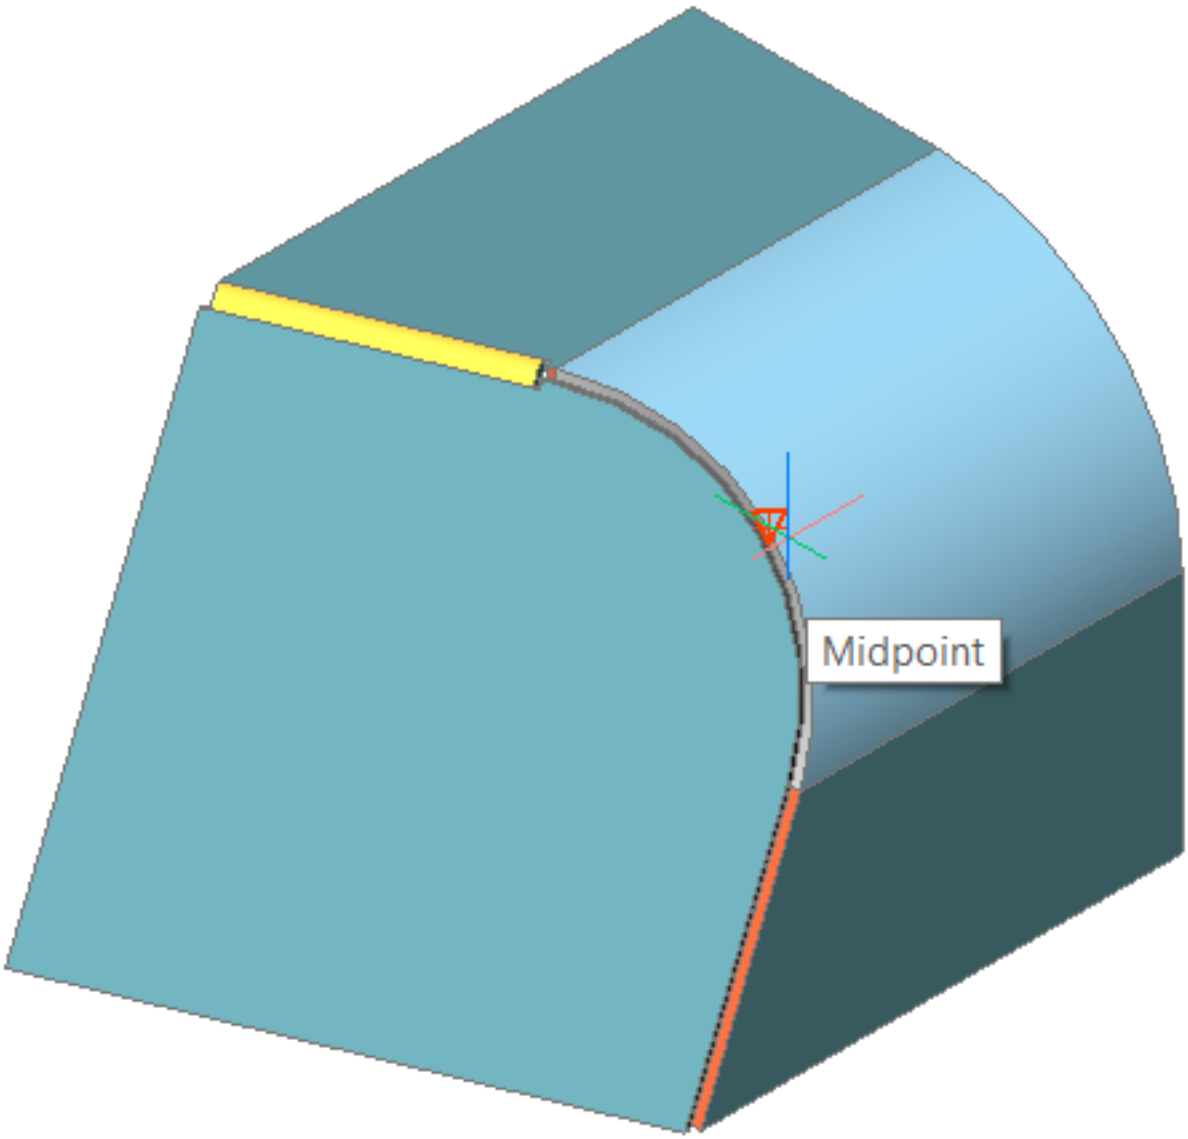

Figure 3.562

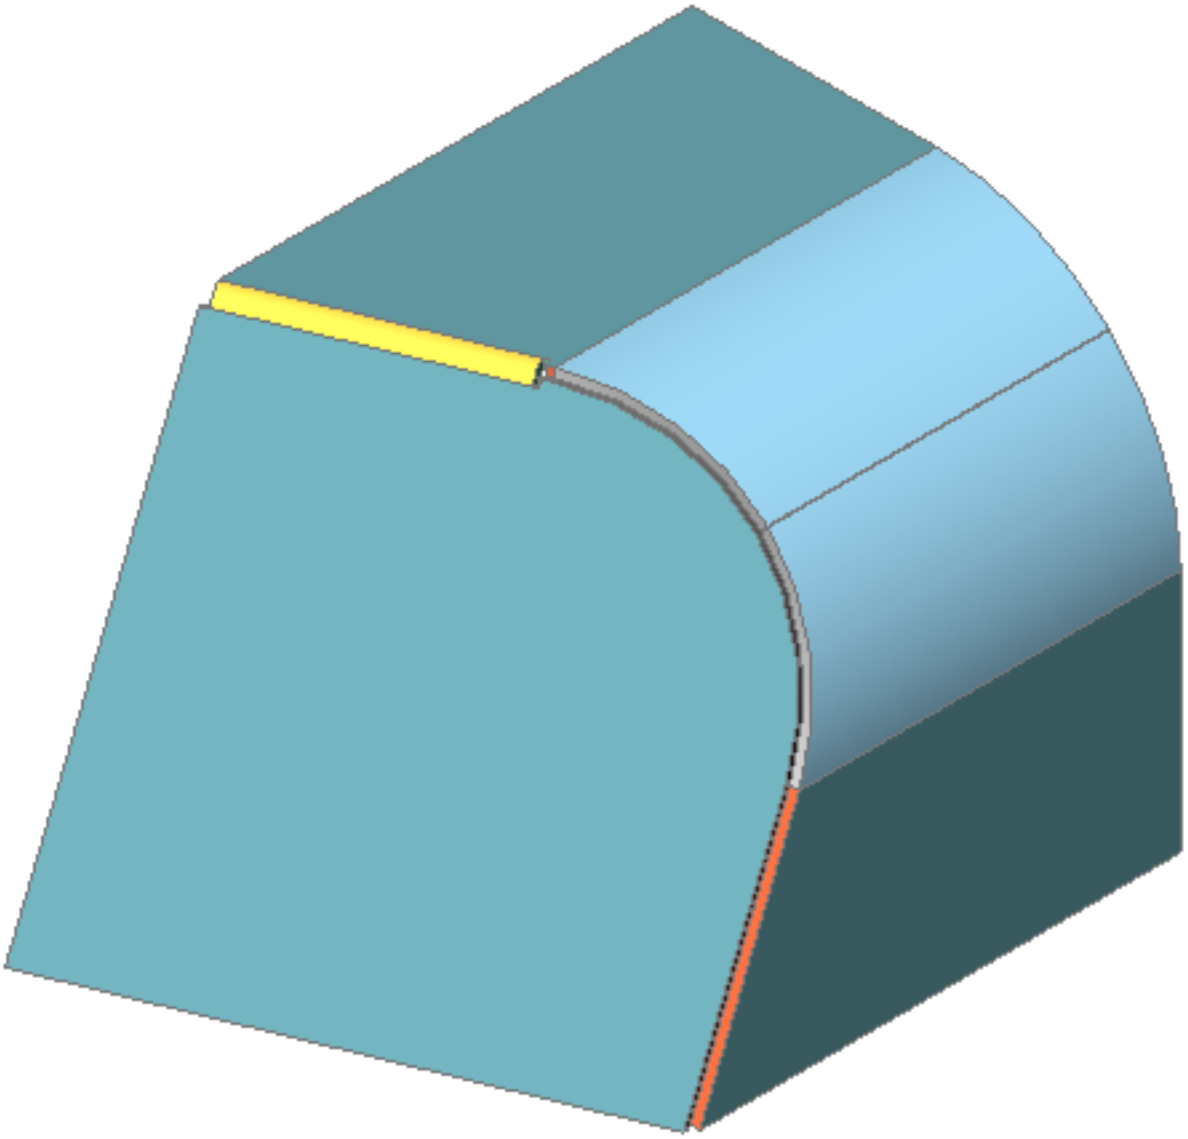

Figure 3.563

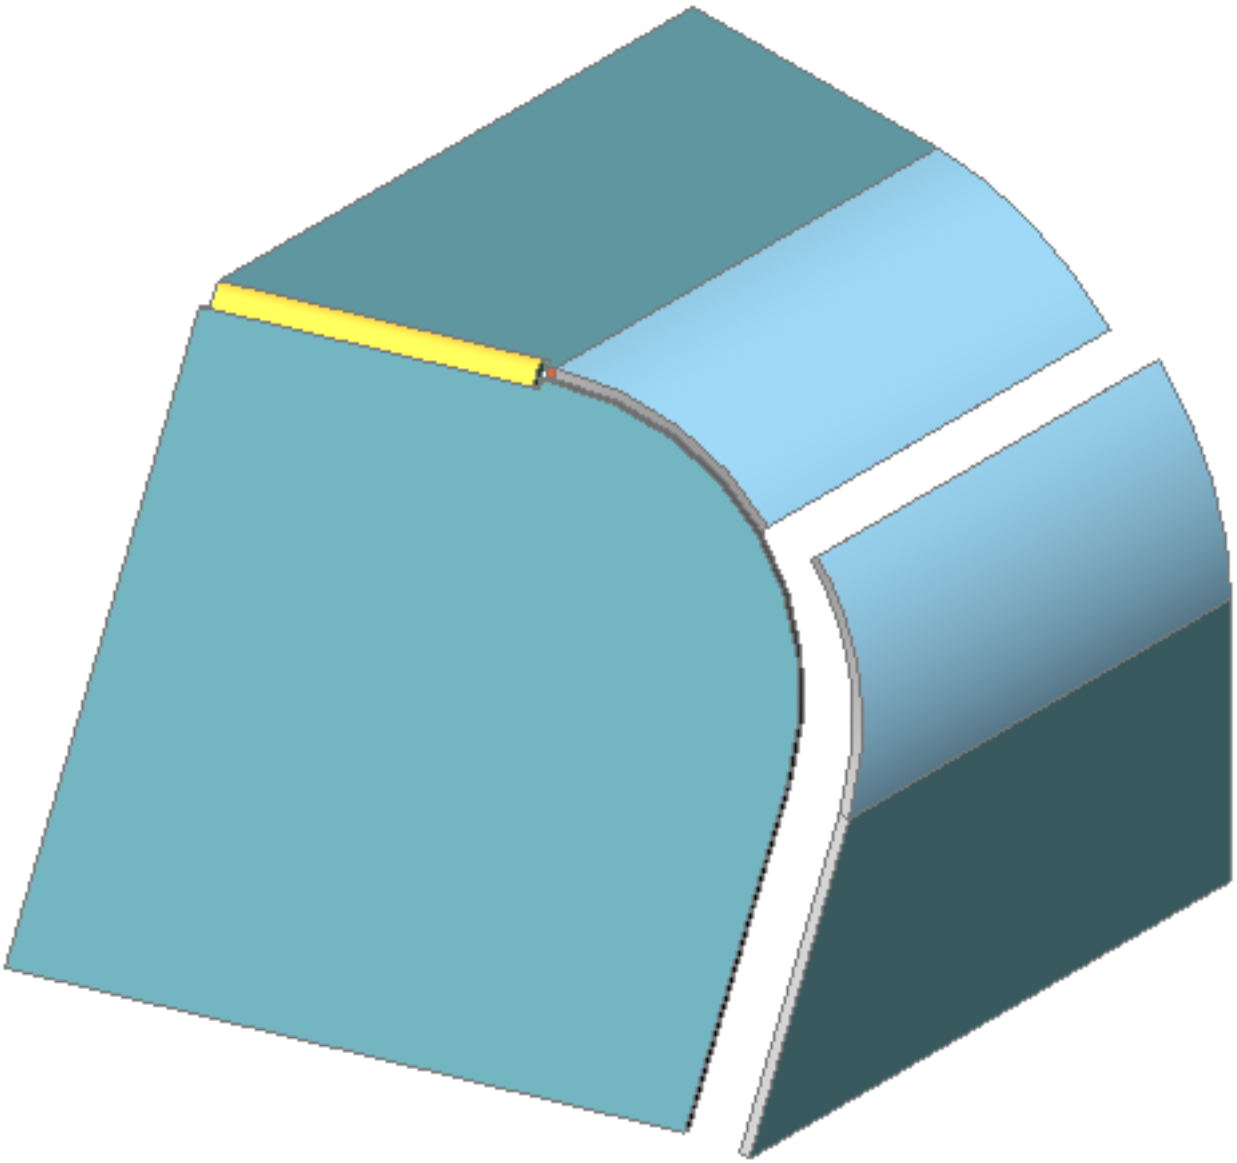


3.9.22 Bend Relief and Corner Relief Feature Operations

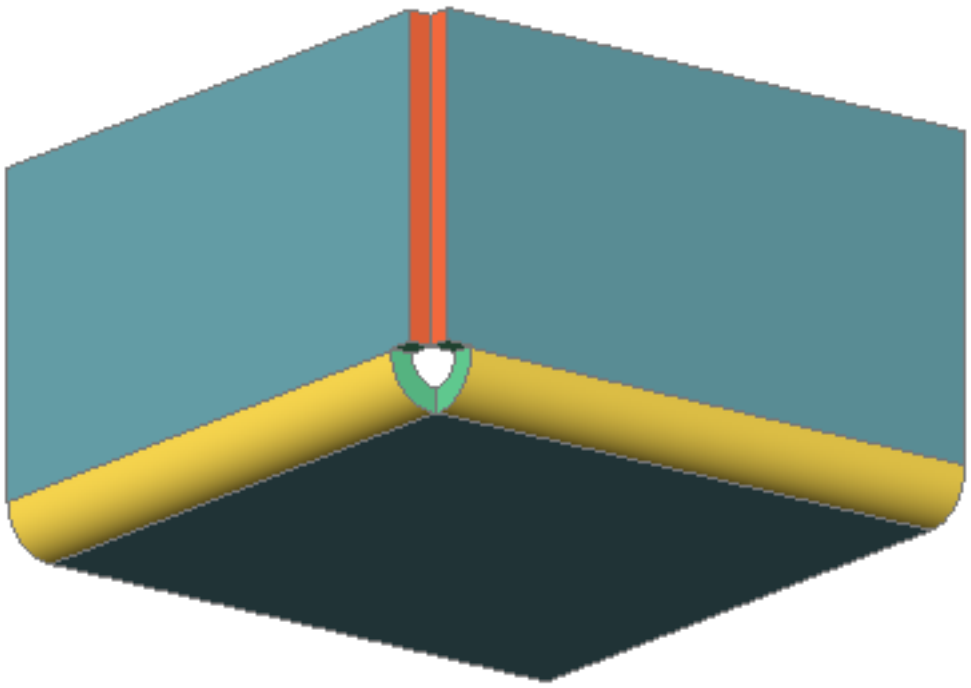
Commands: SMFLANGEEDGE (6.28.14), SMRELIEFCREATE (6.28.22), SMJUNCTIONSWITCH (6.28.19), SMRELIEFSWITCH (6.28.24) Reliefs are needed in sheet metal parts to avoid material tear when bent on press breaks. Basically you should not care about reliefs, because BricsCAD automatically creates all needed reliefs when you create a bend (implicitly or explicitly). However if you rework poor sheet metal parts, you may find it useful to create corner and bend reliefs with the dedicated tools.

Corner Reliefs and Junctions

When you create a flange using the SmFlangeEdge (6.28.14) command, adjacent to a bend edge a corner relief is created automatically in the corner where the three flanges meet. In addition a junction is created between the two flanges, which are not connected with a bend. (3.564 on the next page)

Tutorial: Designing from scratch in BricsCAD Sheet Metal Click here (3.8.15) to watch

Figure 3.564



Creating Missing Reliefs

1. Do one of the following:

   - Click the **Create Relief** tool button ( ) on the **Sheet Metal** ribbon tab.
   - Choose **Create Relief** in the **Sheet Metal** menu.
   - Type **smreliefcreate** in the command bar.

   You are prompted: Select a hard edge, bend face, flange face or 3D solid [Entire model]:

2. Select an item (see the note below). Enter relief size by bend radius ratio or [force Bend reliefs/Auto] <Auto>:

3. Do one of the following:

   - Press Enter or right click to accept the default bend radius ratio.
   - Type a value at the command prompt, then press Enter.

   The relief is created.

(3.568 on page 3176) Selected bend faces	(3.568 on page 3176) Created reliefs

NOTE

- The selected items can be a 3D solid with sheet metal features, a face or a hard edge of the solid.
- To create a relief locally, you can select one or two hard edges, one or two bends or a bend and a hard edge.
- If a 3D solid is selected the command recognizes the places where corner or bend reliefs are needed and creates them automatically.
- If two hard edges or two bends or a bend and a hard edge at a corner are selected, the command tries to create a corner relief.

NOTES

- A **Rip** relief has a very small width of 0.001 * thickness. If you need to remove the relief completely, change its width to 0. This operation removes both the bend relief geometry and the bend relief feature.
- **Smooth**, **Round** and **Rip** bend relief types can be applied only if the current bend relief type is **Rectangular**.

Using the ribbon, menu or toolbar

1. To choose the desired relief type, do one of the following:
   - Click the **Relief** drop-down button in **Sheet Metal / Modify** panel on the ribbon and select **Switch to Rectangular**, **Switch to Smooth**, **Switch to Round** or **Switch to Rip**.
   - Click a tool button on the **SM Relief** toolbar: **Switch to Rectangular Relief** (), **Switch to Smooth Relief** (), **Switch to Round Relief** () or **Switch to Rip Relief** ().
   - Choose the relief type in the **Sheet Metal / Relief** menu.

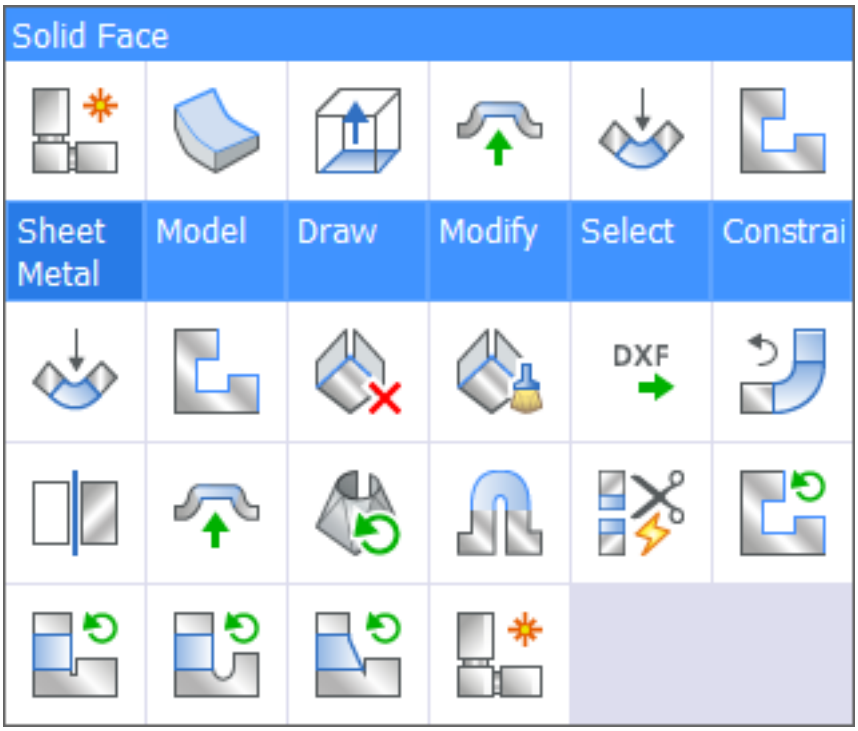
   You are prompted: Select faces, 3d solids to switch reliefs to V-type [RECtangular/CIrcular/V-type/SMooth/RIp/ROund/EXtension/Entire model] <Entire model>:
2. Do one of the following:
   - Press Enter to apply the selected relief type to the entire model.
   - Click a neighboring flange or bend or a face of the bend relief.

   The bend relief is converted.
3. If the command has been called from the Ribbon, the command repeats the main prompt until you press the ESC key to stop.

Using the Quad

1. Hover over a neighboring flange or bend or a face of the bend relief. If the **Select Faces** option of the SELECTIONMODES (1.17.10) system variable is selected, the flange or face highlights; otherwise hold the CTRL key down when hovering until the face highlights.
2. Select the desired relief type in the **Sheet Metal** tab in the Quad (2.3.3). (3.565 on the following page)

Figure 3.565



Switching the Corner Relief Type

The corner relief type can be switched between three types:

(3.575 on page 3180) Rectangular	(3.576 on page 3181) Circular	(3.577 on page 3181) V-type

Using the ribbon, menu or toolbar:

1. To choose the desired relief type, do one of the following:

   - Click the **Relief** drop-down button in **Sheet Metal / Modify** panel on the ribbon and select a relief type.
   - Click a tool button on the **SM Relief** toolbar.
   - Choose the relief type in the **Sheet Metal / Relief** menu.

   You are prompted: Select faces, 3d solids to switch reliefs to V-type [RECtangular/CIrcular/V-type/SMooth/RIp/ROund/EXtension/Entire model] <Entire model>:

2. Do one of the following:

   - Press Enter to apply the selected relief type to the entire model.
   - Click a neighboring flange or bend or a face of the corner relief.

   The corner relief is converted.

3. If the command has been called from the Ribbon, the command repeats the main prompt until you press the ESC key to stop.

Using the Quad:

1. Make sure the **Select Faces** option of the SELECTIONMODES (1.17.10) system variable is selected.
2. Hover over a neighboring flange or bend or a face of the corner relief.
3. Select the desired relief type in **Sheet Metal** command group in the Quad (2.3.3). (3.566 on the facing page)

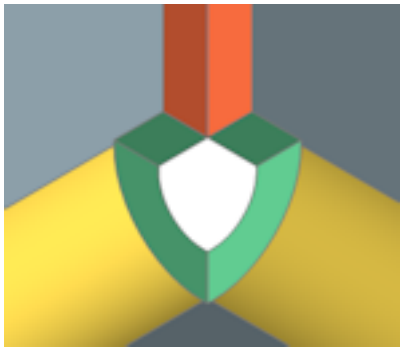

Figure 3.576

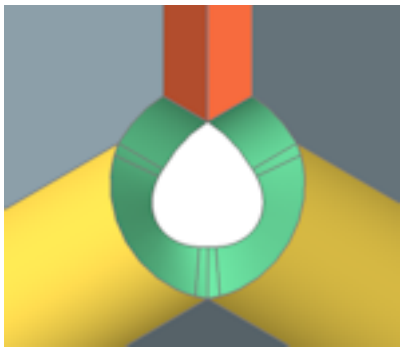

Figure 3.577

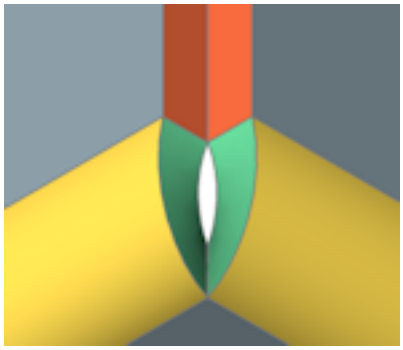

Figure 3.578

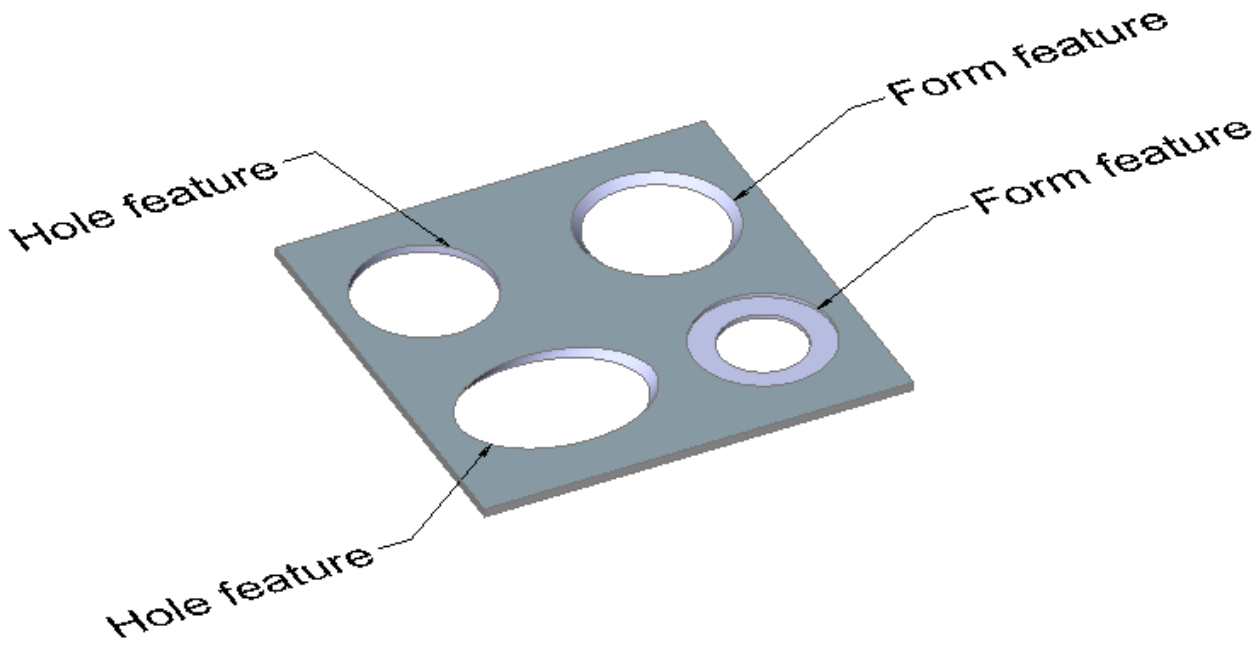

3.9.23 Working with Hole Features

Hole features are a simplified version of **Form Features**. In the image below you can see different features which have only thickness faces (the SmConvert (6.28.4) command respects these rules):

- Orthogonal holes are hole features
- Simple non-orthogonal holes are hole features
- Chamfered orthogonal holes are form features
- If the hole thickness face consists of two different regions, it is form feature

(3.578) Hole features are recognized by the SmConvert (6.28.4) command if the SmConvertRecognizeHoles (1.17.10) user preference is ON. The following basic operations are allowed for hole features:

- SmDelete (6.28.5), SmDissolve (6.28.7), disable and SmSelect (6.28.32) them using commands or in the Mechanical Browser for Sheet Metal (3.9.6).
- Form Feature Modes in the SmUnfold (6.28.31) command, including **Symbol** mode.
- Associate your own 2D geometry in a flattened layout (see for Working with Form and Rib Features (3.9.25) workflow of creation form feature component for creation of unfold symbol).
- Hole features are preserved by the SmRepair (6.28.29) command. Plain hole faces become orthogonal. A hole feature of the same geometry is not affected by the SmRepair (6.28.29) command.

Recognition of Arrays of Hole Features

When hole features exist in a body, SmParametrize (6.28.23) detects rectangular arrays of holes on flanges, according to the following rules:

- holes belong to the same flange
- holes are on a rectangular grid
- there are no gaps (missing elements) in the array
- holes are equally oriented
- the minimal array size is either 1x3 or 2x2

Let's illustrate the workflow on a part with Flange and Bend features. (3.579 on the facing page)

Figure 3.579

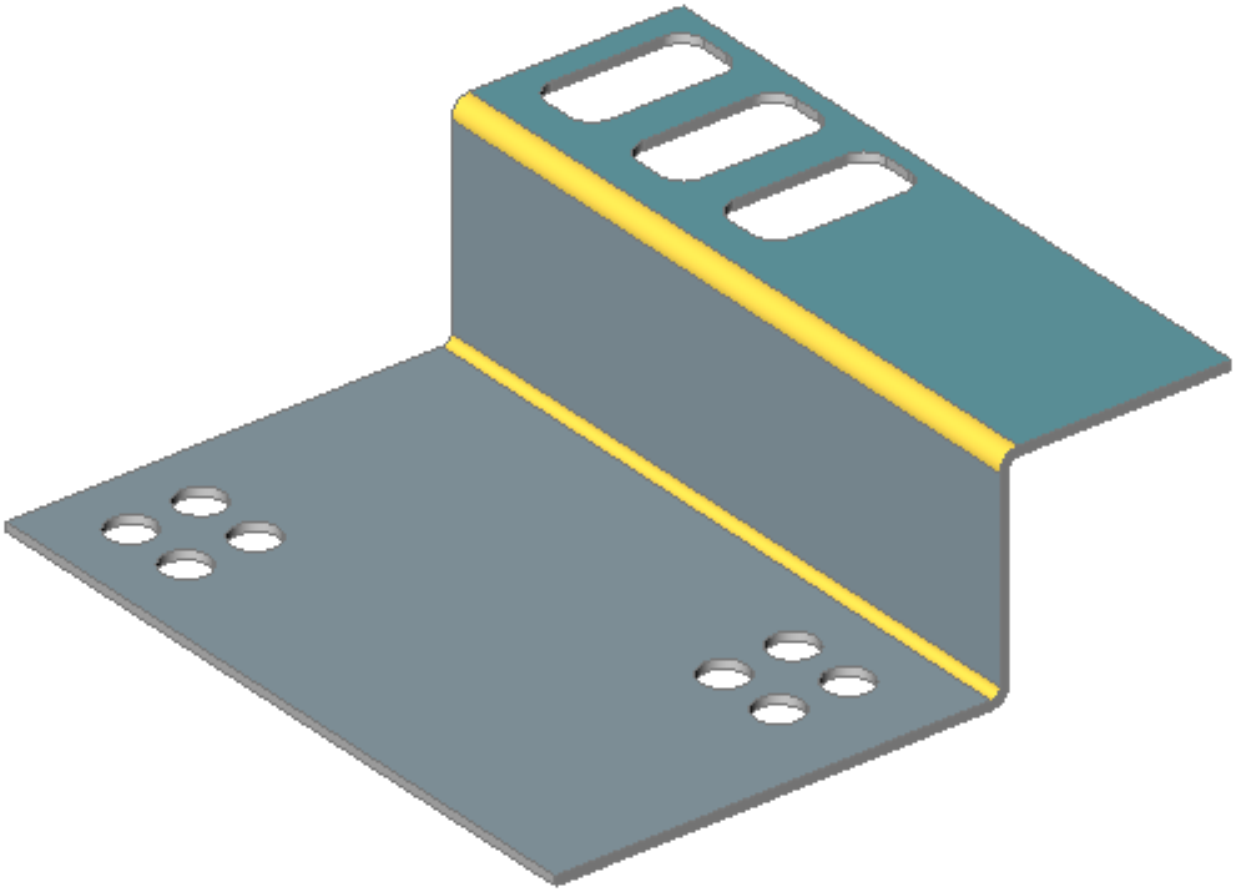

Figure 3.580

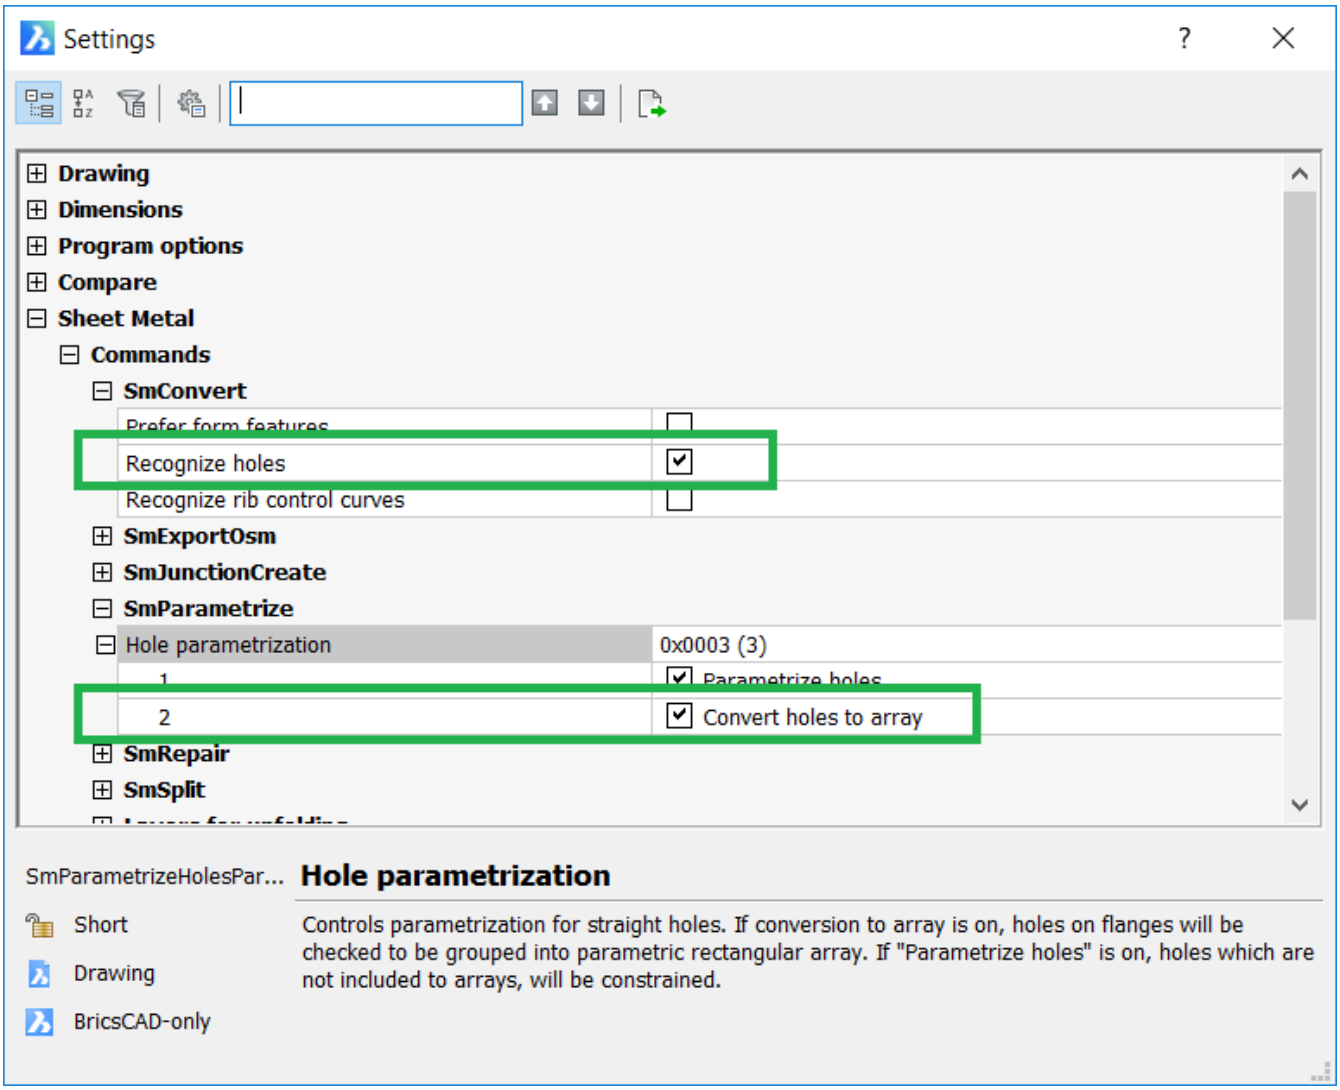

1. In the Settings (1.17.10) dialog go to **Sheet Metal/Commands**.
2. Enable the **Recognize holes** option for the SmConvert (6.28.4) command.
3. Enable the **Convert holes to array** and Parametrize holes options for the SmParametrize (6.28.23) command. (3.580)
4. Run the SmConvert (6.28.4) command.
5. Do one of the following:

   - Click the **Convert to Sheet Metal** tool button ( ) on the **Sheet Metal** toolbar.
   - Click the **Convert to Sheet Metal** tool button ( ) on the **Sheet Metal** ribbon bar.
   - Choose **Convert to Sheet Metal** in the **Sheet Metal** menu.

   You are prompted: Select 3D solids or [Entire model] <Entire model>:
6. Select the 3D solid to convert. **You are prompted:** Select 3D solids or [Entire model] <Entire model>:
7. Press Enter to convert the 3D solid to sheet metal part. Eleven hole features are recognized on the part. (3.581 on the facing page)
8. Run the SmParametrize (6.28.23) command.
9. Do one of the following:

   - Click the **Parametrize** tool button ( ) on the **Sheet Metal** l toolbar.
   - Click the **Parametrize** tool button ( ) on the **Sheet Metal** ribbon bar.

Figure 3.581

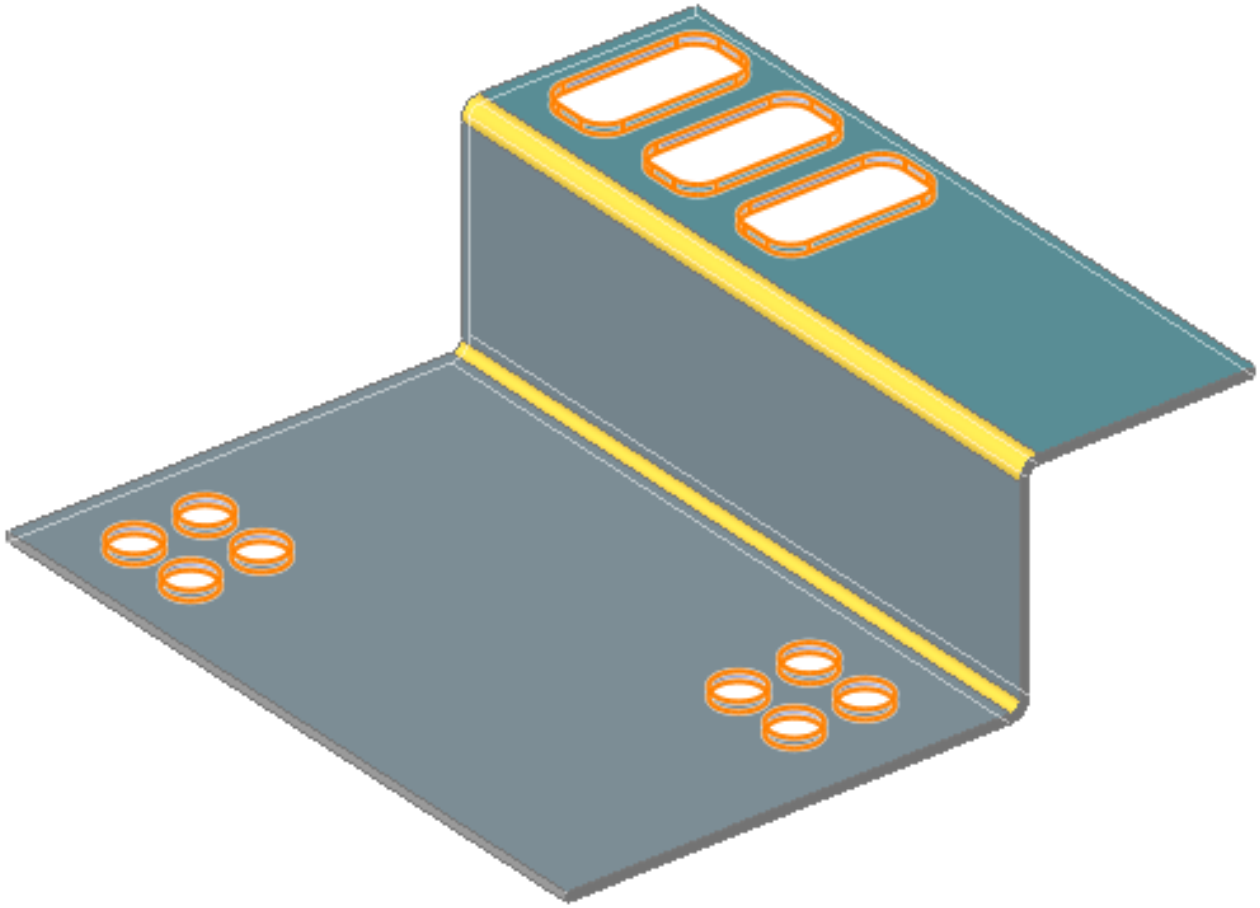

Figure 3.582

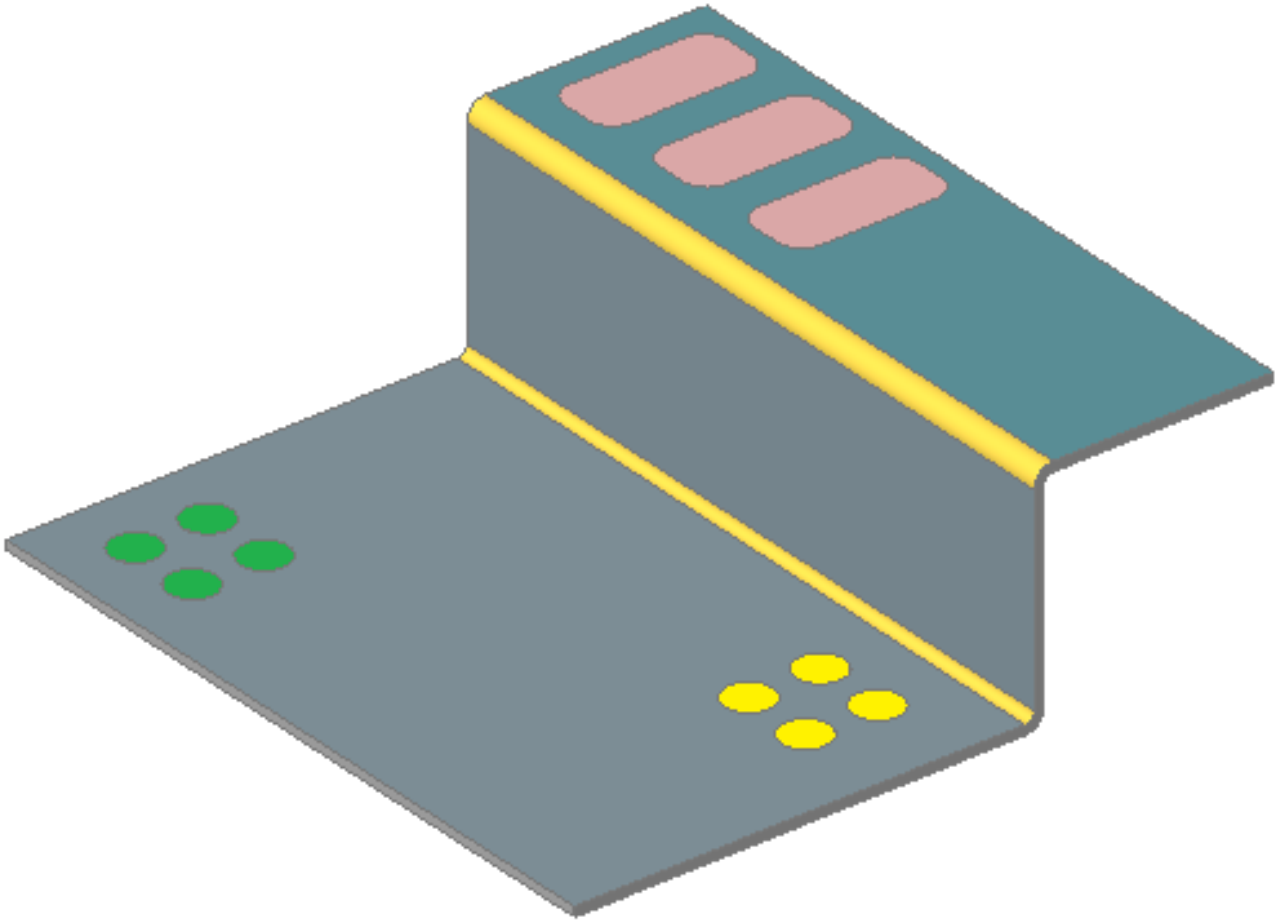


- Choose **Parametrize** in the **Sheet Metal** menu.

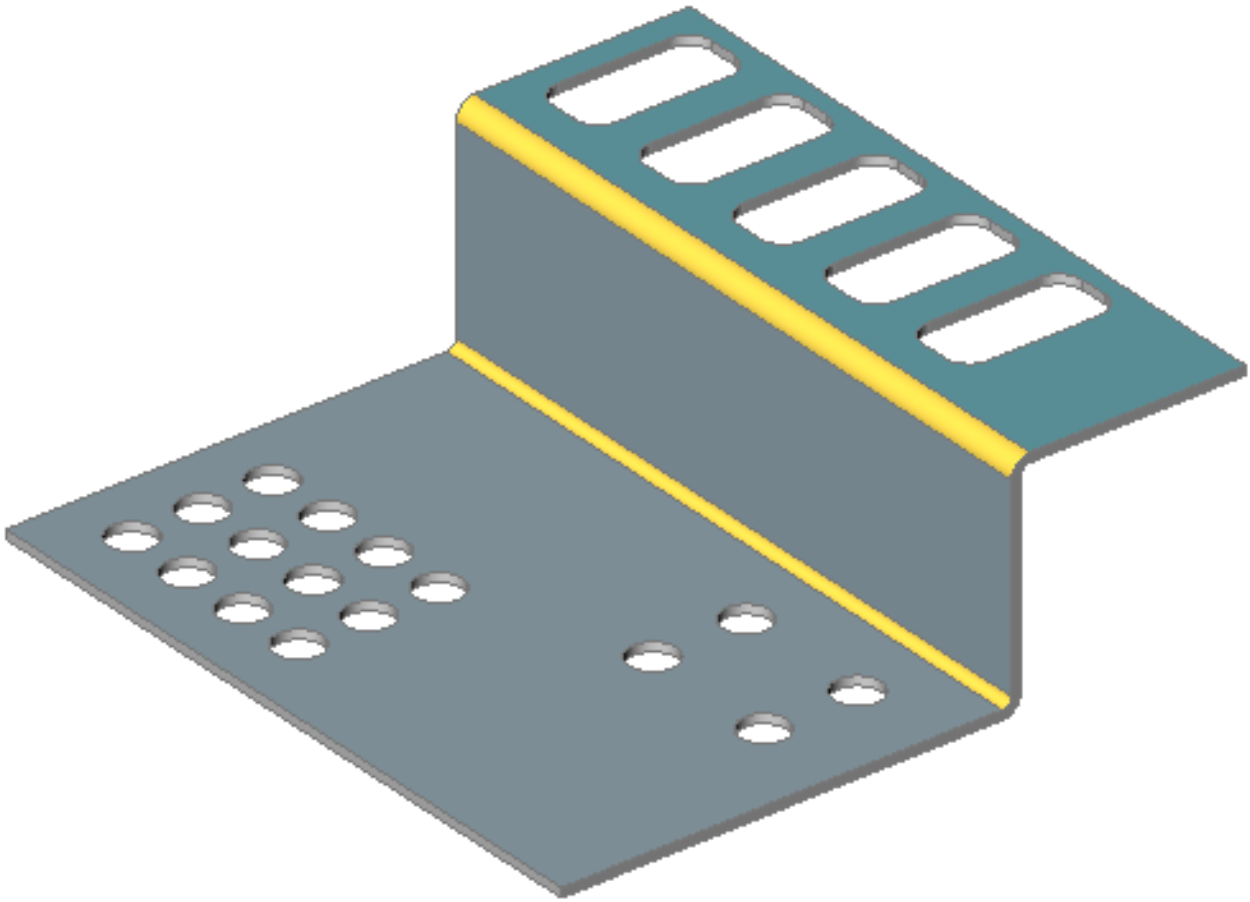
You are prompted: Select 3D solids to parametrize or [Entire model] <Entire model>:

10. Press Enter to process the sheet metal part. The command reports should look like the one below: Created 4 distance constraints Created 3 fix constraints Created 0 coincident constraints Created 0 tangent constraints Created 0 rigid set constraints Created rectangular array 2x2 basing on Hole_3 feature Created rectangular array 2x2 basing on Hole_7 feature Created rectangular array 3x1 basing on Hole_9 feature Total: 7 constraints and 3 array(s) created (Feature names and constraint distribution may differ depending on the BricsCAD version): To examine the arrays you can temporarily unfreeze the BC_SUBTRACT (1.30.25) layer. In the image below the arrays are colored manually. (3.582) Notice that the green and yellow arrays are not unified. Otherwise to array would have missing holes.
11. Edit the Array Properties (3.7.12) in the Mechanical Browser (3.3.2). In the image below the following has been modified:

    - Green array: number of rows and columns from 2x2 to 3x4
    - Yellow array: X and Y spacing
    - Red array: number of rows and columns from 3x1 to 5x1

    (3.583 on the facing page)

Figure 3.583



3.9.24 Unfolding Sheet Metal Parts and Exporting to CAM

Command: SMUNFOLD (6.28.31) Sheet metal parts can be designed in many different ways (3.9.1). To manufacture the sheet metal part a flat pattern with bend annotations is needed, which is then used in a CAM system to program CNC machines, such as laser cutters and press brakes. This flattening operation is called unfolding.

Unfolding a sheet metal body

The SmUnfold (6.28.31) command unfolds sheet metal parts. BricsCAD automatically creates a solid body corresponding to the flat metal sheet needed to manufacture the sheet metal part using bending techniques. This sheet is placed on the XY-plane and is oriented along the coordinate axes similarly to the orientation of the initial body in 3D space. To change the orientation of the unfolding in Z axis, run the SmUnfold (6.28.31) command again and select the opposite face of the initial body. Form features are unfolded according to the **Unfolding Mode** setting in the **Mechanical Browser**. The options are:

- **Keep** (0): allows to keep form features geometry on the unfolded representation.

(3.587 on page 3193)	(3.588 on page 3194)
3D model and unfolded body	2D

- **Remove** (1): removes the form feature geometry from the unfolded representation.

(3.589 on page 3194)	(3.590 on page 3194)
3D model and unfolded body	2D

- **Project** (2): generates a form feature symbol by projecting the form feature edges onto the flange plane.

(3.591 on page 3194)	(3.592 on page 3195)
3D model and unfolded body	2D

- **Contour** (3): generates a form feature symbol by projecting the external contour and holes of the form feature onto the flange plane.

(3.593 on page 3195)	(3.594 on page 3195)
3D model and unfolded body	2D

- **Symbol** (4): creates the unfold symbol on the **UNFOLD_SYMBOL_UP** or **UNFOLD_SYMBOL_DOWN** layer depending on the direction of the form feature.

(3.595 on page 3195)	(3.596 on page 3196)
3D model and unfolded body	2D

The unfold mode for the current sheet metal part can be set in Mechanical Browser (3.3.2). (3.584 on the next page) Lofted bends lying on cylindrical and conical surfaces can be unfolded analytically: the dimensions and shape of the unfolded lofted bend will be as if its middle surface was mathematically unrolled on the plane. This shape can also be achieved by a highly increased number of samples for the lofted bend. You must set the **Unfolding mode** individually for each lofted bend feature. If analytical unfolding is allowed, the option will be present in drop down list: (3.585 on page 3190)

To unfold a sheet metal body

1. Launch the SmUnfold (6.28.31) command. **You are prompted:** Select a flange or lofted bend face to start unfolding [Associative]:
2. Select a face on sheet metal part. **You are prompted:** Select position of the unfolded body:
3. Specify a point. **You are prompted:** Validate the unfolded body and select an option [save 2D geometry/save 3D geometry/Optimize bend annotations/Keep] <Keep>
4. Do one of the following:
   - Save the unfolded 3D solid in a separate drawing file.
   - Convert the unfolded 3D solid to a 2D drawing file (*.dwg or *.dxf)
   - Rearrange the bend annotations.
   - Keep the block with the unfolded part in the sheet metal part model.

The SmUnfold command takes the deformation of the sheet metal material during bending into account. When a flat sheet of metal is bent into a 3D part with a bending tool (e.g. a press brake), the material is plastically deformed, which means it is compressed at the inside of the bend and stretched at the outside. As a result the length of the part measured along its surface is different in the flat and bend states. BricsCAD is able to automatically compute the proper unfolded length of your part based on the material deformation properties. These properties can be defined by setting the value of K-Factor (3.9.8) parameter or by attaching a Bend Table (3.9.7).

Tutorial: Rework an imported model in BricsCAD Sheet Metal Click here (3.8.8) to watch

Managing layer properties of the 2D geometry

The 2D geometry generated by the SmUnfold (6.28.31), SmExport2d (6.28.6), and SmAssemblyExport (6.28.1) commands has different colors for contours, bend lines up, bend lines down, overall dimensions, form features up, form features down, bend annotations and attributes. You can set the colors differently in the **Sheet Metal/Commands/Layers for unfolding** settings group on the Settings dialog (1.17.10). Each entity type is placed on a dedicated layer of which the color is controlled through a series of user preferences: (3.586 on the next page) If the 2D geometry of a form feature was taken from a library (3.9.25) component, its properties are controlled by the properties of this component at the moment of insertion. There are two other modes of **Unfolding Mode** which lead to generation of 2D geometry for form features: **Project** or **Contour**, in these modes 2D geometry will be generated automatically from 3D geometry and its appearance will be controlled by **Form Features Up Layer** and **Form Features Down Layer** settings groups.

To export a sheet metal body

Sheet metal parts created or edited in BricsCAD can be then processed by different CAM systems (such as JET-CAM or CADMAN-B) to generate NC code for cutting and bending machines. The user preference controls the **save 2D geometry** option of the SmUnfold (6.28.31) command to customize the .dxf file to be compatible with the list of popular CAM systems. The SmExport2d (6.28.6) command exports the unfolded representation of a sheet metal body as a 2D profile in *.DXF or *.DWG file format. The SmExportOSM (6.28.8) command exports a sheet metal solid to the *.OSM (Open Sheet Metal) file format (native for the CADMAN-B CAM system).

To export an assembly with sheet metal parts to .dxf

The SmAssemblyExport (6.28.1) command searches the assembly tree for sheet metal design and exports it to a *.DXF file. As a result, a set of *.DXF files, sorted by thickness in different subfolders are created in the output folder. The command generates a HTML report which allows to control the output. Most of the sheet metal parts will be processed automatically. Poor sheet metal parts will be reported by the command to be reworked manually.

3.9.25 Working with Form and Rib Features

Form and Rib features are created by a forming tool. Rib features are produced by imprinting a wheel rolling over the flange following an arbitrary trajectory. We will use 'form' to refer to both form and rib features. Form features can be recognized in imported geometry or inserted from built-in or user-defined libraries. Form features can be edited directly or parametrically. Form features are listed in the Mechanical Browser (3.3.2) with their parameters. Parameters of form features are displayed and can be edited in the Properties Panel (1.15.4) when selected. The following commands apply to form features:

Icon	Command	Description
	SmForm (6.28.17)	Converts a selected set of faces to a form feature. A drawing file with a user-defined form feature can be saved and then inserted using the BmInsert (6.8.16)command.
	SmConvert (6.28.4)	Recognizes form and rib features in imported geometry.
	SmReplace (6.28.26)	Allows replacing form features (including recognized ones) in sheet metal parts with form features from the built-in or user library.
	SmRibCreate (6.28.26)	Creates associative Rib form features on sheet metal parts from 2D profiles. The feature is updated automatically when the defining profile has been modified.
	BmInsert (6.8.16)	Inserts an existing mechanical component or sheet metal form feature into the current drawing.
	SmSelect (6.28.32)	Selects comparable form features. The command works in two modes: • **Similar**: features which have the same set of faces, but possibly different sizes. • **Same**: identical features.

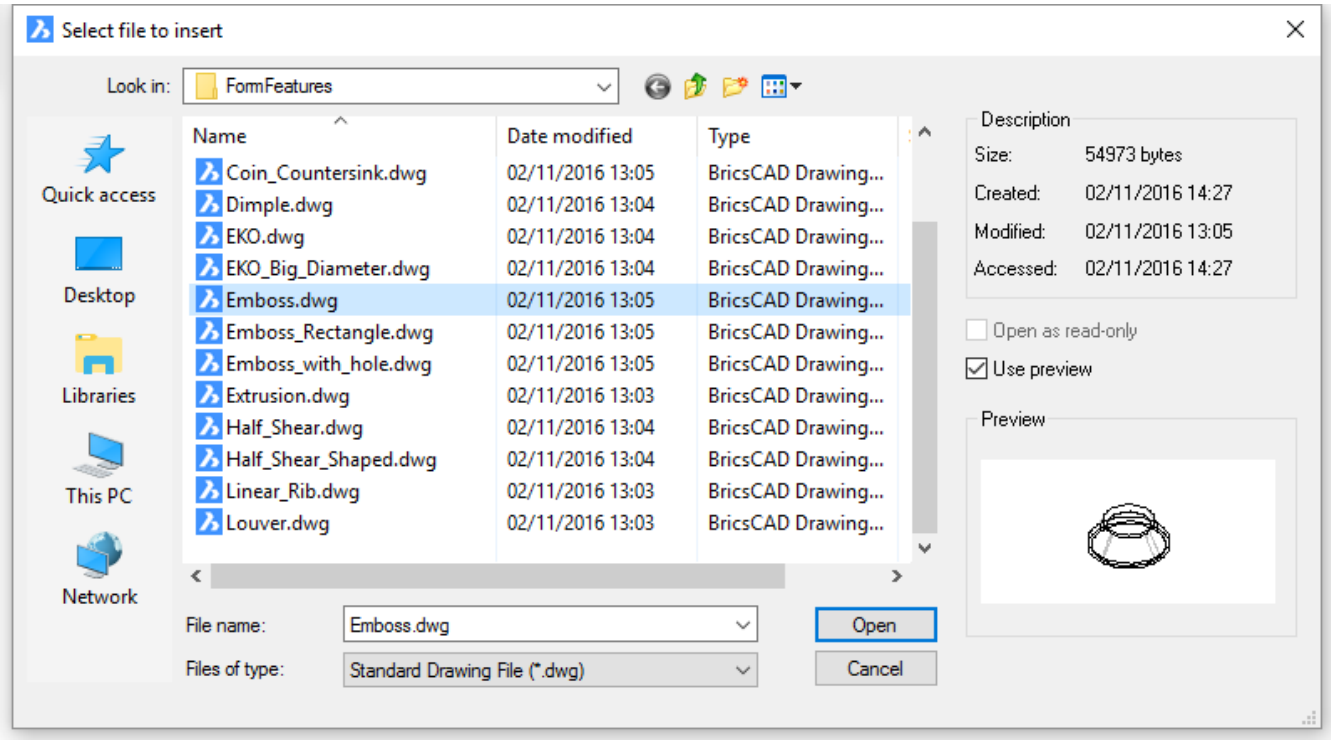
A library of parametrized sheet metal form features is available from the Form Features tab on the Tool Palettes (1.17.7) panel. The library contains the most commonly used form feature types. To insert a form feature to a sheet metal 3D solid, drag the form feature icon from the Tool Palettes (1.17.7) panel or the Components (6.9.26) panel onto a flange of the solid. The SMDEFAULTFORMFEATUREUNFOLDMODE (1.17.10) system variable controls the appearance of form features in 2D and 3D unfolded model representations.

To Insert a Form Feature

Form features are added to a sheet metal part by insertion on the existing flanges. The form features can be inserted by means of BmInsert (6.8.16) command or by drag-and-drop from the **Form Features** tab of Tool Palettes (1.17.7).

1. Make sure Dynamic Dimensions (1.21.9) (DYN) and Dynamic UCS (1.21.21) (DUCS) are active.
2. Do one of the following:
   - Click the **Form Feature** tool button ( ) on the **Sheet Metal** toolbar.
   - Click the **Form Feature** tool button ( ) on the **Sheet Metal** ribbon bar.
   - Choose **Insert Form Feature** in the **Sheet Metal** menu.

Figure 3.597



- Type **bminsert** in the command bar, then press Enter. The **Select file to insert** dialog displays the **FormFeatures** folder **[BricsCAD Installation folder]\Support\DesignLibrary\SheetMetal\FormFeatures: (3.597)** Select the desired form feature, then double click or press the **Open** button.
- Select the form feature from Form Features tab of Components (6.9.26) panel: (3.600 on page 3201)
- Select the form feature on the **Form Features** tab of the Tool Palettes (1.17.7) panel: (3.599 on page 3200)

3. Move the cursor over the flange face you want to insert the feature in. The dynamic UCS aligns to the selected face. The orientation of the UCS depends on the edge the cursro enters the face. Dynamic dimensions display from the origin of the UCS to the insertion point of the form feature. **You are prompted:** Select insertion point or [Edit inserted entity/Rotate component/set Base point/Name/insertion Type/Flip/mUltiple] <0, 0, 0>:
4. (option) Choose an option (see the BmInsert (6.8.16) command for more details):
   - **Edit:** Allows to edit the parameters of the selected insert.
   - **Rotate:** Allows to define the rotation angle of the component.
   - **Base Point:** Allows to specify a different base point to insert the component.
   - **Name:** Allows to define the insert name of the component.
   - **Insertion Type:** Allows to specify the insertion type: Local or External
   - **Flip:** Inserts the form feature in the opposite face of the flange.
   - **Multiple:** Allows to insert multiple inserts of the same component or create an array.
5. To insert a form feature do one of the following:
   - Specify a point.
   - Type a distance in the dynamic dimension fields. Hit the TAB key to go back and forth between the entry fields.
6. Repeat step 5 to insert another copy or press Enter to stop.

In order to have Form Features in the Components (6.9.26) panel, you must create or use the Mechanical Profile (3.3.1) in the Get Started (**??**) dialog. (3.600 on page 3201)

Editing the Parameters of a Library Form Feature

Form features in the form feature library are parametric components. Several parameters control their dimensions. Parameters to control the Length, Width, Height and Radius of the form feature are correspondingly named L, W, H and R. The thickness of the form feature is set equal to the thickness of sheet metal part automatically. The parameters of a single form feature can be edited either in the Properties Panel (1.15.4) or in the Mechanical Browser (3.3.2). Parameters of multiple form features can be edited in the Properties Panel (1.15.4) only.

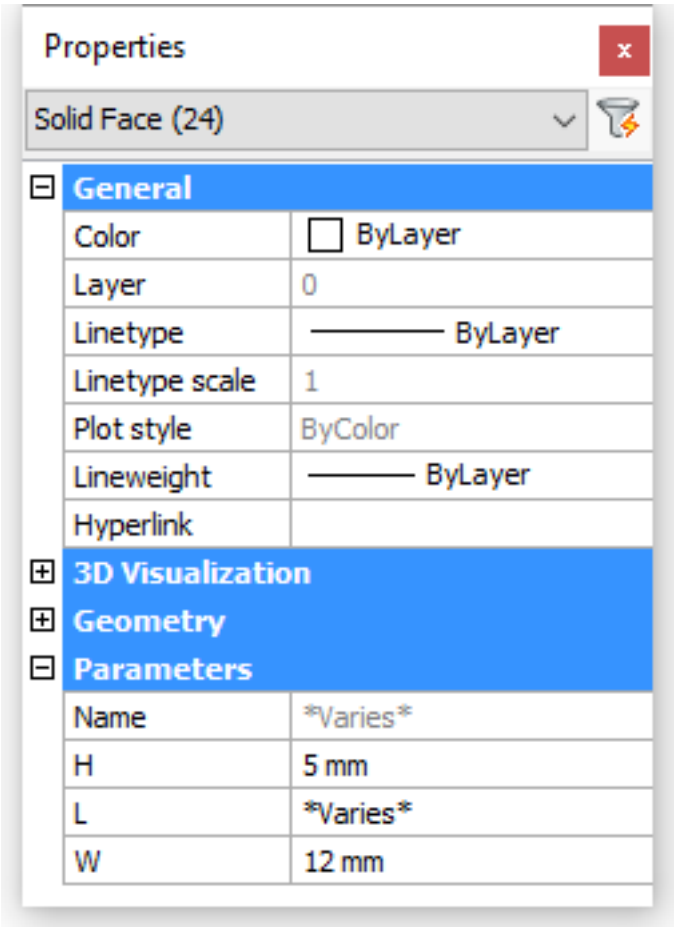
Methods to select form features

- Check the **Select Faces** option of the SELECTIONMODES (1.17.10) system variable, then click the feature(s) in the model.
- Select the feature(s) in the Mechanical Browser (3.3.2), then press the space bar or right click and choose **Select** in the context menu. Press and hold the CTRL key to select multiple form features.
- A sheet metal part can have lots of different form features, which might complicate operations such as deletion or replacement, especially if only a selection of features, that meet certain conditions, need to be processed. In order to help you to select form features more easily, the SmSelect (6.28.32) command allows to select form features that are either identical to a selected feature or similar.

Editing parameters in the Properties Panel

1. Select the form feature(s).
2. Select a parameter in the **Parameters** node in the Properties Panel (1.15.4). (3.601 on the facing page)

Figure 3.601



Editing parameters in the Mechanical Browser

1. Select the form feature in **Form** node of the component structure tree. (3.602 on the next page)
2. Select a parameter in the lower panel of Mechanical Browser (3.3.2) and type a new value.

Creating a custom form feature

1. Open a new drawing using **Mechanical-metric.dwt** as the template.
2. Create the 3D geometry of the form feature. (3.603 on the following page)
3. Execute the SmConvert (6.28.4) ( ) command.
4. Execute the BmMech (6.8.19) ( ) command. **You are prompted:** Name for mechanical component <Component_2>:
5. Type a name for the form feature. **You are prompted:** Convert blocks and external references to mechanical components? [Yes/No] <Yes>:
6. Select the **No** option.
7. In the **Extension type** field in Mechanical Browser (3.3.2) select **Sheet Metal Form Feature**. (3.604 on the next page)
8. Select the Flange_1 and Form_1 features in the **Bodies** node, then right click and select **Disable** in the context menu. (3.605 on page 3207)
9. Create 2 new layers (6.13.17): UNFOLD_SYMBOL_UP and UNFOLD_SYMBOL_DOWN.
10. Turn layers 0 and UNFOLD_SYMBOL_DOWN **Off** and set layer UNFOLD_SYMBOL_UP **Current**.
11. Create the unfold symbol, which will be placed on the face the form feature is placed in. (3.606 on page 3208)

Figure 3.603

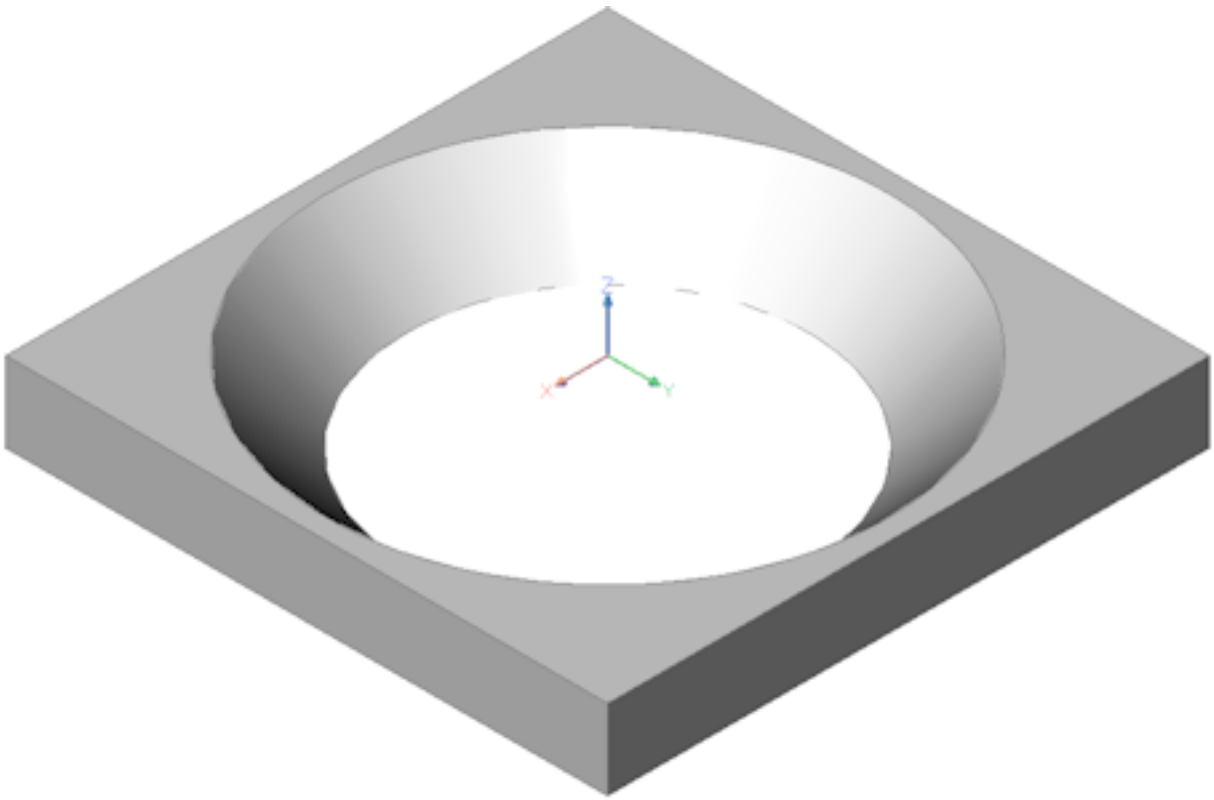

Figure 3.604

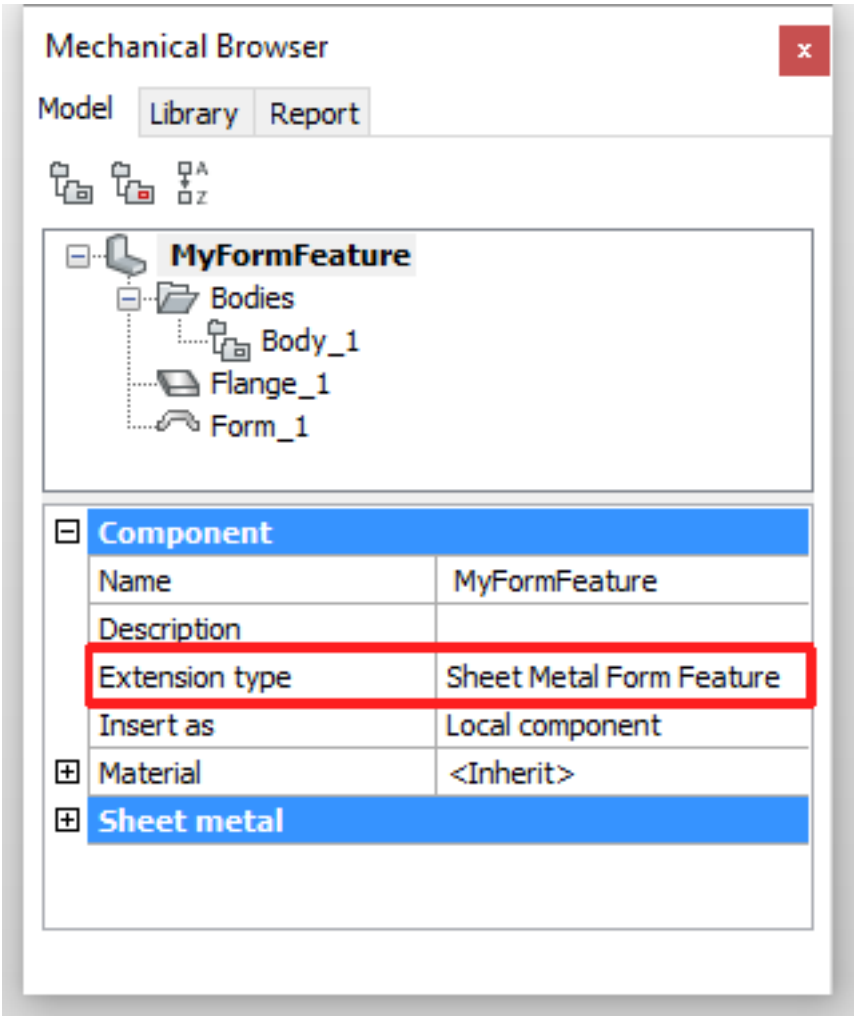

Figure 3.605

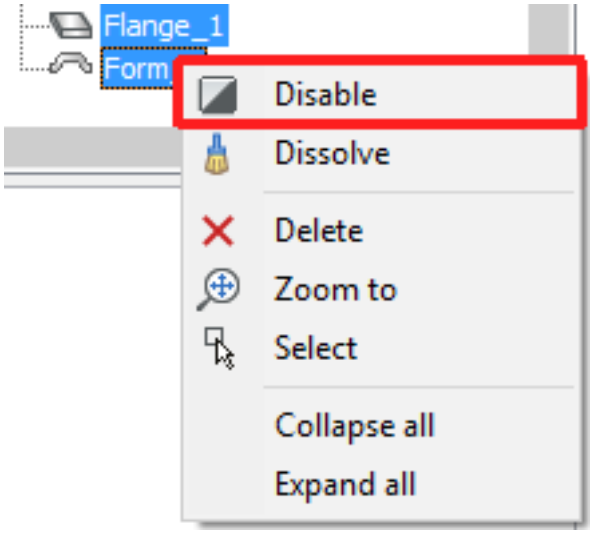

12. Turn **off** the UNFOLD_SYMBOL_UP layer and turn **on** the UNFOLD_SYMBOL_DOWN layer. Set the UNFOLD_SYMBOL_DO layer **current.**
13. Create the unfold symbol, which will be placed on the opposite face the form feature is placed in. (3.607 on the following page)
14. Turn **on** layer 0 and turn the UNFOLD_SYMBOL_UP and UNFOLD_SYMBOL_DOWN layers **off.** Set layer 0 as **current.**
15. Save the drawing.

Figure 3.606

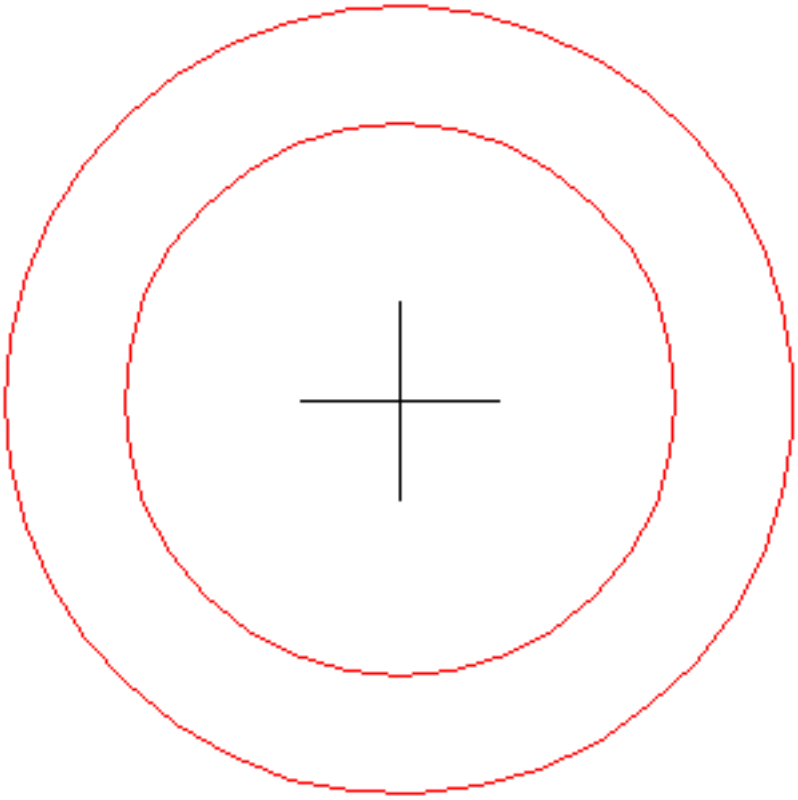

Figure 3.607

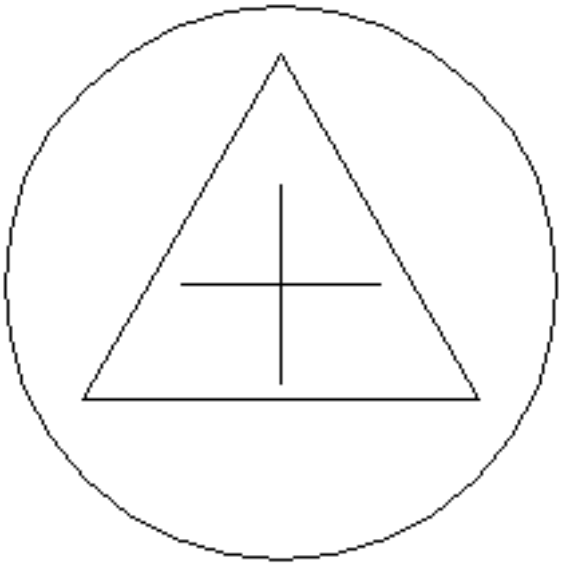

Creating a custom parametric form feature

We will now parametrize the custom form feature we created in the previous procedure. Two parameters are needed here:

- **D** for a diameter of the bigger edge of the conical hole.
- **A** for an angle of the face of the conical hole.

In Sheet Metal we have a default parameter **_SM_THICKNESS** which controls the thickness of the sheet metal part.

1. We will first create an auxiliary body for constraining on a new CONSTRUCTION layer. Make this layer current and switch off all other layers.
2. Create a Region (6.26.18) in the XY plane of the WCS on the CONSTRUCTION layer. (3.608)
3. Apply a DmFix3D (6.12.15) constraint ( ) to the region. (3.609 on the following page)
4. Switch ON layer 0.
5. Apply a DmCoincident3d (6.12.5) constraint ( ) between the region face and the flange top face. (3.610 on the next page)
6. Apply a DmDistance3d (6.12.10) constraint ( ) between the flange top and bottom faces. First select the top face, then hit the TAB key to select the bottom face. Accept the default value in the dynamic dimension.
7. Type _SM_THICKNESS in the **Expression** field of the Distance_3 constraint. (3.611 on page 3211)
8. Since our Form Feature is conical we can modify the flange from parallelepiped to cylinder. (3.612 on page 3212)
9. In the Mechanical Browser (3.3.2) right click the feature name and select **Add new parameter** in the context menu. Rename new parameter to **D**. Select mm for the **Units** field. Type 16 in the **Expression** field. (3.613 on page 3213)
10. Apply a DmRadius3d (6.12.22) constraint ( ) to the top edge of the conical face. Accept the default value in the dynamic dimension.
11. Type D/2 in the **Expression** field of the Radius_5 constraint. (3.614 on page 3214)
12. In the Mechanical Browser (3.3.2) right click the feature name and select **Add new parameter** in the context menu. Rename new parameter to **A** . Leave the **Units** field empty. Type 45 in the **Expression** field.
13. Do one of the following to create a **Cone Angle constraint** to the conical face:
    - Launch the DmAngle3d (6.12.1) command ( ), then choose the **Cone Angle constraint** option, then select the conical face.
    - Hover over the conical face, then choose **Cone Angle constraint** ( ) in the **Constraints** command group in the Quad (2.3.3).

Accept the default value.

14. Type A in the **Expression** field of the ObjectAngle_6 constraint.
15. Since our Form Feature is conical we will modify the flange from parallelepiped to cylinder:
    - Draw a circle on top of the flange. The radius of the circle is 9 mm.
    - Select **Enable Boundary Detection** in the **Settings** panel on the **Home** tab in the Ribbon.
    - Place the cursor over the area between the circle and the square edge of the flange, then choose **Extrude** ( ) in the Quad (2.3.3) and move the cursor downwards. (3.615)
16. Apply a DmConcentric3d (6.12.8) constraint ( ) between the circular edge of the region and the cylindrical face. (3.616 on the next page)
17. Apply a DmRadius3d (6.12.22) constraint ( ) to the cylindrical face. Accept the default value in the dynamic dimension.
18. Type D/2+0.1*_SM_THICKNESS in the **Expression** field of the Radius_8 constraint. (3.617 on page 3217)
19. Set the **Exposed** field of both parameter A and D **On**. (3.618 on page 3217) We will now create 2D constraints for the unfold symbols.
20. Make layer UNFOLD_SYMBOL_UP **current** and switch **off** all other layers.
21. Apply a GcFix (6.15.7) constraint ( ) to both crossing lines indicating the center of the circles.
22. Apply a GcHorizontal (6.15.8) constraint ( ) to the horizontal center line.
23. Apply a GcVertical (6.15.16) constraint ( ) to the vertical center line.
24. Apply a GcConcentric (6.15.4) constraint ( ) between the two circles.

25. Apply a DcLinear (6.10.12) constraint ( ) between the endpoints of the center lines. Accept the default value. (3.619)

26. Apply a DcDiameter (6.10.8) constraint ( ) to both circles. Accept the default value for dia1 (=inner circle) and dia2 (= outer circle). (3.620 on the next page)

27. Adjust the **Expression** fields of the 2D constraints as follows:

    - d1 = 1
    - d2 = d1
    - dia 1 = D - 2*_SM_THICKNESS/tan(A)
    - dia 2 = D

    (3.621 on the facing page)

28. Switch **off** the display of all layers, but layer 0, then save the file. (3.622 on page 3220)

The form feature can now be used to make conical parametric openings in a sheet metal flange. Use the **Insert Form Feature** tool ( ), which launches the BmInsert (6.8.16) command. (3.623 on page 3220) Optionally: Add the form feature as a component to a tool palette (1.17.7).

Figure 3.620

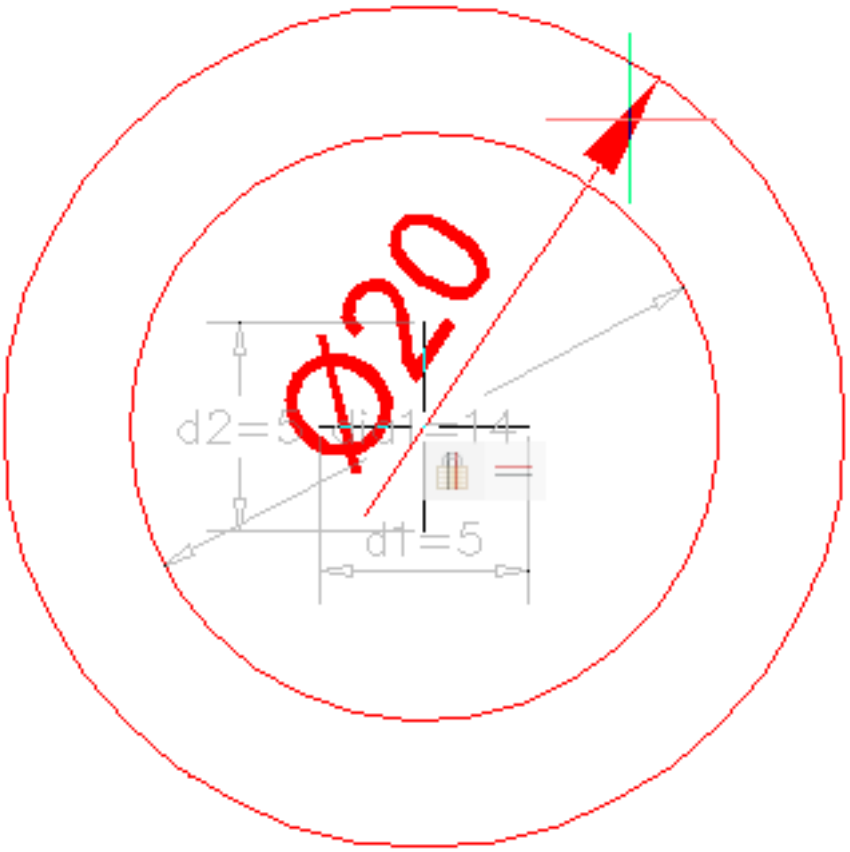

Figure 3.621

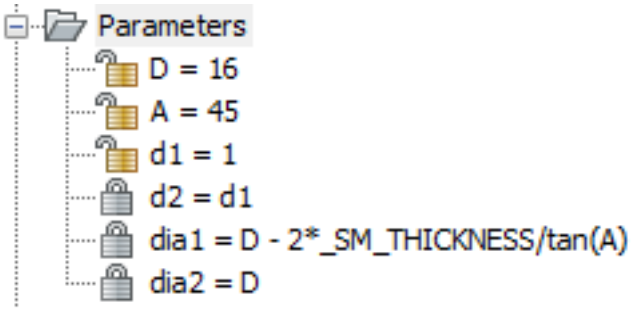

Figure 3.622

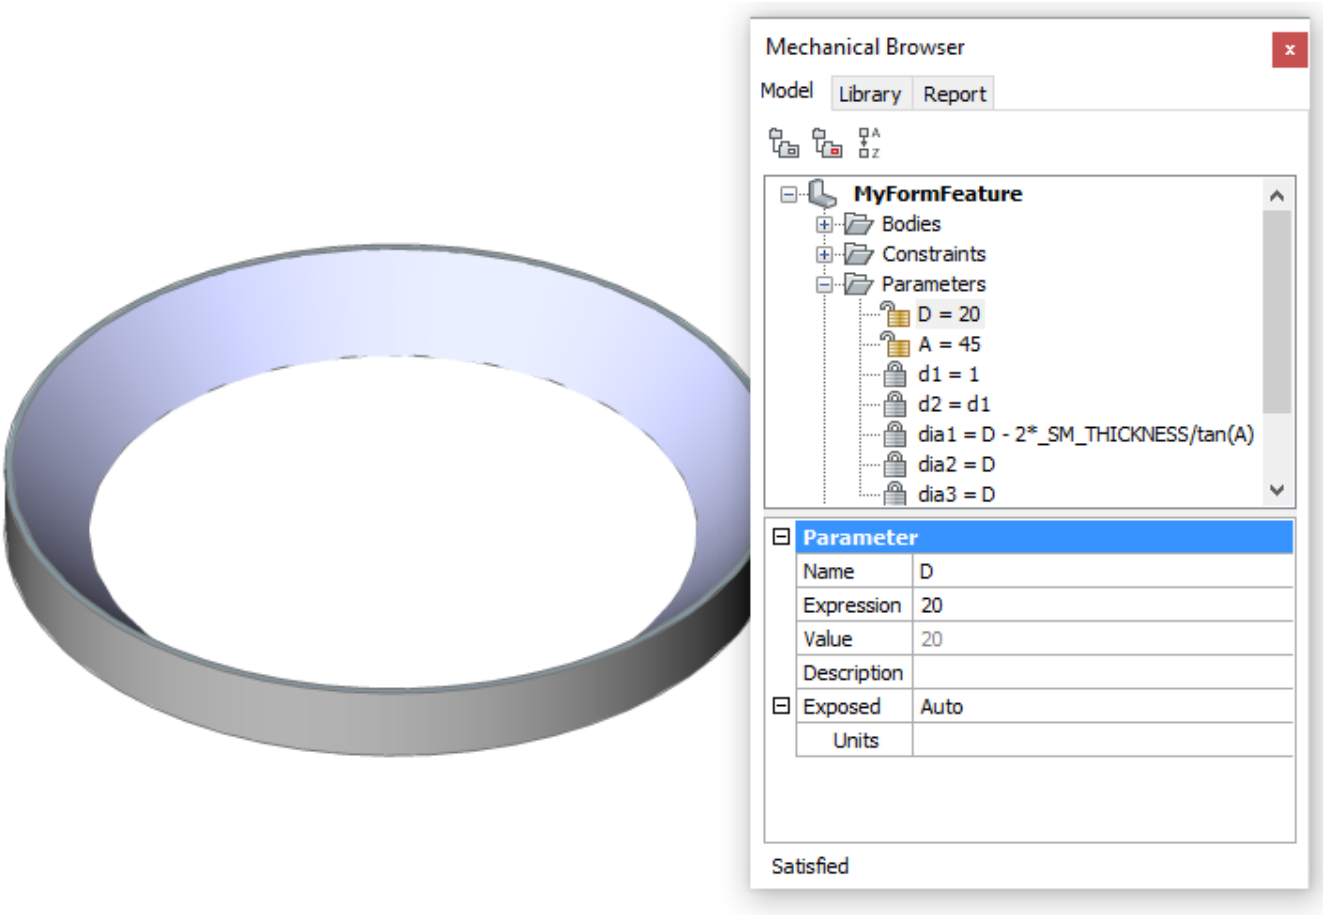

Figure 3.623

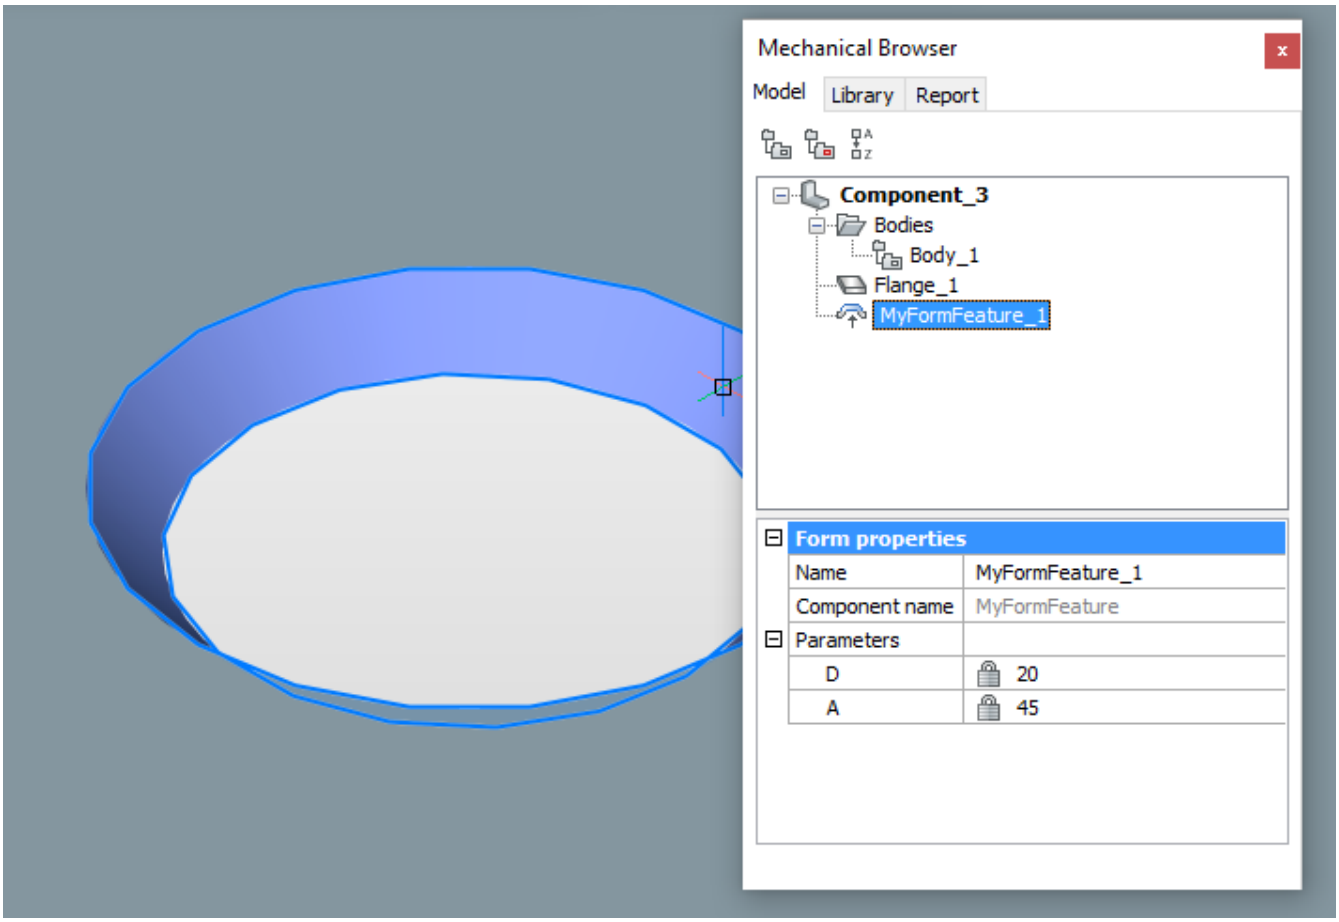

To create a rib feature

Rib features are created by the SmRibCreate (6.28.27) command from a 2D curve on flange face.

1. Do one of the following:

   - Click the **Create Rib Feature** tool button ( ) on the **Sheet Metal** toolbar.
   - Click the **Create Rib Feature** tool button ( ) on the **Modify** panel of the **Sheet Metal** tab on the ribbon.
   - Type **smribcreate** in the command bar, then press Enter.

   Prompts you: Select flange face:

2. Select the flange face. **Prompts you:** Select curve or [Profile radius/Round radius]:

3. Select a curve on the selected flange face. Lines, polylines, circles, arcs, ellipses, elliptical arcs, and splines are accepted. The 2D curves can be open or closed but cannot intersect itself or other form features. (3.624 on the next page) After selection of the curve rib feature is created: (3.625 on the following page)

Figure 3.624

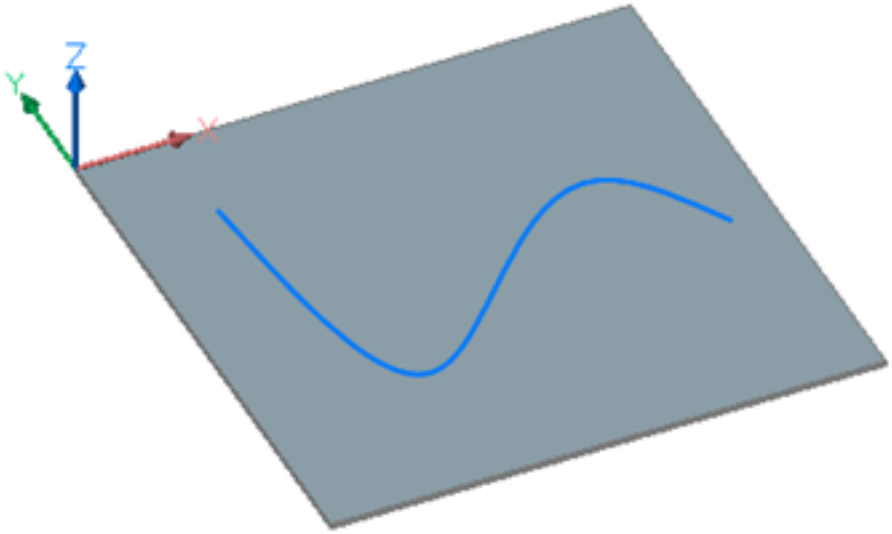

Figure 3.625

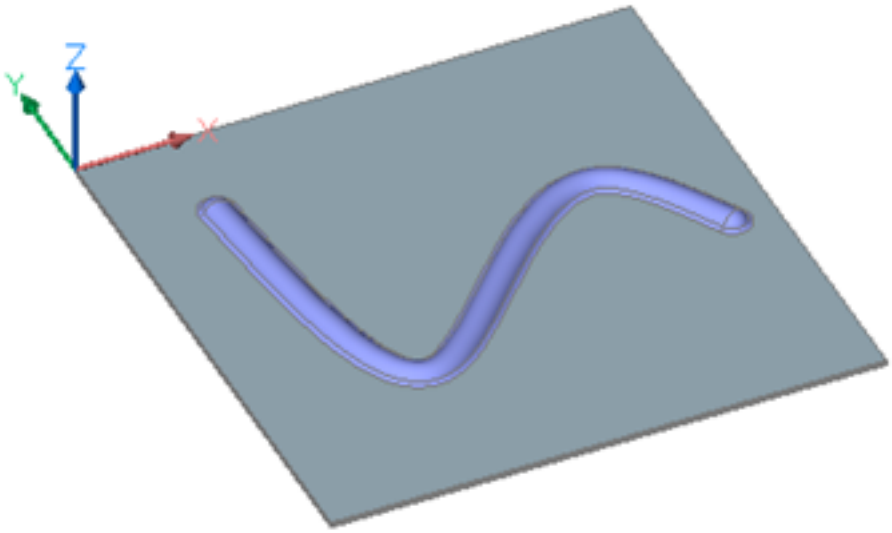


To modify a rib feature

To modify a rib feature:

- Modify the generatrix curve using its grip points.
- Edit the **Profile** and **Round** radius in the Mechanical Browser (3.3.2).

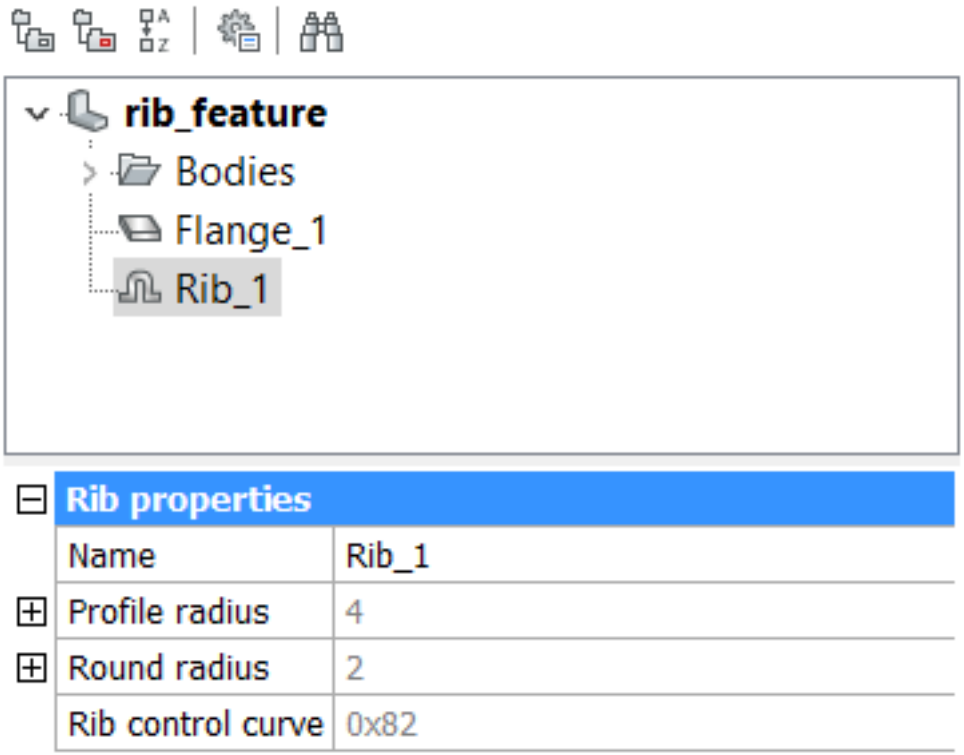
Modify the generatrix curve

1. Select the curve. Because the curve is hidden by the rib feature, press the TAB key to select obscured entities, or select the curve in the Structure (6.27.54) panel.
2. Grip edit the curve. The Rib feature updates according to the changes of the curve.
3. After selecting the flange face, **you are prompted:** Select curve or [Profile radius/Round radius]:
4. Select curve on selected flange side.

Edit the properties in the Mechanical Browser

1. Select the rib feature in the Mechanical Browser (3.3.2). The rib feature highlights in the model.
2. Select the property in the **Rib Properties** grid. (3.626 on the next page)
3. Type a value. The selected rib feature is updated.

Figure 3.626



Understanding the difference between Control and Trajectory curves

When creating a rectangular rib feature, we first draw a rectangle which is then used to create a rib feature by the SmRibCreate (6.28.27) command. When this control curve is grip edited, the rib feature is updated accordingly. (3.627 on the facing page) On the production side, the rectangular control curve is replaced by a filleted trajectory curve, according to the physical limitations of the wheel tool: (3.631 on page 3227) The trajectory curve, however correct, is hard to manipulate, e.g. when you want to move a corner. (3.629 on page 3226) In the design stage we use the **Control Curve**, which is as simple as possible: (3.630 on page 3226) When creating the rib feature, SmRibCreate (6.28.27) adds fillets according to the value of the **Rib fillet radius** parameter in Mechanical Browser (3.3.2). This parameter is not controlled per feature, since it relates to the properties of physical wheel tool: (3.631 on page 3227) When zooming in closely you notice the difference between the 3D geometry of the rib feature and the control curve: (3.632 on page 3227) When the Polyline is grip edited ... (3.633 on page 3228) ... the rib feature is adjusted accordingly: (3.634 on page 3228) This illustrates the associativity between the 2D curve and 3D rib feature. The recognition of rib features in SmConvert (6.28.4) is controlled by the **SmConvertRecognizeRibControlCurves** user preference. When the part is unfolded by the SmUnfold (6.28.31) command, the curves follow the 3D design and have the fillets. The middle curve is called **Trajectory Curve**: (3.635 on page 3229)

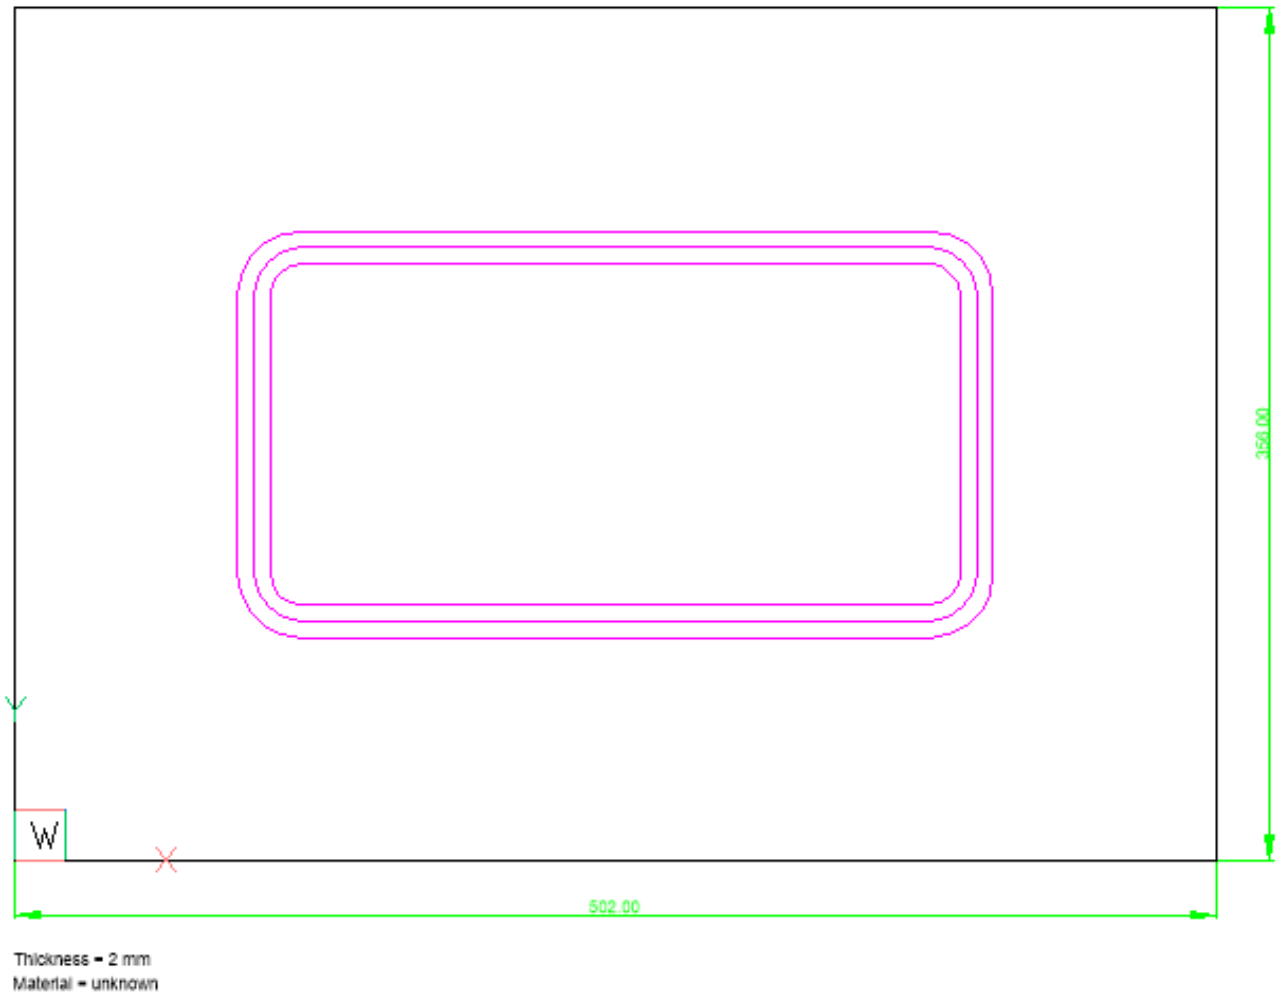

Figure 3.636

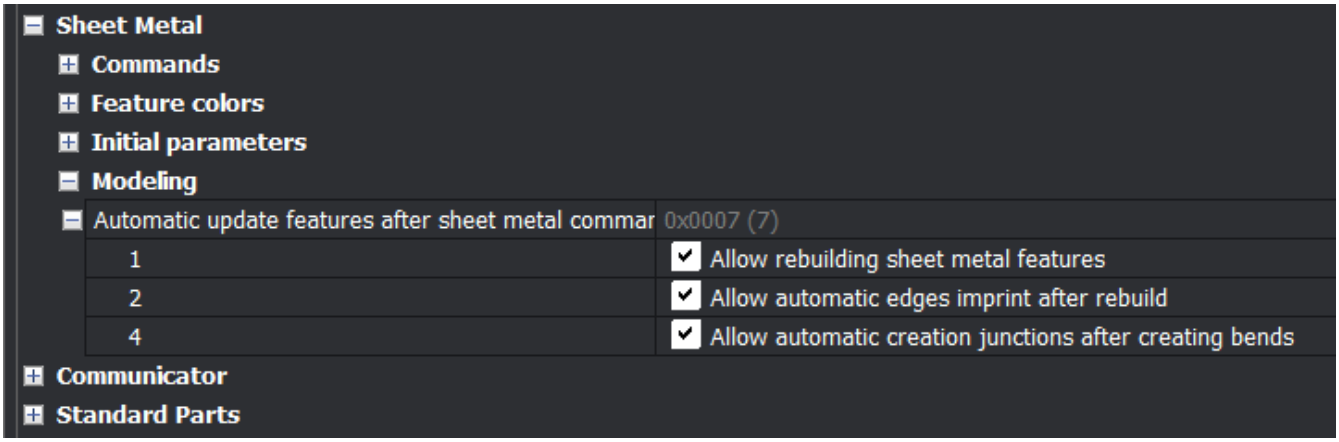


3.9.26 Smart Features

The Smart Features technology manages the local intelligent update of the geometry after executing Sheet Metal commands. The behavior is controlled through the **SmSmartFeatures** user preference. (3.636) Three options are available (more to come in the future):

- Allow rebuilding sheet metal features:
  - corner relief is transformed into two bend reliefs after executing SmSplit (6.28.30) on a flange
  - unnecessary reliefs are removed
- Allow automatic edges imprint after rebuild: automatic imprinting edges for thickness faces.
- Allow automatic creation of junctions after creating bends

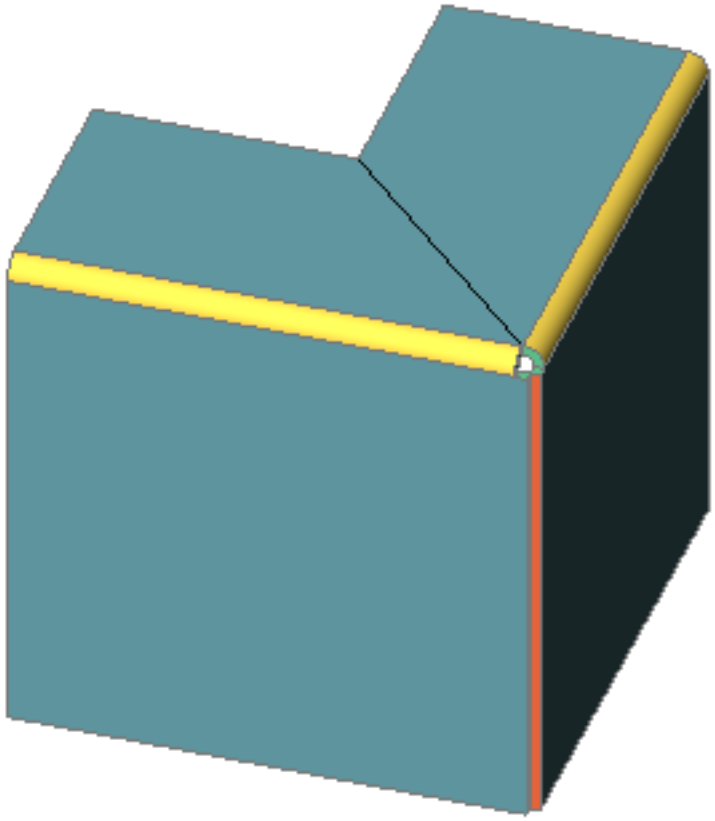
Note: Always keep Smart Features options ON, unless inconsistent behavior occurs.

Transformation of a corner relief into bend reliefs

When splitting a top flange by a line into two separate parts, the corner relief is transformed into two bend reliefs. (3.637 on the facing page)

(3.644 on page 3238) (3.643 on page 3237) Smart features create bend reliefs automatically, which can then be switched to smooth.	(3.644 on page 3238) Without smart features, the corner relief is kept and cannot be switched.

Figure 3.637

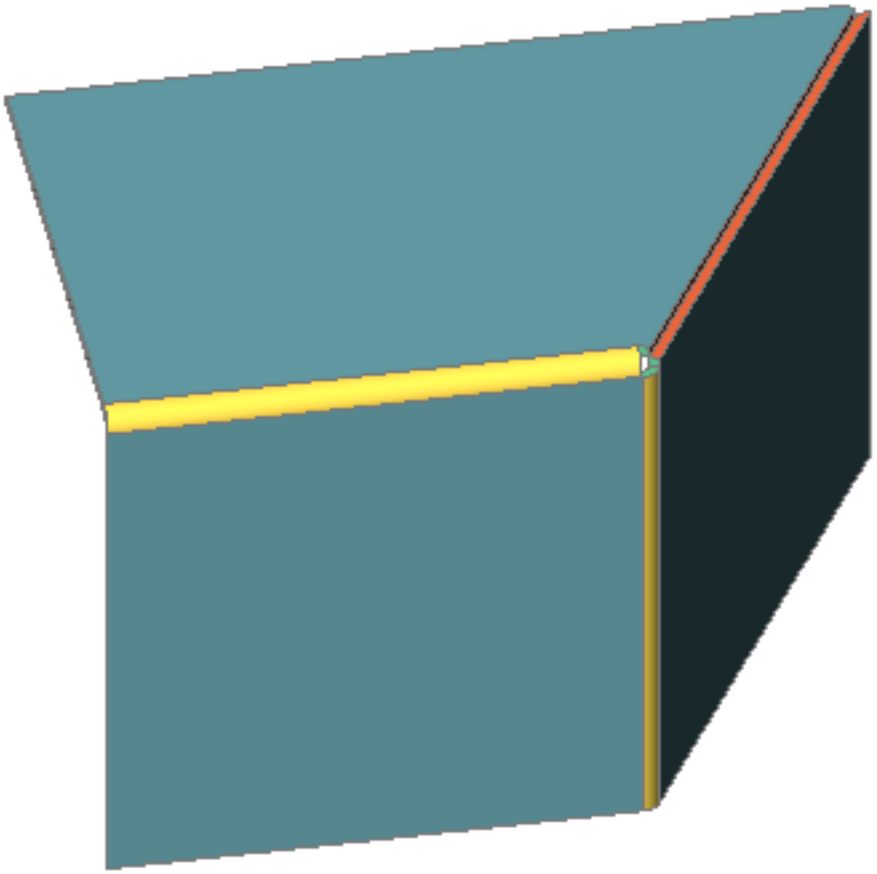


Removing unnecessary cuts

In the model below, a corner relief cut exists, which is needed to prevent the material from being stretched. (3.638 on the following page) When the top bend is converted into a junction, we get to separate parts. The smart features automatically remove the now unnecessary relief.

(3.645 on page 3238) Smart features automatically fill unnecessary cuts, thus simplifying the geometry.	(3.646 on page 3239) Without smart features the corner relief still exists.

Figure 3.638



Automatic imprinting of edges

Imprinted edges on thickness faces separate them into areas which can be reworked automatically, i.e. localized junctions can be converted into bends, see Bend, Lofted Bend and Junction Feature Operations (3.9.16) for more details. Without automatically imprinted edges the SmImprint (6.28.18) command is needed here. In the example below, we will separate a flange using junctions. We turn **Rebuilding sheet metal features** ON, and then use **Automatic edges imprint after rebuild**. (3.639 on the next page)

(3.647 on page 3239) (3.648 on page 3240) Allow automatic edges imprint after rebuild = ON Junction faces are split correctly.	(3.649 on page 3241) (3.650 on page 3242) Allow automatic edges imprint after rebuild = OFF Junction features overlap each other.

Create Junction
Creates junctions from hard edges or bends

Automatic creation of junctions

In certain situations, when hard edges meet at the corner and we create a bend on all but one, which has to become a junction in order to make the part unfoldable. Assume we create bends on the top face of a sheet metal box: (3.640 on the following page) Then the remaining hard edges adjacent to the face have to become junctions. When **SmSmartFeatures** = ON, this is performed automatically: (3.641 on the next page) To be precise, the area of automatic junction creation is located to the common vertex of hard edges (or corner relief when bends are created). The option does not optimize the layout of the unfolded part.

3.9.27 Associative Unfolded Representations of 3D Solids

BricsCAD offers bidirectional associativity between the 3D Sheet Metal part and its flattened appearance. In this mode both representations exist in separate documents: the **Original part** is stored in its native document and the **Flattened part** is stored in temporary document. Associativity is temporary and exists while both documents are opened. In order to work in associativity mode in the next BricsCAD session or once the document was closed, one should repeat steps again.

What Does Associativity Mean?

Associative Unfolded allows you to make cuts on flattened geometry and propagates the changes back to the 3D model. This helps simplify two scenarios:

- Creating complex, non-standard Bends and Corner Relief cuts.
- Avoid self-intersections in unfolding.

In these two scenarios both are easy to do in 2D rather than in 3D. In flattened mode Sheet Metal part is represented as set of separate flat solids (per-feature). Use the SmDelete (6.28.5) command to delete solid flanges and bends on flat patterns. Associativity is bidirectional - changes can be propagated from flattened parts back to 3D models and vice versa. Changes made on one of the representations is propagated to the document with other representations once it becomes active.

Switching to Associativity Mode The associativity mode is turned on using the SmUnfold (6.28.31) command. Make sure there are no faces selected. From **Sheet Metal** section of the Ribbon (6.26.32), select the **Associatively Unfold Body** icon and select **Flange** face. (3.651 on the following page) Application will compute flattening of the given part and switch it to associative mode. Condition of success of given operation is the same as for regular unfolding.Continue working in associativity mode only if no errors or warnings appeared during the operation. A new temporary document containing the flattened part will be created. (3.652 on the next page) **Note:** there is no need to save this document, it's used to propagate editing operations from the flattened solid back to the 3D model. Use Vertical Tile to view both the 3D model and associative unfolding documents. Click **Vertical Tile** button on Toolbar (6.29.33) or Ribbon. (6.26.32) (3.653 on page 3245) **Note:** In the Mechanical Browser (3.3.2) when flattened geometry is selected, it lists features are disabled.

Figure 3.651

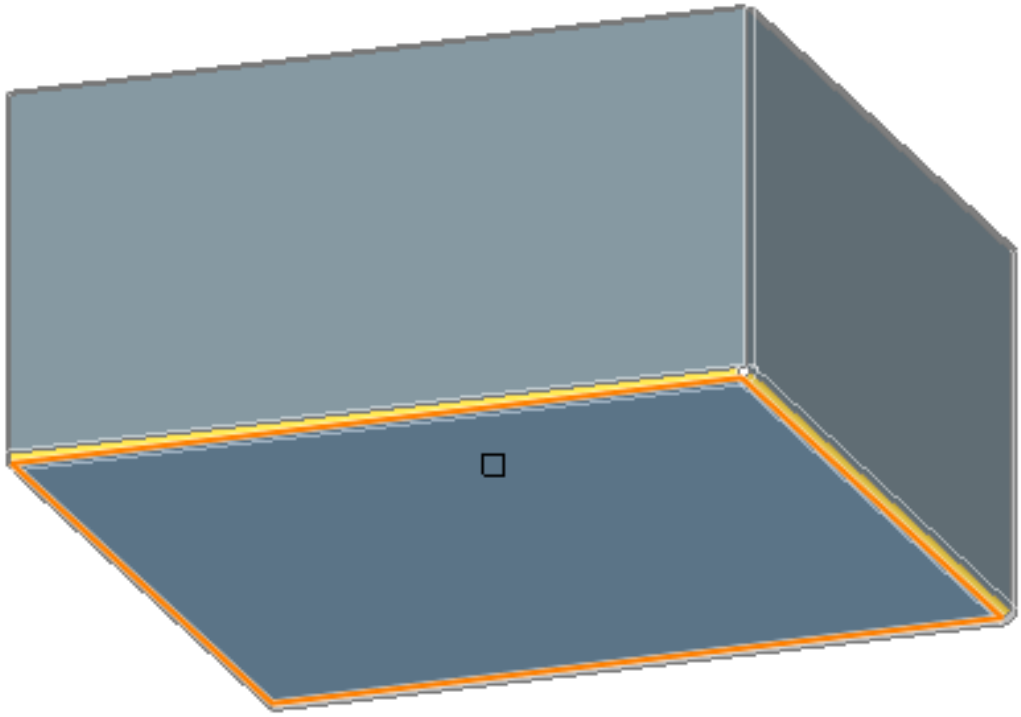

Figure 3.652

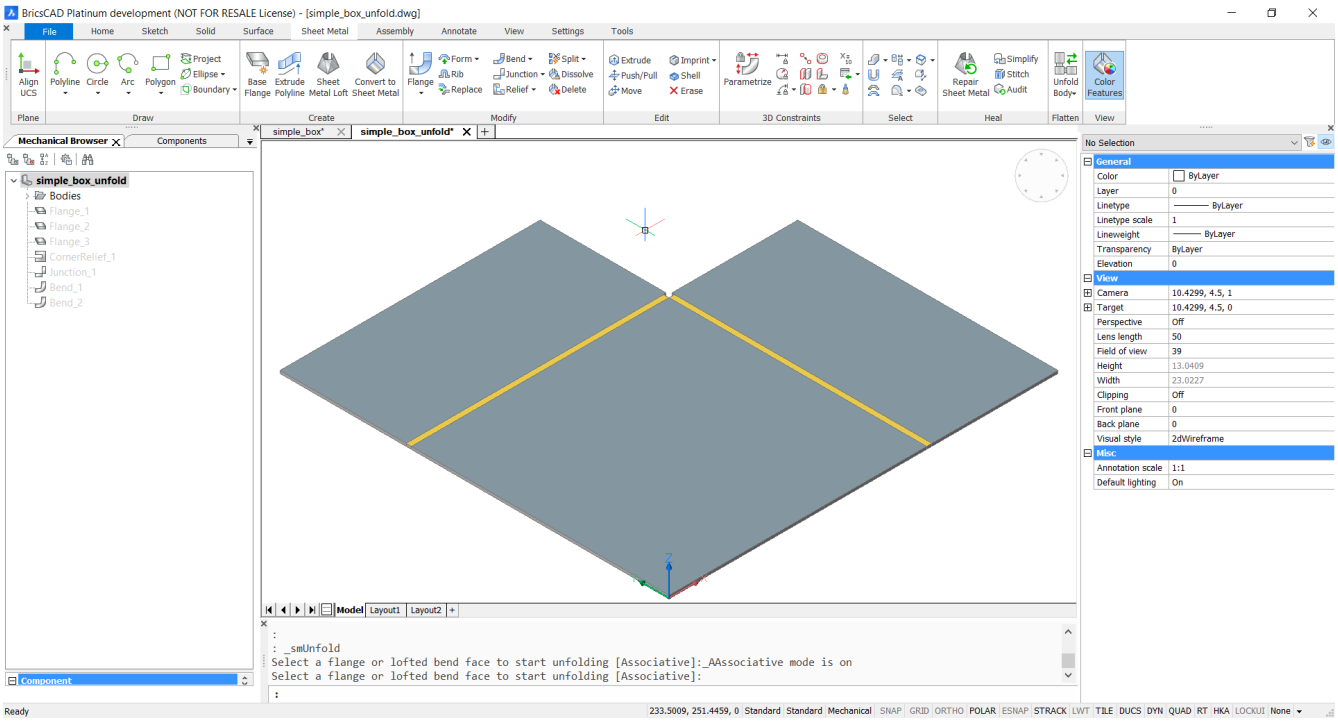

Figure 3.653

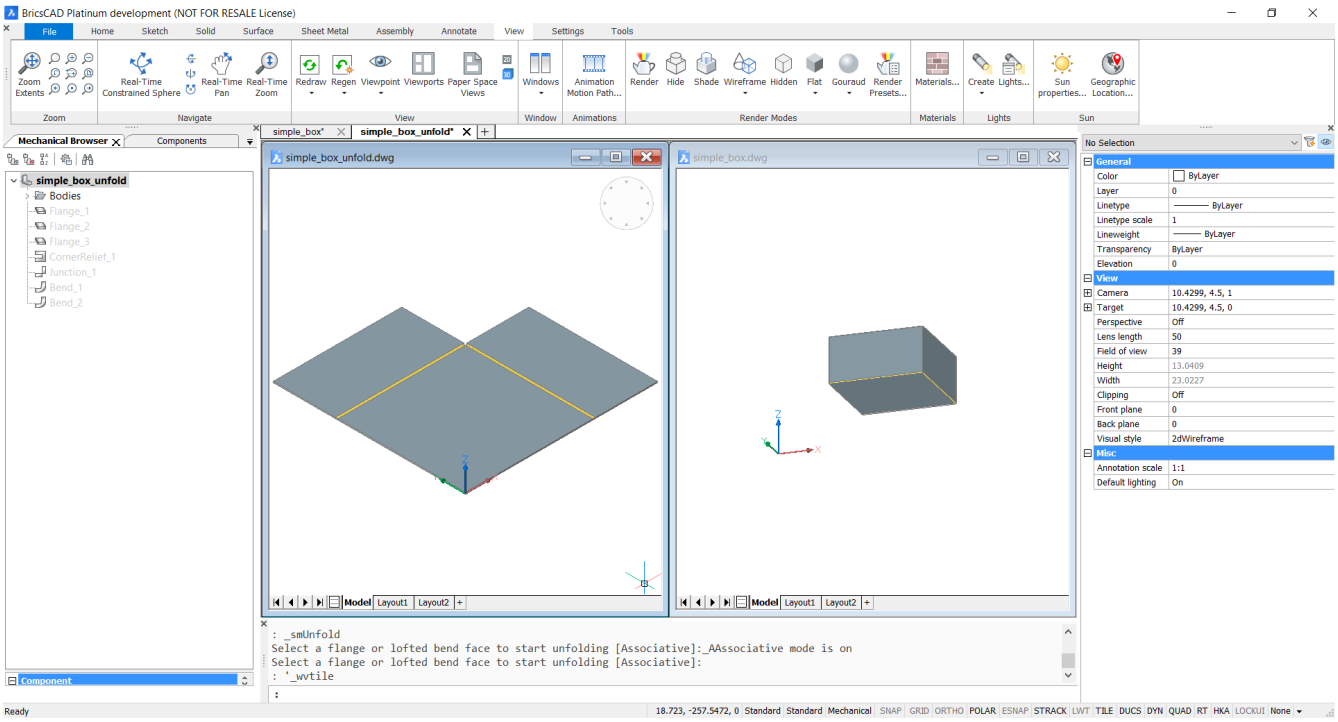

Editing the Geometry

1. Working with flattened design document, draw a circle in the corner (3.654 on the next page)
2. Apply DmExtrude (6.12.14) command to the circle, cutting the volume. (3.655 on page 3247)
3. Click on original document again to make it active. (3.656 on page 3248)
4. Model will be updated and the custom corner relief appears. Application writes to command line: Changes were successfully transferred to source model

Figure 3.654

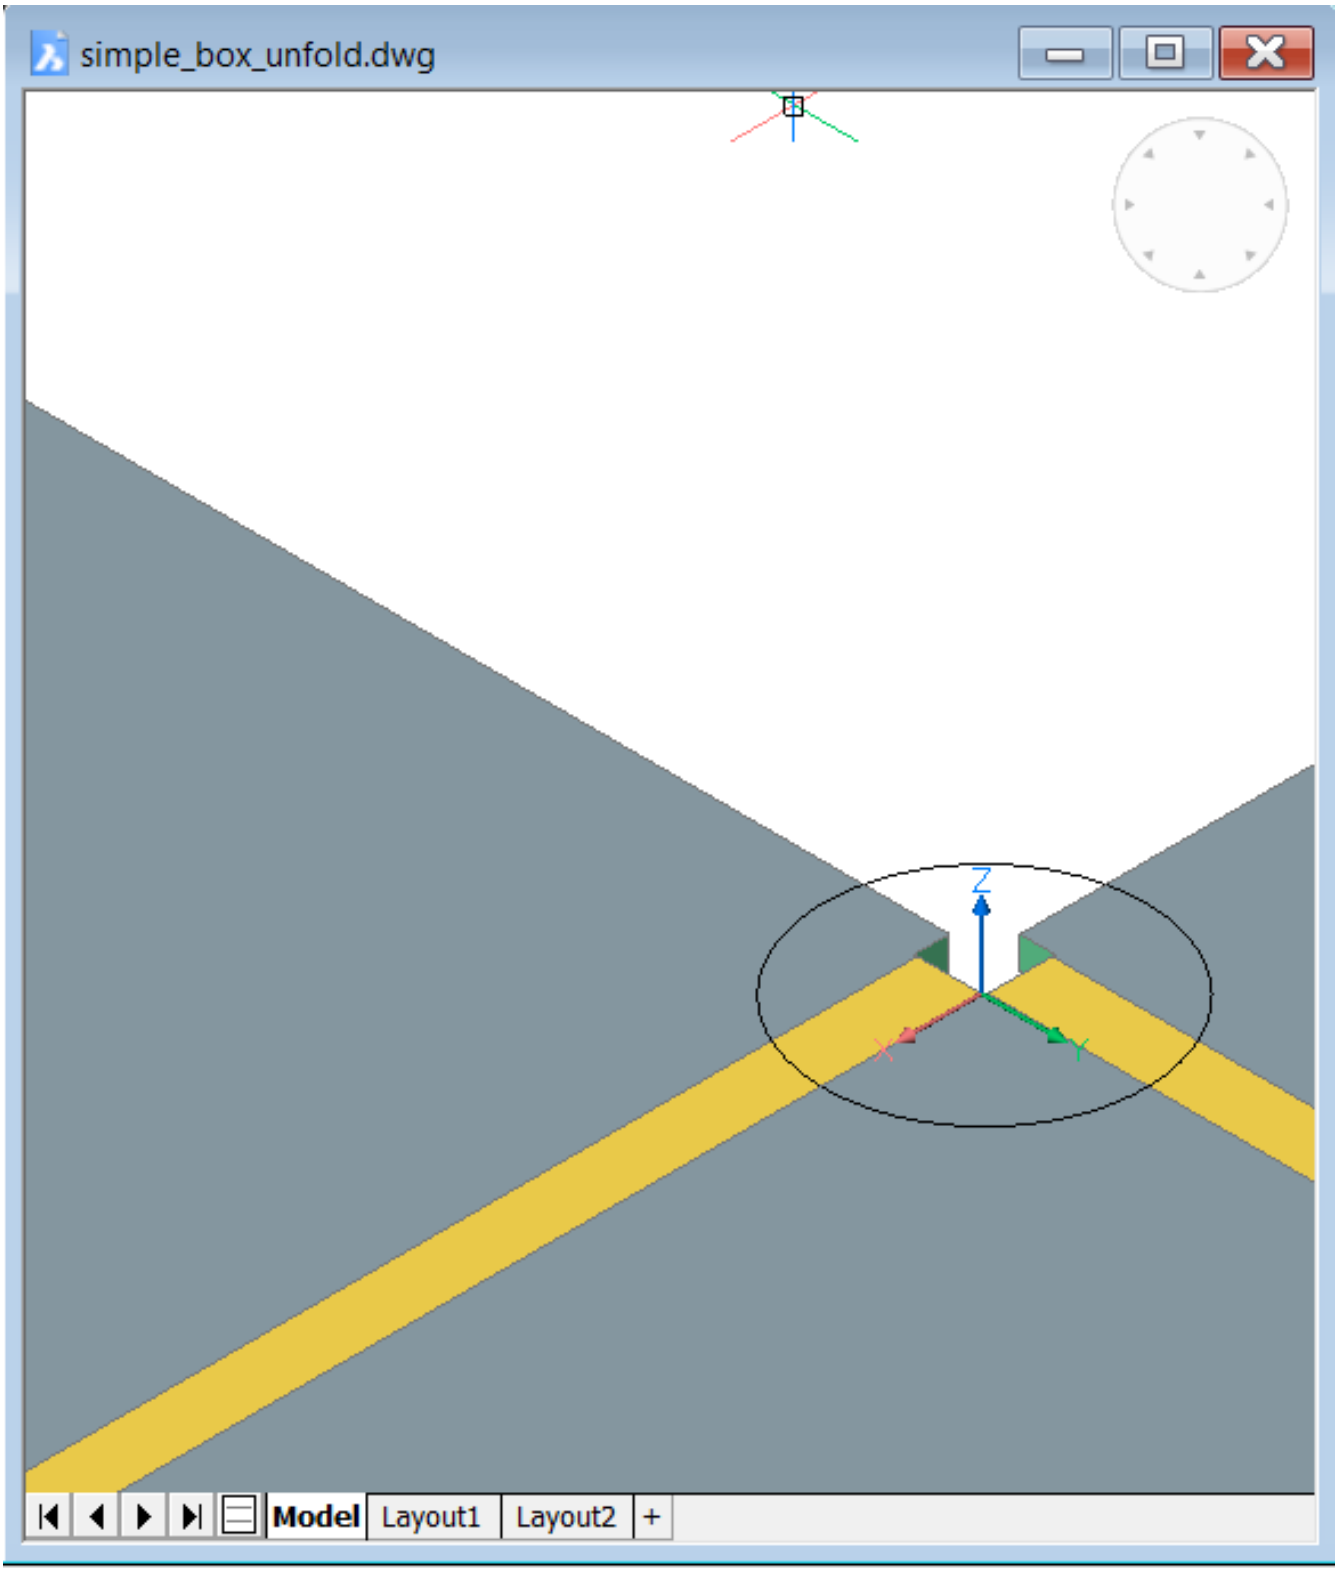

Figure 3.655

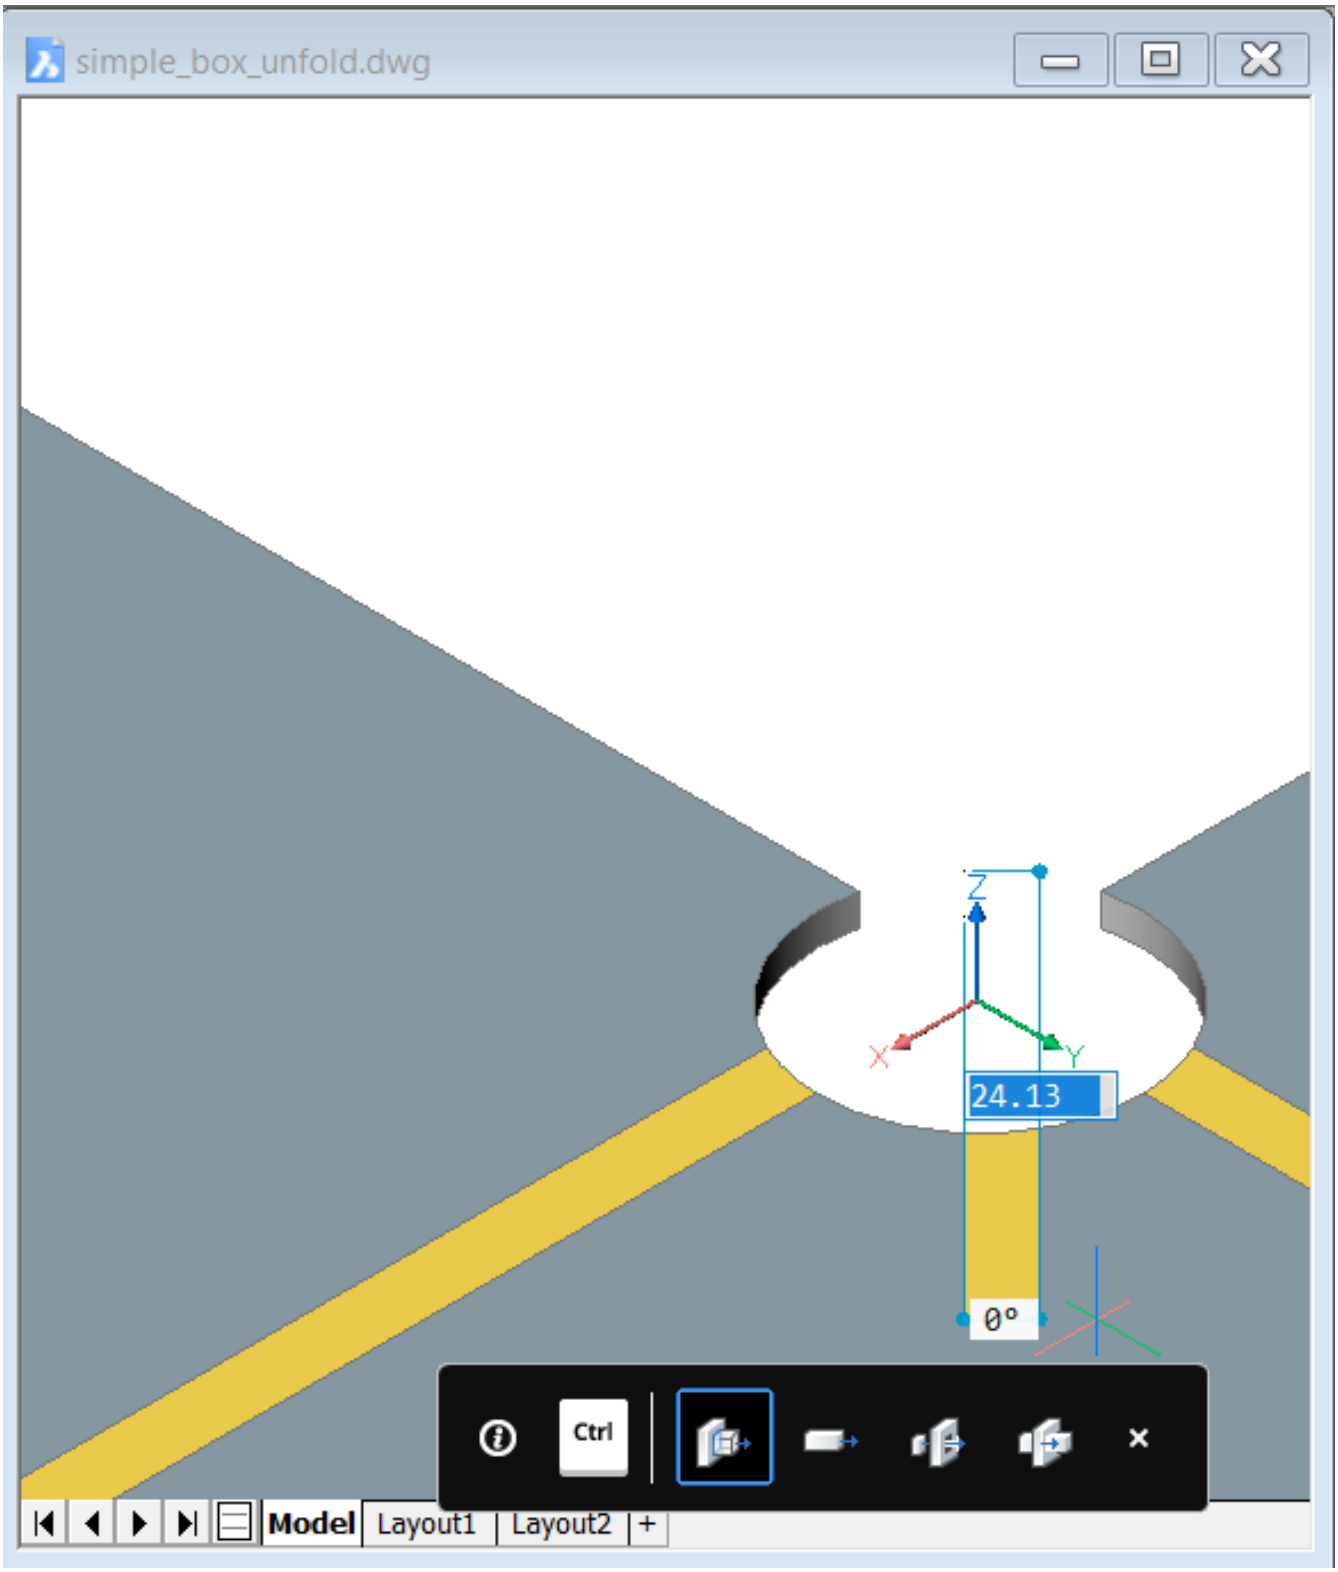

Figure 3.656

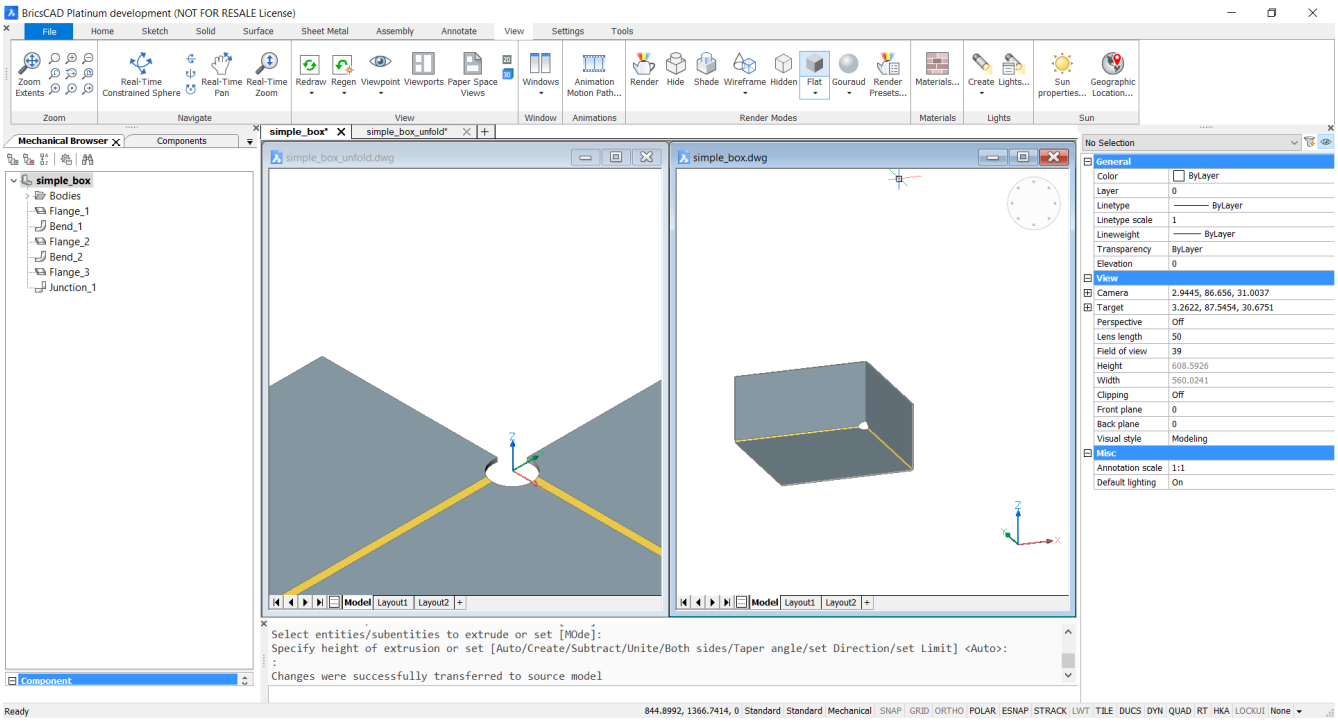

Avoiding Collisions in Flat Pattern

Another useful application of associative unfolding is fixing the so not obvious material collisions. (3.657 on the facing page) In this example, we don't know what changes to apply to the 3D model to avoid the collision when flattened. Let's rework the model with using Associative Unfolding.

1. From **Sheet Metal** section of the Ribbon (6.26.32), select the **Associatively Unfold Body** icon , select **Flange** face, unfold and click **Vertical Tile** button on Toolbar (6.29.33) or Ribbon (6.26.32) to tile the opened documents vertically and zoom to the collision area. (3.658 on the next page)
2. Select boundary circular edge and offset it by 1. (3.659 on page 3250)
3. Draw extra straight lines adjacent to the edge and join them. (3.660 on page 3252)

Figure 3.657

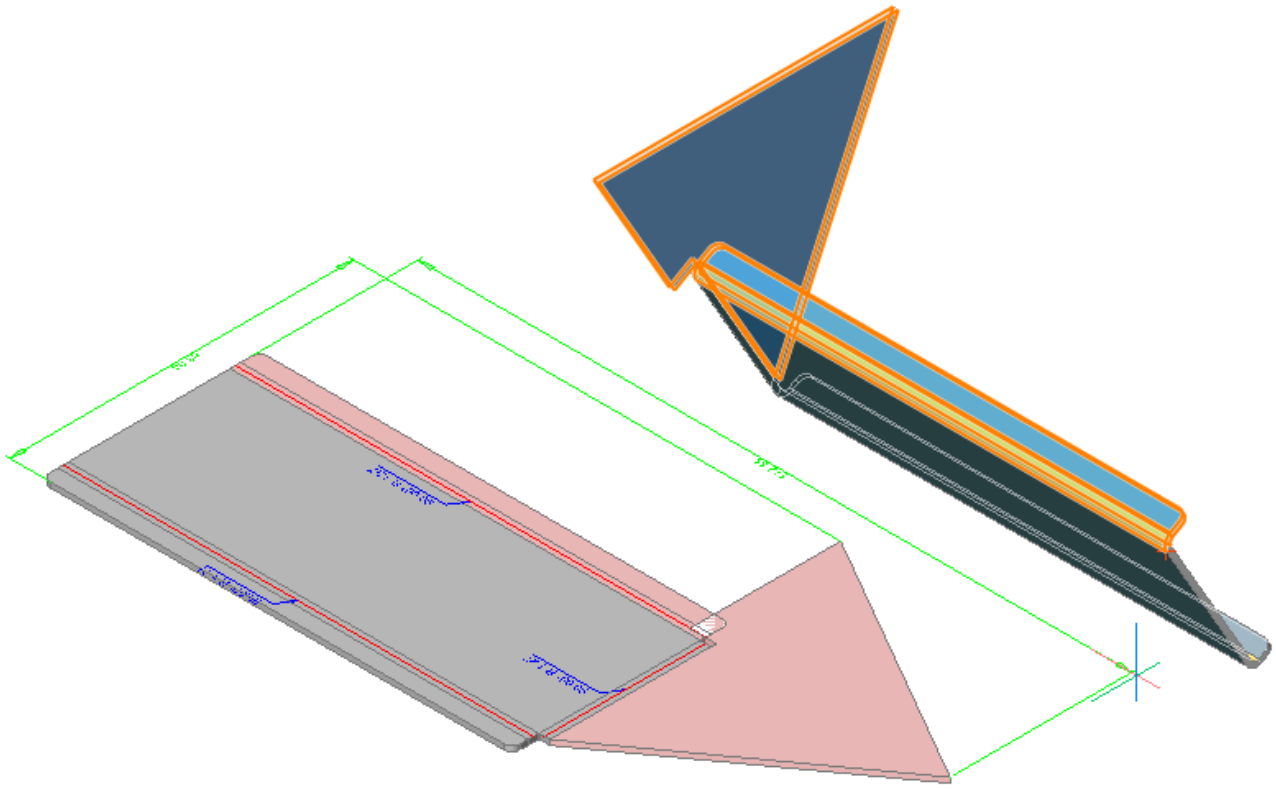

Figure 3.658

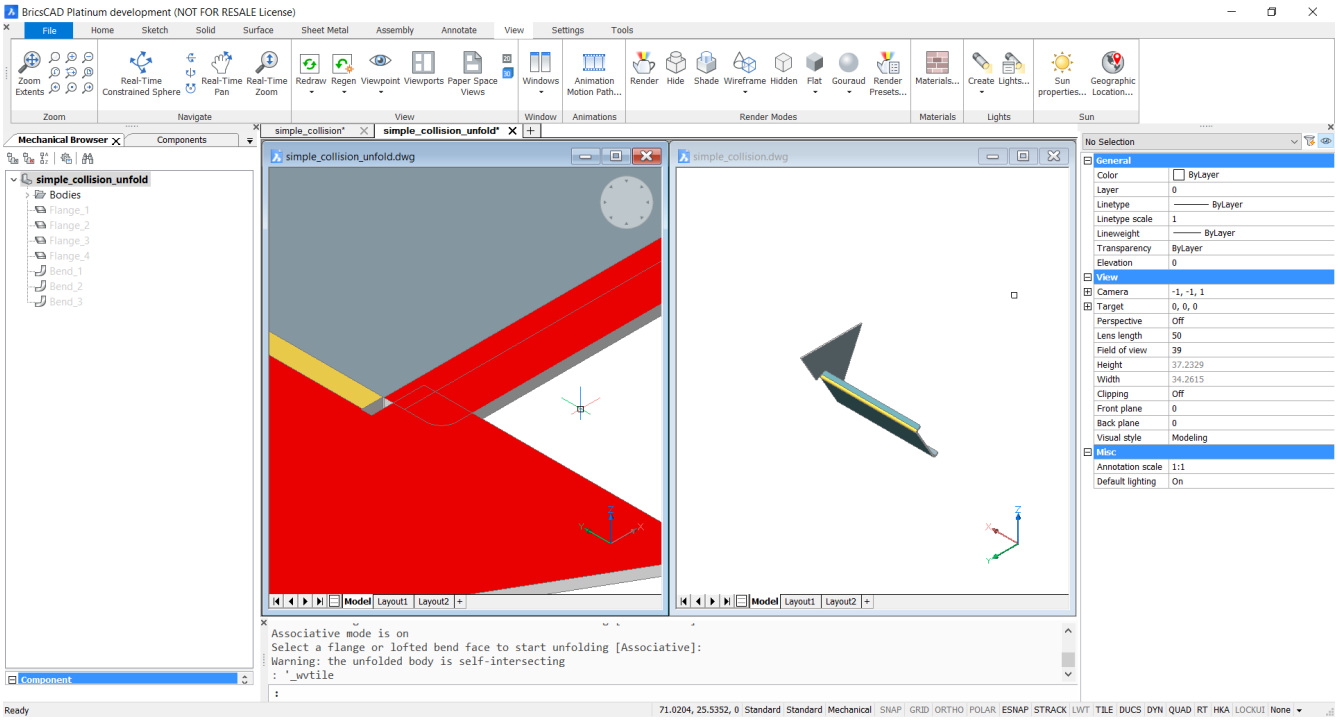

Figure 3.659

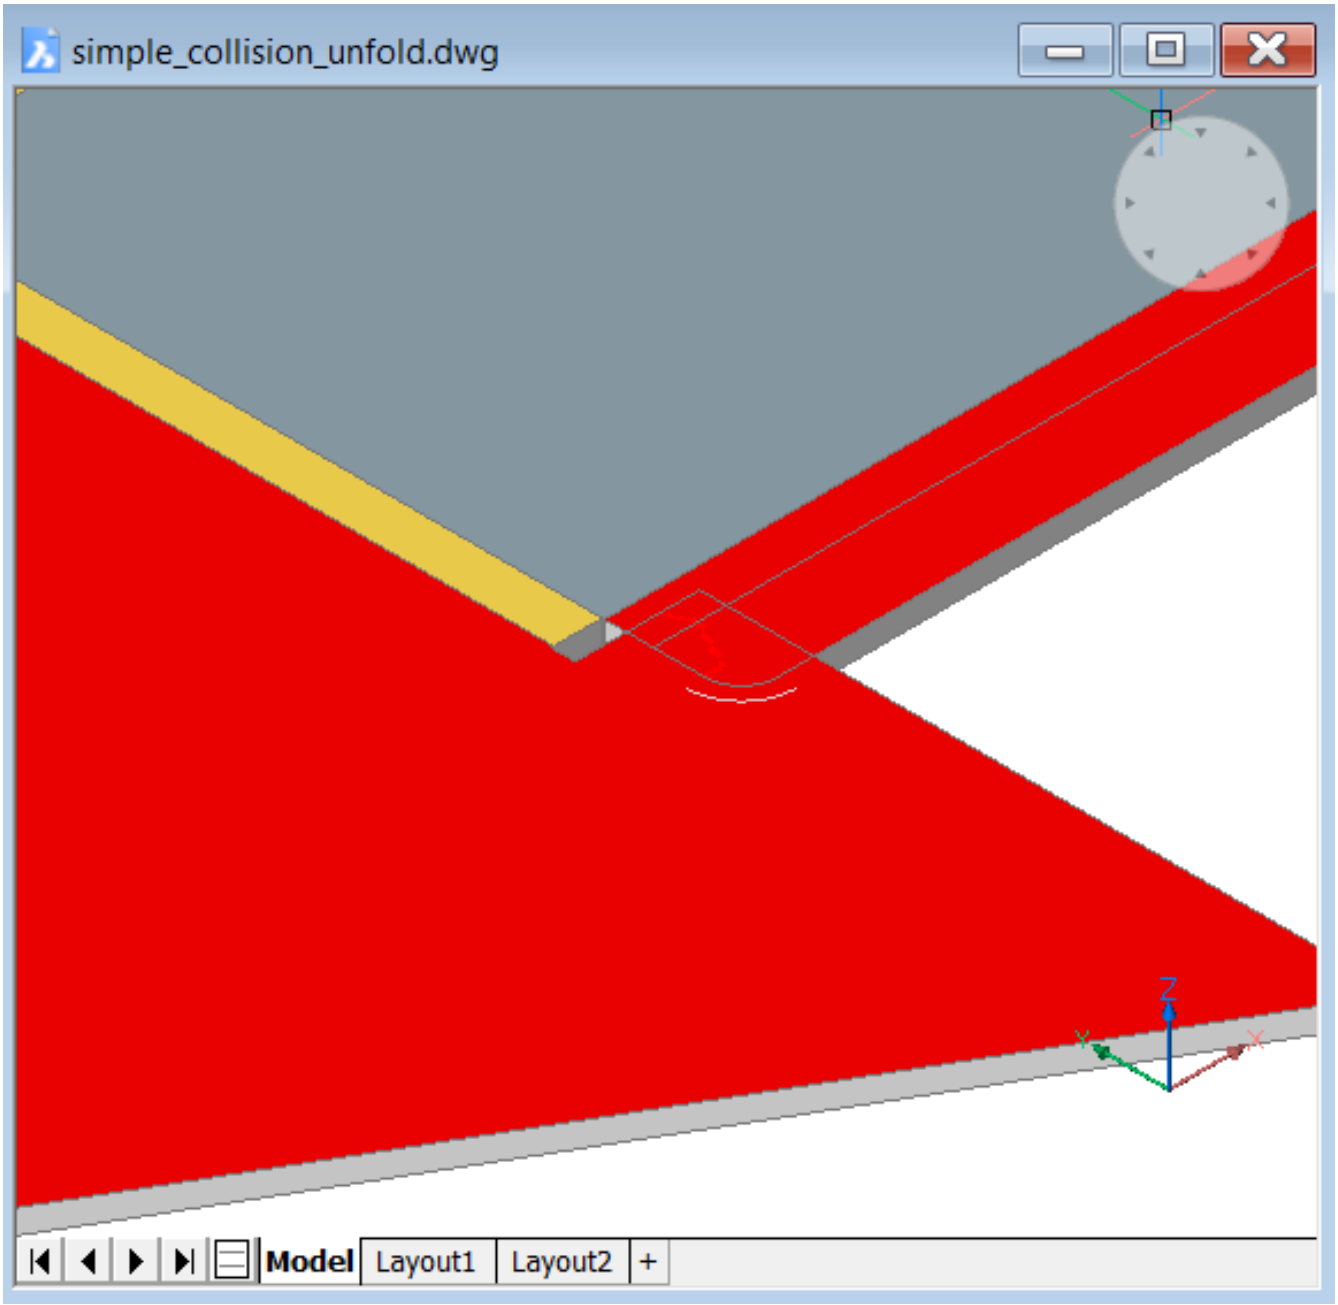

4. DmExtrude (6.12.14) the polyline on both sides. (3.661 on page 3253)
5. DmThicken (6.12.30) the surface by a bigger value. (3.662 on page 3254)
6. Subtract (6.27.58) thickened body from unfolded pattern. (3.663 on page 3255)
7. Erase (6.13.8) the leftover pieces. (3.664 on page 3256)
8. Switch back to the document with the 3D model. (3.665 on page 3257)
9. Make sure that the changes have been propagated. Changes were successfully transferred to the source model. Zoom to the corner that updated. (3.666 on page 3258)
10. To test the 2D unfold, export the file as a .dxf. (3.667 on page 3259)

3.9.28 Converting to Sheet Metal and Repairing

Command: SMCONVERT (6.28.4), SMREPAIR (6.28.29)

To convert 3D geometry to a valid Sheet Metal part

A sheet metal part can be created from any 3D solid geometry, whether created in BricsCAD or imported from another CAD system. However, the geometry might not be a valid sheet metal model: missing bends and reliefs or thickness faces which are not orthogonal to the flange faces. BricsCAD Sheet Metal contains a dedicated toolset to convert such geometry to a valid sheet metal part and add all missing sheet metal features.

1. Do one of the following:

   - Click the **Convert to Sheet Metal** tool button ( ) on the **Sheet Metal** toolbar.
   - Click the **Convert to Sheet Metal** tool button ( ) on the **Sheet Metal** ribbon bar.
   - Choose **Convert to Sheet Metal** in the **Sheet Metal** menu.

   You are prompted: Select 3D solids or [Entire model] <Entire model>:

2. Select the 3D solid to convert.
3. **You are prompted:** Select 3D solids or [Entire model] <Entire model>:
4. Press Enter to convert the 3D solid to a sheet metal part.

The properties of the sheet metal part display in the Mechanical Browser for Sheet Metal (3.9.6).

NOTE

Converted bodies can be unfolded or exported to .dxf or .osm file formats for processing by a CAM system. In some cases it might be necessary to fix converted bodies before unfolding/exporting:

- Create missing reliefs: SmReliefCreate (6.28.22) command.
- Convert hard edges to bends or junctions: SmBendCreate (6.28.3) and SmJunctionCreate (6.28.21) commands.
- Split flanges and lofted bends: SmSplit (6.28.30) command.
- Repair
- sheet metal bodies: SmRepair (6.28.29) command.

To repair a Sheet Metal part

A sheet metal part may have inaccuracies in geometry and topology or sheet metal design issues, which is often the case for imported parts which are designed in geometrical kernels different from ACIS. Examples of such problems are:

- thickness faces, which are not perpendicular to the flange/bend faces.
- lofted bends are not tangential to the adjacent flanges/bends.
- wrong bends.
- general ACIS issues.

Such problems can prevent editing operations from being executed successfully. The recommended workflow to fix such problems is:

- Execute the DmAudit (6.12.2) command to fix general modeling issues.
- Execute the SmRepair (6.28.29) command.

To repair a Sheet Metal body

Sheet metal bodies with thickness faces, which are not perpendicular to the flange/bend faces, cannot be correctly manufactured using traditional tools.

1. Do one of the following:

   - Click the **Repair Sheet Metal** tool ( ) on the **Heal** panel of the **Sheet Metal** ribbon tab;
   - Click the **Repair Sheet Metal** tool ( ) on the **Sheet Metal** toolbar;
   - Choose **Repair Sheet Metal** in the **Sheet Metal** menu;
   - Type **smrepair** in the command bar.

   You are prompted: Select flange face or lofted bend face to repair or [switch on Local repairing/Scan for lost details]:

2. Select the face to be repaired.

(3.668 on the next page) The same model before ...	(3.669 on the following page) ... and after applying a repair operation:

When the model has wrong bends SmRepair transforms them to regular bends:

(3.670 on the next page) Wrong bends, which have a non-tangential connection with the flanges.	(3.671 on page 3263) Correct bends after repairing.

Form features are translated to the new repaired model:

(3.672 on page 3263) Model before repairing	(3.673 on page 3263) The form feature has not been changed while a hole, which is not a form feature, is orthogonalized.

To repair a Sheet Metal body with lofted bends

1. Do one of the following:

   - Click the **Repair Sheet Metal** tool ( ) on the **Heal** panel of the **Sheet Metal** ribbon tab.
   - Click the **Repair Sheet Metal** tool ( ) on the **Sheet Metal** toolbar.
   - Choose **Repair Sheet Metal** in the **Sheet Metal** menu.
   - Type **smrepair** in the command bar.

   You are prompted: Select flange face or lofted bend face to repair or [switch on Local repairing/Scan for lost details]:

2. Select a face of a flange or a lofted bend. The selected face provides the surface to be thickened.

(3.674 on page 3264) Before: the lofted bend is not tangent to the flange. Unfolding is impossible.	(3.675 on page 3264) After: notice the difference in the connection of the blue lofted bend with the top flange, which is smooth now. Unfolding is possible.

Option: If the **SmRepairLoftedBendMerge** user preference is ON, adjacent lofted bends with a tangential connection are merged to a single lofted bend.

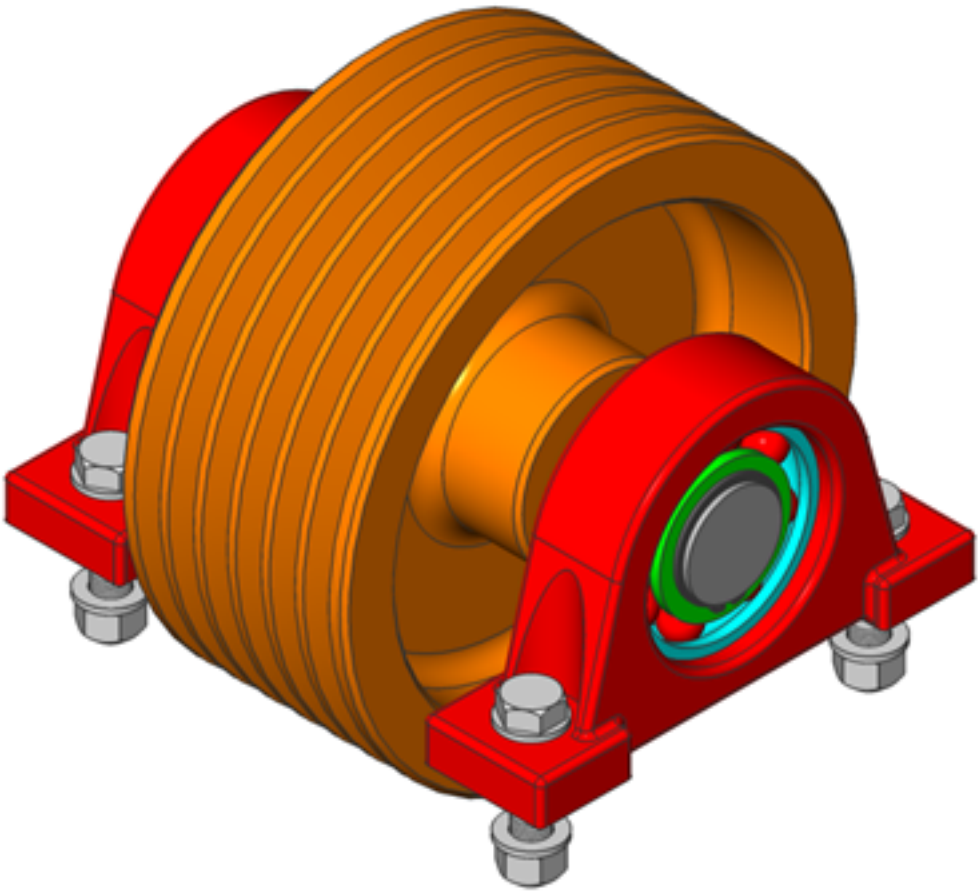
3.10 Generated Drawings - Workflows

3.10.1 Drawing generation

https://www.youtube-nocookie.com/embed/szPH5aOg7p4

1. You need a **BricsCAD Platinum** license for this tutorial.
2. Open the **Small_Deflector_Sheave_assembly.dwg** file from Generative_drafting_files.zip. (3.676 on the next page)

Figure 3.676



3.10.2 1. Creating Base Views

1. Click the **Base Views (6.31.4)** () tool button on the **Annotate | Drawing Views** panel on the **Ribbon (1.17.6)**.
2. Hit **Enter** to accept <**Entire model**>.
3. Hit **Enter** to accept <**Layout1**>.
4. Select the **Orientation | Left** option on the **ViewBase** Prompt menu.
5. Select the **Scale | Standard scales| 1:4** option on the **ViewBase** Prompt menu.
6. Set the position for the left view. (3.677)
7. Set the position for the top view. (3.678 on the next page)
8. Hit **Enter** to accept **<Done>**.
9. Click the **Center Marks (6.9.6)** () tool button on the **Annotate | Dimensions** panel on the **Ribbon (1.17.6)** to add the center mark to the circle in the **left view**.
10. Add a few radius dimensions (6.11.16) () and a linear dimension (6.11.12) (), between bolts, to the left view using the dimensions tools from the **Annotate | Dimensions** panel on the **Ribbon (1.17.6)**. (3.679 on the following page)

Figure 3.677

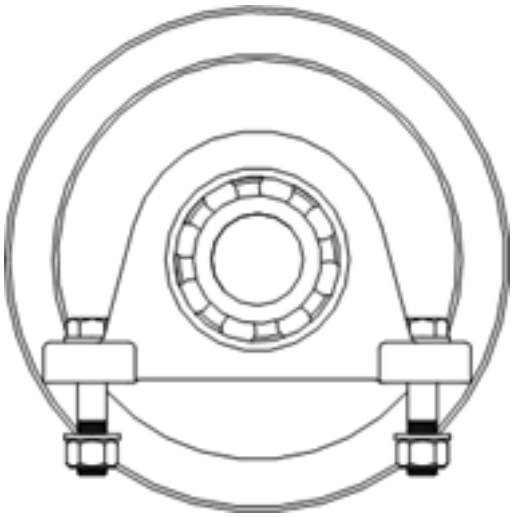


Figure 3.678

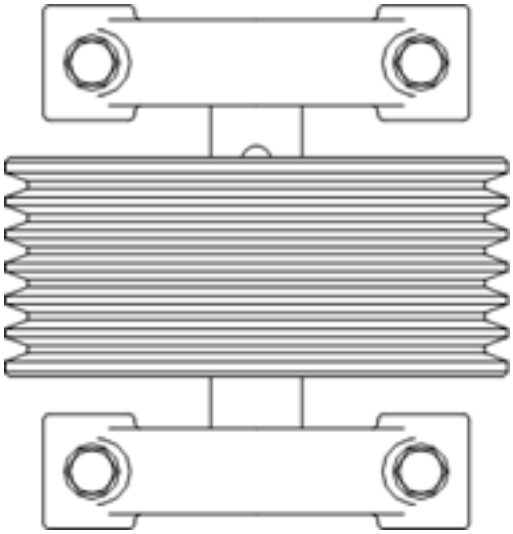

Figure 3.679

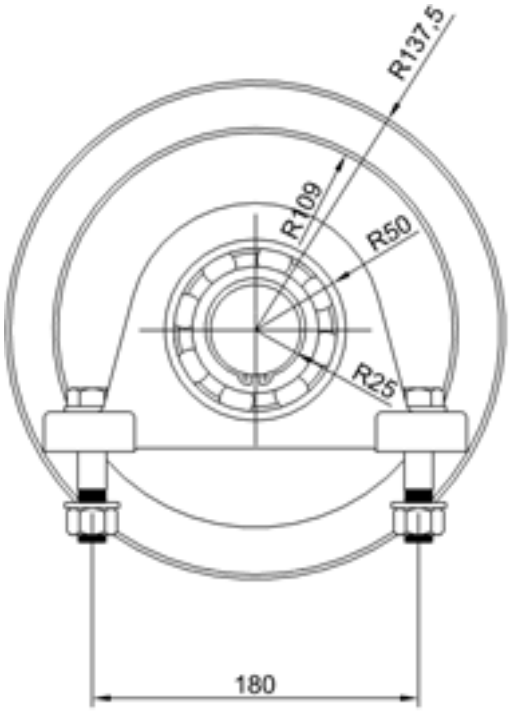

3.10.3 2. Creating Section Views

1. Click the **Section View (6.31.12)** () tool button on the **Annotate | Drawing Views** panel on the **Ribbon (1.17.6)** to create vertical **Section View A-A**.
2. Select the left drawing view.
3. Specify the start point of the vertical section line.
4. Specify the next point of the vertical section line.
5. Move the cursor right and place the section view.
6. Use the **Linear dimension (6.11.12)** () and **Continue (6.11.8)** () tool buttons from the **Annotate | Drawing Views** panel on the **Ribbon (1.17.6)** to add a few linear dimension to **Section View A-A**. (3.680 on the next page)
7. Click the **Section View (6.31.12)** () tool button on the **Annotate | Drawing Views** panel on the **Ribbon (1.17.6)** to create horizontal **Section View B-B**.
8. Select the top drawing view.
9. Specify the start point of the horizontal section line.
10. Specify the next point of the horizontal section line.
11. Move the cursor to the top and tap the CTRL key to turn off alignment. This will allow you to place the section view to the right-hand side.
12. Set the position for the section view. (3.681 on the following page)
13. Repeat step 1.9 to add **Center Marks (6.9.6)** () to the circle of **Section View B-B**.

Figure 3.680

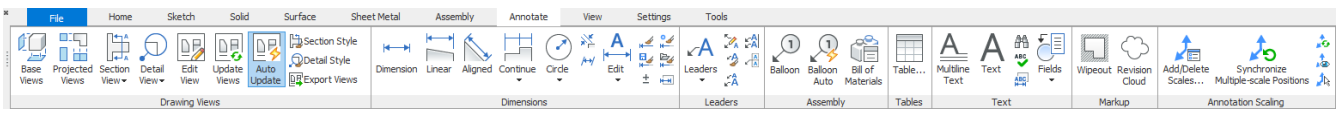
3.11 Generated Drawings

3.11.1 Drawing Views

BricsCAD Mechanical provides a rich toolset to generate drawing views from 3D models of parts and assemblies. Drawings views are created in the paper space of the same .dwg file and the 3D model is created in model space. Drawing views can be annotated using dimensions, leaders, text and tables. Views and annotations are updated when the associative 3D model is changed. The tools to generate, update and annotate drawing views are presented on the **Annotate** ribbon tab of the **Mechanical** workspace: (3.690) Base Views (6.31.4) generates associative orthographic and standard isometric views of a 3D solid model in a paper space layout. Projected Views (6.31.9) generates additional projected views from an existing drawing view. Section View (6.31.12) creates a cross-section view based on a standard drawing view generated by the ViewBase command in a paper space layout. Detail View (6.31.6) creates a detail view of a portion of a standard generated drawing at a larger scale. Edit View (6.31.8) allows you to change the scale and the hidden line visibility of drawing views. Update Views (6.31.13) updates a selection of drawing views obtained by VIEWBASE and VIEWSECTION when VIEWUPDATEAUTO = 0. There are predefined and user-defined styles for Section (6.31.22) and Detail (6.31.7) views. Export Views (6.31.11) exports the content of drawing views, obtained by the ViewBase and ViewSection commands, to the Model Space of the drawing or to a new drawing.

Figure 3.690



Draft-quality drawing views

By default, BricsCAD generates precise (high-quality) drawing views for any 3D model. The edges of such views (including silhouette edges) are represented by 2D entities; lines, circles, arcs and splines. The generation of precise views for a large number of 3D entities can take a significant amount of time. This is because every silhouette edge must be approximated with an analytical 2D curve. You can significantly reduce the time needed to generate drawing views by changing the DRAWINGVIEWQUALITY setting to 0. This enables draft-quality drawing views. Such drawing views are internally represented as 3D solids, which makes it impossible to put annotations on their silhouette edges. However, they look very similar to a precise (high-quality) drawing view and you can use them to quickly create layouts. A draft-quality drawing view can be switched to a high-quality drawing view using its "Geometry" property (change it from "Draft" to "2D").

3.11.2 Drawing Annotations

Creating and editing annotations, review Dimensioning Tools Overview (1.29.1). Dimensions and Multileader (1.29.13) that are in the drawing view are updated upon change of the underlying 3D model. Assembly drawings (3.7.8) can be annotated with BOM balloons. Every balloon refers to a row in a BOM (3.7.11) table generated from the assembly. The BOM table can be placed in paper space (layouts (1.23.13)) with the drawing view of an assembly. Exploded Representations (3.7.8) of assemblies can be used to generate drawing views and annotate them with balloons.

Chapter 4

Communicator for BricsCAD

4.1 Getting Started

4.1.1 Communicator for BricsCAD Installation

The Communicator for BricsCAD comes as a single download file. The version of the Communicator for BricsCAD must be the same as the version of BricsCAD. If you update BricsCAD to the next major version you must also update the Communicator to the same major version. The Communicator for BricsCAD OS requirements and installation procedures are the same as for BricsCAD. The Communicator for BricsCAD requires a separate license. Some features, such as the import and export of the product structure, require a BricsCAD license of BricsCAD Platinum or higher.

Installation Location Requirements Install the Communicator for BricsCAD to a path that contains only ASCII (English) characters. Do not use any Unicode or national alphabet characters in the path.

4.1.2 BricsCAD Communicator

Commands: COMMUNICATORINFO (6.9.24), EXPORT (6.13.18), IMPORT (6.17.10) BricsCAD Communicator is an optional plug-in for Pro and higher editions of BricsCAD that imports and exports 3D data between major CAD formats. Its high-quality conversions facilitate the re-use of 3D CAD data to improve productivity and reduce project costs.

Tutorial: Assembly design with BricsCAD Communicator Click here (3.4.8) to watch.

Supported file formats

Export (Windows)

- **3D PDF:** .pdf
- **ACIS:** .asab, .asat, .sab, .sat

- **VDA-FS:** .vda

You can import an assembly file, as a plain geometry (a nonhierarchical set of entities) or map its product structure into native blocks or mechanical components. PMI (Product and Manufacturing Information) is supported for the following file formats (Communicator license is required): ACIS, CATIA V5, NX, Pro/E / Creo, SolidWorks, XCGM. PMI annotations are imported as graphical elements grouped in blocks. If the assembly contains hidden parts, you can decide how to represent them in BricsCAD: 'import and hide', 'import and set visible' or just 'do not import'. This feature is currently supported on CATIA v5 only. You can change this with the Settings (1.17.10) dialog: (4.3 on the facing page) (fig. 3) You can also set other import options to automatically repair, stitch and simplify imported geometry. **Note** the IGES format has its own options to stitch and simplify. If you import a 3D model from SolidWorks, it makes sense to set an option to map Y axis into Z (because in SolidWorks the vertical axis is Y). For SolidWorks and other native CAD formats, it is possible to specify an alternate search path. This will be used to look for parts absent in the imported assembly folder.

4.2 Settings

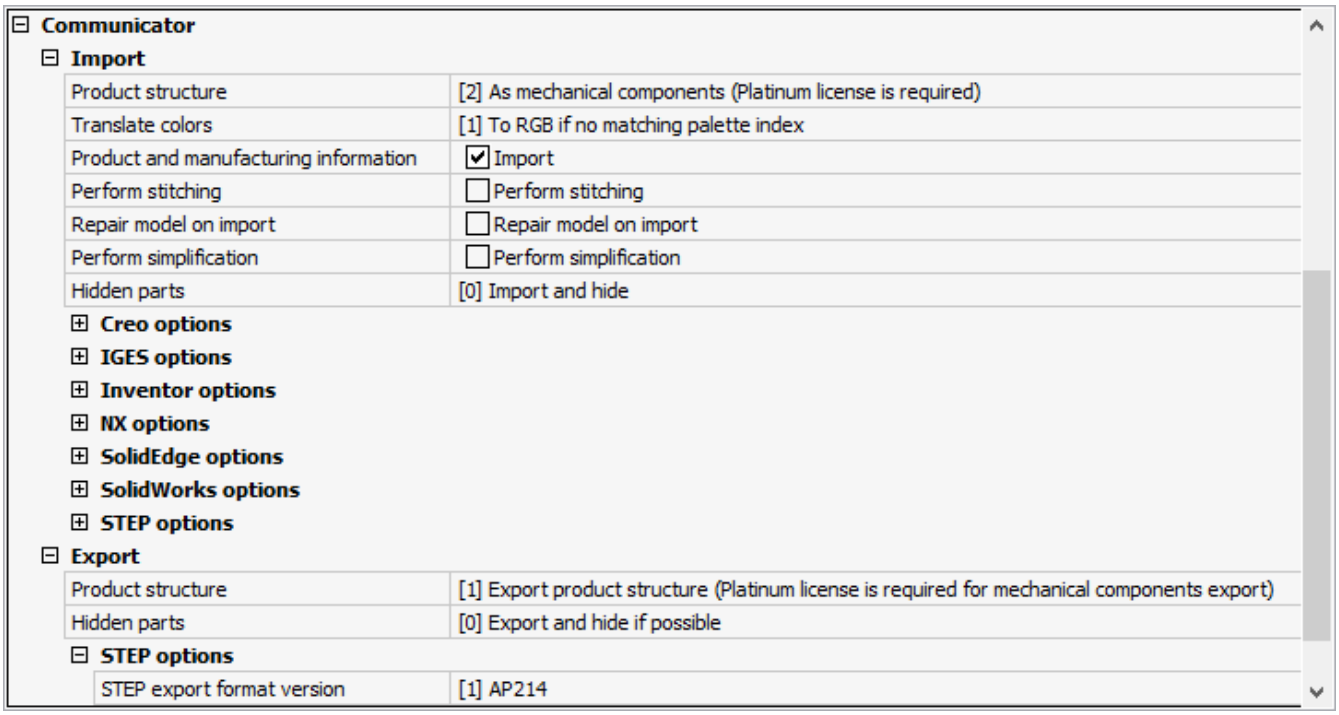
4.2.1 BricsCAD Communicator Settings

Commands: COMMUNICATORINFO (6.9.24), EXPORT (6.13.18), IMPORT (6.17.10), SETTINGS (6.27.25) The Communicator section in the Settings (1.17.10) dialog box allows to customize the behavior of the related commands:

- setting environment options.
- control the import/export of data.
- toggling post-processing operations.

Settings are applicable whe the EXPORT (6.13.18) and IMPORT (6.17.10) commands engage one of Communicator (4.1.2) file formats. (4.4 on the next page)

Figure 4.4



Import Settings

Product Structure **Name**: ImportProductStructure **Description**: Determines how the imported entities will be structured and whether it will form a soup of entities, as a block hierarchy or as an assembly (3.7.1) structure. **Values**:

- **[0] None**: Creates a flat structure without blocks in the modelspace of the target database regardless whether the imported data have an assembly structure or not.
- **[1] As blocks**: The imported data have an assembly structure, which will be converted into a hierarchy of plain blocks; so the structure will be preserved, while the assembly metadata are lost. If the imported data is composed of entities only, they are placed in the modelspace of target database.
- **[2] As mechanical components**: In this mode data will be translated into BricsCAD assembly data, the structure and its properties (i.e. physical materials (2.7.17)). If the imported file has no assembly data, a mechanical component will be created in the BricsCAD target document root anyway.

Translate Colors **Name**: ImportColors **Description**: Determines how the colors (1.25.5) of the imported entities will be assigned: either as true colors or matching to current color palette. **Values**:

- **[0] To RGB**: All the entity colors will be converted to RGB regardless of current palette.
- **[1] To RGB if no matching palette index**: If the entity color is found in the palette, then the entity gets an index color, else a true color.
- **[2] To nearest palette index**: For any true color of the imported entity the nearest match is searched in the palette and this indec color is assigned to the entity.

Product and Manufacturing Information **Name**: ImportPMI **Description**: Determines whether product manufacturing information is imported. Currently such information is imported as exploded data (lines, text, ...) instead of compound entities (e.g. annotations). **Values**: **on/off** checkbox.

Perform Stitching **Name**: ImportStitch **Description**: In some cases imported geometry represents solid (1.18.19) geometry as a set of separate surfaces. In order to be able to work with solid operations on the imported geometry, the DMSTITCH (6.12.29) command has to be applied. If this settings = ON, the DMSTITCH command is executed automatically when the geometry is imported. **Notes:**

- Stitch operations are time consuming when importing large files.

- Check the ImportIgesStitch setting, which can set an override for the IGES file format.

Values: **on/off** checkbox.

Repair Model on Import **Name**: ImportRepair **Description**: Applies operations similar to the DMAUDIT (6.12.2) command in order to improve the quality of the imported geometry. Geometry modeled in CAD systems which use a kernel different from ACIS, often needs to be healed because of possible flaws. **Values**: **on/off** checkbox.

Perform Simplification **Name**: ImportSimplify **Description**: Applies operations similar to the DMSIMPLIFY (6.12.27) command:

- Convert imported splines into canonic surfaces.
- Simplify topology (remove imprinted edges) if possible.

Note: Also check the ImportIgesSimplify setting, which can set an override for the IGES file format. **Values**: **on/off** checkbox.

Hidden Parts **Name**: ImportHiddenParts **Description**: Defines how hidden (invisible) entities in the imported geometry are processed. **Values**:

- **[0] Import and hide**: All entities are imported; invisible entities are hidden. Note that currently there are no user tools to make these hidden entities visible again.
- **[1] Import and set visible**: All entities are imported and visible with regardless of the visibility in the source file.
- **[2] Do not import**: Hidden entities in the source file are not imported.

Creo Options

Alternate Search Paths **Name**: ImportCreoAlternateSearchPaths **Description**: This setting is taken into account when Creo files are imported. The value is a set of semi-colon (;) delimited, fully qualified paths used to search for missing assembly references during product structure import operations. **Values**: string; if empty, the search is performed in the folder of the imported file only.

IGES options

Perform Stitching **Name**: ImportIgesStitch **Description**: In some cases imported geometry represents solid (1.18.19) geometry as a set of separate surfaces. In order to be able to work with solid operations on the imported geometry, the DMSTITCH (6.12.29) command has to be applied. If this settings = ON, the DMSTITCH command is executed automatically when the geometry is imported. This setting determines whether a stitch operation has to be applied to imported entities when the format of the source file is IGES. **Notes:**

- Stitch operations are time consuming when importing large files.
- For file formats other than IGES, the ImportStich setting applies.

Values: **on/off** checkbox.

Perform Simplification **Name**: ImportIgesSimplify **Description**: Determines whether a simplification (6.12.27) operation has to be applied to the imported geometry when the source file format is IGES **Note:** For other formats see the ImportSimplify setting. **Values**: **on/off** checkbox.

Inventor Options

Alternate Search Paths **Name**: ImportInventorAlternateSearchPaths **Description**: Setting is taken into account when Inventor files are imported. The value is a set of semi-colon (';') delimited, fully qualified paths used to search for missing assembly references during product structure import operations. **Values**: string; if empty the search is performed in the folder of the imported file only.

NX Options

Alternate Search Paths **Name**: ImportNxAlternateSearchPaths **Description**: Setting is taken into account when NX files are imported. The value is a set of semi-colon (';') delimited, fully qualified paths used to search for missing assembly references during product structure import operations. **Values**: string; if empty search is performed in the folder of the imported file only.

SolidEdge Options

Alternate Search Paths **Name**: ImportSolidEdgeAlternateSearchPaths **Description**: Setting is taken into account when SolidEdge files are imported. The value is a set of semi-colon (';') delimited, fully qualified paths used to search for missing assembly references during product structure import operations. **Values**: string; if empty search is performed in the folder of the imported file only.

SolidWorks Options

Map SolidWorks Y to BricsCAD Z axis **Name**: ImportSolidWorksRotateYZ **Description**: Corrects the difference between the SolidWorks and BricsCAD coordinate systems. If unchecked, imported geometry in BricsCAD is rotated by 90 degrees compared to its position in SolidWorks. **Values**: **on**/**off** checkbox.

Alternate Search Paths **Name**: ImportSolidWorksAlternateSearchPaths **Description**: Setting is taken into account when SolidWork files are imported. The value is a set of semi-colon (';') delimited, fully qualified paths used to search for missing assembly references during product structure import operations. **Values**: string; if empty search is performed in the folder of the imported file only.

STEP Options

Map Y to BricsCAD Z axis **Name**: ImportStepRotateYZ **Description**: Corrects the difference between coordinate systems in different coordinate systems, i.e. SolidWorks and BricsCAD. This can be helpful to prevent undesired rotation when the origin CAD of STEP file is known, i.e. if it is SolidWorks. **Values**: **on**/**off** checkbox.

Export Settings

Product Structure **Name**: ExportProductStructure **Description**: Determines whether the assembly (3.7.1) structure will be preserved in the target document. **Values**:

- **[0] No product structure**: Exports a flat structure without components in the target document whether the BricsCAD document has a product structure or not.
- **[1] Export product structure**: Exports the BricsCAD product structure data (if existing) to the target document.

Hidden Parts **Name**: ExportHiddenParts **Description**: Determines if invisible entities are exported or not. Entities can be invisible because of:

- the result of the HIDEOBJECTS (6.16.10) command.
- sitting on a hidden layer. (6.13.17)
- owned by an invisible (3.7.3) component.

Values:

- **[0] Export and hide if possible**: Exports hidden entities. If the target format supports hidden entities, hidden entities in the source document will be hidden also in target document.
- **[1] Do not export**: Invisible entities are skipped.

STEP Options

STEP Export Format Version **Name**: ExportStepFormatVersion **Description**: Allows to select available specifications of the STEP format. **Values**:

- **[0] AP203**: Selects AP203 protocol.
- **[1] AP214**: Selects AP214 protocol.
- **[2] AP242**: Selects AP242 protocol.

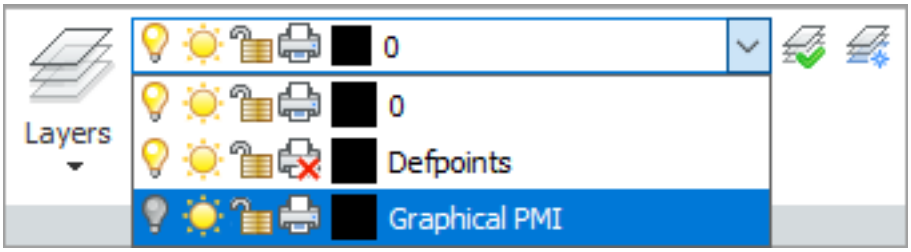
4.3 Tutorials

4.3.1 Import PMI

https://www.youtube-nocookie.com/embed/TVBBrWgVS4E You need **BricsCAD Platinum** and **Communicator** licenses for this tutorial.

1. Create a new file.
2. Launch the Import (6.17.10) command.
3. Select the Geared_Traction_Machine_2_PMI.SLDPR file in the **Import file** dialog box. Click the **Ok** button.
4. Switch off the **Graphical PMI** layer in the drop-down **Layers** menu, in the **Home| Layers** panel, on the Ribbon (1.17.6). (4.5)
5. Click the **Audit (6.12.2)** ( ) tool button on the **Sheet Metal | Heal** panel on the Ribbon (1.17.6).
6. Click **Entire model** on the **DmAudit** prompt menu or press **Enter.**
7. Click **Fix** on the **DmAudit** prompt menu or press **Enter**.
8. Save as Geared_Traction_Machine_2_PMI.dwg file.

Figure 4.5



Chapter 5

BricsCAD Shape

5.1 Getting Started

5.1.1 The Shape user interface

https://www.youtube-nocookie.com/embed/s1lIETo2E3U Let's explore the Shape user interface. The toolbar at the top of your screen gives you fast access to the most used tools. Left-click on any icon in the toolbar to use the tool. Many top-level tools offer sub-menus. Hover over the icon, left click and hold. The sub-menu will fly out to show these additional tools. The icons on the right side of your screen give you access to a set of collapsible panels The top-most icon opens the Tips panel. You'll find more details on how to use the tools in Shape here. We'll tell you more about the other panels in later tutorials.

5.1.2 How to navigate in BricsCAD Shape

https://www.youtube-nocookie.com/embed/Ce9KIjYbarE Model navigation in BricsCAD Shape can be done in three ways. The Pan command slides your viewpoint. You can click and hold your mouse wheel to Pan. Press and hold CONTROL + SHIFT and the right mouse button to Pan. Or you can start the Pan command. The Zoom command moves your viewpoint in and out. You can scroll your mouse wheel to Zoom in and out. You can press and hold CONTROL + SHIFT and the left mouse button to Zoom. Double-click the mouse wheel to Zoom Extents. The second option is to start the Zoom command. You can rotate your viewpoint around the model. Press and hold SHIFT and the mouse wheel, then move the mouse to rotate your viewpoint. Or you can start the real-time rotate command. Finally, the “lookfrom” widget lets you select preset 3D views quickly.

5.1.3 How to select elements in BricsCAD Shape

https://www.youtube-nocookie.com/embed/ROAIqPfdiNE Model elements in BricsCAD Shape are solids. They are made up of edges and faces. You can select faces by moving your cursor over the face and left-clicking your mouse. Press the ESC key to clear your selection. You can select edges by moving your cursor over the edge. Then press & hold CTRL and left-click your mouse. To select an entire solid, move the cursor over any face of the solid, press & hold CTRL and left-click your mouse. To select multiple faces, just left-click them, one-by-one. To select multiple edges or multiple solids, press & hold CTRL and left-click them, one-by-one. Sometimes, the element or elements you want to select are hidden behind others. To select hidden elements, press the TAB key while hovering over the element. Each time you press TAB, you'll cycle to the next element underneath the cursor. When the element you want is highlighted, just left-click to select it.

5.1.4 How to use the Quad cursor & Rollover tips in BricsCAD Shape

https://www.youtube-nocookie.com/embed/SecgCMi2LiI

In BricsCAD Shape, the user interface includes everything that you need and nothing that you don't. Hover over a model element, and a Rollover Tip will display that element's properties. Different types of elements will display different property sets. The Quad cursor is a context-sensitive tool panel. Right-click on any empty space on your screen, and you'll see the Quad in its "No Selection" state. Move your cursor onto the displayed icon, and the Quad expands. The most relevant commands are on the top bar, and the pulldowns will show all available commands by category. Next, move your cursor over any model element. The Rollover Tip will appear. Then, move your cursor onto the Rollover Tip. The Quad opens, and shows you the tools that you can use on the selected element.

5.1.5 How to hide and isolate objects in BricsCAD Shape

https://www.youtube-nocookie.com/embed/NHJpHaZvC9o

When model elements block your view, you can HIDE them easily. To hide one or more elements, just highlight them, raise the Quad and left-click 'Hide Entities'. The opposite of hiding an element is isolating it. Highlighting one or more entities, and selecting 'Isolate Entities' from the Quad will hide all the non-highlighted elements in your model. Hiding and Isolating are temporary functions that you can use to simplify your model while working on it. When you want to see all the elements in your model, just raise the "No Selection" Quad and left-click "Show Entities".

5.1.6 How to work with layers in BricsCAD Shape

https://www.youtube-nocookie.com/embed/p1QFV9sdf5g

Using layers to group model elements is a time-tested way to organize 3D models. Open the Layer panel by left-clicking the “stacked sheets” icon. It is located on the vertical toolbar, on the right-hand edge of your screen. Turn layers on and off in the Layer Panel. Do this by moving the cursor over the lightbulb icon to the right of each layer name, and left-clicking the mouse. Toggling layers is a simple way to isolate model elements, to help with navigation and viewing. You can create a new layer by left-clicking the green “plus sign” at the top of the layer panel. The current layer is indicated by the blue dot, shown in the column to the left of the layer names. To change the current layer, just left-click in that column. To change the layer of a model element, hover over the element, move the cursor onto the Rollover Tip, and click the desired new layer name in the “Layer” pull-down list.

5.1.7 How to change the visual style in BricsCAD Shape

https://www.youtube-nocookie.com/embed/PIqsRBwYsvk

BricsCAD Shape uses Visual Styles to control the appearance of your model. Open the Visual Styles panel by left-clicking the "camera" icon, located on the vertical toolbar, on the right-hand edge of your screen. Each defined Visual Style, when selected, will change the look of your entire model. In the Visual Styles panel, you can change the perspective view. Moving the perspective slider all the way to the left will turn perspective off. The Quality slider controls the on-screen rendering quality of your model.

5.2 Getting Started

5.2.1 Welcome to BricsCAD Shape

https://www.youtube-nocookie.com/embed/QCsp_NKtOlo

What is BricsCAD Shape?

BricsCAD® Shape is the new conceptual modeling tool from Bricsys. It's made to help architects and engineers streamline their 3D schematic design work. Shape is the fastest way to get designs out of your head and in front of your clients. It's CAD-accurate, using a powerful direct modeling engine. You can use it as a live presentation tool, too. Potentially best of all, Shape offers a clean, simple user interface that you can learn in 30 minutes or less.

BricsCAD Shape lets you create without limits

Shape's smart modeling tools make it easy to capture in 3D. The multi-functional "Shape" tool can be used to create walls, slabs, structural elements and more. Direct modeling features let you drag, connect, push/pull and extrude as you like. Wall connections are automatically mitered for you. BricsCAD Shape also offers everything you need to present your designs. It comes with a library of materials, textures and pre-built 3D components. You can use the included collection of doors and windows, or create your own custom versions easily. Make your model look the way you want using the Visual Styles panel in Shape.

How is BricsCAD Shape different from other tools?

First, BricsCAD Shape is CAD-accurate from the start. Under the simple UI is the same fast and proven parametric, 3D direct modeling engine that's in BricsCAD Platinum. Shape creates solid models, stored in industry-standard DWG – just like BricsCAD® BIM. Unlike competing products, Shape's solid models are fully accurate – never approximated. Every element that you create in Shape can be modified deeply, anytime, on the fly. Your concept models open directly in BricsCAD BIM. You'll never lose time starting over again. Make the smart move – directly from concept to BIM with BricsCAD Shape with no loss of detail.

BricsCAD Shape accelerates your BIM workflow

The Bricsys BIM workflow starts in 3D with Shape, and stays in 3D – speeding 2D construction documentation with the world's best drafting tools. No breaks or transitions in your workflow, all in DWG, with a friendly, familiar user interface that you'll appreciate. It won't take long for you to be productive in BricsCAD Shape or BricsCAD BIM.

Stop sketching. Start shaping!

Get your free copy of BricsCAD Shape! BricsCAD Shape delivers the tools you need, and none that you don't. Even the learning materials are clean and simple – check out "30 minutes to Shape" on YouTube.

5.2.2 Further documentation

Many of the modelling tools that are used in BricsCAD and BricsCAD BIM are also available in Shape. For this reason we refer to the following articles for a more in depth explanation of the different tools: BricsCAD - Direct Modeling Operations (1.26.2) BricsCAD BIM - Modeling Techniques Furthermore, you can get an overview of all available commands in Shape by typing in COMMANDS in the command line.

5.2.3 The basic concepts of modelling

Navigation

Useful shortcuts:

- Hold down the **middle mouse button** to **pan**
- Hold down **shift** and the **middle mouse button** to **rotate**
- Scroll the **mouse wheel** to **zoom in or out**
- Click any of the locations on the 'LookFrom' widget to view your model from a certain angle

Highlight vs Select

Hover over an object, to highlight, left-click to select this entity. It is not always necessary to select an entity to perform an operation, for example, you can highlight a surface. This will trigger the Quad to open. You can find the command you want to perform on that surface, without having to select the surface first. You can only **highlight** one entity at a time. However, you can **select** as many entities as you want. For this reason, the highlight function is particularly useful when performing an operation on one single entity.

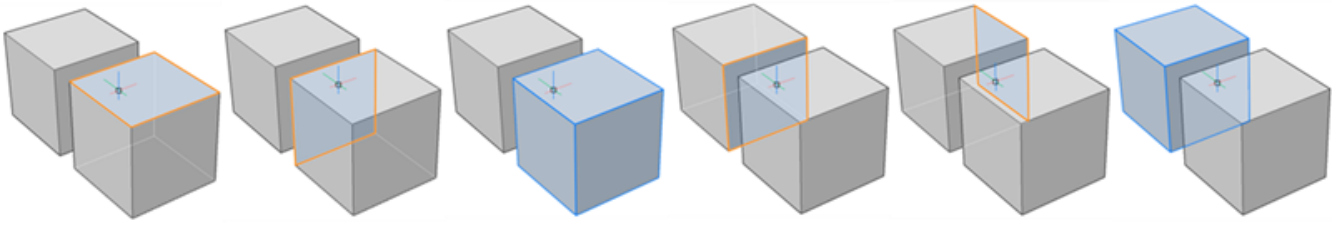
Selection modes

A solid has different subentities: faces and edges. It is possible to select these faces or edges individually to perform operations on them, for example, offset an edge or extrude a face. Select any of these subentities using the **Ctrl** and **Tab** keys.

To highlight a solid **face**, hover over it with your cursor. The face will display in orange. To select it, left-click it while highlighted. To select multiple solid faces, left-click them one by one. (5.19 on page 3318)	To highlight a **solid**, hover over one of its faces and hold down the **Ctrl** key. The solid will display in blue. To select it, left-click it while it is highlighted. To select multiple solid faces, left-click them one by one. (5.20 on page 3319)	To highlight an **edge**, hover over the edge and hold down the **Ctrl** key. The edge will display in orange. To select it, left-click it while it is highlighted. To select multiple solid faces, left-click them one by one. (5.21 on page 3319)

To cycle through all entities or subentities that are 'underneath' the cursor, hit the **Tab** key and do not move the cursor. This can be used to select an entity that is not visible because it is behind another element. For instance, to select the back face of the front cube in the image below or one of the faces of the second cube, you can keep the cursor at the same location and hit the **Tab** key to cycle through the different entities. (5.1) With a combination of the **Ctrl** and **Tab** keys you can highlight and select any entity type or subentity type.

Figure 5.1



Selection windows

Use a selection window to select one or multiple elements at once. To use a selection window, left-click on any empty space in your model area, and move the cursor until the window covers everything that you want to select. There are two types of selection windows:

- **Blue selection window** appears when you create the window from **left to right**. This selection window will only select elements that are entirely covered by this selection window.
- **Green selection window** appears when you create the window from **right to left.** This selection window will select all elements that intersect entirely or partially with the window.

In this example, the blue selection window will only select the left cube, whereas the green selection window will select both cubes. (5.2) A selection window will, by default, only select entire elements (i.e. solids, lines, polylines, blocks, …) but not subentities (such as solid faces or solid edges). Hit **Ctrl** once during the selection window creation, to select only solid faces. The selection mode of the window will be indicated by a small icon in the bottom right corner: (5.3 on the following page) Hit **Ctrl** twice during the selection window creation, to select only solid edges. The selection mode of the window will be indicated by a small icon in the bottom right corner: (5.4 on the next page)

Figure 5.2

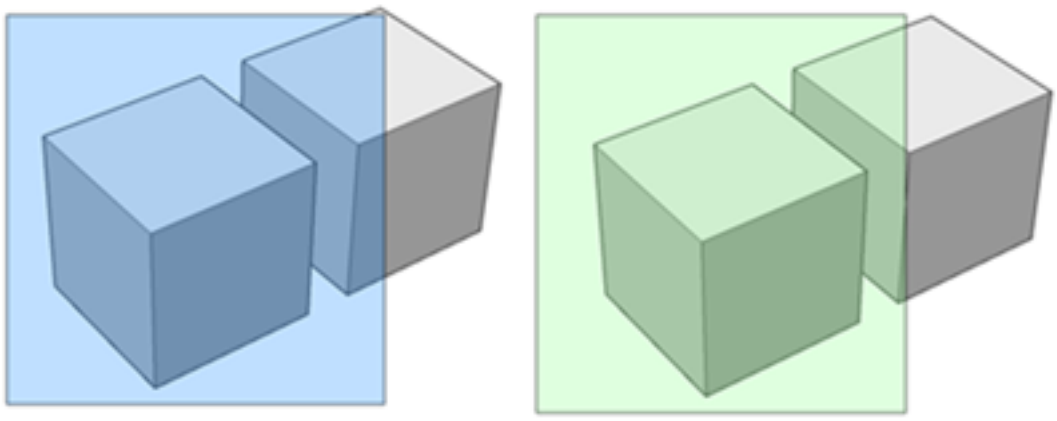


Figure 5.3

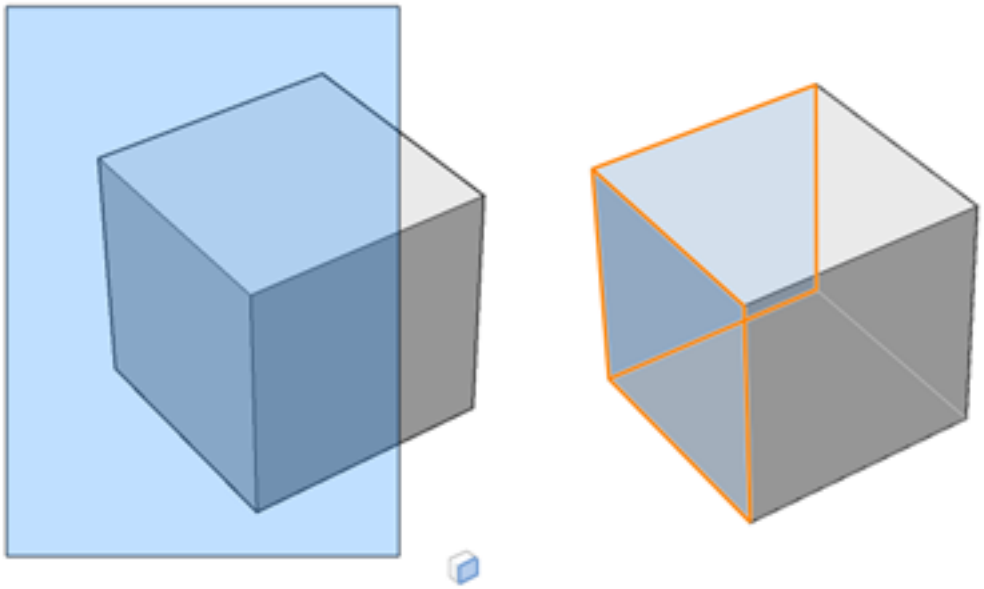

Figure 5.4

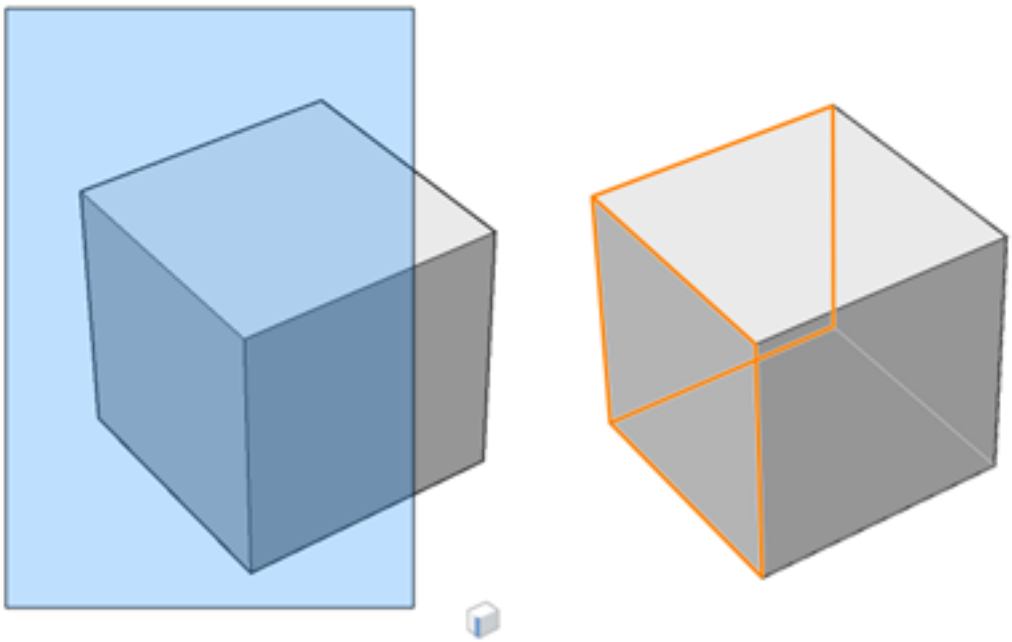

Boundaries vs Faces

Boundaries on top of planar faces will be detected automatically. A boundary can be created by a set of 2D entities (lines, arcs, circles, etc) or on top of a surface (e.g. a solid face): (5.5 on the following page) The area marked in green is an automatically detected boundary. This boundary can be used to create a new solid, extrude a hole in the existing solid, create an offset and more. Another boundary that is recognized is where multiple solids have touching faces: (5.6 on the next page) The area marked in green is an automatically detected boundary. To select the entire face of the box instead of this boundary, press the **Tab** key to cycle through subentities, as explained earlier.

Figure 5.5

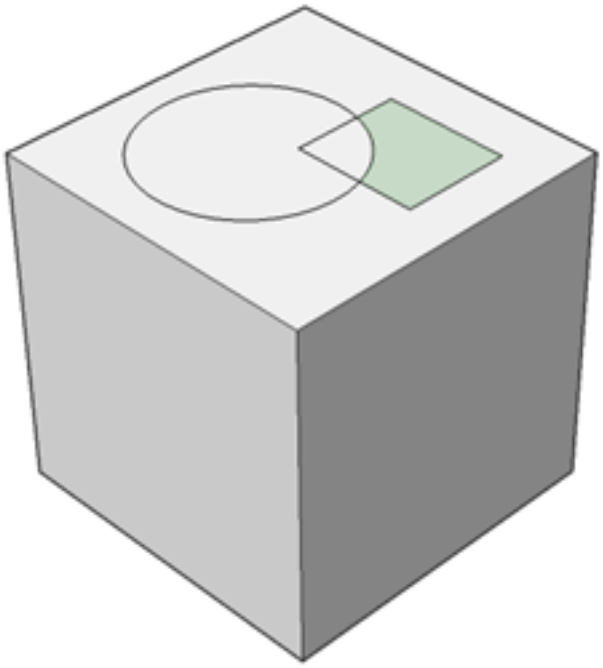

Figure 5.6

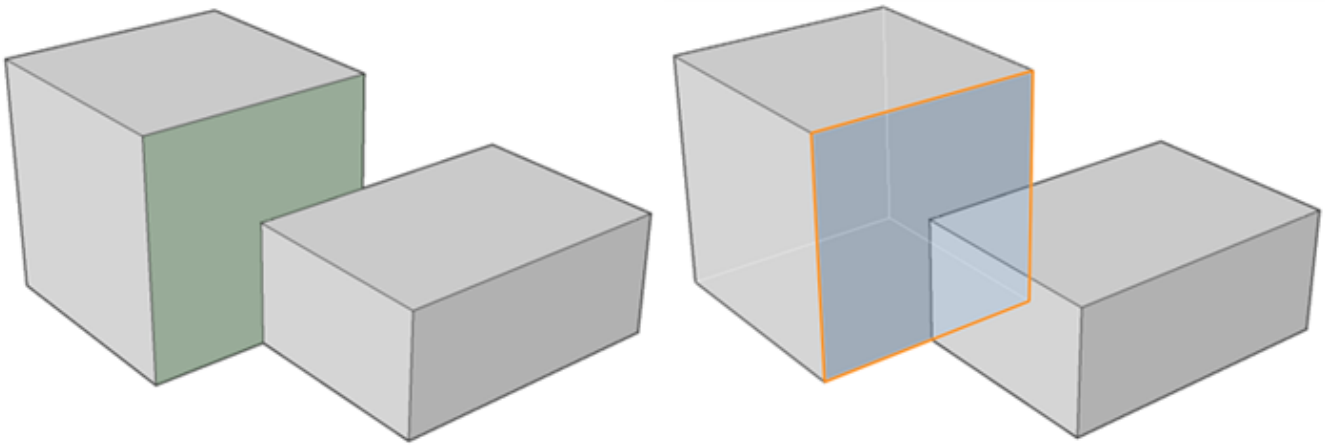

The Quad & Rollover Tips

When an entity is highlighted, a 'toolbar' appears at your cursor. This is called the Rollover Tip, and consists of:

- An overview of **what you have highlighted** or selected (in the example below: a 'solid face')
- The icon of the **last used command on this entity type** (in the example below: 'copy')
- Some relevant **properties** (in the example below: color, layer and area)

(5.7 on the following page) Move the cursor **over the icon** (without clicking it), to expand the toolbar. This expanded toolbar is called the **Quad**. (5.8 on the next page) The top row of icons displays the most recently used commands on this entity type. Note that the Quad will adapt to the entity type you have highlighted or selected. It will only show tools that are relevant for the selected entity type. It will display **different tools** for a solid than for an edge, a line or a block reference. Beneath the row of icons are different tabs. Hover the cursor over one of these tabs to expand the Quad further. This will display even more tools relevant to the selected entity type. (5.9 on page 3311) The Quad can also be called on a **selection set**. To use the Copy command on 3 solids, you can either:

- **Select** the first two solids and **highlight** the third solid to open the Quad
- **Select** all three solids and hover over one of the solids to open the Quad
- **Select** all three solids and **right-click** to open the Quad

Finally, to call the Quad when **nothing** is highlighted or selected, just right-click on an empty space on the modeling canvas to open the **No-selection Quad**. Alternatively, use the Command Line or the Toolbar at the top of your screen to call the Quad. Icons with a little triangle in the bottom right corner are expandable toolbars that contain similar tools. Hold the left mouse button down slightly longer to expand these toolbars.

Figure 5.7

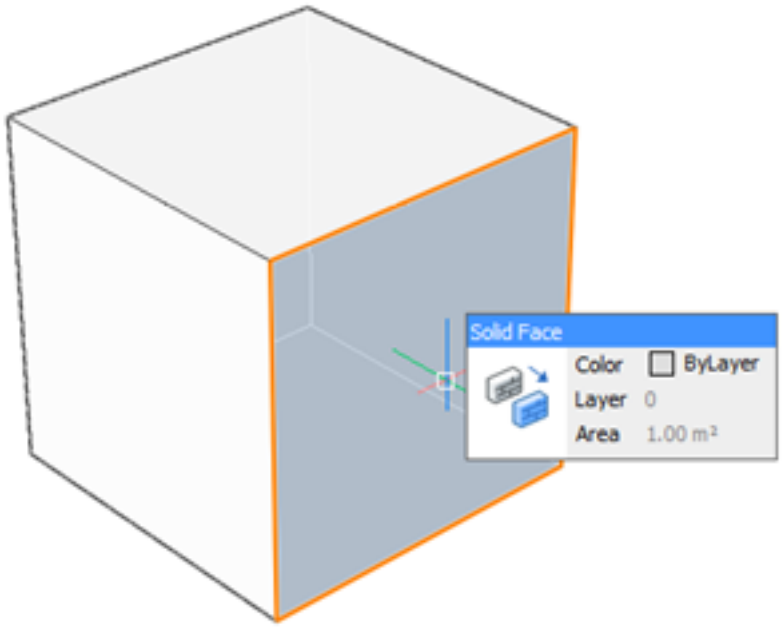

Figure 5.8

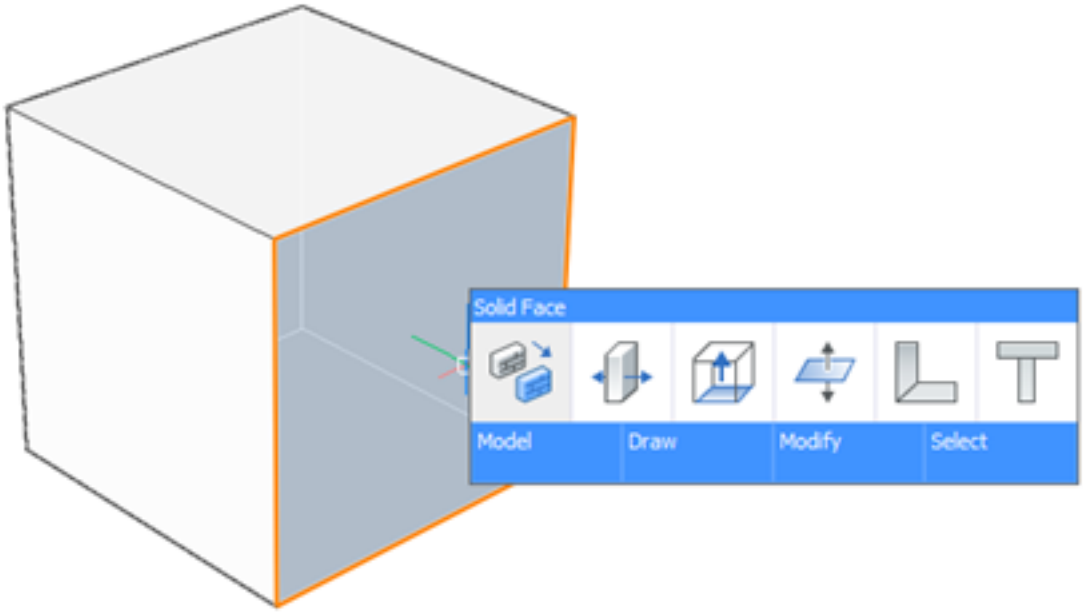

Figure 5.9

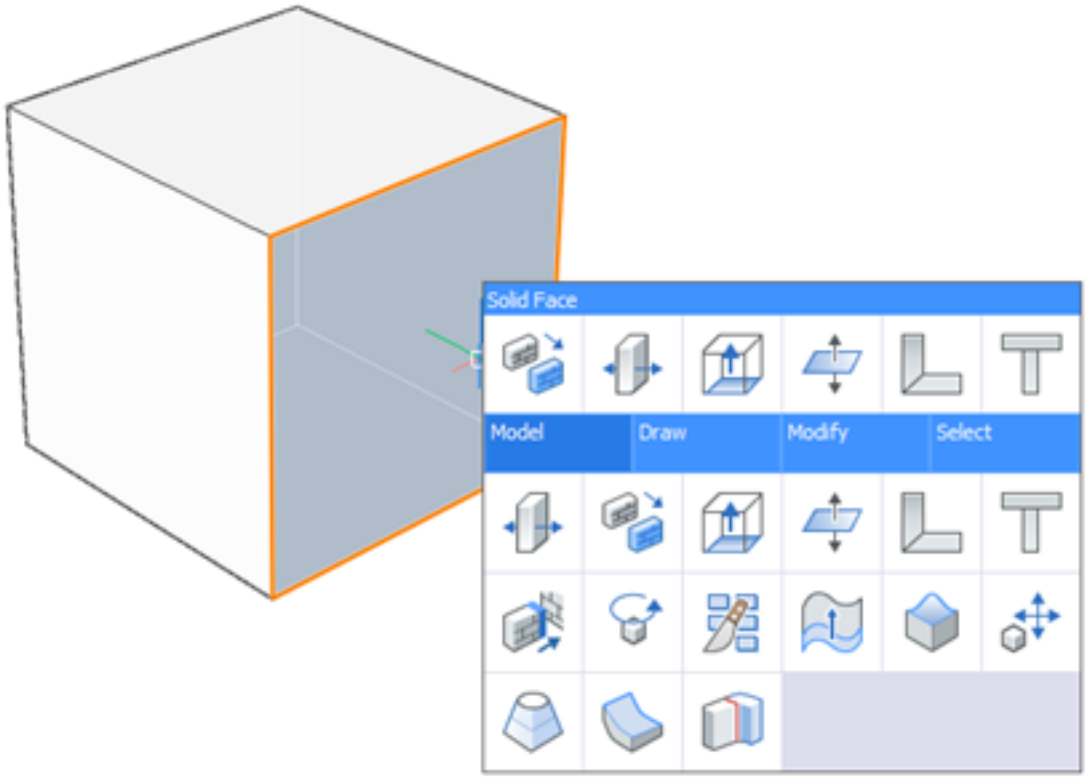

Exercise on basic concepts

Procedure: Draw a box

1. Right-click on the empty space to open the No-Selection Quad and move the cursor over the icon.
2. Under the Model tab, click the **BOX** icon
3. You are prompted: **Set corner of box or [Center]:** Type in **0,0,0** and press **Enter**
4. Two dynamic dimensions are displayed that control the length and width of the box (see image). The dynamic dimension highlighted in blue is the active one. (5.10)
5. Type in a value of **1000** and press the **Tab** key to switch to the other dynamic dimension **Note** the first dimension is now highlighted in pink. This is to indicate that a value was entered, and this value is now locked on this dynamic dimension. (5.11 on the following page)
6. Type in a value of **1000** and press **Enter**. **Or** press **Tab** again to switch back to the first dynamic dimension

Figure 5.10

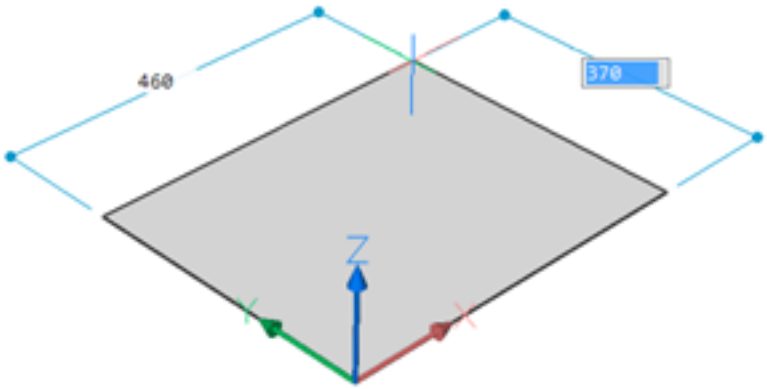

Figure 5.11

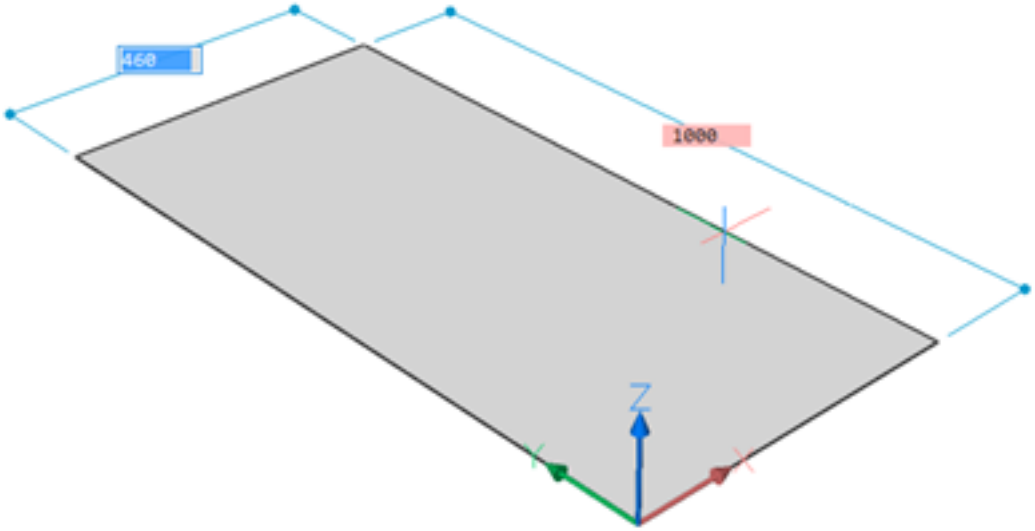

Figure 5.12

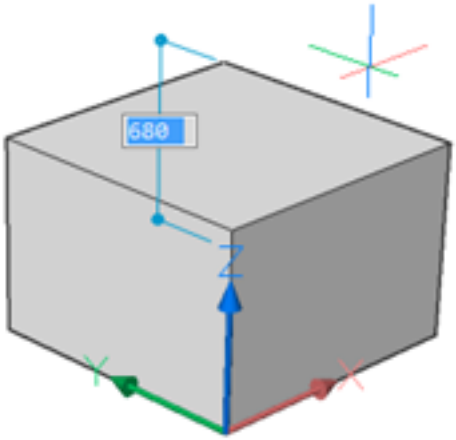
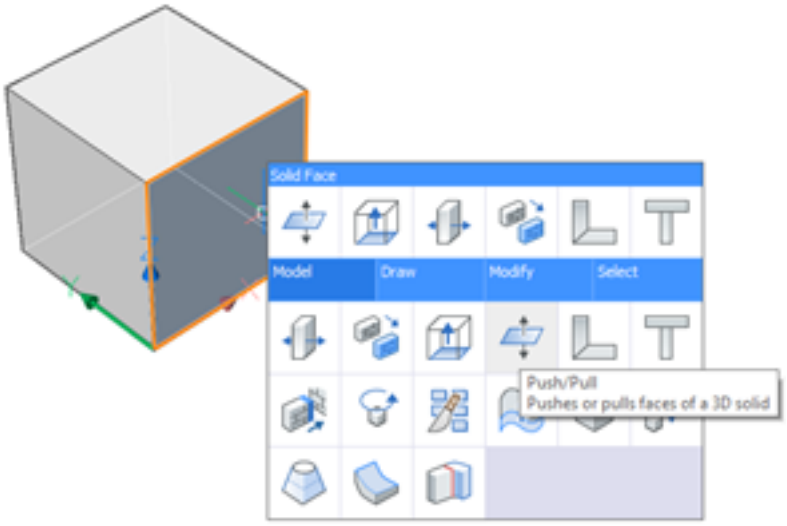


7. A dynamic dimension appears that controls the height of the box. Type in a value of **1000** and press **Enter**. (5.12)

Procedure: Manipulate a face

1. Move your cursor over a side face of the box until it is highlighted
2. Move your cursor over the icon to open the Quad.
3. Under the Model tab of the Quad, click the **PUSHPULL** icon . (5.13 on the facing page)
4. Type in a value in the dynamic dimension box and press **Enter** or left-click on the new location for this face.

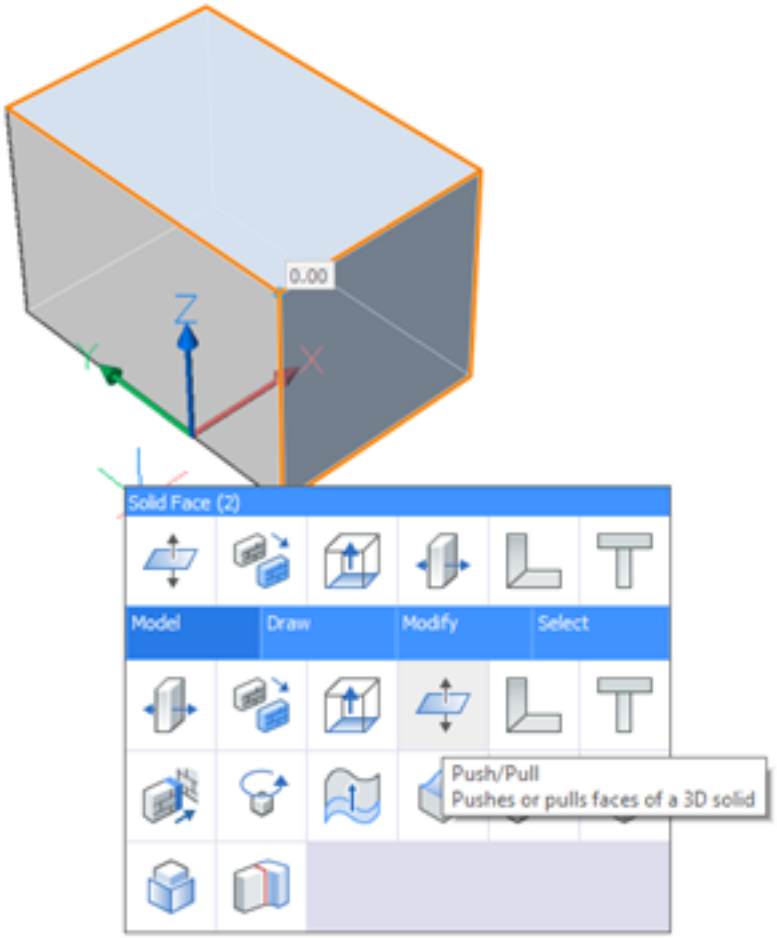
Figure 5.13



Procedure: Manipulate multiple faces

1. Left-click to select a side face of the box.
2. Select the top face of the box.
3. When you have both faces selected, right-click anywhere on an empty space in the canvas to open the Quad.
4. Under the Model tab, click the **PUSHPULL** icon . (5.14 on the next page)
5. Both faces will now be pushed in or pulled the same distances.
6. Type in a value and hit **Enter** or left-click.

Figure 5.14

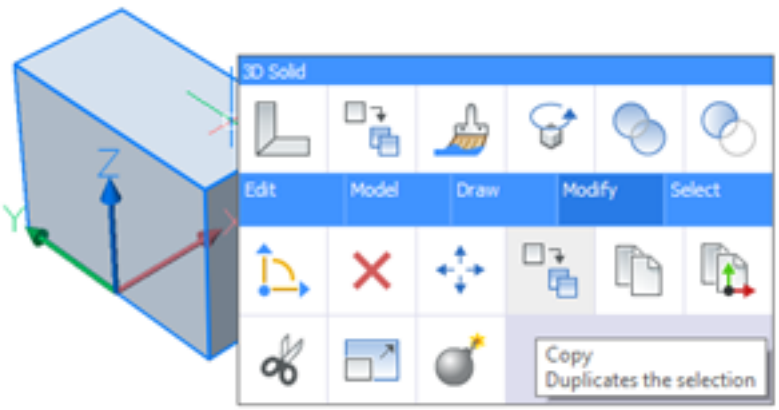


0.00
Z
Solid Face (2)
Model
Draw
Modify
Select
Push/Pull
Pushes or pulls faces of a 3D solid

Procedure: Copy a solid

1. Hold the **Ctrl** key and hover over one of the faces of the box to highlight the box.
2. To open the Quad move your cursor over the icon. Under the Modify tab, click the **COPY** icon (5.15)
3. You are prompted for a **Base Point.** Left-click one of the corners of the box.
4. You are prompted for the **Second point.** Left-click where you want the copy of the box to be.
5. You can continue to place copies or press **Enter** or **Esc** to exit the command.

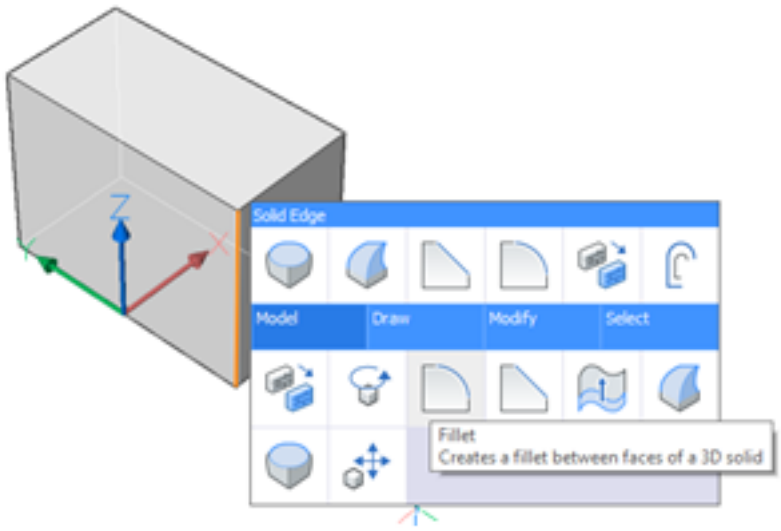
Figure 5.15



Procedure: Manipulate an edge

1. Hold the **Ctrl** key and hover over one of the edges of the box to highlight an edge.
2. In the Quad under the Model tab, click the **FILLET** icon (5.16)
3. Type in a fillet radius and press **Enter.**

Figure 5.16



Procedure: Manipulate multiple edges

1. Press **Ctrl + Z** to undo your fillet action.
2. Create a selection window around the entire box and press the **Ctrl** key twice until a small icon indicating 'edge selection' appears. (5.17 on the following page)
3. You should now have selected all 12 edges of the box. In the Quad under the Model tab, click the **FILLET** icon.
4. Type in a fillet radius and press **Enter.** (5.18 on the next page)

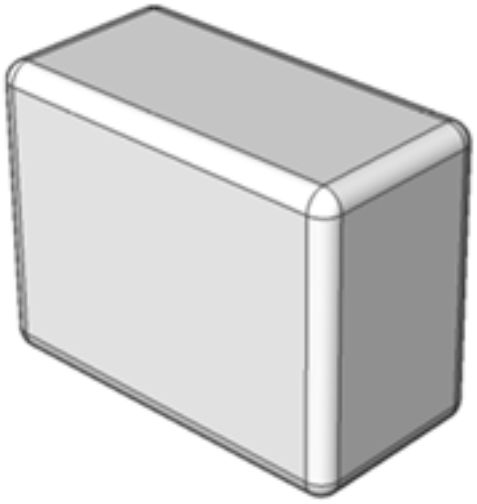

Figure 5.19

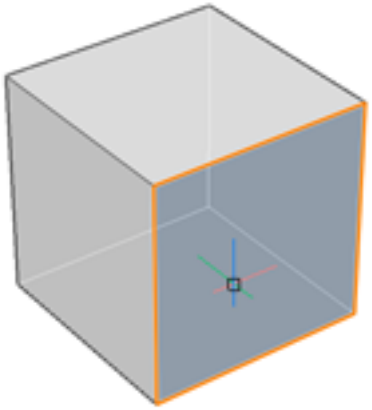

Figure 5.20

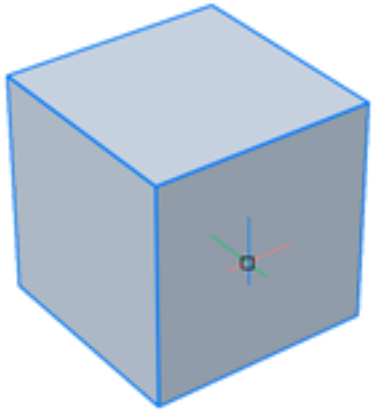

Figure 5.21

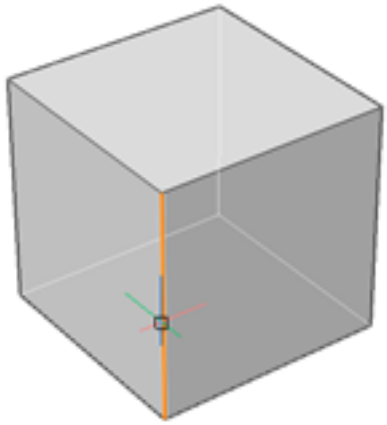


5.3 3D Modeling

5.3.1 How to create a wall in BricsCAD Shape

https://www.youtube-nocookie.com/embed/EuAnBK8BdVI Select the start point of the wall. Move the cursor to the next point, and left-click it. You can continue creating joined wall segments. Simply right-click your mouse, or press ENTER, to stop creating additional wall segments. Move your cursor up to set the wall height, or type in a value. Right-click to accept the default wall width, or press the TAB key to type in a new value. Values you enter here become the new defaults for wall height and width. In Shape, it's easy to use new or existing linework as a guide. The cursor snaps to line endpoints automatically. The TOOLTIP at the bottom of the screen reminds you to press the CTRL key to cycle through the wall justification options: left, center or right.

5.3.2 How to create a layout in BricsCAD Shape

https://www.youtube-nocookie.com/embed/QdFOvGo_AKs You will use the Shape tool. Select your start point, move the cursor to the next point and left-click again. Shape automatically creates wall connections. Press the enter key or right-click once to accept. You can move your cursor to set the wall height, or simply type in a new height. Then, you can press the TAB key to change the width, or just right-click to accept the default value. You can also use an existing 2D plan to start your layout. Use the Shape tool. Press E, for “Entity” and select the outside border. Move up to set the height, type in a value, or right-click to accept the default value. You can press the CTRL key to cycle through the wall justification options: left, center or right. Finally, let's use the Shape tool with the “E” option to finish the interior walls.

5.3.3 How to use selection boxes in BricsCAD Shape

https://www.youtube-nocookie.com/embed/h4wMXoQ4Ozw

You can select multiple model elements using a selection box. By default, selection boxes see and select entire solids. If you press the CTRL key ONCE while the selection box is active, you will only see faces. The tooltip at the bottom of the screen shows these different modes. The CTRL key cycles between these modes. If you press CTRL once more, you will only see edges. Draw a selection box from left to right, it will display in blue. Blue selection boxes will only see elements that are completely inside the box. Draw a selection box from right to left, it will display in green. Green selection boxes will see all elements that lie inside the box, AND all elements that cross the boundaries of the box.

5.3.4 How to detect boundaries - BricsCAD Shape

https://www.youtube-nocookie.com/embed/wsaOK8Q8ctc BricsCAD Shape automatically detects and highlights closed boundaries, as you hover over different model elements. When a boundary is detected, it will be highlighted. To select it, just left-click inside the highlighted boundary. After you select a boundary, you can use it to create new elements or modify existing elements. Remember, if you don't want to select the boundary but for example the face or the solid, just press TAB until the element you want is highlighted.

5.3.5 How to connect walls in BricsCAD Shape

https://www.youtube-nocookie.com/embed/n8gtD2HrNbQ

Connecting walls is easy Select two walls, raise the Quad and click the “CONNECT” tool. The TOOLTIP at the bottom of your screen reminds you that there are different connection options available.You can cycle through the three connection options by pressing the CTRL key. We can use the CONNECT tool to connect disjoint walls. Highlight any face, and the “Connect with Nearest” tool makes it happen.

5.3.6 How to push or pull solids in BricsCAD Shape

https://www.youtube-nocookie.com/embed/7yWFzyk7BBU

Push/Pull is a basic modelling tool. It's a local editor for single solids. Push/Pull requires a positive distance and a direction. It won't let you create a void. Move in the positive direction, and push/pull lets us increase the width of this solid. Simplicity is power with push/pull editing in BricsCAD Shape.

5.3.7 How to extrude in BricsCAD Shape

https://www.youtube-nocookie.com/embed/5iJJ00KdEq8

The EXTRUDE tool creates 3D elements from 2D line work. You can EXTRUDE (6.13.25) a selected boundary, for example, to create a floor slab between existing walls. EXTRUDE can subtract geometry, also. Note the TOOLTIP that appears, reminding you of the CTRL key options for the tool. Pressing the CTRL key cycles through all of the available EXTRUDE options.

5.3.8 Using the Manipulator in BricsCAD Shape

Youtube

The manipulator is a visual tool that rotates, moves, or mirrors solid elements, around or along a single axis. Press and hold the CTRL key, move the cursor to the element of choice and left-click. By holding down the left mouse button slightly longer, the manipulator should appear. Move the cursor onto one of the three manipulator arcs and left-click to rotate your solid. Then, move the cursor onto one of the three axis shafts and left-click for a constrained move along that axis. To move your selection in 2D, constrained to a plane, left-click one of the three white plane indicators. To mirror your selected solid, left-click one of the blue axis arrows. Precise manipulation is always available through the manipulator's dynamic dimensions. You can rotate and re-locate the manipulator on the selected solid by left-clicking on the white orientation dots.

5.3.9 Using components in BricsCAD Shape

https://www.youtube-nocookie.com/embed/a0rr3q7nfpI

You can drag and drop content from the right-side panel directly into your BricsCAD Shape session. Open the component library by left-clicking the “hot-air balloon” icon. It is located on the vertical toolbar, on the right-hand edge of your screen. The pull-down list box shows the component categories. Left-click on the category name to select it, or search for specific types of components in the Search box. Let's place some furniture in our model. To select a component from the panel, hover the cursor over the component that you want to use, then click and hold the left mouse button. Next, simply drag the component into your model. Move it to the desired position and release the left mouse button. Hover over the icon, left-click and hold.

5.3.10 How to create windows and doors in BricsCAD Shape

https://www.youtube-nocookie.com/embed/oUUGQRZ70RA

BricsCAD Shape includes a collection of doors and windows in the components library. Open the components library by left-clicking the “hot-air balloon” icon. It is located on the vertical toolbar, on the right-hand edge of your screen. Click the “Doors" icon on the Components panel. To select a door from the panel, hover the cursor over the door that you want to insert, then click and hold the left-mouse button. Drag the door onto a wall. When releasing the left mouse button, you will be able to position the window in the wall precisely using Dynamic Dimensions. You can enter a precise value for a distance, or press TAB to go to the next value. The TOOLTIP at the bottom of your screen reminds you of your options. Press CTRL to toggle between door positioning and door size. Enter the desired values for the height and width of the door by pressing the TAB key. When you're done sizing and placing the door, press the ENTER key. This is the same for a window. Change “Doors” to “Window” in the pull-down list box. Drag a window into the wall. You can change the size and location of a window just as you did with the door.

5.3.11 Create a custom window in BricsCAD Shape

https://www.youtube-nocookie.com/embed/KQmMNQhh5Kg

You can create custom windows easily in BricsCAD Shape. Use the POLYLINE (1.25.12) tool to draw the outline of the window on the wall face. Use the POLYGON (6.24.61) tool to draw the outline of the window on the wall face. Use the RECTANGLE (1.25.18) tool to draw the outline of the window on the wall face. Move the cursor inside the window outline and, when the boundary is highlighted, choose “CREATE WINDOW” from the Quad. The available window styles are shown in a dialog box. Move your cursor over the window design of your choice, and left-click it. The window is automatically created. You can create a custom window from a wall boundary. Select face of the outer wall and use the “OFFSET (6.23.3)” tool from the Quad. Move the cursor to re-size the new boundary, or key in a value and press ENTER. Then, highlight the offset boundary and select “CREATE WINDOW” from the Quad. Once again, the available window styles are shown in a dialog box.

5.3.12 Using materials in BricsCAD Shape

https://www.youtube-nocookie.com/embed/wj1SbA7Nz7o

BricsCAD Shape includes a collection of materials and color swatches in the materials library. Open the materials library by left-clicking the "paintbrush" icon. It is located on the vertical toolbar, on the right-hand edge of your screen. To assign a material to an element in your model, hover the cursor over the material or color swatch that you want to insert, then click and hold the left-mouse button. Drag the material onto the model element, and release the mouse button. You can filter by selecting a category from the drop-down list It is possible to apply a material to multiple elements at once by preselecting them.

5.3.13 How to create sections in BricsCAD Shape

https://www.youtube-nocookie.com/embed/bV56_fdn7MU You can use Sections to cut through your model dynamically. A Section can be created by opening the Quad and left-clicking 'define section', found under the Model tab. Then, selecting any solid face in your model will create the Section, parallel to the selected solid face. If you don't choose a surface to attach the Section, a horizontal Section plane will be created. A Section can be toggled on and off by double-left-clicking its handle, or by highlighting the Section plane and using 'Clip Display' from the Quad. A Section element has three grip edit points. Selecting the Section's handle turns the grips on for editing. You can move the start and end grips to change the orientation and width of the Section. You can move the midpoint grip to reposition the section plane. If you left-click the arrow displayed near the midpoint grip, you will flip the clipping direction of the Section.

5.3.14 How to create steel structural profiles in BricsCAD Shape

https://www.youtube-nocookie.com/embed/MwYysLRnuzQ BricsCAD Shape offers standard structural steel profiles to speed the creation of structural elements. Included are American, British and European standards. Use the Profile tool to create a beam or a column. Select the start point of the column. Move the cursor to the next point and left-click, or type in a value and press Enter. Continue to create elements, or press enter when you're done. You can change the profile using the Profile panel. Open the profile panel by left-clicking the "profile" icon. It is located on the vertical toolbar, on the right-hand edge of your screen. Select a standard and choose a profile. You can also search for specific profiles. To select a profile, hover over profile you want, then click and hold the left mouse button. Drag the profile into the beam or column and release the left mouse button. To connect elements, select them, raise the quad and use the Connect tool, found on the Model tab. You can toggle between different connection types by pressing the CTRL key. You can also create your own profiles from scratch. We'll draw a square, and offset it a given distance to create the new profile shape. To change the profile of an existing beam, select the beam and use "apply profile" from the quad. Select the new profile. The beam shape updates. Press enter to apply the change. Left-click to place the component, or use Dynamic Dimensions to precisely position it. You can enter a precise value for a distance, or press TAB to go to the next value. Press enter to accept the final position.

5.3.15 How to create a roof in BricsCAD Shape

https://www.youtube-nocookie.com/embed/YSHL0uXLyzU Need a gable style roof? It's easy with BricsCAD Shape. Using the Shape tool we will create a pitched roof slab. Align the drawing plane to the wall surface, by pressing SHIFT while hovering over the wall surface. You can change the alignment of the slab by pressing the CTRL key. To fix the angle, press TAB and enter a value. Press enter to accept. To change the slab profile thickness, press the TAB key. Let's repeat the process for the roof profile on the other side. To have the slabs join at the top of the roof, select both elements and select the CONNECT tool from the quad. Use the CTRL key to cycle through the available connection options. Using “BIM drag” you can extend the slabs to have the appropriate length. Now that the roof creation is completed, let's extend the walls to reach the roof. Highlight the top face of one wall, then from the quad, click the “select aligned faces” tool. Next, select “connect with nearest”. To view the inside of the house, hide the roof slabs.

5.4 FAQ

5.4.1 What are the Shape minimum system/hardware requirements?

See Minimum System Requirements and Recommendations

5.4.2 What are the recommended system/hardware requirements for Shape?

See Minimum System Requirements and Recommendations

Chapter 6

Command Reference

6.1 Getting Started

6.1.1 Command Prefixes

The following prefixes can be used with the BricsCAD commands:

Prefix	Type	Result
' (single quote or apostrophe)	Transparency	Allows a command to be executed inside another command. E.g. If you are drawing a line, type **'zoom** at the command prompt to temporarily interrupt
- (dash)	Command line	Executes a non-dialog version of a command. All command options are available in the c E.G. Type **-layer** at the command prompt to suppress the Drawing Explorer / Layers dialog This is especially useful if you need to execute such commands in a script.
_ (underscore)	Global	Executes the original English command (global command) in translated version of BricsC It is recommended to use the global command prefix in scripts, or when defining keyboard
. (period)	None required	Executes temporarily removed commands that have been temporarily removed from BricsCAD using the UNDEFINE (6.30.4) command.

Command prefixes can be combined. E.g. if the ZOOM command is temporarily undefined **'.zoom** executes the ZOOM command transparently.

6.1.2 Prompt Option Format

  User preference which controls how command options display in the command line prompts. **The command prompt format is:** Required input [FirstOption/SecondOption/ThirdOption] <what happens if you just press ENTER>: **e.g. the first prompt of the COPY command:** Enter base point [Displacement/mOde] <Displacement >:

Accessing the preference

command bar: **promptoptionformat** settings dialog: **Program Options / Display / Prompt Option Format** : **promptoptionformat Prompts you in the command bar.** New value for PromptOptionFormat <0>: (**Type 0, 1, 2, 3 or 4)**

Options

A command option has a keyword , a description and a shortcut . The shortcut is the keyword, without its lowercase characters. e.g. the third option of the CIRCLE (6.9.12) command: Keyword = TanTanRad Description = Tangent-Tangent-Radius Shortcut = TTR

Option	Description
0	Description only; adjust casing to mark shortcut: **Select center of circle or [2 Point/3 Point/Tangent-Tangent-Radius/turn Arc into circle/Multiple circles]:** This is the default prompt option format in the English version. In other versions the default prompt option format depends on local standards.
1	Show keyword only: **Select center of circle or [2Point/3Point/TanTanRad/Arc/Multiple]:**
2	Show description and keyword in brackets: **Select center of circle or [2 Point(2Point)/3 Point(3Point)/Tangent-Tangent-Radius(TanTanRad)/Turn arc into circle(Arc)/Multiple circles(Multiple)]:**
3	Show Description and shortcut in brackets: **Select center of circle or [2 Point(2P)/3 Point(3P)/Tangent-Tangent-Radius(TTR)/Turn arc into circle(A)/Multiple circles(M)]:**
4	Show local keyword and global keyword in brackets; this is relevant in localized versions only. **Select center of circle or [2Point/3Point/TanTanRad/Arc/Multiple]:**

NOTE	The PromptOptionTranslateKeywords (1.17.10) user preference controls whether translations of command option keywords are loaded or not. If disabled, the local keyword will be a copy of the global (English) keyword. As a result global shortcuts can be used without an underscore.

6.2 2

6.2.1 2dIntersection

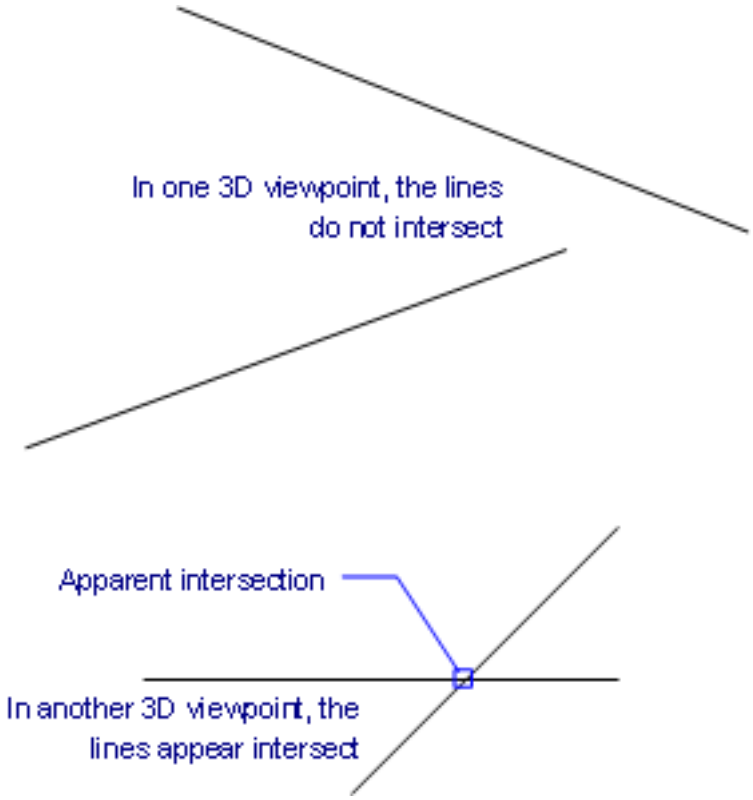
(6.2981 on page 6079) Toggles the apparent intersection entity snap, which snaps to the intersections of entities, even when they only appear to be intersecting in 3D space.

Figure 6.1

Accessing the Command

command bar: **2dintersection** transparent: **2dintersection** aliases: **apparent planviewint** toolbar: **Entity Snaps |**  ribbon: **Home | Entity Snaps | Snap to Apparent**
: **2dintersection** Displays no prompt in the command bar. Each time you enter the command, it toggles the entity snap: on, then off, then on, and so on. Keep an eye on the Entity Snaps toolbar to see if this entity snap is on or off. This entity snap snaps to intersecting entities, including those that appear to intersect in 3D space: (6.2 on the next page) When 2dIntersection entity snap is on, the cursor snaps to the real and apparent intersections of entities.

Figure 6.2



Command Option

Option	Description
2dIntersection	Entering this command toggles apparent intersection entity snap on and off. This command can be entered transparently during commands, but must be entered without the transparency apostrophe prefix (').

Procedures

How to set Entity Snaps (1.21.15)

Related Commands

OSnap (6.23.16) - toggles entity snap modes through the Settings dialog box. -OSnap (6.23.13) - toggles entity snap modes at the command prompt. Aperture (6.4.14) - sizes the aperture cursor for entity snaps. 3dIntersection (6.3.7) - toggles intersection snap mode. Apparent (6.4.16) - toggles apparent intersection snap mode, like 2dIntersection. Center (6.9.3) - toggles center snap mode. Endpoint (6.13.7) - toggles endpoint snap mode. Extension (6.13.22) - toggles extension snap mode. From (6.14.13) - enters coordinates relative to a reference point. GCenter (6.15.5) - toggles geometric center entity snap. Insertion (6.17.18) - toggles insertion snap mode. Intersection (6.17.19) - toggles intersection snap mode. Mtp (6.21.35) - specifies a point midway between two other points. Midpoint (6.21.16) - toggles midpoint snap mode. Nearest (6.22.2) - toggles nearest snap mode. Node (6.22.7) - toggles node (point) snap mode. None (6.22.8) - turns off all entity snap modes. Parallel (6.24.5) - toggles parallel snap mode. Perpendicular (6.24.25) - toggles perpendicular snap mode. Quadrant (6.25.7) - toggles quadrant snap mode. Tangent (6.29.10) - toggles tangent snap mode.

6.3 3

6.3.1 3D

(6.2981 on page 6079) Draws basic 3D mesh entities, including boxes, cones, cylinders, dishes, domes, meshes, pyramids, spheres, tori, and wedges (short for "three dimensional"). **Note:** Separate commands are available for each type of entity, such as AI_Box for drawing mesh boxes.

Figure 6.3

Accessing the Command

command bar: **3d** : **3d Prompts you in the command bar:** [Wedge/Pyramid/Box/Cone/cyLinder/Sphere/DIsh/DOme/Torus/Me
(**Enter an option)**

Command Options

Option	Description
Wedge	Draws 3D wedges. See Ai_Wedge (6.5.21) command. (6.4 on the next page)
Pyramid	Draws 3D pyramids. See Ai_Pyramid command. (6.5 on the following page)
Box	Draws 3D boxes. See Ai_Box (6.5.7) command. (6.6 on page 3345)
Cone	Draws 3D cones. See Ai_Cone command. (6.7 on page 3345)
cyLinder	Draws 3D cylinders See Ai_Cylinder (6.5.9) command. (6.8 on page 3345)
Sphere	Draws 3D spheres. See Ai_Sphere (6.5.17) command. (6.9 on page 3346)
DIsh	Draws 3D dishes (bottom half of spheres). See Ai_Dish (6.5.12) command. (6.10 on page 3346)
DOme	Draws 3D domes (top half of spheres). See Ai_Dome (6.5.19) command. (6.11 on page 3346)
Torus	Draws 3D tori (donuts). See Ai_Torus (6.5.20) command.
Mesh	Draws 3D meshes; prompts you: (6.12 on page 3347) **First of four corners for polygon mesh - (pick a point, or enter x,y,z coordinates.) Second corner - (pick a point, or enter x,y,z coordinates.) Third corner - (pick a point, or enter x,y,z coordinates.) Last corner for mesh - (pick a point, or enter x,y,z coordinates.) Number of divisions along primary axis (between 2 and 256) - (enter a number.) Number of divisions along secondary axis (between 2 and 256) - (enter a number.)**

Related Commands

Ai_Box (6.5.7) - draws 3D boxes as mesh surfaces. Ai_Cone (6.5.8) - draws 3D cones as mesh surfaces. Ai_Cylinder (6.5.9) - draws 3D cylinders as mesh surfaces. Ai_Dish (6.5.12) - draws 3D dishes as mesh surfaces. Ai_Dome (6.5.19) - draws 3D domes as mesh surfaces. Ai_EdgeSurf (6.5.14) and EdgeSurf (6.13.2) - draws edge-defined surfaces as mesh surfaces. Ai_Pyramid (6.5.15) - draws 3D pyramids as mesh surfaces. RevSurf (6.26.28) - draws revolved surfaces as mesh surfaces. RuleSurf (6.26.51) - draws ruled surfaces as mesh surfaces. Ai_Sphere (6.5.17) - draws 3D spheres as mesh surfaces. TabSurf (6.29.7) - draws tabulated surfaces as mesh surfaces. Ai_Torus (6.5.20) - draws 3D donuts as mesh surfaces. Ai_Wedge (6.5.21) - draws 3D wedges as mesh surfaces.

6.3.2 3dArray

(7.3 on page 6132) Constructs static rectangular and polar arrays in rows, columns, and levels (short for "three dimensional array").

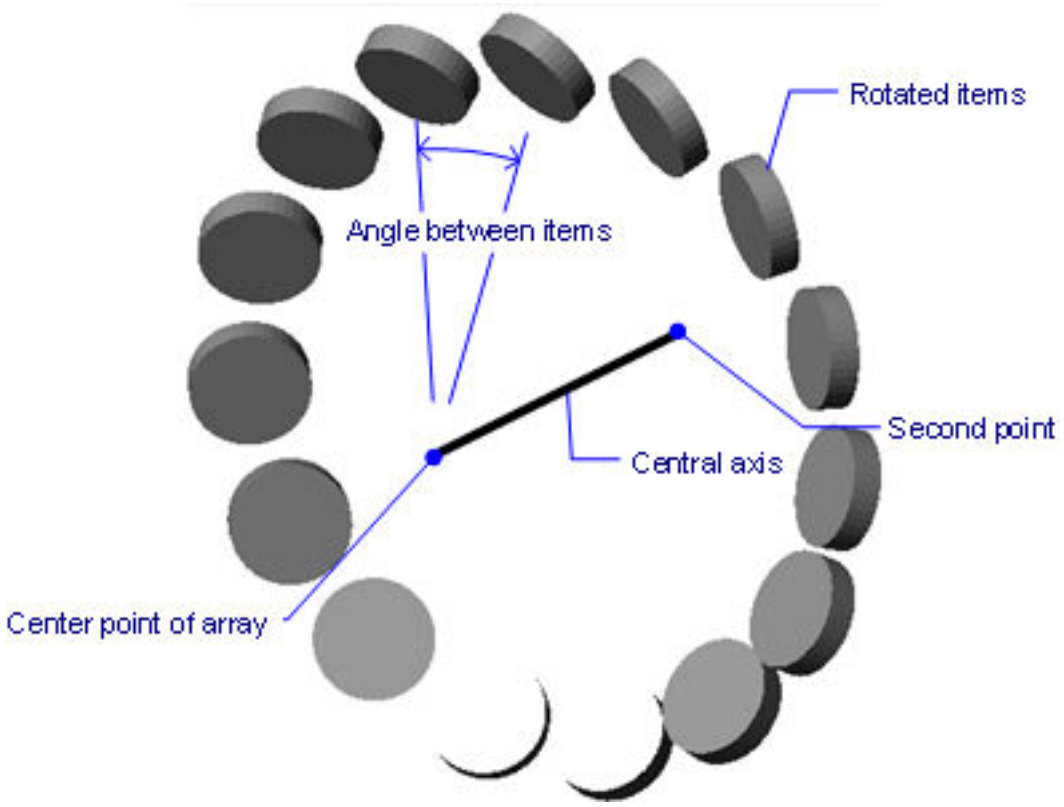
Accessing the Command

 command bar: **3darray** aliases: **3a, array3d** menu bar: **Modify | 3D Array** toolbar: **Modify | Arrays |**  :**3darray Prompts you in the command bar:** Select entities to array: **(Choose one or more entities)** Entities in set: 1 Select entities to array: **(Choose more entities, or press Enter to continue)** Type of array: Polar/<Rectangular>: **(Type P or R)** Prompts for creating 3D rectangular arrays: Number of rows in the array <1>: **(Enter a number, or press Enter to accept the default)** Number of columns <1>: **(Enter a number, or press Enter to accept the default)** Number of levels <1>: **(Enter a number, or press Enter to accept the default)** Vertical distance between rows: **(Enter a number, or press Enter to accept the default)** Horizontal distance between columns: **(Enter a number, or press Enter to accept the default)** Depth between levels: **(Enter a number, or press Enter to accept the default)**

- **Prompts for creating 3D polar arrays:**

(6.14 on the next page) ENTER to specify angle between items/<Number of items to array>: **(Enter a number, or press Enter)** Angle to array (+ for ccw, - for cw) <360>: **(Enter a number, or press Enter to accept the default)** Rotate entities around the array? No/<Yes>: **(Type Y or N)** Center point of array: **(Pick a point, or enter x,y,z coordinates)** Specify second point along central axis of array: **(Pick a point, or enter x,y,z coordinates)**

Figure 6.14



Command Options

Option	Description
Select entities to array	Specifies the entities to be arrayed. Use any entity selection method; press Enter when you are done.
Polar	Creates polar (circular) arrays; see Polar Array Options, below.
Rectangular	Creates linear, rectangular, or square arrays; see Rectangular Array Options, below.

Rectangular Array Options	Description
Number of rows in the array	Specifies the number of rows (x direction); for a linear array, enter 1. To draw the array downwards, enter a negative number.
Number of columns	Specifies the number of columns (y direction). To draw the array to the left, enter a negative number.
Number of levels	Specifies the number of levels (z direction). To draw the array downwards, enter a negative number.
Vertical distance between rows	Specifies the distance between rows of entities.
Horizontal spacing between columns	Specifies the distance between columns of entities.
Depth between levels	Specifies the distance between levels of entities.

Polar Array Options	Description
ENTER to specify angle between items	Specifies the angle between each copy.
Number of items to array	Specifies the number of items in the array; enter a number larger than 1.
Angle to array	Determines the extent and direction of the array. • Enter 360 for a full circle of copies. • Enter a smaller number to draw a partial polar

Related Commands

ArrayClassic (6.4.22) - creates a static polar or rectangular array of entities through a dialog box. -Array (6.4.20) - creates a static polar or rectangular array of entities; displays prompts at the command bar. Array (6.4.19) - associatively distributes entity copies in an evenly spaced rectangular, polar or path array. ArrayPath (6.4.26) - associatively distributes entity copies evenly along a path into multiple rows, and levels. ArrayPolar (6.4.41) - associatively distributes entity copies evenly in a circular pattern about a center point or axis of rotation, using multiple rows, and levels. ArrayRect (6.4.28) - associatively distributes entity copies into any number of rows, columns, and levels. ArrayEdit (6.4.25) - edits associative array entities and their source entities. MInsert (6.21.15) - inserts arrays of blocks.

Figure 6.15

6.3.3 3dCompare

(6.2673 on page 5786) * Command only available on the Windows platform Performs a geometric comparison of solids and surfaces between two drawing files. The result is shown in a new drawing and reported in the Mechanical Browser (3.3.2) panel.

Accessing the Command

 command bar: **3dcompare** toolbar: **3D Compare|Compare 3D** ribbon: **tools| Compare 3D|Compare 3D** : **3dcompare** Displays a dialog box: (6.16 on the next page) Do the following:

1. Click the **Browse** button (...) of the **Model 1** and **Model 2** fields and select the two DWG drawing files you want to compare.
2. Set the options.
3. Click the **OK** button.

The selected files are attached to a new drawing that is named **Compare_<File_1>_<File_2>.dwg**. In this drawing, a layout named "Comparison" is created automatically with two viewports, one for each drawing, illustrating the differences between the drawings using colors. (6.17 on the following page) At the same time, the Mechanical Browser panel opens automatically, and lists the differences between the two drawings. (6.18 on page 3353)

Compare Two Models dialog box

Option	Description
Model 1	Specifies the file name of the first drawing to compare.
Model 2	Specifies the file name of the second drawing to compare.
Tolerance	Threshold value for geometry comparison: determines how close two models must be to be considered unchanged.
Compare block references	Determines if the content of blocks should be compared: • **Yes** - compares solids and surfaces in blocks • **No** - ignores solids and surfaces in blocks This command works with regular blocks and inserts of arbitrary depth, which contain solids or surfaces, including assemblies that use block structures.
Compare entities on frozen layers	Determines if entities on frozen layers should be compared: • **Yes** - solids and surfaces on frozen layers are compared • **No** - solids and surfaces on frozen layers are ignored

The value of the 3DCOMPAREMODE (1.17.10) system variable controls the display in the viewports of the Comparison layout; in the Settings dialog box, search for "3dcomparemode."

Compare 3D buttons

The buttons in the 3D Compare toolbar or Compare 3D ribbon panel (of the Tools tab) switch between view modes. (6.19)

Icon	Name	Description
	Compare3D	Displays the Compare Two Models dialog box; see the description below.
	Left Viewport	Shows the differences between the two drawings in the left viewport of the Comparison layout.

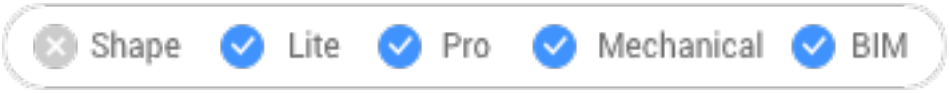
Figure 6.19

	Right Viewport	Shows the differences between the two drawings in the right viewport of the Comparison layout.
	Single	Shows the differences in model space. When switching to this option, the layout viewport displays options are disabled.

Related Commands

MechanicalBrowserOpen (6.8.32) - displays the Mechanical Browser. DwgCompare (6.10.51) - compares a selected drawing with the current drawing during a comparison session.

Figure 6.20



6.3.4 3dDwf

(6.2947 on page 6049) Creates 3D DWF or 3D DWFx files based on the value of the DwfFormat user preference.

Accessing the Command

Keyboard: **3ddwf : 3ddwf** Displays the **Export 3D DWF** file dialog box: Depending on the current value of the **DwfFormat** user preference the default file type is either *.dwf or *.dwfx. Do the following:

- Click the **Save as type** button to select the file type if necessary.
- Accept the default name or type a name in the **File name** field.
- Click the **Save** button.

Command Options

No command options.

Related Commands

Export (6.13.18) - exports drawings in a variety of vector and raster formats.

Figure 6.21

6.3.5 3dConvert

(6.2981 on page 6079) Converts 3D solids to polyface meshes.

Accessing the Command

command bar: **3dconvert** : **3dconvert Prompts you in the command bar:** Select ACIS entities to convert: **(Choose one or more 3D solids)** Select ACIS entities to convert: **(Choose more 3D solids, or press Enter to continue)** The 3D model looks no different following conversion.

Command Options

Option	Description
Select ACIS entities to convert	Chooses the 3D solids to be converted to polyface meshes.

Related Commands

Box (6.6.18) - creates 3D boxes as solid models. Cone (6.9.46) - creates 3D cones as solid models. Cylinder (6.9.49) - creates 3D cylinders as solid models. Dish (6.10.42) - creates the lower half of 3D balls as solid models. Dome (6.10.35) - creates the upper half of 3D balls as solid models. Extrude (6.13.25) - extrudes 2D entities into 3D solid models. Interfere (6.17.17) - creates 3D volumes of intersecting 3D solid models. Intersect (6.17.20) - removes volumes not in common between two solid models. Revolve (6.26.45) - revolves 2D entities into 3D solid models. Slice (6.27.40) - cuts 3D solids into two parts. SolidEdit (6.27.42) - edits the bodies, faces, and edges of 3D models. Sphere (6.27.50) - creates 3D balls as solid models. Subtract (6.27.58) - removes one solid model from a second. Torus (6.29.29) - creates 3D donuts as solid models. Union (6.30.6) - joins two or more solid models into a single entity. Wedge (6.33.6) - creates 3D wedges as solid models.

Figure 6.22

6.3.6 3dFace

(7.3 on page 6132) Draws 3D 4-edged faces with optional invisible edges.

Accessing the Command

command bar: **3dface** aliases: **3f, face** menu bar: **Model | Meshes | 3D Face** toolbar: **Meshes | 3D Faces |**

ribbon: **Model | Meshes | 3D Face** : **3dface Prompts you in the command bar:** First point of 3D face [Invisible]: **(Pick a point, or type I)** Second point [Invisible]: **(Pick a point, or type I)** Third point of 3D face [Invisible]: **(Pick a point, or type I)** Last point [Invisible]: **(Pick a point, or type I)** Third point of 3D face [Invisible]: **(Pick a point, or type I, or press Enter to stop)** (6.23) This command repeats the **Invisible edge/<Third point of 3D face [Select Invisible edge(Invisible)]>** prompt so that adjoining faces can be drawn: (6.24 on the next page)

Figure 6.23

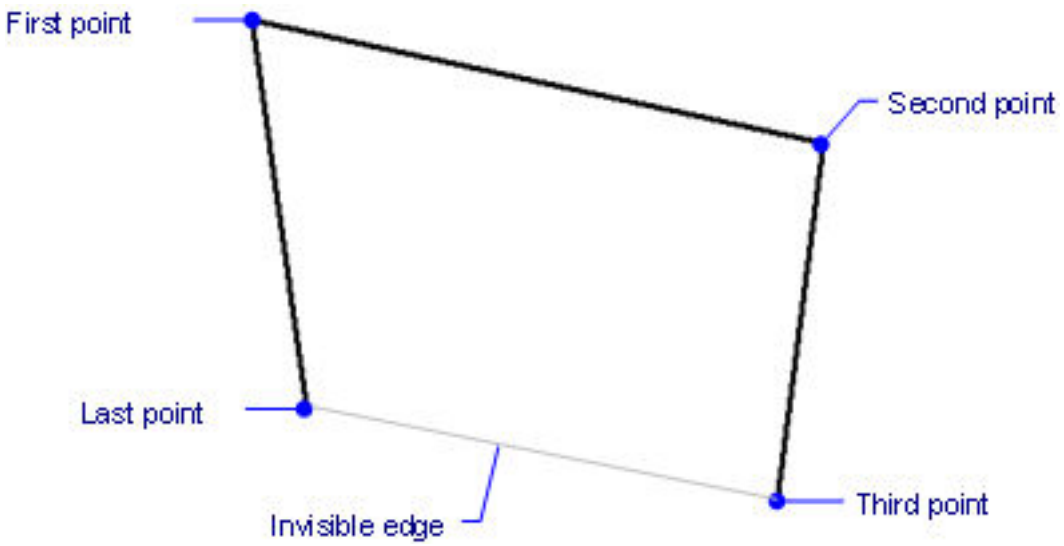


Figure 6.24

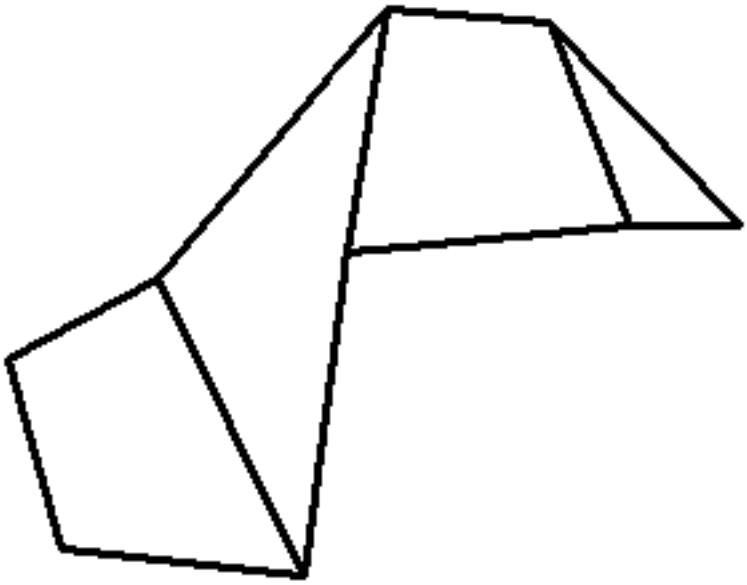


Command Options

Option	Description
First point of 3D face	Specifies the location of the first corner of the face. Pick a point, or enter x,y,z coordinates.
Second point	Specifies the location of the second corner of the face. Pick a point, or enter x,y,z coordinates.
Third point of 3D face	Specifies the location of the third corner of the face. Pick a point, or enter x,y,z coordinates.
Last point	Specifies the location of the fourth corner of the face. Pick a point, or enter x,y,z coordinates.
Invisible edge	Makes the next edge invisible; prompts you: **Third point of 3D face - (specify a point for the next vertex).**

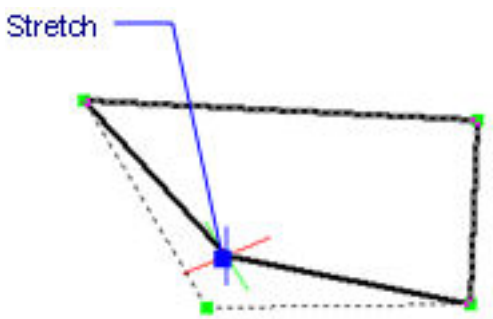
Grips Editing

3D faces can be edited directly through grips:

1. Select the 3D face. Notice that it has several grips.
2. Drag a grip to stretch the face.

(6.25)

Figure 6.25



Related Commands

3dMesh (6.3.9) - draws 3D surface meshes of size m x n. PEdit (6.24.24) - edits 3D meshes. PFace (6.24.23) - draws 3D multi-sided meshes.

Figure 6.26

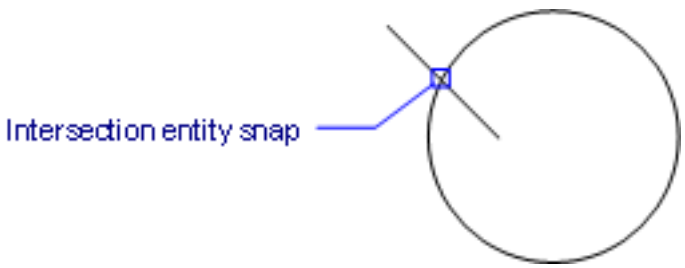
6.3.7 3dIntersection

(6.2981 on page 6079) Toggles Intersection entity snap, which snaps to the intersection of two entities.

Accessing the Command

command bar: **3dintersection** transparent: **3dintersection** alias: intersection (6.17.19)toolbar: **Entity Snaps |** ribbon: **Home | Entity Snaps | Snap to Intersection** : **3dintersection** Displays no prompts in the command bar. Each time you enter the command, it toggles the entity snap, either on or off. (6.1791 on page 5006) This entity snap snaps to entities that physically intersect each other; to snap to apparent intersections, use 2dintersection entity snap.

Figure 6.27



Command Options

Option	Description
3dIntersection	Entering this command toggles Intersection entity snap mode. This command can be entered transparently during commands, but must be entered without the apostrophe prefix (').

Procedure

How to set Entity snaps (1.21.15)

Related Commands

OSnap (6.23.16) - toggles entity snap modes in the Settings dialog box. -OSnap (6.23.13) - toggles entity snap modes in the command bar. Aperture (6.4.14) - sizes the aperture cursor for entity snaps. 2dIntersection (6.2.1) - toggles apparent intersection snap mode. Apparent (6.4.16) - toggles apparent intersection snap mode. Center (6.9.3) - toggles center snap mode. Endpoint (6.13.7) - toggles endpoint snap mode. Extension (6.13.22) - toggles extension snap mode. From (6.14.13) - allows to enter relative coordinates with respect to a reference point. GCenter (6.15.5) - toggles Geometric Center (GCenter) entity snap. Insertion (6.17.18) - toggles insertion snap mode. Intersection (6.17.19) - toggles intersection snap mode. Midpoint (6.21.16) - toggles midpoint snap mode. Mtp (6.21.35) - allows to specify a point as the midpoint between two points. Nearest (6.22.2) - toggles nearest snap mode. Node (6.22.7) - toggles node (point) snap mode. None (6.22.8) - turns off all entity snap modes. Parallel (6.24.5) - toggles parallel snap mode. Perpendicular (6.24.25) - toggles perpendicular snap mode. Quadrant (6.25.7) - toggles quadrant snap mode. Tangent (6.29.10) - toggles tangent snap mode.

Dialog Box Options

Option	Description
 Turn off all 3D snaps	Toggles the currently selected 3D snap modes between on and off; equivalent to the ZNone (6.35.6) command.
 Vertex	Snaps to the closest vertex of a 3D entity, equivalent to the ZVertex (6.35.9) command. (6.2979 on page 6077)
 Midpoint of edge	Snaps to the midpoint of a face edge, equivalent to the ZMidpoint (6.35.4) command. (6.2961 on page 6065)
 Center of face	Snaps to the center of planar or curved 3D faces; equivalent to the ZCenter (6.35.1) command. (6.2953 on page 6058)
Knot	Snaps to a knot on a spline, equivalent to the ZKnot command. (6.2959 on page 6064)
 Perpendicular to planar face	Snaps to a point perpendicular to a face; equivalent to the ZPerpendicular (6.35.8) command. (6.2976 on page 6075)
 Nearest to face	Snaps to a point on the face of a 3D entity that is nearest to the cursor, equivalent to the ZNearest (6.35.5) command. (6.2964 on page 6067)
 3D Intersection	Snaps to the intersection of linear entities, edges and polar or entity snap tracking lines with faces; equivalent to the ZIntersection (6.35.2) command. (6.2956 on page 6061)
 Point cloud nearest point	Snaps to the nearest point in a point cloud. (6.38 on page 3369)

Related Commands

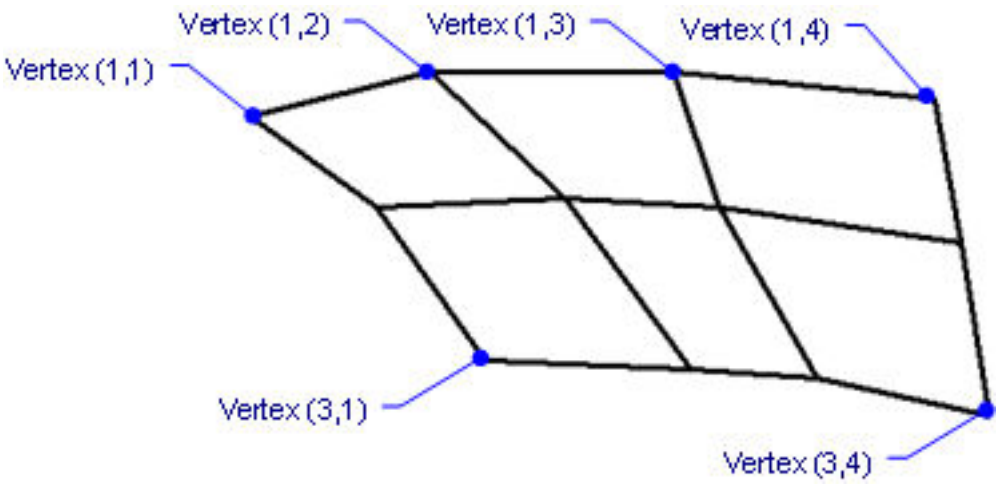
6.3.9 3dMesh

(7.3 on page 6132) Draws 3D surface meshes.

Accessing the Command

command bar: **3dmesh** alias: **mesh** menu bar: **Model | Meshes | Polygon Mesh** toolbar: **Meshes | 3D Face** |  ribbon: **Model | Meshes | Polygon Mesh** : **3dmesh Prompts you in the command bar:** Number of vertices in M direction (between 2 and 256): **(Enter a number)** Number of vertices in N direction (between 2 and 256): **(Enter a number)** Position of vertex (0, 0): **(Pick a point, or enter x,y,z coordinates) Command continues prompting you for the coordinates of vertices** Vertex (3, 4): (Pick another point, or enter x,y,z coordinates.) (6.40)

Figure 6.40



Command Options

Option	Description
Number of vertices in M direction	Specifies the number of vertices in the primary direction. Enter a number between 2 and 256. A single face is made from a 2x2 vertex. (6.42 on the following page)
Number of vertices in N direction	Specifies the number of vertices in the secondary direction. Enter a number between 2 and 256.
Position of vertex (n, n)	Specifies the position of the vertex. Pick a point, or enter x,y,z coordinates.

Grips Editing

3D meshes can be edited directly through grips:

1. Select the 3D mesh . Notice that it has several grips.
2. Drag a grip to stretch the mesh.

(6.41)

Related Commands

3dFace (6.3.6) - draws 3D 4-edged faces with optional invisible edges. PEdit (6.24.24) - edits 3D meshes. PFace (6.24.23) - draws 3D multi-sided meshes.

Figure 6.42

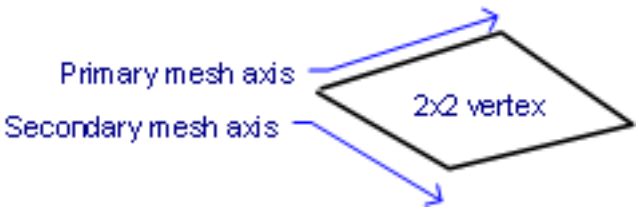

Figure 6.43

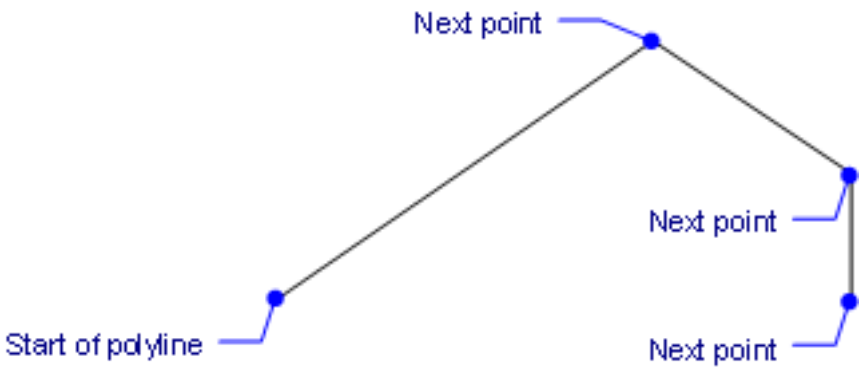
6.3.10 3dPoly

(7.3 on page 6132) Draws 3D polylines (short for "three dimensional polylines").

Accessing the Command

 command bar: **3dpoly** alias: **3p** menu bar: **Draw | 3D Polyline** toolbar: **Draw |Polylines |**  ribbon: **Draw | Draw | Polylines | 3D Polyline** : **3dpoly Prompts you in the command bar:** Select start of polyline or [Follow]<ENTER to use last point>: **(Pick a point, or enter x,y,z coordinates, or press Enter to select the last point entered)** Next point: **(Pick another point, or enter x,y,z coordinates)** Next point or [Undo]: **(Pick a point, or choose an option)** Set next point or [Close/Undo]: **(Pick a point, or choose an option)** Set next point or [Close/Undo]: **(Pick a point, or choose an option, or press Enter to end the command)** (6.44) You edit 3D polylines with the PEdit (6.24.24) command or with grips.

Figure 6.44



Command Options

Option	Description
ENTER to use last point	Uses the last point as the start point of the 3D polyline.
Select start of polyline	Specifies the starting point of the polyline. Pick a point, or enter x,y,z coordinates.
Follow	Draws the first segment at the same angle as the previously drawn segment, whether a line or 3D or 2D polyline; move the mouse to indicate the length.
Next point	Specifies the next vertex of the polyline: • Pick a point • Enter x,y,z coordinates • Press Enter to exit the command
Undo	Removes the last-drawn segment.
Close	Closes the polyline and ends the command.

Procedures

Selecting subentities (1.32.7)

Grips Editing

3D polylines can be edited directly through grips:

1. Select the 3D polyline. Notice that it has a grip at the end of each segment.
2. Drag a grip to stretch the segment.

Figure 6.46

6.3.11 -3dOsnap

(6.2981 on page 6079) Toggles entity snap modes for 3D entities at the command line (short for "3D object snap").

Accessing the Command

command bar: **-3dosnap** transparent: **'-3dosnap** : **-3dosnap Prompts you in the command bar:** 3d Snaps: [nearest (ZNEA)/vertex (ZVER)/midpoint (ZMID)/center (ZCEN)/perpendicular (ZPER)/knot (ZKNO)/intersection (ZINT)/PointCloud Nearest/clear entity snaps (NON)/ON/OFF]: **(Enter an option.)** To set more then one snap mode at the same time, separate their names with commas; you need to type the uppercase portion of each snap name only. e.g.: ZNEA,ZMID,PCN sets the nearest, midpoint and point cloud nearest 3D snap modes.

Command Options

Option	Description
ZNEArest	Snaps to a point on the face of a 3D entity that is nearest to the cursor, equivalent to the ZNearest (6.35.5) command.
ZVERtex	Snaps to the closest vertex of a 3D entity, equivalent to the ZVertex (6.35.9) command.
ZMIDpoint	Snaps to the midpoint of a face's edge, equivalent to the ZMidpoint (6.35.4) command.
ZCENter	Snaps to the center of a flat or curved 3D face, equivalent to the ZCenter (6.35.1) command.
ZPERpendicular	Snaps to a point perpendicular to a face, equivalent to the ZPerpendicular (6.35.8) command.
ZKNOt	Snaps to a knot on a spline, equivalent to the ZKnot (6.35.3) command.
ZINTersection	Snaps to the intersection of linear entities, edges and polar or entity snap tracking lines with faces, equivalent to the ZIntersection (6.35.2) command.
PointCloud Nearest	Snaps to the nearest point cloud point.
ON	Enables all currently set 3D snap modes.
OFF	Disables all currently set 3D snap modes.
NON	Switches all 3D snap modes off; equivalent to the ZNone (6.35.6) command.

Related Commands

3dOsnap (6.3.8) - sets the entity snap modes for 3D entities through the Settings dialog box. OSnap (6.23.16) - sets entity snaps through the Settings dialog box. -OSnap (6.23.13) - toggles entity snap modes at the command line. Aperture (6.4.14) - sizes the aperture cursor for entity snaps. Zcenter (6.35.1) - toggles the 3D center entity snap. Snaps to the center of planar or curved 3d faces. Zintersection (6.35.2) - Toggles the 3D intersectionpoint snap. Snaps to the intersection of linear entities, edges and polar or entity snap tracking lines with faces. Zknot (6.35.3) - toggles the 3D knot entity snap. Snaps to a knot on a **spline**. Zmidpoint (6.35.4) - toggles the 3D midpoint snap. Snaps to the midpoint of a face edge. Znearest (6.35.5) - toggles the 3D nearest entity snap. Snaps to a point on the face of a 3D entity that is nearest to the cursor. Znone (6.35.6) - disables all 3d snap modes. Zperpendicular (6.35.8) - toggles the 3D perpendicular entity snap. Snaps to a point perpendicular to a face. Zvertex (6.35.9) - toggles the 3D vertex entity snap. Snaps to the closest vertex of a 3d entity.

6.4 A

6.4.1 AcisIn

(6.2981 on page 6079) Imports SAT and SAB files in ACIS format (as exported by other CAD systems), and then creates 3D solid models from the data.

Figure 6.47

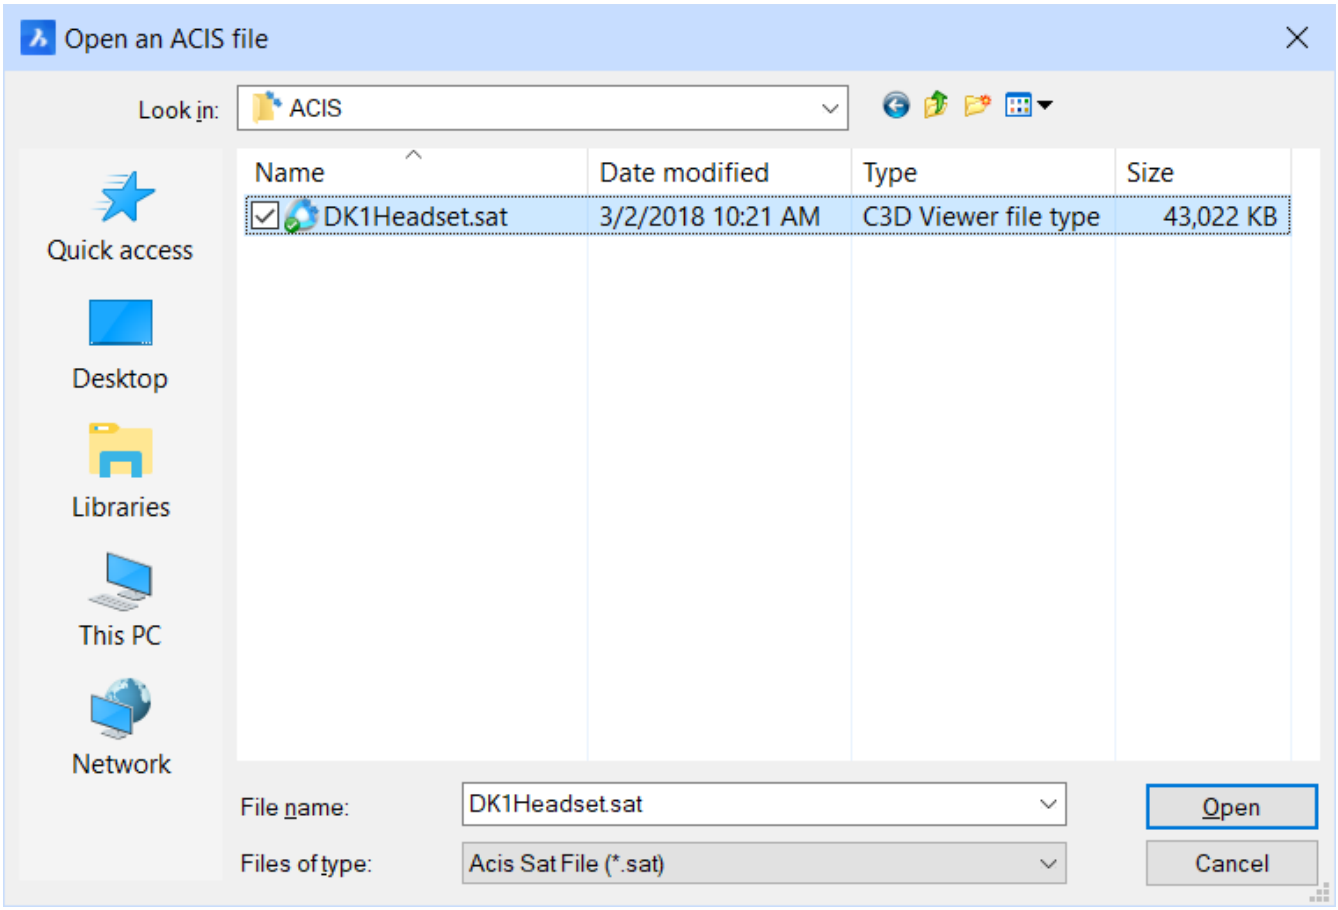
Accessing the Command

 command bar: **acisin** menu bar: **Insert | Acis In** : **acisin** Displays a dialog box: (6.48 on the next page)

1. Choose a SAT or SAB file.
2. Click **Open**. The data in the file is converted to 3D solid entities, and then placed on layer 0.

Use this command to import 3D solids from other CAD packages. Use the AcisOut (6.4.2) command to create SAT or SAB files.

Figure 6.48



Dialog Box Options

Option	Description
File name	Specifies the name of the ACIS file.
Files of type	Choose an ACIS format: • SAB - ACIS binary format; short for "save as binary." • SAT - ACIS ASCII format; short for "save as text."
Open	Opens the 3D solid in the current drawing. If you cannot see the entity, use the Zoom (6.35.7) All command.

Related Commands

AcisOut (6.4.2) - exports 3D solids and surface entities in SAT format. ConvToSolid (6.9.34) - converts 3D entities into solid models.

Figure 6.49

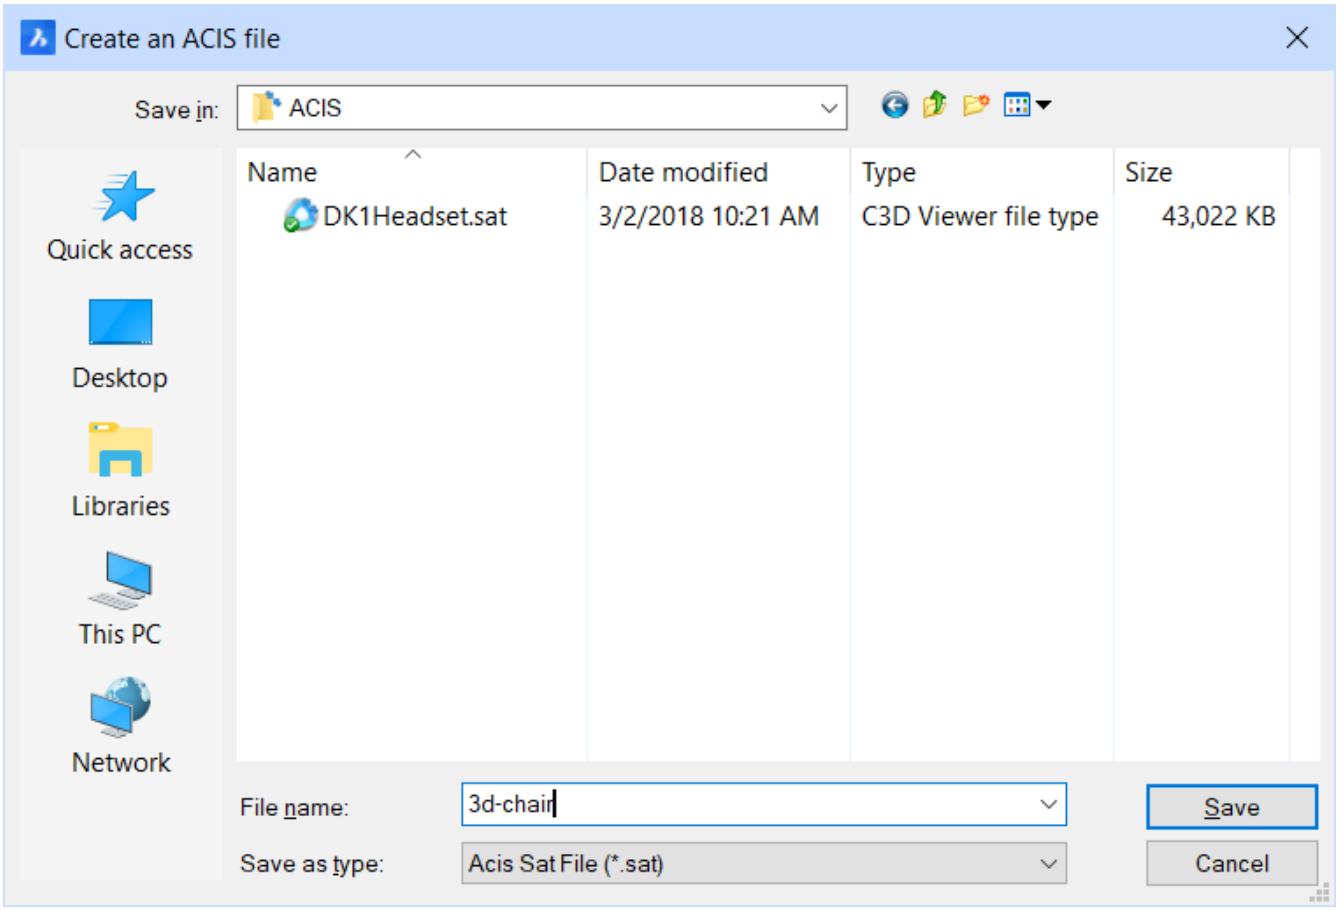
6.4.2 AcisOut

(6.2981 on page 6079) Exports 3D solids and surface entities in ASCII or binary ACIS format. Exported files can be shared with other 3D CAD programs capable of solid modeling.

Accessing the Command

command bar: **acisout** menu bar: **Insert | Acis Out** : **acisout Prompts you in the command bar:** Select ACIS entities to save: **(Choose one or more 3D solids or surface entities)** Select ACIS entities to save: **(Press Enter to continue the command)** Displays a dialog box: (6.50 on the next page) Name the SAT file, chose a format, then click **Save**. The 3D solid entities are converted to binary or ASCII data in the file. Use the AcisIn (6.4.1) command to import SAT files.

Figure 6.50



Command Options

Option	Description
File name	Names the ACIS file.
Files of type	Choose an ACIS format: • **SAB** - ACIS binary format; short for "save as binary." • **SAT** - ACIS ASCII format; short for "save as text."
Save	Saves the selected 3D solid entities.

Related Commands

AcisIn (6.4.1) - imports ACIS solids into the drawing. ConvToSolid (6.9.34) - converts 3D entities into solid models.

Figure 6.51

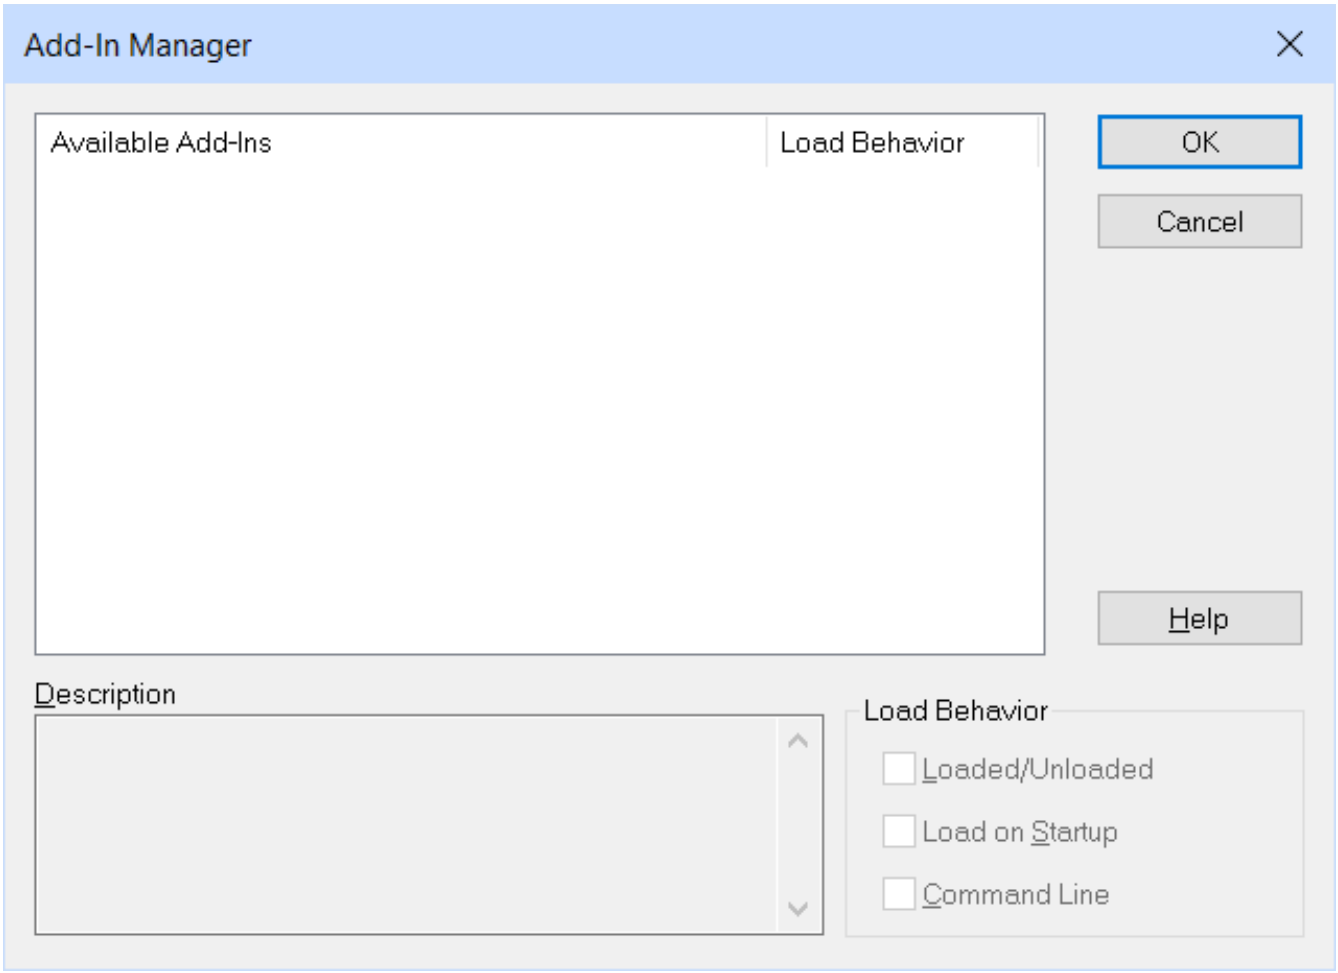
6.4.3 AddInMan

(6.2981 on page 6079) * Command only available on the Windows platform Displays the Add-In Manager for controlling how Visual Basic for Applications modules are loaded.

Accessing the Command

command bar: **addinman** shortcut: **hift+F11** alias: **Alias** menu bar: **Tools | VBA | Add-in Manager** : **addinman** Displays a dialog box: (6.52 on the next page) Change the load behavior of add-ins programs, and then click **OK**.

Figure 6.52



Add-In Manager
Available Add-Ins
Load Behavior
OK
Cancel
Help
Description
Load Behavior
Loaded/Unloaded
Load on Startup
Command Line

Command Options

Option	Description
Available Add-Ins	Lists the names of VBA COM modules available to BricsCAD. "VBA COM" is short for Visual Basic for Applications Common Object Model.
Load Behavior	Determines how modules are loaded: • **Loaded/Unloaded** - toggles the module between loaded and unloaded. • **Load on Startup** - loads modules when BricsCAD starts up.
OK	Saves the changes, and then dismisses the dialog box.
Cancel	Undoes the changes, and then dismisses the dialog box.

Related Commands

AppLoad (6.4.17) - selects external routines to load when BricsCAD starts. Commands (6.9.23) - lists the names of internal and external commands. CuiLoad (6.9.56) and CuiUnload (6.9.51) - loads and unloads menu files. Customize (6.9.47) - customizes the user interface. MenuLoad (6.21.14) and MenuUnload (6.21.13) - loads and unloads menu files. Netload (6.22.3) - loads a .NET application. Security (6.32.8) - depending on the selected security level (Low, Medium or High) VBA macros are allowed to run automatically or not. VbaLoad (6.32.2) and -VbaLoad (6.32.3) - loads VBA projects VbaRun (6.32.6) and -VbaRun (6.32.7) - runs VBA macros. VbaIde (6.32.1) - opens the VBA integrated development environment. VbaMan (6.32.4) - manages VBA projects. VbaUnload (6.32.9) - unloads VBA projects.

Figure 6.53

6.4.4 About

(7.3 on page 6132) Opens the About dialog box, with version and copyright information

Accessing the Command

command bar: **about** transparent: **'about** menu bar: **Help | About BricsCAD** ribbon: **Home | Help | About BricsCAD** : **about** Displays a dialog box: (6.54 on the next page) Click **OK** to close the dialog box.

Figure 6.55

6.4.5 Alignment

(6.2673 on page 5786) Creates horizontal, vertical and 3D alignments to represent a reference system used to position linear objects in space.

Accessing the Command

Commandline: **ALIGNMENT** Quad: **Model | Alignment** Ribbon: **Civil | Create | Alignment : Alignment** **You are prompted:** Create [Horizontal/Vertical/3D]<Horizontal>: **(Press enter for Horizontal, or use one of the available options in the command bar)** Select TIN surface or [pick Pi point]: **(select a TIN surface, or use one of the available options in the command bar)** Pick horizontal alignment PI point [undo]: **(select PI points and press enter or undo)** Pick origin point for vertical alignment view or [Automatic 3d alignment]: **(pick a point for the vertical alignment view or select Automatic 3d alignment)** Pick vertical alignment PVI point [Undo]: **(pick vertical alignment points (optional), enter to exit the command)**

Command Options

Option	Description
Horizontal	You are prompted: **Select TIN surface or [Pick Pi point]: (Select a TIN surface or select PI points and press enter or undo)**
Vertical	You are prompted: **Select horizontal alignment or vertical alignment view: (select a alignment view.)** You are prompted: **Pick vertical alignment PVI point [Undo]: (pick vertical alignment PVI points or enter.)**
3D	You are prompted: **Select vertical alignment: (Select a vertical alignment.)**

Procedures

Creating an Alignment (1.26.10) Creating a Horizontal Alignment without 3D alignments (1.26.10) Creating a Vertical Alignment (1.26.10) Creating an Alignment from Civil 3D drawing (1.26.10)

Related Commands

AlignmentEdit (6.4.8) - Edit an Alignment. AlignmentView (6.4.9) - Creates a vertical alignment view for the selected horizontal alignment. Corridor (6.9.41) - Creates a corridor from a corridor template, 3D alignment and/or TIN Surface. CorridorEdit (6.9.42) - Adds or removes regions for a selected corridor. Grading (6.15.25) - Creates a graded surface on existing toposurfaces. Tin (6.29.14) - Creates a topographical surface from an imported points file or placing new points.

Figure 6.56

6.4.6 AddSelected

(6.2981 on page 6079) Creates new entities based on an existing entity that you select.

Accessing the Command

command bar: **addselected** menu bar: **Edit | Add Selected** toolbar: **Standard |** toolbar: **Modify |** ribbon: **Home | Settings | Select | Add Selected** : **addselected Prompts you in the command bar:** Select an entity: **(Select an entity in the drawing)** Launches the command that creates the selected entity type. For instance, select a spline and the program immediately starts the Spline command. Some entities are not yet supported.

Command Options

Option	Description
Select an entity	Select one entity in the drawing: • Entity type is supported - the program starts the drawing command to create that entity. • Entity type is not supported - the program reports "This entity type is not yet supported"

Related Commands

All entity creation commands.

Figure 6.57

6.4.7 Align

(6.2981 on page 6079) Aligns one entity with another through moving, rotating, and scaling.

Accessing the Command

command bar: **align** alias: **al** menu bar: **Modify | Align** toolbar: **Modify |** ribbon: **Home | Modify | Align** : **align Prompts you in the command bar:** Select entities: **(Select one or more source entities; do not select "destination" entities)** Entities in set: 1Select entities: **(Select more entities, or else press Enter to end entity selection)** Specify first source point: **(Pick a point on or near the source entity)** Specify first destination point: **(Pick the matching point on or near the destination entity)** Specify second source point: **(Pick another point on or near the source entity)** Specify second destination point: **(Pick the matching point on or near the destination entity)** Specify third source point: **(Press Enter for 2D entities; pick source and destination points for 3D alignment)** Scale objects based on alignment points [Yes/No] <No>: **(Enter Y or N)**

Command Options

Option	Description
Select entities	Selects entities that are to be aligned; do not select destination entities, otherwise they are also moved.

To move entities, specify one pair of source and destination points to move entities: (6.58 on the next page) (6.59 on the facing page)

Option	Description
Specify first source point	Specifies the source alignment point, such as #1a in the figure above.
Specify first destination point	Specifies the destination alignment point, such as #1b in the figure.

To move and rotate entities, specify a second pair of source and destination points to move and rotate entities: (6.60 on the next page) (6.61 on page 3392)

Option	Description
Specify second source point	Specifies the second source alignment point, such as #2a in the figure above. If you press Enter at this prompt, the source object moves.
Specify second destination point	Specifies the matching destination point, such as #2b in the figure.

To move and rotate 3D entities, specify a third pair of source and destination points to move and rotate 3D entities.

Option	Description
Specify third source point	Specifies the source point for 3D alignment; press Enter to move and rotate 2D entities.
Specify third destination point	Specifies the matching destination point.

To scale the source entities:

Option	Description
Scale objects based on alignment points	Optionally scales the source object: • **Yes** - scales objects relative to the picked points • **No** - does not scale objects

- Aligning an entity in 3D (1.32.14)

Related Commands

Move (6.21.29) - moves entities in 3D. Rotate (6.26.29) - rotates entities in 2D. Rotate3D (6.26.31) - rotates entities in 3D. Scale (6.27.6) - scales entities.

Figure 6.62

6.4.8 AlignmentEdit

(6.2673 on page 5786) Edit an alignment.

Accessing the Command

Commandline: **ALIGNMENTEDIT** Ribbon: **Civil | Modify | Edit Alignment : AlignmentEdit You are prompted:** Select horizontal or vertical alignment: **(select a horizontal or a vertical alignment)** Pick point to continue alignment or [Add Pi/Remove Pi/change Tin surface]:

Command Options

Option	Description
Add Pi	Add a Pi Point to the alignment. You are prompted: **Pick point to add new PI: (pick point).**
Remove Pi	Remove a Pi point. You are prompted: **Pick point near PI to remove: (pick point).**
change Tin surface	Changes the Tin surface of the alignment. You are prompted: **Select TIN surface to add: (select TIN surface).**

Procedures

Continuing a horizontal alignment with AlignmentEdit (1.26.10) Adding PI to an existing horizontal alignment (1.26.10) Removing PI to an existing horizontal alignment (1.26.10) Adding additional TIN Surface to Vertical alignment view (1.26.10)

Related Commands

Alignment (6.4.5) - Creates horizontal, vertical and 3D alignments to represent a reference system used to position linear objects in space. AlignmentView (6.4.9) - Creates a vertical alignment view for the selected horizontal alignment. Corridor (6.9.41) - Creates a corridor from a corridor template, 3D alignment and/or TIN Surface. CorridorEdit (6.9.42) - Adds or removes regions for a selected corridor. Grading (6.15.25) - Creates a graded surface on existing toposurfaces. Tin (6.29.14) - Creates a topographical surface from an imported points file or placing new points.

Figure 6.63

6.4.9 AlignmentView

(6.2673 on page 5786) Creates a vertical alignment view for the selected horizontal alignment.

Accessing the Command

Commandline: **ALIGNMENTVIEW** Ribbon: **Civil | Create | Vertical Alignment View : AlignmentView You are prompted:** Select horizontal alignment: **(Select a horizontal alignment)** Pick origin point for vertical alignment view: **(Select a point as origin for the vertical alignment view)**

Procedures

Creating a Vertical Alignment View (1.26.10)

Related Commands

Alignment (6.4.5) - Creates horizontal, vertical and 3D alignments to represent a reference system used to position linear objects in space. AlignmentEdit (6.4.8) - Edit an Alignment. Corridor (6.9.41) - Creates a corridor from a corridor template, 3D alignment and/or TIN Surface. CorridorEdit (6.9.42) - Adds or removes regions for a selected corridor. Grading (6.15.25) - Creates a graded surface on existing toposurfaces. Tin (6.29.14) - Creates a topographical surface from an imported points file or placing new points.

Figure 6.64

6.4.10 AlignSpace

(6.2981 on page 6079) Adjusts viewport angle, zoom factor, and pan position based on alignment points specified in model space and paper space. This command works only in paper space.

Accessing the Command

command bar: **alignspace** transparent: **'alignspace** : **alignspace Prompts you in the command bar:** First alignment point in Model space: **(Click inside the viewport you want to align, and then pick the first alignment point)** Second alignment point in Model space or <None>: **(Click on a second point in the same viewport, or enter N)** First alignment point in Paper space: **(Click a point in paper space; this point will be made coincident with the first alignment point)** Second alignment point in Paper space: **(Click another point in paper space; this point will be made coincident with the second alignment point)** Activate the viewport which will be used for alignment. **(Click in a viewport, and then press Enter)**

Command Options

Option	Description
First (second) alignment point in Model space	Follow these steps: 1. In a layout tab, click a paperspace viewport to make it current. 2. Pick a first alignment point that represents a position in model space. 3. Choose one: • Pick a second alignment point that specifies the view size and rotation in model space • Or, enter **N** to skip this step
None	Press Enter to skip the selection of the second alignment point in model space. The selected point will automatically coincide with the alignment point you pick in paper space.
First (second) alignment point in Paper space	Follow these steps: 1. Click a point in paper space; this point will be made coincident with the first alignment point in model space 2. Click another point in paper space; this point will be made coincident with the second alignment point of model space, if any
Activate the viewport which will be used for alignment	Choose a layout viewport by clicking in it, and then press Enter

Procedures

- To align model space and paper space points. (1.23.16)

Related Commands

MvSetup (6.21.34) - creates multiple paper space viewports; aligns, rotates and scales paper space viewports. MView (6.21.37) - creates one or more viewports in layout tabs. MSpace (6.21.32) - switches to model space. PSpace (6.24.59) - switches to paper space.

Figure 6.65

6.4.11 AnimationEditorClose

(6.2673 on page 5786) Closes the Animation Editor panel.

Accessing the Command

command bar: **animationeditorclose** : **animationeditorclose** Displays no prompts in the commandline.

Command Options

No command options.

Related Commands

ANIMATIONEDITOROPEN (6.4.12) - Opens the Animation Editor panel.

Figure 6.66

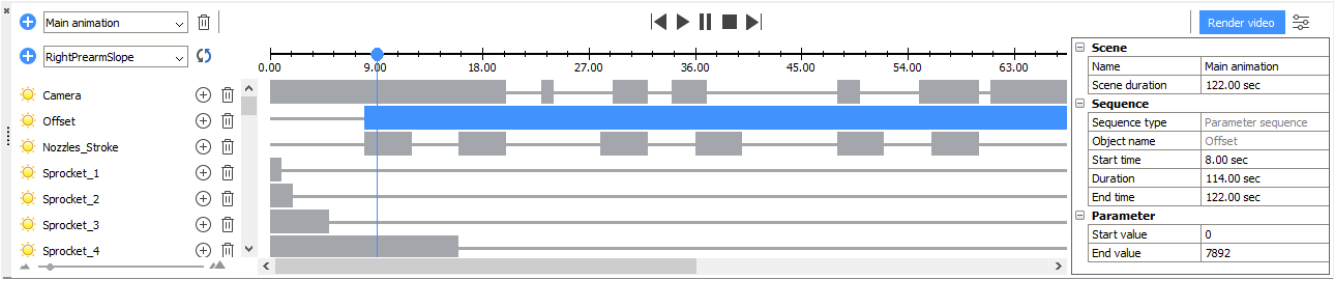
6.4.12 AnimationEditorOpen

(6.2673 on page 5786) Opens the Animation Editor (3.7.10) panel.

Accessing the Command

command bar: **animationeditoropen** menu bar: View | **Animation Editor** ribbon: **View | Animation | Animation Editor** context menu*: **Animation Editor** * Place the cursor over a toolbar or a ribbon panel, then right-click. See also: Dockable Panels (1.15.7). : **animationeditoropen** Displays a panel: (6.67) Use the Animation Editor to create schedules for multi-parametric animations with complex camera movements and render them as 2D videos.

Figure 6.67



Command Options

Option	Description
Context menu	Right-click on any animation sequence: (6.68 on the next page) • **Delete** - removes the sequence from the animation
	Click to add an empty scene. Opens a dialog: (6.69 on page 3401) • **Scene name** - name of the scene • **Duration** - scene duration, in seconds
(6.70 on page 3401)	Displays the list of the scenes in the document.
	Click to remove the selected scene.
	Click to jump to the previous animation sequence during the animation playback.
	Click to start the animation playback.
	Click to pause the animation playback.
	Click to stop the animation playback.
	Click to jump to the next animation sequence during the animation playback.
	Click to render the video. Opens the dialog: (6.71 on page 3401) • **Render frame rate (fps)** - framerate of the video. • **Resolution** - resolution of the video, select from the list of supported resolutions. • **File format** - format of the output video: – avi – mpg – wmv • **Start time -** time position of the animation to start the render. • **End time** - time position of the animation to end the render. • **Cancel -** click to close the dialog without starting the render. • **Render** - click to start rendering. Opens the dialog: (6.72 on page 3402) **(Specify the location and the name of the output video)**

	Click to toggle the the configurator panel.
 (6.73 on page 3402)	Click to add a new timeline for the selected object. Contains a list of the entities to animate.
	Updates the model state to the current cursor position
	Click to disable the timeline.
	Click to enable the timeline.
	Click to add a new animation sequence at the cursor position.
 (6.74 on page 3402)	Click to remove the timeline. Move the slider to change the scale of the timeline.

Procedures

How to add a new scene (3.7.10) How to add an animation for a parameter (3.7.10) How to add a camera movement (3.7.10) How to remove an animation sequence (3.7.10) How to render the animation (3.7.10)

Related commands

ANIPATH (6.4.13) - Records the animation of a camera moving along a path or panning in a 3D model and saves it to a movie file. ANIMATIONEDITORCLOSE (6.4.11) - Closes the animation editor panel.

Command Options

Option	Description
Link camera to	Defines the location of the camera. Select an option: Point : Links a camera to a static point in the drawing. If **Link target to** is set to **Point** , this option is not available for the camera. (6.77 on page 3407) Do one of the following: • Click the list button, and choose a previously saved point. • Click the **Pick** ( ) button. You are prompted to specify a point in the drawing. (6.82 on page 3408) Type a name for the point, then click the **OK** button. The point is added to the points list. • Click the **Delete** button ( ) to remove the currently selected point from the points list. Path : Links a camera to a linear entity in the drawing. (6.79 on page 3408) Do one of the following: • Click the list button, and choose a previously saved path. • Click the **Pick** ( ) button. You are prompted to pick a linear entity in the drawing. A path can be a line, arc, elliptical arc, circle, polyline, 3D polyline, or spline. (6.84 on page 3409) Type a name for the path, then click the **OK** button. The path is added to the paths list. • Click the **Delete** button ( ) to remove the currently selected path from the paths list.

Link target to	Defines the target point of the camera. If the camera is linked to a point, the target must be linked to a path. If the camera is linked to a path, the target can can be linked to either a point or a path. Select an option: Point : Links the target to a static point in the drawing. If **Link camera to** is set to **Point** , this option is not available for the target. (6.81 on page 3408) Do one of the following: • Click the list button, and choose a previously saved point. • Click the **Pick** ( ) button. You are prompted to specify a point in the drawing. (6.82 on page 3408) Type a name for the point, then click the **OK** button. The point is added to the points list. • Click the **Delete** button ( ) to remove the currently selected point from the points list. Path : Links a target to a linear entity in the drawing. (6.83 on page 3408) Do one of the following: • Click the list button, and choose a previously saved path. • Click the **Pick** ( ) button. You are prompted to pick a linear entity in the drawing. A path can be a line, arc, elliptical arc, circle, polyline, 3D polyline, or spline. (6.84 on page 3409) Type a name for the path, then click the **OK** button. The path is added to the paths list. • Click the **Delete** button ( ) to remove the currently selected path from the paths list.
Animation Settings	Allows to control the output of the movie file. (6.85 on page 3409) Frame rate (FPS) : defines the number of frames per second. When you change the **Frame rate** , the **Number of frames** will be adjusted according to the **Duration** . Number of frames : specifies the total number of frames in the movie. When you change the **Number of frames** , the **Duration** will be adjusted accordingly. Duration (seconds) : specifies the duration in seconds of the movie. When you change the **Duration** , the **Number of Frames** will be adjusted accordingly. Reverse : Reverser the sequence of the frames. Corner deceleration : Slows down the camera at corners in the animation path. Visual style : Defines the visual style for the movie. Click the button, then select a visual style in the list. All visual styles (6.31.15) in the current drawing are available. Resolution : Sets the width x height resolution of the movie. Click the button to select a resolution. Available resolutions are: 160x120, 320x240, 640x480, 800x600, 1024x768, 1280x1024, 1600x1024, 1920x1080, 1920x1200. Format : Specifies the file format of the movie. Available formats are: **avi** , **mpg** and **wmv** .
Preview	Displays the movement of the camera.

OK	Generates the movie. Displays a **File** dialog: 1. Select a folder. 2. Type a name for the movie. 3. (option) Select a file type, thus overriding the previously selected **Format** setting. 4. Click the **Save** button to create the movie file.

Related Commands

Camera (6.9.1) - creates perspective views. -Render (6.26.35) - generates a photorealistic rendering using materials and lights through the command bar. Render (6.26.21) - generates a photorealistic rendering using materials and lights through a dialog box. -VisualStyles (6.31.17) - manages visual style definitions at the command line. VisualStyles (6.31.15) - creates and controls visual style definitions in the Drawing Explorer.

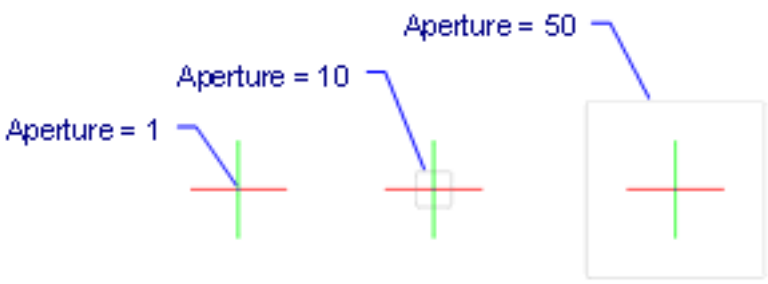
6.4.14 Aperture

(6.2981 on page 6079) Sets the size of selection area for snapping to entities.

Accessing the Command

 command bar: **aperture** transparent: **'aperture** alias: **ap** menu bar: **Settings | Entity Snap Precision** toolbar: **Settings |**  ribbon: **Settings | Entity Snap Precision** : **aperture Prompts you in the command bar:** Selection area for entity snap (1-50 pixels) <10>: **(Enter a value between 1 and 50, or press Enter to keep the default value.)** (6.87) The aperture cursor works with entity snaps only. The program searches the area inside the rectangular aperture cursor for geometric features, such as endpoints and mid points. A large aperture cursor makes it easier for you to hover over geometric features, but then the program may find too many matching entity snap points; a smaller one may be more difficult for you to position over geometry, but is more precise at snapping to geometric features. The default value of 10 is a good compromise. By default, the aperture cursor is turned on. Use the **ApBox** system variable to turn it off.

Figure 6.87



Command Options

Option	Description
Selection area for entity snap	Changes the size of the aperture cursor; range is between 1 and 50 pixels wide.

Related Commands

OSnap (6.23.16) - toggles entity snap modes in the Settings dialog box. -OSnap (6.23.13) - toggles entity snap modes in the command bar.

Figure 6.88

6.4.15 AnnoUpdate

(6.2981 on page 6079) Updates the annotative style of selected annotative entities to match the current style.

Accessing the Command

 command bar: **annoupdate** ribbon: **Home | Annotation Scaling | Update Annotations** : **annoupdate Prompts you in the command bar:** Select annotative entities: **(Select entities)** Entities in set: <x> Select annotative entities: **(Select more entities, or press Enter to finish the command)** <x> found <y> were updated

Command Options

Option	Description
Select annotative entities	• Select one or more annotative entities, such as text, dimensions, and hatch patterns • Enter **all** to select all of them; the program will ignore non-annotative entities

Related Commands

AnnoReset - resets all scale representations of the selected annotative entities to the location of their current scale representation.

Figure 6.89

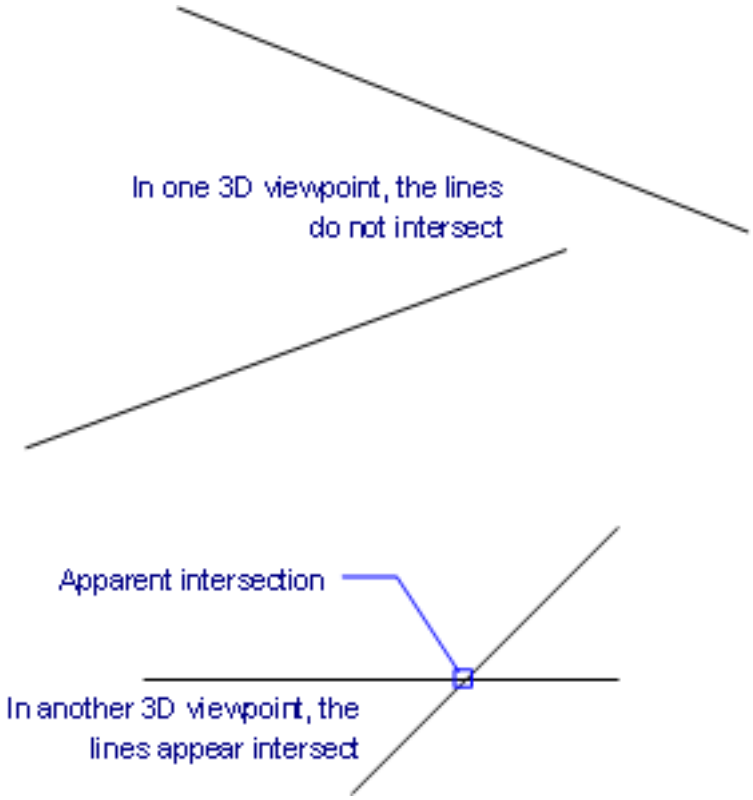
6.4.16 Apparent

(6.2981 on page 6079) Toggles Apparent intersection entity snap; snaps to the intersections of entities, even when they only appear to intersect in 3D space.

Accessing the Command

command bar: **apparent** transparent: **apparent** aliases: **app**, **planviewint, 2dintersection (6.2.1)**toolbar: **Entity Snaps |** ribbon: **Home | Entity Snaps | Snap to Apparent** : **apparent** Displays no prompt in the command bar. Each time you enter the command, it toggles the apparent entity snap mode, from on to off, to on again. (6.1796 on page 5007) This entity snap snaps to intersecting entities, including those that appear to intersect in 3D space.

Figure 6.90



Command Option

Option	Description
Apparent	Entering this command toggles apparent intersection (2dInsersection) entity snap This command can be entered transparently during commands, but must be entered without the apostrophe prefix (').

Related Commands

OSnap (6.23.16) - toggles entity snap modes in the Settings dialog box. -OSnap (6.23.13) - toggles entity snap modes in the command bar. Aperture (6.4.14) - sizes the aperture cursor for entity snaps. 2dIntersection (6.2.1) - toggles apparent intersection snap mode. 3dIntersection (6.3.7) - toggles intersection snap mode. Center (6.9.3) - toggles center snap mode. Endpoint (6.13.7) - toggles endpoint snap mode. Extension (6.13.22) - toggles extension snap mode. From (6.14.13) - allows to enter relative coordinates with respect to a reference point. GCenter (6.15.5) - toggles Geometric Center (GCenter) entity snap. Insertion (6.17.18) - toggles insertion snap mode. Intersection (6.17.19) - toggles intersection snap mode. Midpoint (6.21.16) - toggles midpoint snap mode. Mtp (6.21.35) - allows to specify a point as the midpoint between two points. Nearest (6.22.2) - toggles nearest snap mode. Node (6.22.7) - toggles node (point) snap mode. None (6.22.8) - turns off all entity snap modes. Parallel (6.24.5) - toggles parallel snap mode. Perpendicular (6.24.25) - toggles perpendicular snap mode. Quadrant (6.25.7) - toggles quadrant snap mode. Tangent (6.29.10) - toggles tangent snap mode.

Figure 6.94

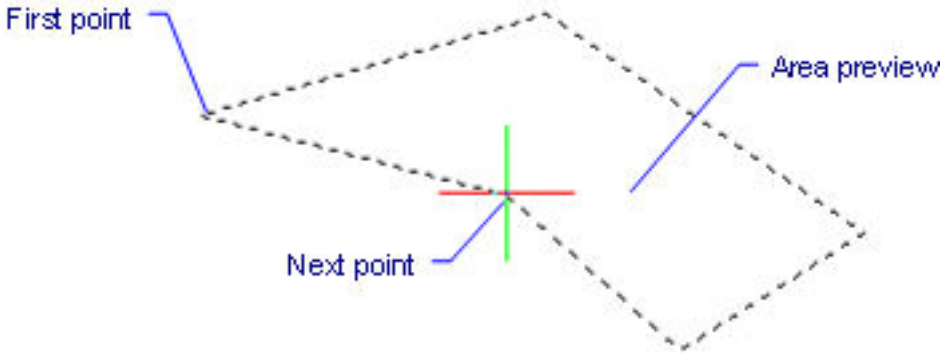
6.4.18 Area

(6.2981 on page 6079) Finds the area and perimeter of 2D entities.

Accessing the Command

 command bar: **area** alias: **aa** menu bar: **Tools | Inquiry | Area** toolbar: **Inquiry** |  ribbon: **Tools | Inquiry | Area** : **area Prompts you in the command bar:** Select first point [Entity/Add/Subtract]: **(Pick a point, or enter an option)** <Next point>: **(Pick a point)** <Next point>: **(Pick another point)** <Next point>: **(Pick another point, or else press Enter to end the command)** Use entity snap modes to ensure your picks are accurate. As you pick points, BricsCAD previews the area with a dashed polygon. (6.95) When you press Enter to indicate you have ended picking points, BricsCAD reports the area and perimeter like this: **Area = 6.1836 sq. units, Perimeter = 11.2968** This command does not work with solids (2D), traces, rays, xlines, or hatches. To find the area of hatches, use the Properties command.

Figure 6.95



Command Options

Option	Description
Entity	Provides the area and/or perimeter of the selected entity. The information reported by this command varies according to the entity selected: • Line and sketch - length • Arc and elliptical arc - length • Circle and ellipse - area and perimeter • Closed polyline and closed spline - area and perimeter • Open polyline and spline - area and perimeter, as if they were closed • 3D objects - surface area
Add	Allows you to add up the areas of two or more entities. The prompt changes to: **Adding: Entity/Subtract/ <First point>** - **(pick a point, enter an option, or press Enter to exit Adding mode.)**
Subtract	Allows you to removes areas and/or entities from the total area and perimeter; this option can only be used after you have found the area of at least one entity. The prompt changes to: **Subtracting: Entity/Subtract/ <First point>** - **(pick a point, enter an option, or press Enter to exit Subtracting mode.)**
First point	Specifies the first point of the area to be measured. The prompt changes to: **<Next point>** - **(pick another point, or press Enter to end the area specifying.)**

Related Commands

Dist (6.10.36) - reports the 2D and 3D distances between two points. Id (6.17.4) - reports the x,y,z coordinates of picked points. List (6.20.34) - lists the area and other parameters of entities in the command bar. MassProp (6.21.2) - reports the properties of solid models and regions. Properties (6.24.54) - lists the area and other parameters of entities in a palette.

Figure 6.96

6.4.19 Array

(7.3 on page 6132) Creates 2D and 3D arrays of entities in rectangular or polar patterns, or along a path.

Accessing the Command

 command bar: **array** alias: **ar** menu bar: **Modify | Array | 2D Array** toolbar: **Modify |**  **ribbon:** : **array Prompts you in the command bar:** Select entities: **(Select an entity)** Entities in set: 1 Select entities: **(Select more entities or press Enter to stop selecting entities)** Enter array type [Rectangular (6.4.28)/PAth (6.4.26)/POlar (6.4.41)] <Rectangular>: **(Choose an array type or press Enter to accept the default)** The default array type is saved by the ArrayType variable. The ArrayAssociativity variable controls whether static or associative arrays are created.

Command Options

Option	Description
Rectangular	Distributes entity copies into any number of rows, columns, and levels (z direction). See the ArrayRect (6.4.28) command.
Path	Distributes entity copies evenly along a path into multiple rows and levels. See the ArrayPath (6.4.26) command.
Polar	Distributes entity copies evenly in a circular pattern about a center point or axis of rotation, using multiple rows and levels. See the ArrayPolar (6.4.41) command.

Related Commands

3dArray (6.3.2) - creates 3D arrays. -Array (6.4.20) - creates a polar or rectangular array of entities; displays prompts at the command bar. ArrayClassic (6.4.22) - creates a static polar or rectangular array of entities through a dialog box. ArrayEdit (6.4.25) - allows editing associative array entities and their source entities. ArrayPath (6.4.26) - associatively distributes entity copies evenly along a path into multiple rows, and levels. ArrayPolar (6.4.41) - associatively distributes entity copies evenly in a circular pattern about a center point or axis of rotation, using multiple rows, and levels. ArrayRect (6.4.28) - associatively distributes entity copies into any number of rows, columns, and levels. MInsert (6.21.15) - inserts arrays of blocks.

Figure 6.97

6.4.20 -Array

(7.3 on page 6132) Creates a static polar or rectangular array of entities; displays prompts at the command bar.

Accessing the Command

command bar: **-array** : **-array Prompts you in the command bar:** Select entities to array: **(Select one or more entities.)** Entities in set: 1 Select entities to array: **(Press Enter to end entity selection.)** Type of array [Polar/Rectangular] <Rectangular>: **(Enter an option.)** This command creates linear, rectangular, and polar arrays.

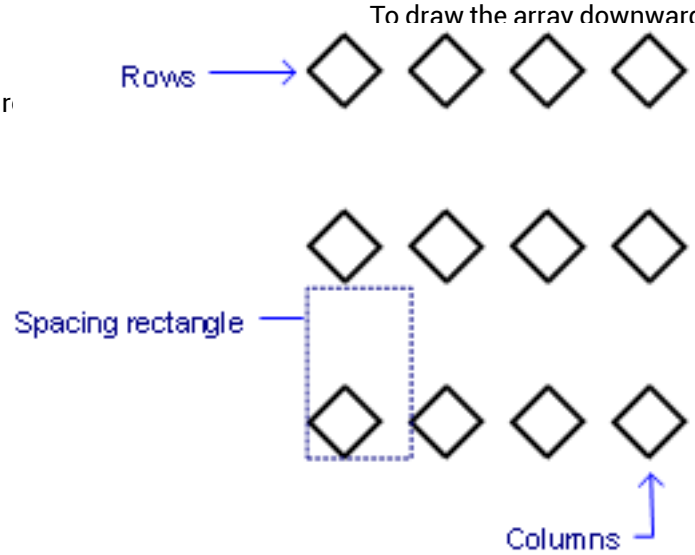
Command Options

Option	Description
Select entities to array	Specifies the entities to be arrayed. Use any entity selection method; press Enter when you are done.
Polar	Creates polar (circular) arrays. Prompts you: **Center of polar array or [Base]: (Pick a point, or type B.) ENTER to specify angle between items/<Number of items to array>: (Enter a number, or press Enter.) Angle to fill (+ for ccw, - for cw)<360>: (Type a positive or negative value or press Enter to fill 360°.) Rotate entities around the array? [Yes-Rotate entities(Yes)/No-Do not rotate(No)]<Yes>: (Type N or Y.)**
Rectangular	Creates linear, rectangular, or square arrays. Prompts you: **Number of rows in the array <1>: (Enter the number of rows.) Number of columns <1>: (Enter the number of columns.) Vertical distance between rows, or spacing rectangle: (Specify the distance between rows, or pick two points.) Horizontal distance between columns: (Specify the distance between columns.)**

Rectangular arrays have rows and columns: (6.98)

Rectangular Array Options	Description
Number of rows in the array	Specifies the number of rows; for a linear array, enter 1. To draw the array downwards, enter a negative number.
Number of columns	umns. To draw the array to nber.
Vertical distance between r	een rows of entities.

Figure 6.98



Spacing rectangle	Specifies two points that indicate the spacing between rows and columns.
Horizontal distance between columns (6.1574 on page 4830)	Specifies the distances between columns of entities.

Polar Array Options	Description
Base	Relocates the base point of the selected entities.
Center of polar array	Specifies the center point; enter coordinates or pick a point.
ENTER to specify angle between items	Specifies the angle between each copy.
Number of items to array	Specifies the number of items in the array; enter a number larger than 1
Angle to array	Determines the extent and direction of the array. Enter 360 for a full circle of copies; enter a smaller number to draw a partial polar array. Enter a positive angle to draw the array counter clockwise; enter a negative number to draw the array clockwise.
Rotate entities around the array	Determines whether copies are rotated when they are arrayed: • No does not rotate entities; all copies look the same as the original. • Yes rotates copies. (6.100 on the next page) (6.101 on the following page)

Related Commands

3dArray (6.3.2) - creates 3D arrays. Array (6.4.19) - associatively distributes entity copies in an evenly spaced rectangular, polar or path array. ArrayClassic (6.4.22) - creates a static polar or rectangular array of entities through a dialog box. ArrayEdit (6.4.25) - allows editing associative array entities and their source entities. ArrayPath (6.4.26) - associatively distributes entity copies evenly along a path into multiple rows, and levels. ArrayPolar (6.4.41) - associatively distributes entity copies evenly in a circular pattern about a center point or axis of rotation, using multiple rows, and levels. ArrayRect (6.4.28) - associatively distributes entity copies into any number of rows, columns, and levels. MInsert (6.21.15) - inserts arrays of blocks.

6.4.21 Arc

(7.3 on page 6132) Draws arcs by a variety of methods.

Accessing the Command

command bar: **arc** alias: **a** menu bar: **Draw | Arc** toolbar: **Draw |** ribbon: **Draw | Draw | Arc** : **arc Prompts you in the command bar:** Enter start of arc or [Center]: **(Pick a point, enter coordinates, or enter an option)** Enter second point or [Angle/Center/Direction/End/Radius]: **(Pick a point, enter coordinates, or enter an option)** End point: **(Pick a point or enter coordinates)** (6.103 on the following page) **Subsequent uses of this command change the initial prompt to:** Enter start of arc or [Center/Follow] <Follow>: **(Pick a point, enter coordinates, or enter an option)** This command draws arcs by many methods. The full list is in the Draw | Arc menu shown below: (6.104 on the next page) On each Arc icon a large green dot ( ) indicates the first point that you pick. A small green dot ( ) indicates the second point, and a small white dot ( ) indicates the final point.

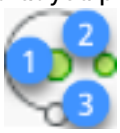

Figure 6.103

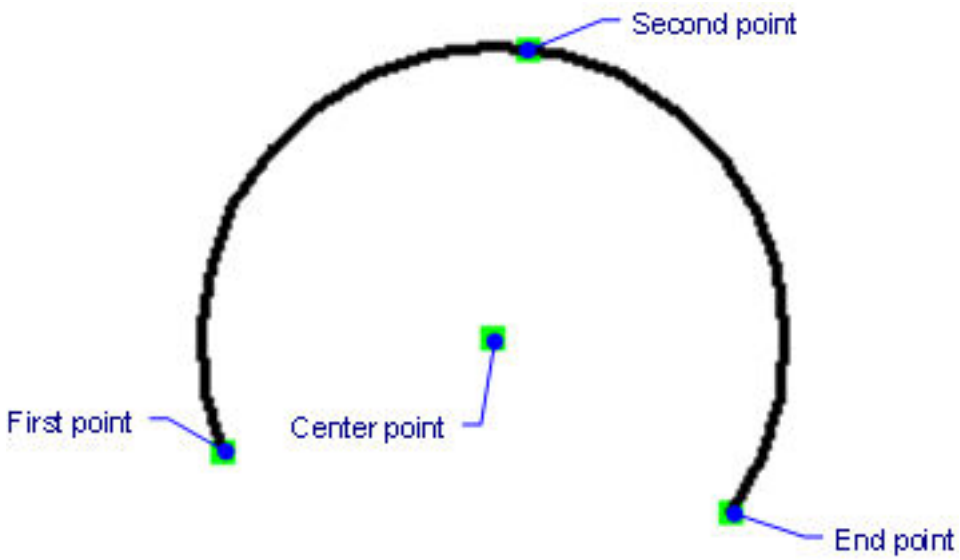

Figure 6.104

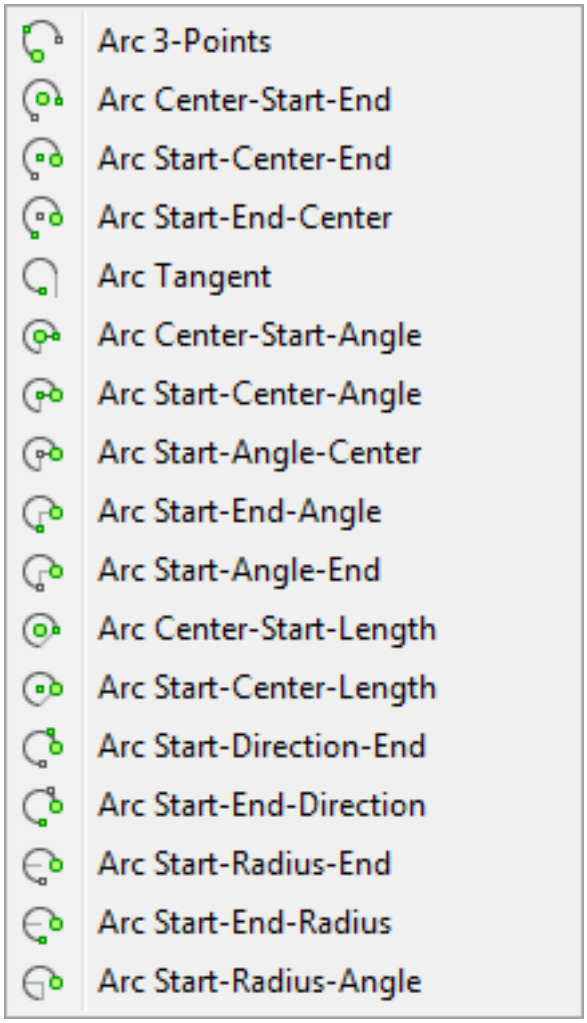


Command Options

Option	Description
ENTER to use last point	Continues the arc tangent from the last point picked.
Center	Specifies the center point of the arc.
Follow	Continues the arc tangent from the last point picked (same as pressing Enter).
Start of arc	Specifies a different start point for the new arc.
Angle (6.106 on page 3429)	Specifies the included angle, the angle between the arc's start point and • Endpoint • Center point
Center  (6.107 on page 3429)	Specifies the center point of the arc; after this, you can specify one of the following to complete the arc: • Endpoint • Included angle • Length of the chord
Direction	Specifies the direction of the tangent to the arc's start point; following this, you specify the following: • End point
End point	Specifies the arc's end point; following this, you can specify the following: • Center point • Included angle • Direction of tangency • Radius
Radius	Specifies the arc's radius; following this, you can specify the following: • Endpoint • Included angle
Second point	Specifies a point along the arc's circumference; following this, you specify the following: • Endpoint

Procedures

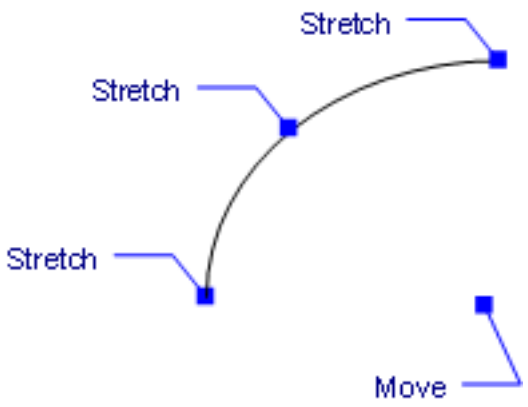
- General procedure to draw an arc (1.25.15)
- Editing an arc (1.25.15)

Grips Editing

Arcs can be edited directly through grips:

1. Select the arc. Notice that it has four grips.
2. Drag the grips to perform the following actions:

Figure 6.105



3. • Drag the endpoint and midpoint grips to stretch the arc.
   • Drag the center grip to move the arc.

(6.105)

Related Commands

Circle (6.9.12) - draws arcs and circles. Ellipse (6.13.5) - draws elliptical arcs. Join (6.18.1) - joins arcs. PEdit (6.24.24) - converts arcs to polylines. PLine (6.24.27) - draws connected polyline arcs. DimRadius (6.11.16) and DimDiameter (6.11.9) - dimensions arcs. Change (6.9.10) - changes the endpoints of arcs. Entity snaps that work with arcs: Center (6.9.3) - snaps to the center of arcs. Endpoint (6.13.7) - snaps to the endpoints of arcs. Quadrant (6.25.7) - snaps to the 90-degree points on the circumference of arcs. Tangent (6.29.10) - snaps to the tangency of arcs.

Command Options

Rectangular Array Option	Description
 Select Entities	To select entities to be arrays: 1. Click the **Select Entities** button () 2. The Array dialog box temporarily closes, and you prompted to to select entities: **Select entities to array** - Select one or more entities 3. Press Enter to return to the dialog box
Rows Count	Specify the number of rows: • Enter a value for the number of rows • Click the spin arrows to increase or decrease the distance Notice that the preview window updates with the number of rows.
 Rows Offset	Specify the offset distance between subsequent rows. A positive offset distance adds rows from left to right, a negative one right to left. Do one of the following: • Type a distance in the **Rows Offset** field. • Click the **Pick Points** button () • The Array dialog box temporarily closes and prompts you: **Vertical distance between rows** - Specify two points in the drawing
Columns Count	Specify the number of columns: • Enter a value for the number of columns. • Click the spin arrows to increase or decrease the distance. Notice that the preview window updates with the number of columns.
 Columns Offset	Specify the offset distance between columns. A positive offset distance adds columns from bottom to top, while a negative distance places columns from top to bottom. Do one of the following: • Type a distance in the **Columns Offset** field. • Click the spin arrows to increase or decrease the distance • Click the **Pick Points** button (). The **Array** dialog box temporarily closes, and then prompts you: **Horizontal distance between columns** - specify two points in the drawing

 Spacing Rectangle	Specifies the spacing between rows and columns with a rectangle that you pick in the drawing: • Length of rectangle = distance between columns • Width of rectangle = distance between rows The distance is measured from the start of one entity to the start of the next. 1. Click the **Pick Points** button () 2. The Array dialog box temporarily closes and prompts you: **Specify spacing rectangle** - specify two points in the drawing.
 Slope Angle	Specifies the angle of the array from the x axis (0 degrees). Do one of the following: • Type an angle in the **Slope angle** field. • Click the **Pick Points** button (). The **Array** dialog box temporarily closes and prompts you: **Select angle of array** - pick two points in the drawing Notice that the preview window updates with the number of columns.

(6.110 on page 3436)

Polar Array Options	Description
 Select Entities	To select entities to be arrays: 1. Click the **Select Entities** button () 2. The Array dialog box temporarily closes, and you prompted to to select entities: **Select entities to array** - Select one or more entities 3. Press Enter to return to the dialog box
Center	Specifies the center point of the array. Do one of the following: • Enter coordinates in the X and Y fields. • Click the **Pick Point** button (). The Array dialog box temporarily closes and you are prompted: **Base/Center of polar array** - specify a point in the drawing.

Angle between	Specifies the angle between each copy of the entity in the array. Do one of the following: • Click the **Calculate** radio button to calculate the angle from the **Angle to fill** and **Number of items**. • Type an angle in the **Angle** field. • Click the **Pick Points** button (). The Array dialog box temporarily closes, and you are prompted: **Specify angle between** - pick a point in the drawing. As you do, a line displays dynamically between your pick point and the previously-selected center point.
Angle to fill	Determines the extent and direction of the array. • Enter 360 for a full circle of copies • Enter a smaller number to draw a partial polar array • Enter a positive angle to draw the array counter clockwise • Enter a negative number to draw the array clockwise Do one of the following: • Click the **Calculate** radio button to calculate the angle from **Angle between** and **Number of items** . • Type an angle in the **Angle** field. • Click the **Pick Points** button (). The Array dialog box temporarily closes and prompts you: **Specify angle between** - pick a point in the drawing. As you do, a line displays dynamically between your pick point and the previously-selected center point.
Number of items	Specifies the number of items in the array. Do one of the following: • Click the **Calculate** radio button to calculate the angle from the **Angle between** and **Angle to fill** . • Enter a number larger than 1. Notice that the preview window updates with the number of items.
Rotate items as copied	Determines whether copies are rotated when they are arrayed: • **No** - does not rotate entities; all copies have the same orientation as the original • **Yes** - rotates copies

Entity base point	Relocates the base point of the selected entities. Do one of the following: • Check the **Use Default** option (= lower left corner of the selection set bounding box). • Click the **Pick Point** button (). The Array dialog box temporarily closes and prompts you: **Base/Center of polar array** - specify a point in the drawing.

Related Commands

3dArray (6.3.2) - creates 3D arrays. -Array (6.4.20) - creates a polar or rectangular array of entities; displays prompts at the command bar. Array (6.4.19) - associatively distributes entity copies in an evenly spaced rectangular, polar or path array. ArrayEdit (6.4.25) - allows editing associative array entities and their source entities. ArrayPath (6.4.26) - associatively distributes entity copies evenly along a path into multiple rows, and levels. ArrayPolar (6.4.41) - associatively distributes entity copies evenly in a circular pattern about a center point or axis of rotation, using multiple rows, and levels. ArrayRect (6.4.28) - associatively distributes entity copies into any number of rows, columns, and levels. MInsert (6.21.15) - inserts arrays of blocks.

Figure 6.111

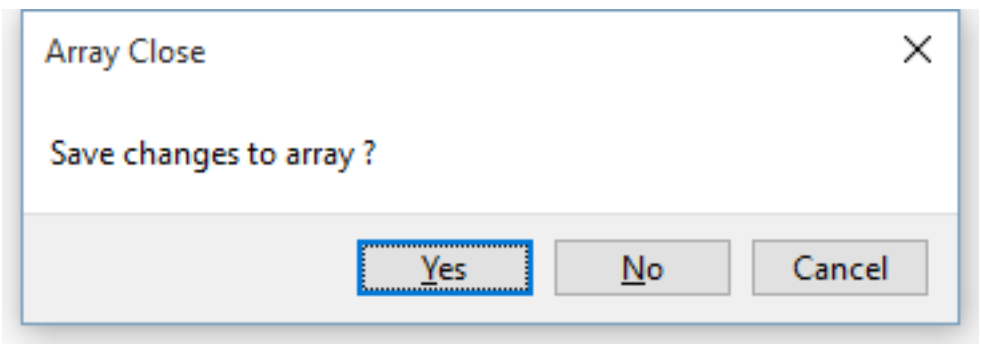
6.4.23 ArrayClose

(7.3 on page 6132) Exits the associative array editing state, displaying a dialog box to save or discard the changes made to the array's source entities. **Note:** This command is available only after an associative array is checked out with ARRAYEDIT (6.4.25) command.

Accessing the Command

command bar: **arrayclose** : **arrayclose** Displays a dialog box: (6.116 on page 3443)

Figure 6.112



Command Options

Option	Description
Yes	Saves the changes made to the source entities of the array and exits the array editing state.
No	Exits the array editing state and discards all changes, thus returning to the original state of the array.
Cancel	Closes the dialog box and stays in the array editing state.

Related Commands

ArrayEdit (6.4.25) - allows editing associative array entities and their source entities. -ArrayClose (6.4.24) - Exits the array editing state and prompts you in the command bar to save or discard the changes made to the array source entities.

Figure 6.113

6.4.24 -ArrayClose

(7.3 on page 6132) Exits the array editing begun by the ARRAYEDIT (6.4.25) command, after prompting you at the command line to save or discard the changes you made to the source entities in the array; applies to associative arrays only.

Accessing the Command

 command bar: **-arrayclose** Quad: **Modify|** and : **-arrayclose Prompts you in the command bar:** Save changes to array? [Yes/No] <Yes>: **(Type Y or N)**

Command Options

Option	Icon	Description
Yes		Saves the changes made to the source entities of the array, and then exits the array editing state.
No		Exits the array editing state and discards all changes, thus returning the array to its original state.

Related Commands

ArrayEdit (6.4.25) - edits the entity(ies) that make up associative array. ArrayClose (6.4.23) - exits the array editing mode, and displays a dialog box to save or discard the changes made to the array source entities.

Figure 6.114

6.4.25 ArrayEdit

(7.3 on page 6132) Edits the entities that make up associative arrays.

Accessing the Command

command bar: **arrayedit** menu bar: **Modify | Array | Edit Array** toolbar: **Arrays |** : **arrayedit Prompts you in the command bar.** Select associative array: **(Select an array entity) The following prompts depend on the type of the selected array entity -- rectangular, path or polar.** Rectangular Array Options [Source/REPlace/Base point (6.4.28)/Rows (6.4.28)/COLumns (6.4.28)/Levels (6.4.28)/RESet/eXit]<eXit>: **(Select an option)** Path Array Options [Source/REPlace/Method (6.4.26)/Base point (6.4.26)/Items (6.4.26)/Rows (6.4.26)/Levels (6.4.26)/Align items (6.4.26)/Z direction (6.4.26)/RESet/eXit]<eXit>: **(Select an option)** Polar Array Options [Source/REPlace/Base point (6.4.41)/Items (6.4.41)/Angle between (6.4.41)/Fill angle (6.4.41)/Rows (6.4.41)/Levels (6.4.41)/ROTate (6.4.41)/RESet/eXit]<eXit>: **(Select an option)**

Command Options

Option	Description
Source	Edits the source entities of the array. Prompts you: 1. **Select item in array - (select one of the items in the selected array entity.)** 2. Displays a dialog box: (6.115 on the following page) 3. Click the **OK** button on the **Array Editing State** dialog box. 4. Notice that only the selected item in the array is now displayed so that you can modify, add, and delete entities. 5. When done, type ArrayClose (6.4.23) at the command prompt; a message box displays: (6.116 on page 3443) 6. Click the **Yes** button. Notice that all the items of the array are now displayed. The change(s) you made to the one item are applied to all items in the array.

Replace	Replaces some or all items in the array. Prompts you: **Select replacement objects - (select one or more entities) Entities in set: 1 Select replacement objects - (select more entities, or press Enter to end entity selection) Enter base point of replacement objects or [Key point] <centroid> - (do one of the following actions)**: • Press Enter to use the centroid (center point) of the selection • Specify a point. • **Select key point on replacement object as base point** - when you move the cursor over the selected entities, all keypoints highlight one by one. Click to select a keypoint. **Select an item in the array to replace or [Source objects] - (do one of the following):** • Select one or more items in the array • **Source objects** - replaces all items
Reset	Restores erased entities, and removes any item overrides. Hold the **Ctrl** key to select more than one item in the associative array, then tap the **Delete** key to erase the selection.
Exit	Accept the changes and conclude the command.

Related Commands

6.4.26 ArrayPath

(7.3 on page 6132) Associatively distributes entity copies evenly along a path into multiple rows, and levels.

Accessing the Command

command bar: **arraypath** menu bar: **Modify | Array | Path Array** toolbar: **Modify | Arrays |** ribbon: **Sketch | Arrange |** (Mechanical and SheetMetal workspaces) ribbon: **Solid | Edit |** (Mechanical and SheetMetal workspaces) ribbon: **Model | Modify 3D |** (BIM workspace) ribbon: **Change | Arrange |** (BIM and 3D Modeling workspaces) : **arraypath Prompts you in the command bar:** Select entities to array: **(Select an entity)** Entities in set: 1 Select entities to array: **(Select more entities, or else press Enter to end entity selection)** Type = Path, Associative = Yes Select path curve: **(Select an entity -- line, polyline, arc, circle, ellipse, elliptical arc, spline, helix, or 3D polyline)** [ASsociative/Method/Base point/Tangent direction/Items/Rows/Levels/Align items/Z direction/eXit]<eXit>: **(Enter an option, or else press Enter to end the command)**

Command Options

Option	Description
Associative	Determines whether an array entity is created or a series of copies of the selected entities. The default setting is saved by the ARRAYASSOCIATIVITY (1.17.10) system variable. Prompts you: **Create associative array? [Yes/No]<Yes> - (enter an option):** • **Yes** : An Array entity is created. • **No** : A series of copies of the selected entities is created. Parameters for associative arrays can be specified with parametric expressions set in the Array properties, found in bottom part of the Mechanical Browser (3.3.2), Properties panel (6.24.54), or though the ARRAYEDIT (6.4.25) command. The **End offset** parameter is available only when the Method = Divide. (6.118 on page 3448) Entities making up associative array are modified with the ARRAYEDIT (6.4.25) command.
Method	Specifies how to distribute entities along the path. Prompts you: **Enter path method or [Divide/Measure]<Measure>** - **(choose an option)**: • **Divide** - distributes a specified number of items evenly-spaced along the path • **Measure** - places a sufficient number of items along the path, separated by the interval specifie
Base point	Sets the base point of the array. Items are placed relative to the base point. Prompts you: **Enter base point** - **(specify a point in the drawing)**

Tangent direction	Determines how the items are aligned relative to the starting direction of the path. Prompts you: **Select first point of tangent direction vector or [Normal] - (enter an option)**: • **2 points** - specify two points that define the tangency of the first item relative to the starting direction of the path. Depending on the Align Items setting, the other items are placed parallel to the first item or at the specified tangent direction relative to the direction of the path; see figures below, where the blue arrowhead indicates the tangency direction: (6.119 on page 3449) • **Normal** - orients the Z direction of the first item with the starting direction of the path; see figure below: (6.120 on page 3449)
Items	Specifies the number of items or the distance between items, depending on the Method setting. • **Divide method prompts you:** (**Enter number of items along path <xxx>) -** specifies the number of items in the array. • **Method Measure method prompts you: (Enter the distance between items along path <xxx>)** - Specify a distance by entering a value or picking two points. (xxx == maximum number items possible) **Enter number of items or [Fill entire path] <xxx> - (enter an option):** • **Enter a number of Items** - places items along the entire path at the specified distance. This option allows you to specify a smaller number if you only want to place items along a portion of the path. • **Fill entire path** - fills the entire path with items at the given spacing; the number of items changes should the length of the path be modified, such as by grips editing; see below.

Rows	Specifies the number of rows in the array, the distance between them and the incremental elevation. Prompts you: 1. **Enter the number of rows <1>** - **(specify the number of rows)** 2. **Enter the distance between rows or [Total] <1.0>** - **(enter an option):** • **Distance** - specify the distance between subsequent rows by entering a value or picking two points • **Total** - specify the distance between the first and the last row. 3. **Enter the incrementing elevation between rows <0.0>** - **(defines the increasing or decreasing elevation for each subsequent row.)**
Levels	Create 3D arrays by specifying the number and spacing of levels. (6.121 on page 3450) Prompts you: 1. **Enter the number of levels <1>** - **(specifies the number of levels)** 2. **Enter the distance between levels or [Total] <xxx>** - **(enter an option)** • **Distance** - specifies the distance between subsequent levels • **Total** - specifies the distance between the bottom and the top level
Align items	Specifies whether to align each item tangent to the path's direction. Alignment is relative to the first item's orientation. Prompts you: **Align arrayed items to path? <Yes>/No>** - **(enter an option):** • **Yes** - each item is placed tangent to the path direction; see top figure below • **No**- each item keeps the orientation of the first item; see bottom figure below (6.122 on page 3450)
Z direction	Determines whether to maintain the items' original Z direction or to bank the items naturally along a 3D path. Prompts you: **Maintain Z direction for all items in the array? [Yes/No]<Yes>** - **(enter an option:)** • **Yes** - Z-direction (vertical) is maintained; see figure below at left • **No** - items banked along the helix; see figure below at right (6.123 on page 3451)
Exit	Accept the current settings and conclude the command.

Grips Editing

When grips editing the path, the array entity is recreated along the modified path.

(6.124 on page 3451) Editing the path length.	(6.125 on page 3452) Editing the path shape.

6.4.27 ArrayEditExt

(7.3 on page 6132) Provides additional editing of associative arrays:

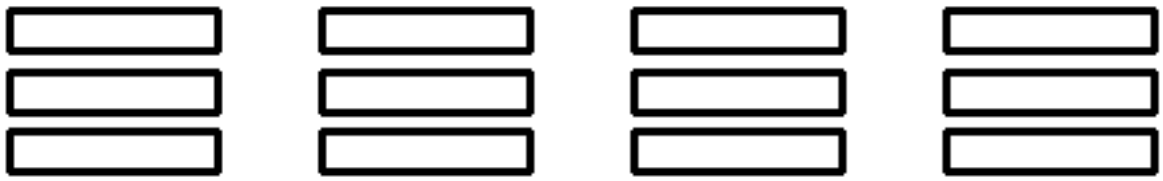
- For all elements of the array, interactively adjusts the spacing between them, and changes the number of elements
- For an individual element in the array, moves (offsets), scales, rotates, or deletes it.

Note: Arrays edited by this command must have been made associatively by the Array (6.4.19) command; it does not work with arrays created by the ArrayClassic (6.4.22) or -Array (6.4.20) commands.

Accessing the Command

command bar: **arrayeditext** : **arrayeditext Prompts you in the command bar:** Select option [SPacing/REsizing/Offset item/Scale item/Rotate item/Delete item]: **(Enter an option)** Select item in array: **(Select a single entity from an associative array)** Original associative array for the examples illustrated below: (6.127)

Figure 6.127



Command Options

Option	Description
SPacing	Adjusts the spacing of an entire associative array interactively; prompts you: 1. **Select item in array** - **(select one element of the array; the entire array will be re-spaced)** 2. **Enter radius and angle between items** - **(enter an option):** • Move the cursor to change the spacing and radius • Enter a distance value at the prompt (a value for the angle is ignored) (6.128 on the next page)
REsizing	Resizes the entire array by adding an removing entities interactively; prompts you: 1. **Select item in array** - **(select one element of the array)** 2. **Enter new number of items** - **(enter an option):** • Move the cursor to change the size • Enter a number for how many items the array should hold (6.129 on page 3456)
Offset item	Moves one entity of an associative array to a different location; prompts you: 1. **Select item in array** - **(select the entity you wish to move)** 2. **Enter base point or center** - **(pick a point from which to move the entity, or enter x,y coordinates)** 3. **Enter displacement vector** - **(pick a point to which to move the entity„ or enter x,y coordinates)** (6.130 on page 3456)
Scale item	Resizes an entity of an associative array; prompts you: 1. **Select item in array** - **(select the entity you wish to resize)** 2. **Enter base point or center** - **(specify the point from which the scaling takes place)**; the entity will move towards or away from the host array, depending on the location of the base point **Enter scale** - **(move the cursor, or enter a scale factor; numbers larger than 1 make the entity larger, numbers smaller than 1 make it smaller)** (6.131 on page 3456)

Rotate item	Rotates an entity of an associative array; prompts you: 1. **Select item in array - (select the entity you wish to rotate)** 2. **Enter base point or center - (specify the point about which the rotation takes place; the entity will rotate around the host array, depending on the location of the base point)** 3. **Enter rotation angle - (move the cursor, or enter an angle; positive numbers rotate counter clockwise, negative numbers rotate clockwise)** (6.132 on the next page)
Delete item	Deletes an entity of an associative array; prompts you: **Select item in array - (erases the entity, without warning; use the U command to return it, if you erased it by accident)** (6.133 on the following page)

(7.3 on page 6132) Associatively distributes copies of entities into any number of rows, columns, and levels.

Accessing the Command

 command bar: **arrayrect** menu bar: **Modify | Array | Rectangular Array** toolbar: **Arrays** ribbon:

- **Sketch | Arrange** (Mechanical and SheetMetal workspaces)
- **Solid | Edit** (Mechanical and SheetMetal workspaces)
- **Model | Modify 3D** (BIM workspace)
- **Change | Arrange** (BIM and 3D Modeling workspaces)

: **arrayrect Prompts you in the command bar:** Select entities to array: **(Select an entity)** Entities in set: 1 Select entities to array: **(Select more entities, or else press Enter to end entity selection)** Type = Rectangular, Associative = Yes [ASsociative/Base point/COUnt/Spacing/COLumns/Rows/Levels/eXit]<eXit>: **(Enter an option, or else press Enter to end the command)**

Command Options

Option	Description
Associative	Determines whether an array entity is created or a series of copies of the selected entities. The default setting is saved by the ArrayAssociativity (1.17.10) system variable. Prompts you: **Create associative array? [Yes/No]<Yes>** - **(enter an option):** • **Yes** - creates an associative array, which can be edited later with the ArrayEdit (6.4.25) command • **No** - creates a non-associative array, which consists of copies of the entities laid out in a pattern The associative arrays parameters can be specified using a parametric expressions. Expressions can be set in the array properties in bottom part of the Mechanical Browser (3.3.2), Properties panel (6.24.54) or via the ArrayEdit (6.4.25) command. (6.135 on page 3460)
Base point	Sets the base point of the array. Prompts you: **Enter base point** - **(specify a point in the drawing.)** Items are placed relative to the base point.
Count	Specifies the number of rows and columns. Prompts you: 1. **Enter the number of columns <xx>** - **(type a value, or else press Enter to accept the current number.)** 2. **Enter the number of rows <xx>** - **(type a value, or else press Enter to accept the current number)**

Spacing

Specifies the spacing between columns and/or rows. Prompts you: **Enter the distance between columns or [Unit cell] <xx.x>** - **(type a value, or else press Enter to accept the current spacing)** Unit cell option prompts you:

1. **Select first point of unit cell** - **(Specify a point).** A rectangle is displayed dynamically. (If dynamic input is on, then the width and height of the spacing rectangle are displayed.)
2. **Opposite corner** - **(specify a point, or else enter the desired column and row spacings in the dynamic entry fields. Press the Tab key to switch back and forth between the entry fields, and then press Enter to confirm the values.)**

Columns

Specifies the number of columns and the spacing between subsequent columns. Prompts you:

1. **Enter the number of columns <xx>** - **(type a value, or else press Enter to accept the current number.)**
2. **Enter the distance between columns or [Total] <xx.x>** - **(enter an option:)**
   - **Distance** - specifies the distance between subsequent columns
   - **Total** - specifies the distance between the first and the last column

Rows

Specifies the number of rows and the spacing between subsequent rows. Prompts you:

1. **Enter the number of rows <xx>** - **(type a value, or else press Enter to accept the current number.)**
2. **Enter the distance between rows or [Total] <xx.x>** - **(enter an option)**:
   - **Distance** - specify the distance between subsequent rows
   - **Total** - specifies the distance between the first and the last row
3. **Enter the incrementing elevation between rows <0.0>** - **(specifies the increasing or decreasing elevation for each subsequent row.)**

Levels	Creates 3D arrays by specifying the number and spacing of levels. (6.136 on the next page) Prompts you: 1. **Enter the number of levels <1>** - **(specifies the number of levels)** 2. **Enter the distance between levels or [Total] <xxx>** - **(enter an option):** • **Distance** - specifies the distance between subsequent levels by typing a value or picking two points. • **Total** - specifies the distance between the bottom and the top level
Exit	Accept the current settings and conclude the command.

Related Commands

3dArray (6.3.2) - creates 3D arrays. -Array (6.4.20) - creates a polar or rectangular array of entities; displays prompts at the command bar. Array (6.4.19) - associatively distributes entity copies in an evenly spaced rectangular, polar or path array. ArrayClassic (6.4.22) - creates a static polar or rectangular array of entities through a dialog box. ArrayEdit (6.4.25) - allows editing associative array entities and their source entities. ArrayPath (6.4.26) - associatively distributes entity copies evenly along a path into multiple rows, and levels. ArrayPolar (6.4.41) - associatively distributes entity copies evenly in a circular pattern about a center point or axis of rotation, using multiple rows, and levels. Blockify (6.6.13) - automatically detects equally shaped solids in a model and replaces them by block references. Searches the drawing for an identical set of entities (2D and 3D) and replaces them by block references. Optionally replaces block patterns by arrays. MInsert (6.21.15) - inserts arrays of blocks. -BmParameters (6.8.25) - allows to list and edit the parameters of inserted components and associative array.

6.4.29 AttachmentsPanelClose

(6.2981 on page 6079) Closes the Attachments panel.

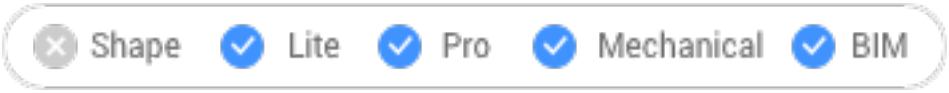
Accessing the Command

command bar: **attachmentspanelclose** : **AttachmentsPanelClose** BricsCAD closes the Attachments panel. Reopen it with the AttachmentsPanelOpen command.

Related Commands

AttachmentsPanelOpen (6.4.30) - opens the Attachments panel to control DWG, PDF, image, and point cloud attachments.

Figure 6.138



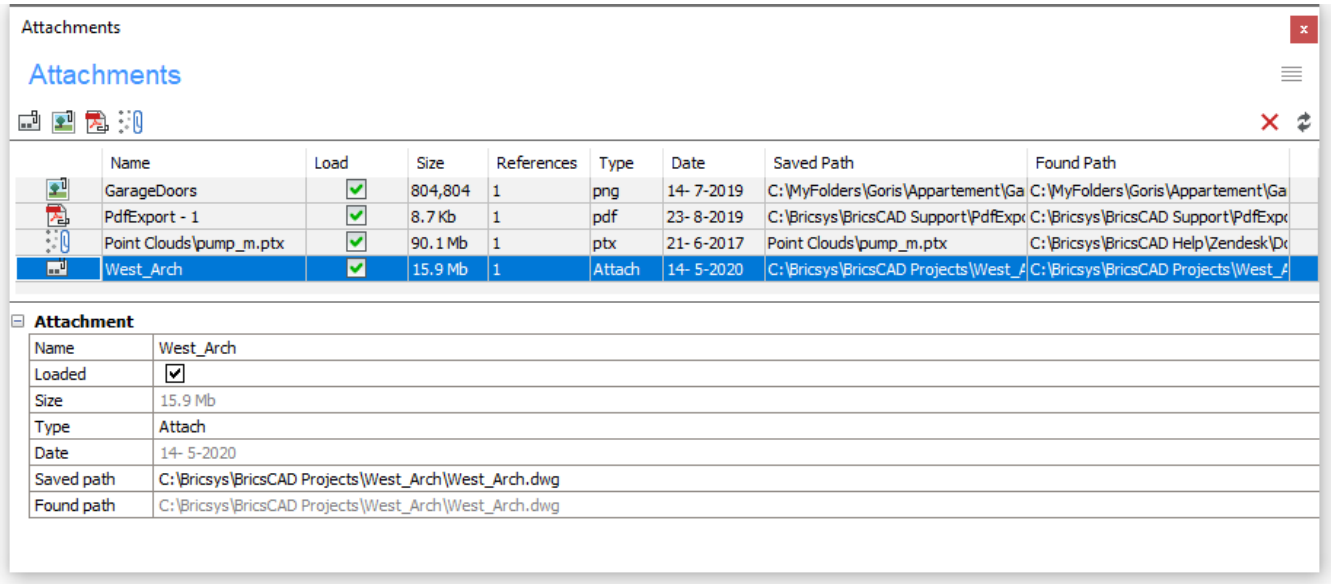
6.4.30 AttachmentsPanelOpen

(6.2947 on page 6049) Displays the Attachments panel for managing external references (DWG), raster images, PDF files, and point clouds that are attached to the current drawing.

Accessing the Command

command bar: **attachmentspanelopen** : **attachmentspanelopen** Displays the Attachments panel with a list of files attached to the current drawing. (6.139 on the facing page)

Figure 6.139



Command Options

Options	Description
Attach DWG	Displays the Open File to Attach dialog box like the -XRef (6.34.8) command
Attach Image	Displays the Select Image File dialog box like the ImageAttach (6.4.29) command
Attach PDF	Displays the Select PDF Underlay File dialog box like the PDFAttach (6.24.17) command
Attach Point Cloud	Displays the Preprocessed Point Cloud Data File dialog box like the PointCloudAttach (6.24.35) command
Detach	Detaches the selected attachment from the drawing
Refresh	Updates the display.
Load	Toggles the display of the attachment in the drawing; turn off to hide the attachment
Saved Path	Allows to reset the path to the external reference. Click the Browse button (...), then select the source document in a File dialog.

Procedures

To open or close a panel (1.15.7)

Related Commands

AttachmentsPanelClose (6.4.29) - closes the Attachments panel. ImageAttach (6.34.8) - attaches raster images to the current drawing. PDFAttach (6.24.17) - attaches PDF files to the current drawing. PointCloudAttach (6.24.35) - attaches BPT processed point cloud files to the current drawing. - (6.34.8)XRef (6.4.29) - attaches drawing files to the current drawing.

Figure 6.140

6.4.31 AttDef

(6.2981 on page 6079) Defines how a block's attributes will be created through a dialog box.

Accessing the Command

 command bar: **attdef** aliases: **at**, **ddattdef** menu bar: **Tools | Attributes | Define Attributes** toolbar: **Attributes** |  ribbon: **Insert | Blocks | Define Attributes** : **attdef** Displays a dialog box: (6.141 on the facing page) Enter options, and then click **OK**. To create and use attributes, follow these steps:

1. Use this command to define attributes.
2. Use the Block (6.6.11) command to combine attributes and symbols into a block.
3. Use the Insert (6.17.13) command to insert the blocks, answering the prompts with data with attributes.
4. When it is necessary to edit the values of the attributes, use the AttEdit (6.4.34) command.
5. To extract attribute values to external data files, use the AttExt (6.4.38) or DataExtraction (6.10.4) commands.

(6.142 on the next page) You can use the AttDisp (6.4.33) command to toggle the display of attributes in drawings on and off.

Figure 6.141

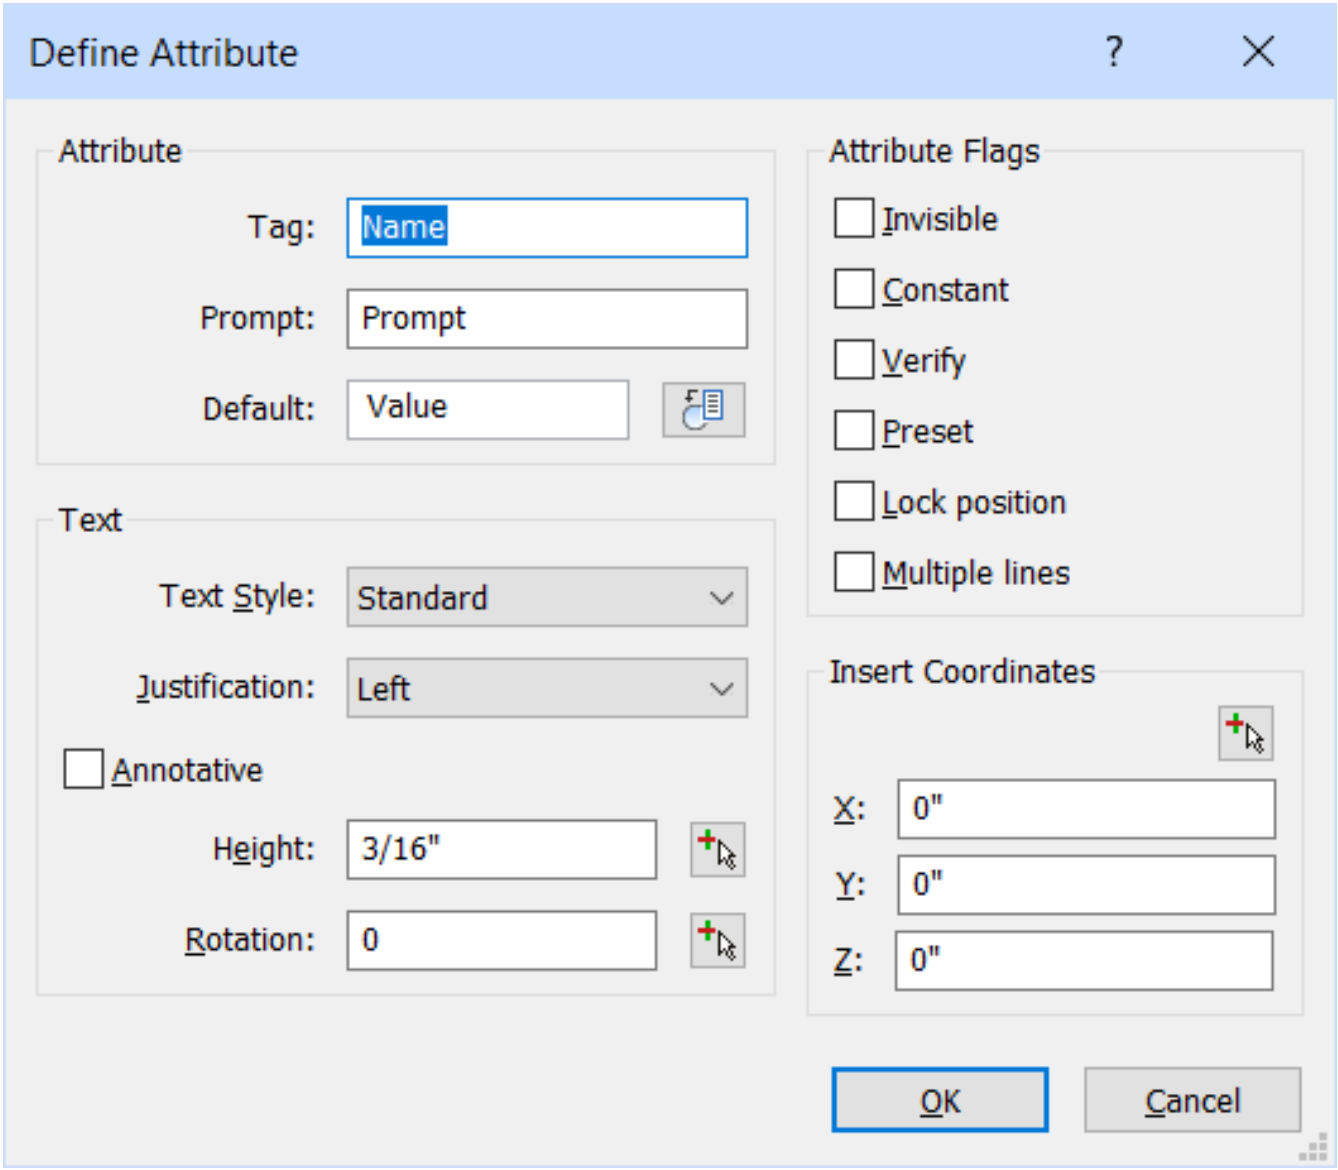


Figure 6.142

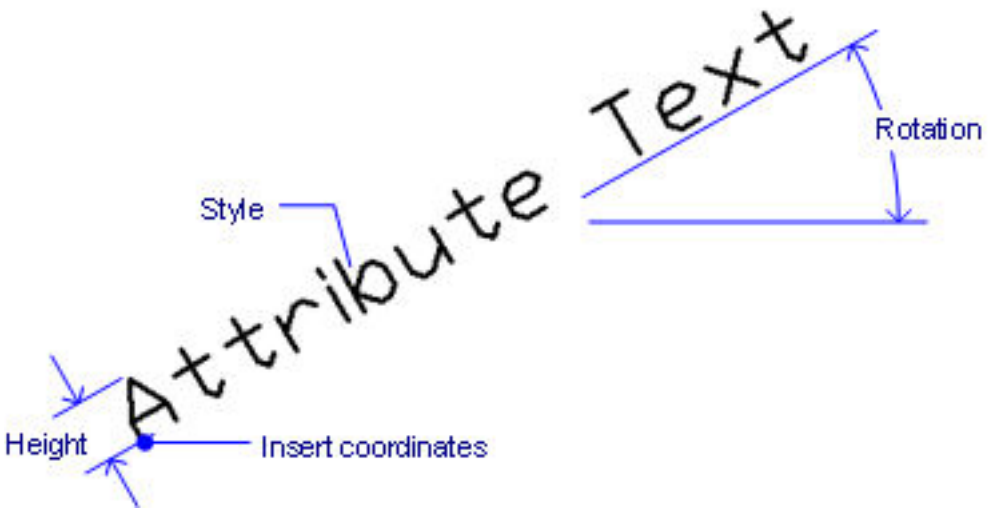

Command Options

Attribute Options	Description
Tag	Specifies the name of the attribute; this is the name by which BricsCAD identifies the attribute. You can use up to 255 letters, numbers, and punctuation.
Prompt	Specifies the user prompt; this is displayed at the command prompt when the attribute is later inserted in the drawing. You can leave this field blank; BricsCAD uses the tag as the prompt during attribute insertion.
Default	Specifies the default value; this is displayed in angle brackets, like <360>. As with other defaults, the user need only press Enter to accept this value. Click the **Insert Field** button () to assign a field value to the attribute (see the FIELD (6.14.7) command).

Text Options	Description
Text Style	Specifies the text style for the attribute text; choose from one of the styles defined in the drawing. (You can create additional text styles with the **Style (6.27.55)** command.)
Justification	Specifies the justification of the attribute text, such as Center or Fit.
 Height	Specifies the height of the attribute text, unless overridden by the text style. Enter a value, or click the button to pick two points in the drawing: 1. Dismisses the dialog box temporarily. 2. Prompts you at the command prompt **Select text height** - enter a value, or pick two points in the drawing
 Rotation	Specifies the rotation angle of the rotation text. Enter a value, or click the button to pick two points in the drawing: 1. Dismisses the dialog box temporarily. 2. Prompts you at the command prompt **Select text angle** - enter an angle, or pick two points in the drawing.
Annotative	Sets the Annotative property of the attribute text.

Attribute Flags Options	Description
Invisible	Hides the attributes from view; they are not displayed and not printed. Hidden attributes can, however, be displayed with the **AttDisp (6.4.33)** command.
Constant	Specifies a default value that the user cannot change.
Verify	Forces the user to enter the value a second time; this helps to ensure the value is entered correctly.
Preset	Inserts attributes without prompting the user; the attributes can be changed later with the **AttEdit (6.4.34)** command.

Lock Position	**On** - locks the position of the attribute within the block reference. **Off** - unlocked attributes can be moved relative to the rest of the block using grip editing.
Multiple lines	**On** - allows the use of multiline text **Off** - limits text to a single line When the **Multiple lines** flag is checked, the button (...) displays next to the dimmed **Default** text field. (6.143) When you click the button, the **Define Attribute** dialog box temporarily closes to let you define a multiline text entity. Prompts you: **Specify location of multiline attribute** - specify a point, and then the MTEXT (6.21.38) command launches. Type the text for the attribute, then click the **OK** button on the Text Formatting toolbar to return to the Attribute Definition dialog box.

Insert Coordinates Options	**Description**
Insert Coordinates	Dismisses the dialog box temporarily, and then prompts you at the command prompt: **Select insertion point** - enter coordinates, or pick a point in the drawing.
X	Specifies the x coordinate of the attribute's insertion point.
Y	Specifies the y coordinate.
Z	Specifies the z coordinate.

Procedures

- Defining attributes (1.30.13)

Related Commands

-AttDef (6.4.32) - defines attributes through the command bar. AttDisp (6.4.33) - toggles the display of attribute text. AttEdit (6.4.34) - edits attribute values and properties. -AttExt (6.4.35) - extracts attributes from drawings to data files through the command bar. AttRedef (6.4.36) - redefines a block and updates associated attributes. AttSync (6.4.37) - synchronizes attribute definitions in all block references of a specified block definition. BattMan (6.6.1) - manages the attributes of a block definition. Block (6.6.11) and -Block (6.6.12) - create blocks from attribute definitions and entities. DataExtraction (6.10.4) - exports entity properties, block attributes and drawing information to a an external file. DdAtte (6.10.14) - edits the values of attributes through a dialog box. EAttEdit (6.13.1) - edits attribute values and most properties. Explode (6.13.16) - reduces attributes to tags. Field (6.14.7) - inserts a field in a multiline text, table cell or attribute. Insert (6.17.13) - inserts blocks and prompts for attribute values through a dialog box. -Insert (6.17.14) - insert blocks and prompts for attribute values through the command bar. InsertAligned (6.17.15) - inserts blocks repeatedly, and inserts mirrored blocks. Properties (6.24.54) - edits attribute values and properties. RefEdit (6.26.13) - edits blocks and attributes in-place.

Figure 6.143

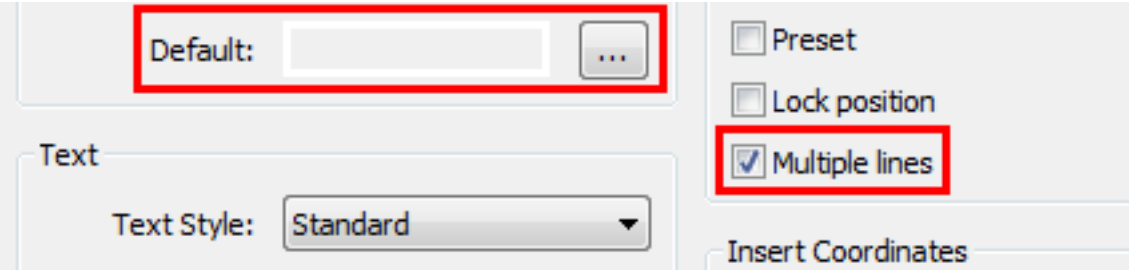

Figure 6.144

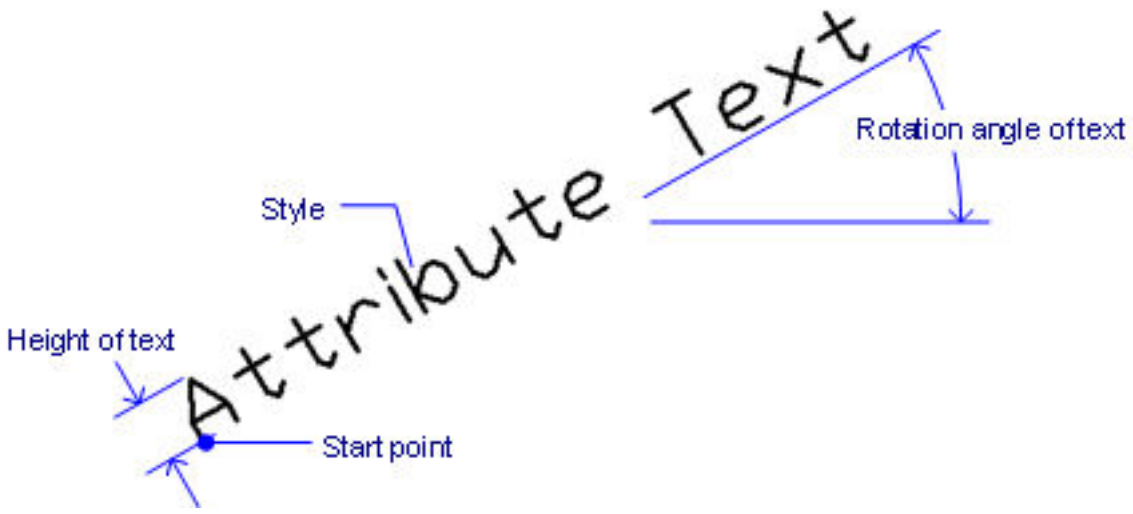
6.4.32 -AttDef

(6.2981 on page 6079) Defines attribute data (used by blocks) at the command prompt. This command is meant for use by macros, scripts, and LISP routines. To specify attributes with a dialog box, use the **AttDef (6.4.31)** command.

Accessing the Command

command bar: **-attdef** : **-attdef Prompts you in the command bar:** Toggle attribute modes : Constant=Off Invisible=Off Preset=Off Verify=Off Lock position=Off Multiple lines=Off <done>: **(Enter an option, or else press Enter to continue)** Name of attribute: **(Enter a name of up to 255 characters)** Prompt: **(Enter a prompt of up to 255 characters)** Default text: **(Enter a default value of up to 255 characters)** Text: Style/Align/Fit/Center/Middle/Right/Justify/<Start point>: **(Pick a point, or enter an option)** Height of text <0.2000>**: (Enter a value, or else press Enter to accept the default height)** Rotation angle of text <0>: **(Enter a value, or press else Enter to accept the default)** (6.145)

Figure 6.145



Command Options

Toggle Attribute Modes Options	Description
Constant	Type **C** , then press Enter to toggle the constant mode: • **Off** - users can change the value of the attribute • **On** - users cannot change the value.
Invisible=Off	Type **I** , then press Enter to toggle the invisibility mode: • **Off** - displays the attribute in the drawing • **On** - hides the attribute Invisible attributes are not displayed nor printed, but can be displayed with the AttDisp (6.4.33) command.
Preset=Off	Type **P**, then press Enter to toggle the prest mode: • **Off** - prompts the user to enter values • **On** - inserts attributes automatically, without prompting the user The value of attributes can be changed later with the AttEdit (6.4.34) command.
Verify=Off	Type **V**, then press Enter to toggle the verify mode: • **Off** - user enters the attribute value once • **On**- forces the user to enter the value a second tim to ensure the value is entered correctly
Lock position=Off	Type **L**, then press Enter to toggle the lock-position mode: • **Off** - users can move attributes using grip editing • **On** - locks the position of the attribute within the block reference
Multiple lines=Off	Type **M**, then press Enter to toggle the multiple-lines mode: • **Off** - forces the use only of single-line text • **On** - allows the use uses multiline text

Additional Options	Description
Name of attribute	Specifies the tag of the attribute; this is the name by which BricsCAD identifies the attribute. You can use up to 255 letters, numbers, and punctuation.
Prompt	Specifies the user prompt; this is displayed at the command prompt when the attribute is later inserted in the drawing. You can leave this field blank; BricsCAD uses the tag as the prompt during attribute insertion.
Default text	Specifies the default value, which is displayed in angle brackets, such as <360>. As with other defaults, you need need only to press Enter to accept this value. If the **Multiple lines** mode is on, you are prompted: **Next line or <done>** - **(type the next line of the Mtext, or else press Enter to stop.)**

Text	Specifies the style and justification of the text: • **Style** - specifies the name of the text style; enter the name of a style present in the drawing • **Align** - aligns the text between two points; the text height is adjusted to maintain its aspect ratio • **Fit** - aligns the text between two points; the text height is maintained • **Center** - centers the text's baseline on the pick point • **Middle** - centers the text on the pick point • **Right** - right justifies the text • **Justify** - accesses additional justification options. • **Start point** - left-justifies the text
Height of text	Specifies the height of the attribute text, unless overridden by the text style or justification. Enter a value, or pick two points to indicate the height.
Rotation angle of text	Specifies the rotation angle of the rotation text. Enter a value, or pick two points to indicate the angle relative to the positive x axis.

Related Commands

RefEdit (6.26.13) - edits blocks and attributes in-place.

Figure 6.146

6.4.33 AttDisp

(6.2981 on page 6079) Toggles the display of attribute text in the drawing, between turn all off, turn all on, or turn on only non-visible ones.

Accessing the Command

command bar: **attdisp** transparent: **'attdisp** alias: **ad** menu bar: **Tools | Attributes | Attribute Display** toolbar: **Attributes |** ribbon: **Insert | Blocks | Attribute Display** : **attdisp Prompts you in the command bar:** Attribute display mode [ON/OFf/Normal] <Normal>: **(Enter an option)** When attributes are off or invisible, they do not display in the drawing and are not plotted.

Command Options

Option	Description
Attribute display mode	Changes the display of attribute values: • **ON** - displays all attributes, including those set to invisible mode by the AttDef (6.4.31) command • **OFF** - hides all attributes • **Normal** - displays attributes, except those set to invisible mode

Related Commands

DataExtraction (6.10.4) - exports entity properties, block attributes and drawing information to a an external file. Insert (6.17.13) - inserts blocks and prompts for attribute values through a dialog box. -Insert (6.17.14) - insert blocks and prompts for attribute values through the command bar. Properties (6.24.54) - edits attribute values and properties. RefEdit (6.26.13) - edits blocks and attributes in-place.

Figure 6.147

6.4.34 AttEdit

(6.2981 on page 6079) Edits the values and properties of attributes. This command is meant for editing attributes globally with macros, scripts, and LISP routines. For editing individual attributes, it is easier to use the dialog box of the EAttEdit (6.13.1) command.

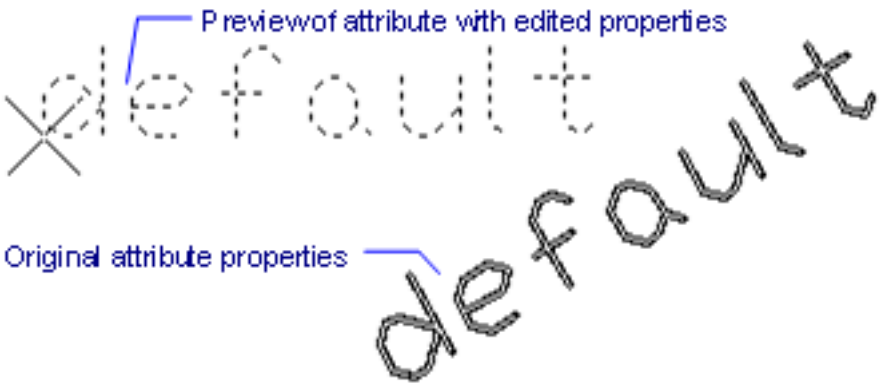
Accessing the Command

 command bar: **attedit** alias: **-ate** menu bar: **Tools | Attributes | Edit Attributes** toolbar: **Attributes |**  ribbon: **Insert | Blocks | Edit Attributes** : **attedit Prompts you in the command bar:** Edit attributes one at a time? [Yes/No] <Yes>: **(Enter Y or N)**

- Y (yes) - edits attributes one at a time; allows changes to values and properties
- N (no) - edits attributes globally; allows changes to values only

As you change the attribute text, the program previews them: (6.148) **To edit the values and all properties of attribute text one attribute at a time:** Edit attributes one at a time? <Y> **(Press Enter to edit them one at a time)** Edit attributes of which blocks? <*>: **(Press Enter for all, or else specify the names of specific block)** Edit attributes with these names <*>: **(Press Enter for all, or else specify the individual attribute tag names)** Edit attributes with this text <*>: **(Press Enter for all, or else specify specific attribute values)** Select attributes: **(Select one or more attributes)** Entities in set: 1 Select attributes: **(Press Enter to end entity selection)** 1 attributes were selected. [Position/Angle/Text/Style/Color/Height/Layer/Next/pRev/Quit]<Next>: **(Enter an option, or else press Enter to exit the command) To edit the values of all attributes:** Edit attributes one at a time? <Y>: **(Type N) Global edit of attribute values.** Edit only attributes visible on screen? <Y> **(Type Y or N)** Edit attributes of which blocks? <*>: **(Press Enter for all, or else specify the specific names of blocks)** Edit attributes with these names <*>: **(Press Enter for all, or else specify specific attribute names)** Edit attributes with this text <*>: **(Press Enter for all, or else specify the value)** Select attributes: **(Select one or more attributes)** Entities in set: 1 Select attributes: **(Press Enter to end entity selection)** 1 attributes were selected. Text to change: **(Enter the name of the attribute value you wish to edit)** New text: **(Enter the new value)**

Figure 6.148



Command Options

Option	Description
Edit attributes of which blocks	Specifies the names of blocks; you can use wildcards to specify similarly named blocks: • * refers to all characters in the block's name • ? refers to individual characters
Edit attributes with these names	Specifies the names of attributes. You can use wildcards to specify similarly named tags.
Edit attributes with this text	Specifies the values of attributes. You can use wildcards to specify similarly named values.
Select attributes	Chooses the attributes to edit.
Position	Moves the attribute's insertion point: **Enter text insertion point - (pick a new point, or enter coordinates.)**
Angle	Changes the rotation angle of the attribute text. Prompts you: **New rotation angle <0> - (enter a new angle, or pick two points to specify the angle.)**
Text	Changes the value of the attribute. Prompts you: **[Change/Replace]<Replace> - (type C or R)**: • **Change** - searches and replaces text. • **Replace** - new attribute text replaces the text of the currently selected attribute.
Style	Changes the text style of the attribute; the style name must exist in the drawing. (Use the Style (6.27.55) command to create or edit text styles.) **New text style or ENTER for no change <Standard> - (enter a different style name, or else press Enter to keep the style.)**
Color	Changes the color of the attribute text: **New color <BYLAYER> - (enter a different color name or number.)**
Height	Change the height of the attribute text: **New text height <0.2> - (enter a different text height, pick two points in the drawing, or else press Enter to keep the height.)**
Layer	Changes the layer of the attribute; the layer name must exist in the drawing. (Use the Layer command to create layers.) **New layer or ENTER for no change <0> - (enter a different layer name, or else press Enter to keep the layer.)**
Next	Goes to the next attribute; if there are no more attributes to edit, exits the command.
pRev	Goes to the previous attribute, if any.
Edit only attributes visible on screen	Determines which group of attributes to edit: • **Y** (yes) - edits only attributes visible in the current viewport. • **N** (no) - edits all attributes in the drawing.
Text to change	Specifies the attribute value to change.
New text	Specifies the replacement value.
Quit	Exits the command.

Figure 6.149

6.4.35 -AttExt

(7.3 on page 6132) Copies data from attributes to a text file via the command line.

Accessing the Command

command bar: **-attext** alias: **-at** The template .**txt** file must exist before this command is used. See the AttExt (6.4.38) command for the format of this file. : **-attext You prompted:** Select Entities or extract attributes as [Entities/Dxf/Cdf/Sdf] <CDF>: **(Enter an option or press Enter.)** BricsCAD displays the Attribute Extract Template File dialog box. Choose a template .**txt** file, and then click **Open**. (6.150 on the next page) BricsCAD displays the Attribute Extract Output File dialog box. Specify a file name, and then click **Save**. (6.151 on the following page) The attribute values and other data are extracted, and saved to the output file. BricsCAD then reports the number extracted: **15 records extracted.** If you select blocks without attributes and non-block entities, BricsCAD ignores them. If you ignore this option by entering DXF, SDF, or CDF directly, then BricsCAD selects all attributes in the drawing.

Figure 6.150

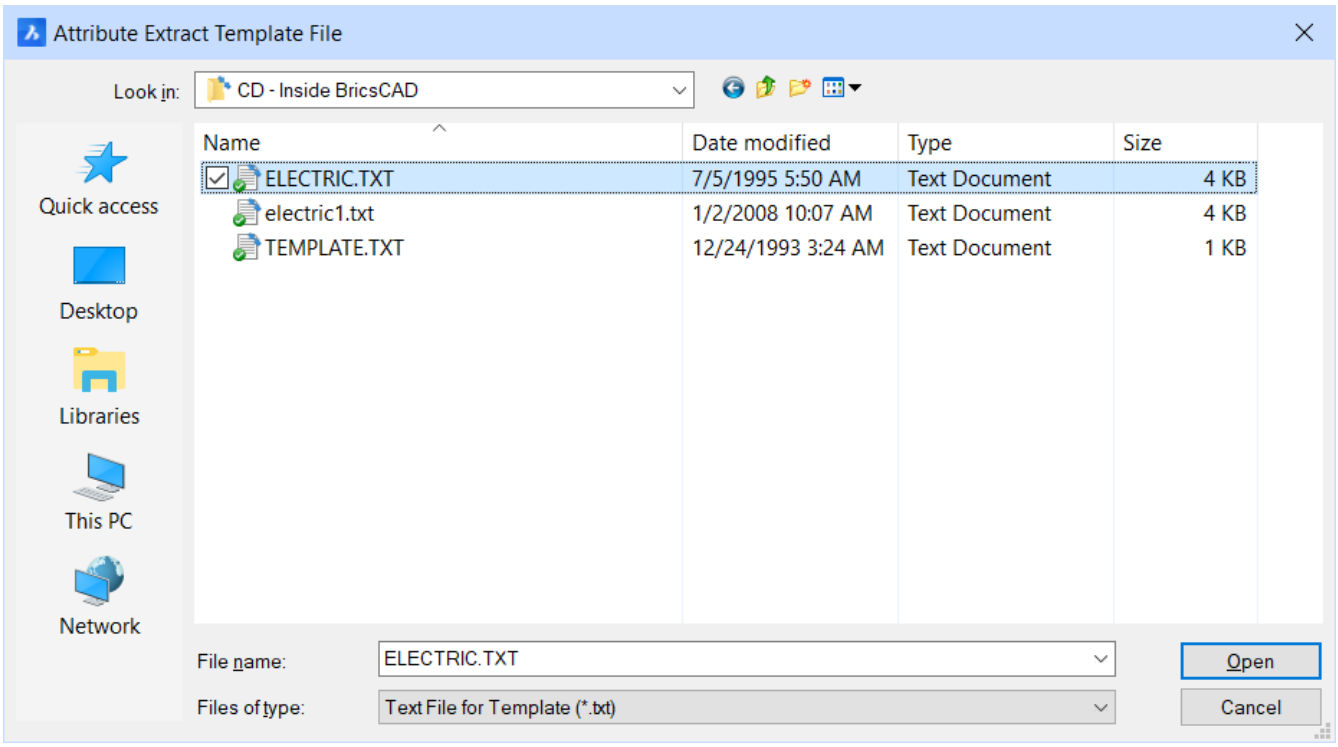

Figure 6.151

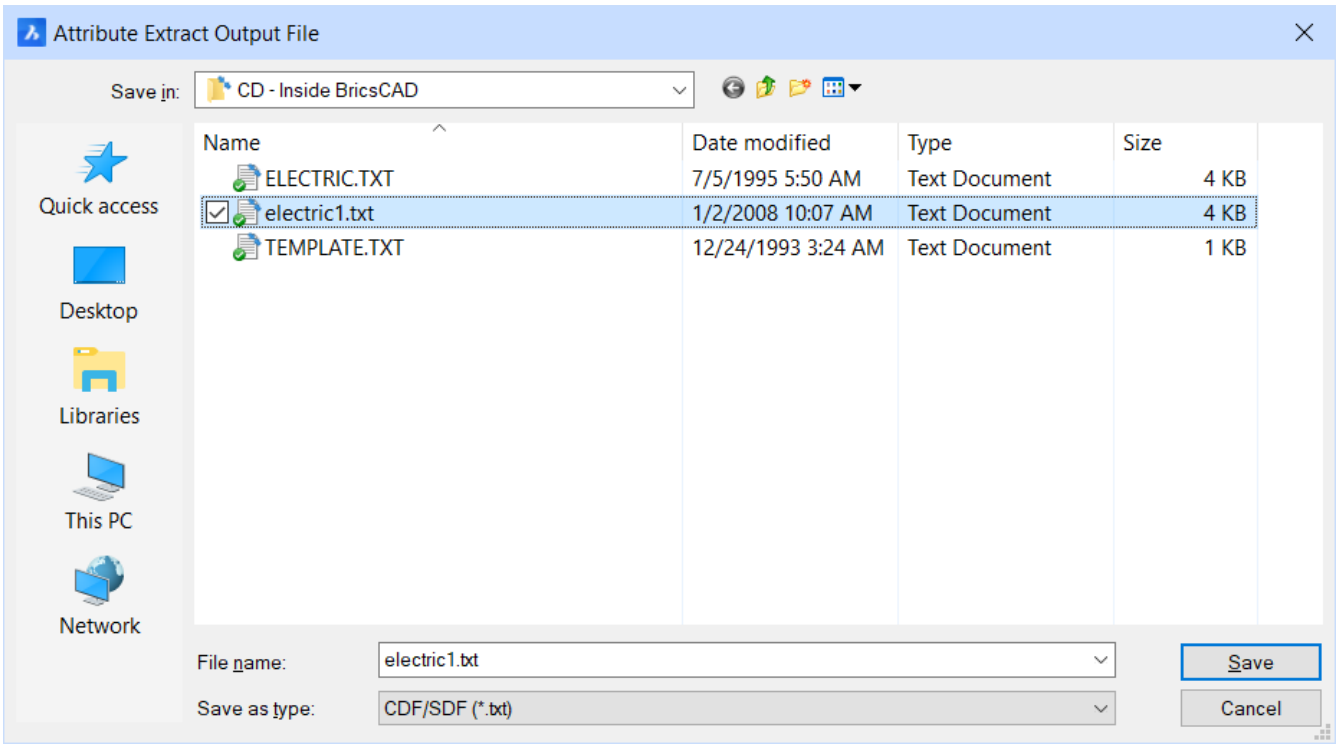

Command Options

Option	Description
Select Entities	Prompts you to select entities. Enter E for the following prompts: **Select entities** - **(choose one or more blocks with attributes)**. **Select entities** - **(press Enter to continue the command)**. If you ignore this option by entering DXF, SDF, or CDF directly, then BricsCAD selects all attributes in the drawing.
Extract attributes as: DXF/CDF/SDF	Specifies the data format: • **DXF** - exports the attribute values in a partial DXF format; this format is meant for use with other computer programs that can read .dxx files (DXf eXtraction). • **CDF** - exports the attributes with commas separating values; this format is meant for use with spreadsheets and databases. • **SDF** - exports the attributes in fixed-width format; this format is meant for use in word processors.

Figure 6.152

6.4.36 AttRedef

(6.2981 on page 6079) Redefines a block and updates associated attributes.

Accessing the Command

command bar: **attredef** menu bar: **Tools | Attributes | Redefine Attribute Block** : **attredef Prompts you in the command bar:** Enter name of block you wish to redefine: **(Type the name of an existing block)** Select entities for block: **(Select entities and attributes to be included in the block definition)** Select entities for block: **(Select more entities, or else press Enter to stop selecting entities)** Specify new base point: **(Specify the origin point of the block)** The following rules apply to existing block references:

- New attributes use default values.
- Values of old attributes that are included in the new block definition are preserved.
- Old attributes that are not included in the new block definition are deleted.
- Format or property changes made with the ATTEDIT (6.4.34) or EATTEDIT (6.13.1) commands are removed.
- Extended data associated with the block are deleted.

Command Options

Option	Description
Enter name of block you wish to redefine	Specify the name of a block
Select entities for block	Select entities (and optionally the attributes) that should become part of the block
Specify new base point	Pick a point or enter coordinates

Figure 6.153

6.4.37 AttSync

(6.2981 on page 6079) Synchronizes attribute definitions in all block references of a specified block definition.

Accessing the Command

command bar: **attsync** menu bar: **Tools | Attributes | Synchronize Attributes** : **attsync Prompts you in the command bar:** Enter an option [Select/Name/?]<Select>: **(Press Enter or choose an option)** Select a block: **(Select a block in the drawing)** ATTSYNC block? [Yes/No]<Yes>: **(Press Enter to synchronize all instances of the selected block)**

Command Options

Option	Description
Select	Selects the block whose attributes should be used as the template for synchronizing other blocks. Prompts you: **Select a block** - **(select a block in the drawing; skips the next prompt).**
Name	Selects the block definition to be synchronized. Prompts you: **Enter name of block to sync or ? to list attributed blocks** - **(type the name of a block containing attributes, or enter ? to display a list block names that contain attributes in the current drawing).**
Select a block	This prompt appears when you start with the Name option; it mimics the Select option.
ATTSYNC block?	Synchronizes attributes in the specified blocks: **Yes** - synchronizes attributes in the block **No** - does not synchronize the block

Related Commands

AttDef (6.4.31) - defines attributes through a dialog box. -AttDef (6.4.32) - defines attributes through the command bar. A (6.4.33)ttDisp (6.4.33) - toggles the display of attribute text. AttEdit (6.4.34) - edits attribute values and properties. -AttExt (6.4.35) - extracts attributes from drawings to data files through the command bar. AttRedef (6.4.36) - redefines a block and updates associated attributes. BattMan (6.6.1) - manages the attributes of a block definition. Block (6.6.11) and -Block (6.6.12) - create blocks from attribute definitions and entities. DataExtraction (6.10.4) - exports entity properties, block attributes and drawing information to a an external file. EAttEdit (6.13.1) - edits attribute values and most properties. Explode (6.13.16) - reduces attributes to tags. Insert (6.17.13) - inserts blocks and prompts for attribute values through a dialog box. -Insert (6.17.14) - insert blocks and prompts for attribute values through the command bar. InsertAligned (6.17.15) - inserts blocks repeatedly, and inserts mirrored blocks. Properties (6.24.54) - edits attribute values and properties.

Figure 6.154

6.4.38 AttExt

(6.2981 on page 6079) Copies data from attributes to a text file via a dialog box. Deprecated: use instead the DataExtraction (6.10.4) command.

Accessing the Command

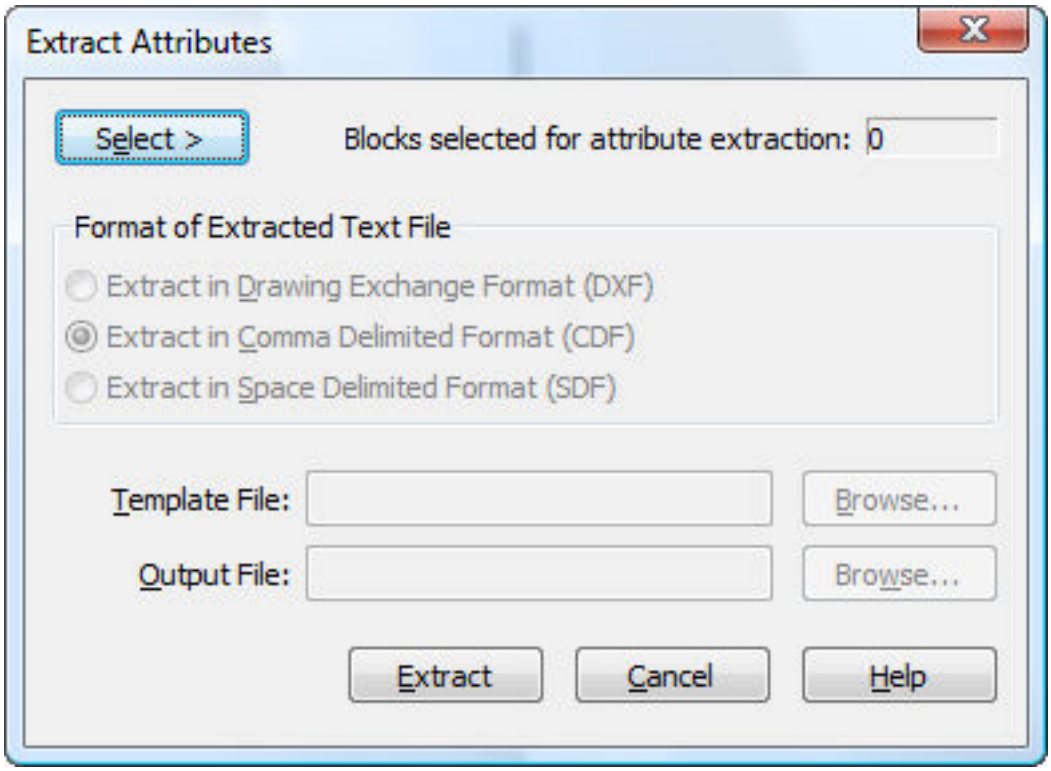
 command bar: **attext** aliases: **ax, ddattext** menu: **Tools | Attributes | Extract Attributes** toolbar: **Tools | Attributes |**  ribbon: **Insert | Blocks | Extract Attributes** : **attext** Displays a dialog box: (6.155 on the facing page) Enter options, and then click **Extract** . If you select blocks without attributes and non-block entities, BricsCAD ignores them. The template file determines which attributes are extracted and the format of related data. For example, a **template.txt** file contains the following fields: BL:NAME C008000 BL:NUMBER N003000 PRODUCT C016000 BL:X N016004 BL:Y N016004 This means that the AttExt command will extract the following values:

- BL:NAME C008000 - Name of the block formatted to 8 characters.
- BL:NUMBER N003000 - Count (number) of the block, formatted to a 3-digit number.
- PRODUCT C016000 - Values of the attribute with the "Product" tag, formatted to 16 characters.
- BL:X N016004 and BL:Y N016004 - The x and y coordinates of the block's insertion point, formatted to 16 digits, including 4 decimal places.

The table below lists all available data extraction parameters. The table uses the follow codes: C = indicates alphanumeric field N = indicates numeric field fff = indicates width of field, in characters (max = 999) ddd = indicates number of decimal places (max = 999) 0 = indicates zero.

Data	Format
Attribute tag (numeric)	Nfffddd
Attribute tag (alphanumeric)	Cfff000
Block name	BL:NAME Cfff000
Block counter	BL:NUMBER Nfff000
Block handle (identifier)	BL:HANDLE Cfff000
Block's layer name	BL:LAYER Cfff000
Block nesting level	BL:LEVEL Nfff000
Block insertion, x coordinate	BL:X Nfffddd
Block insertion, y coordinate	BL:Y Nfffddd
Block insertion, z coordinate	BL:Z Nfffddd
Block's rotation angle	BL:ORIENT Nfffddd
Block's x scale factor	BL:XSCALE Nfffddd
Block's y scale factor	BL:YSCALE Nfffddd
Block's z scale factor	BL:ZSCALE Nfffddd
Block's x extrusion direction	BL:XEXTRUDE Nfffddd
Block's y extrusion direction	BL:YEXTRUDE Nfffddd
Block's z extrusion direction	BL:ZEXTRUDE Nfffddd

Figure 6.155



Command Options

Option	Description
Select	Dismisses the dialog box temporarily so that you can select blocks with attributes: **Select entities - (choose one or more blocks with attributes.) Select entities - (press Enter to return to the dialog box.)**
Extract in Drawing Exchange Format (DXF)	Exports the attribute values in DXF format as .dxx files. This format is meant for use with other computer programs that can read .dxf files.
Extract in Comma Delimited Format (CDF)	Exports the attributes with commas separating values. This format is meant for use with spreadsheets and databases.
Extract in Space Delimited Format (SDF)	Exports the attributes in fixed-width format. This format is meant for use in word processors.
Template File	Specifies the name of the .txt template file. The file must exist before this command is used.
Browse	1. Displays the Attribute Extract Template File dialog box. Choose a file. 2. Click **Open**.
Output File	Specifies the name of the output file,
Browse	1. Displays the Attribute Extract Template File dialog box. Specify a file name. 2. Click **Save**.
Extract	Exports the attribute values to the output file.

Procedures

- Extracting attribute information (1.30.16)

Related Commands

Figure 6.156

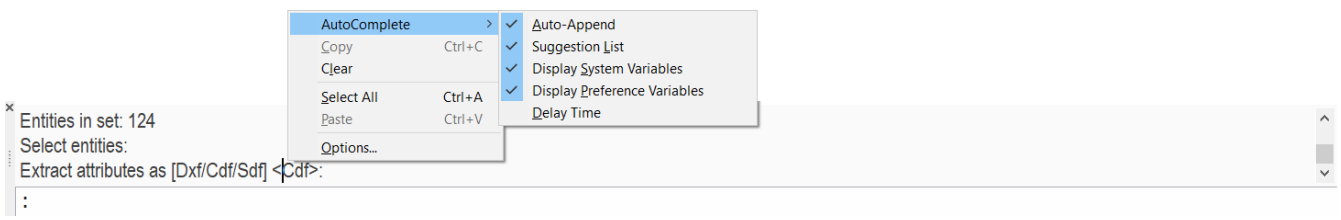
6.4.39 AutoComplete

(6.2981 on page 6079) Specifies how the auto-complete function works in the command bar.

Accessing the Command

command bar: **autocomplete** transparent: **'autocomplete** context menu: **Right-click the command bar** : **autocomplete** Prompts you in the command bar: Enter an automatic completion option [Append/List/System variables/Delay/ON/OFf] <ON>: **(Choose an option.)** The auto-complete options are saved in the AutoCompleteMode system variable. Alternatively, you can right-click the command bar, and then choose options from the AutoComplete item in the context menu. (6.157)

Figure 6.157



Command Options

Option	Description
Append	Prompts you: **Automatically append suggestions as you type? [Yes/No] <Yes> - (enter Y or N)**: • **Yes** - automatically completes the command as you type • **No** - does not complete the command
List	Prompts you: **Display a list of suggestions? [Yes/No] <Yes>** - **(enter Y or N)**: • **Yes** - display a list of command name and other suggestions • **No** - do not display suggestions
System variables	Prompts you: **Include system variables in suggestions? [Yes/No] <Yes>** - **(enter Y or N)**: • **Yes - includes system variables and user preferences in the list of suggestions** • **No** - does not include system variables; leaving out variables helps declutter the list
Delay	Specifies the delay time before the list of suggestions displays. Prompts you: **Specify the delay time in seconds <0.50>** - **(type the desired delay time, and then press Enter).**
ON	Switches on auto-complete mode.
OFF	Switches off auto-complete mode.

Procedures

- Using autocomplete in the command bar (1.15.2)

Related Commands

Commands - lists the names of commands used by the program Settings - controls the values of variables through a dialog box SetVar - controls and lists variables at the command line

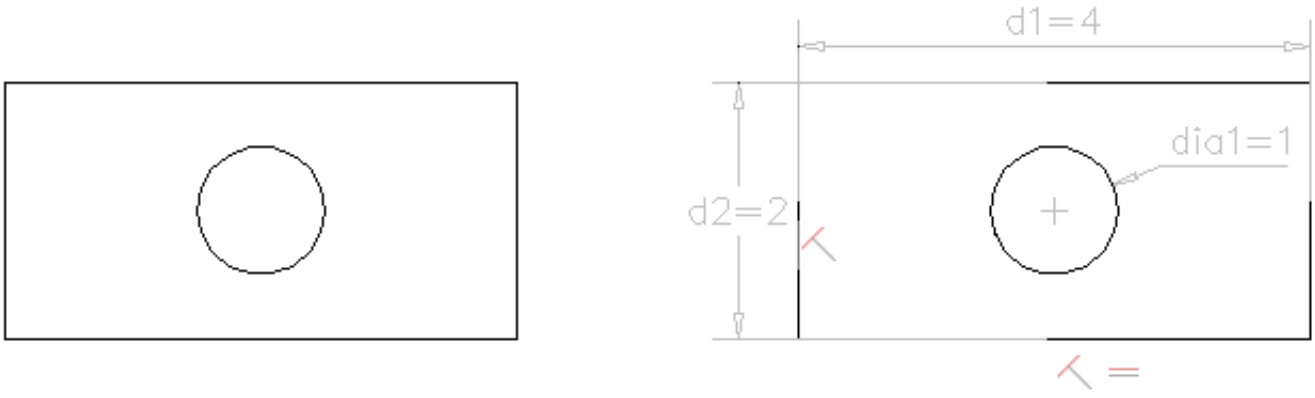
6.4.40 AutoConstrain

(6.2947 on page 6049) Automatically applies 2D geometric and dimensional constraints to selected 2D geometry.

Accessing the Command

command bar: **autoconstrain : autoconstrain You are prompted:** Select entities [selection options (?)]: (Select entities to be constrained.) Entities in set: 2 Select entities [selection options (?)]: (Select more entities or press Enter.)
1 perpendicular constraint(s) applied 1 horizontal constraint(s) applied 2 aligned dimensional constraint(s) applied 1 radial dimensional constraint(s) applied (6.159) Lite license: Constraints can be edited in the Parameters and Constraints panel (6.24.10). Pro or higher license: Constraints can be edited in the Mechanical Browser panel (3.3.2).

Figure 6.159



Command options

No command options.

Related Commands

DimConstraint (6.10.30) - applies a dimensional constraint to an entity or between constraint points on entities; converts associative dimensions to dynamic dimensions. GeomConstraint (6.15.17) - applies geometric relationships between entities and/or valid constraint points on entities.

Figure 6.160

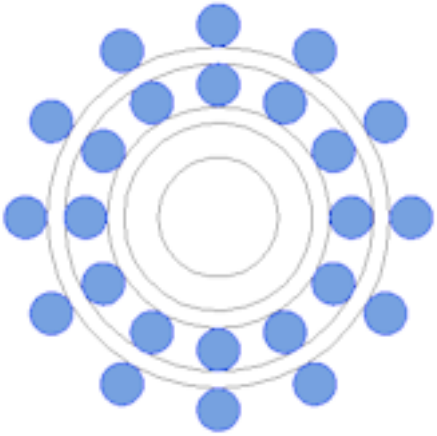
6.4.41 ArrayPolar

(7.3 on page 6132) Associatively distributes entity copies evenly in a circular pattern about a center point or axis of rotation, using multiple rows, and levels.

Accessing the Command

command bar: **arraypolar** menu bar: **Modify | Array | Polar Array** toolbar: **Modify | Arrays |** ribbon: **Sketch | Arrange |** (Mechanical and SheetMetal workspaces) ribbon: **Solid | Edit |** (Mechanical and SheetMetal workspaces) ribbon: **Model | Modify 3D |** (BIM workspace) ribbon: **Change | Arrange |** (BIM and 3D Modeling workspaces) : **arraypolar Prompts you in the command bar:** Select entities to array: **(Select an entity)** Entities in set: 1 Select entities to array: **(Select more entities, or else press Enter to end entity selection)** Type = Polar, Associative = Yes Enter center point of array or [Base point/Axis of rotation]: **(Specify a point, or else choose an option)** [ASsociative/Base point/Items/Angle between/Fill angle/ROWs/Levels/ROTate/eXit]:<eXit>: **(Select an option, or else press Enter to end the command)** (6.161)

Figure 6.161



Command Options

Option	Description
Center point	Specifies the center point of the polar array. The axis of rotation is parallel to the Z-axis of the current coordinate system.
Axis of rotation	Specifies the axis of rotation by prompting you to pick two points.
Associative	Determines whether an array entity is created or a series of copies of the selected entities. The properties of array entities can be modified using the Arrayedit (6.4.25) command. The default setting is saved by the Arrayassociativity (1.17.10) system variable. Prompts you: **Create associative array? [Yes/No]<Yes>** - **(enter an option:)** • **Yes** - creates an associative array • **No** - creates a non-associative array, which is like a series of copies made in a round pattern The associative arrays parameters can be specified using a parametric expressions. Expressions can be set in the array properties in bottom part of the Mechanical Browser (3.3.2), Properties panel (6.24.54) or via the ArrayEdit (6.4.25) command. (6.162 on page 3489)
Base point	Sets the base point of the array, so that items are placed relative to the base point. Prompts you: **Enter base point** - **(specify a point in the drawing)**
Items	Specifies the number of items in the array. Prompts you: **Enter number of items in array <xx> - (type a value or press Enter to accept the current number.)**
Angle between	Specifies the angle between two subsequent items. Prompts you: **Enter angle between items <xx.xx>** - **(type a value, or else press Enter to accept the current angle)**
Fill Angle	Specifies the angle between the first and the last item. Prompts you: **Enter the angle to fill (+=ccw, -=cw) <xx.xx> - (type a value, or else press Enter to accept the current angle)**
Rows	Specifies the number of rows and the spacing between subsequent rows. Prompts you: 1. **Enter the number of rows <xx>** - **(type a value or press Enter to accept the current number)** 2. **Enter the distance between rows or [Total] <xx.x>** - **(enter an option:)** • **Distance** - specifies the distance between subsequent rows • **Total** : specifies the distance* between the first and the last row 3. **Enter the incrementing elevation between rows <0.0>** - **(defines the increasing or decreasing elevation for each subsequent row.)**

Levels	Creates 3D arrays by specifying the number and spacing of levels. (6.163 on the facing page) Prompts you: 1. **Enter the number of levels <1>** - (**specify the number of levels.**) 2. **Enter the distance between levels or [Total] <xxx>** - **(enter an option:)** • **Distance** - specify the distance* between subsequent levels by typing a value or picking two points. • **Total** - specify the distance* between the bottom and the top level.
Rotate	Determines whether items in the array are rotated. Prompts you: **Rotate arrayed items? <Yes>/No** - **(enter an option:)** • **Yes** - rotates items around the circular path • **No** - preserves the orientation of the source entities
Exit	Accept the current settings and conclude the command.

Related Commands

3dArray (6.3.2) - creates 3D arrays. -Array (6.4.20) - creates a polar or rectangular array of entities; displays prompts at the command bar. Array (6.4.19) - associatively distributes entity copies in an evenly spaced rectangular, polar or path array. ArrayClassic (6.4.22) - creates a static polar or rectangular array of entities through a dialog box. ArrayEdit (6.4.25) - allows editing associative array entities and their source entities. ArrayPath (6.4.26) - associatively distributes entity copies evenly along a path into multiple rows, and levels. ArrayRect (6.4.28) - associatively distributes entity copies into any number of rows, columns, and levels. MInsert (6.21.15) - inserts arrays of blocks. -BmParameters (6.8.25) - allows to list and edit the parameters of inserted components and associative array.

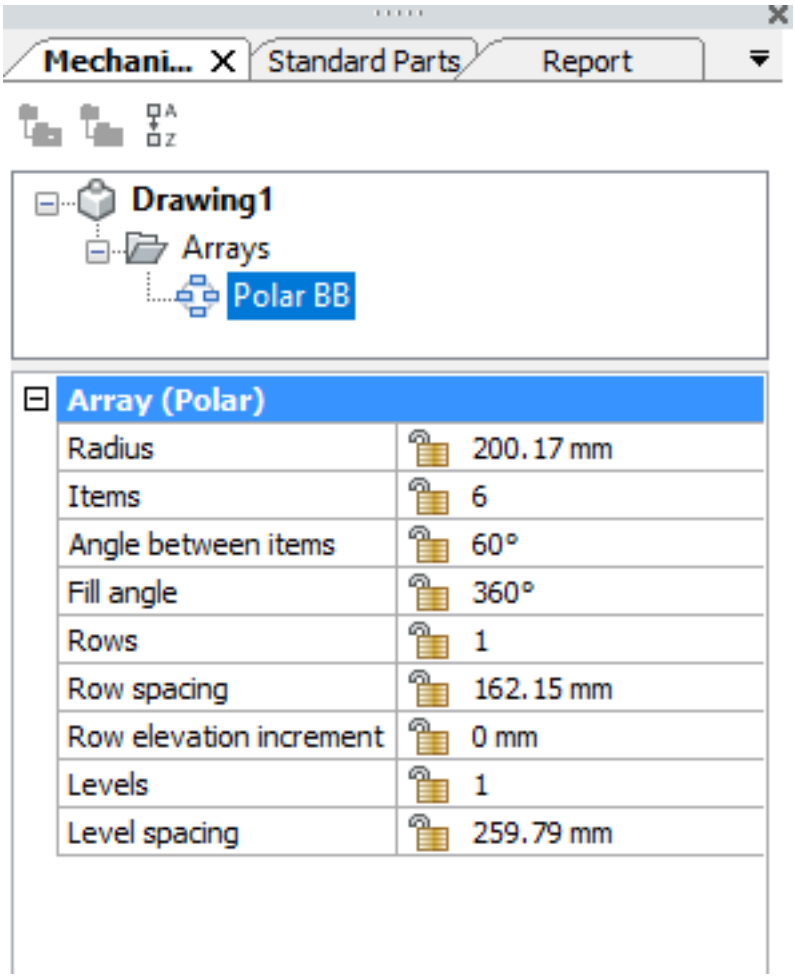

Figure 6.163

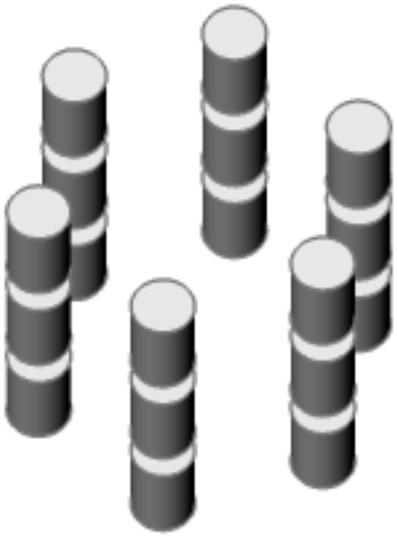

Figure 6.164

6.4.42 Audit

(7.3 on page 6132) Checks the current drawing for errors and optionally repairs the drawing and removes duplicate ACIS attributes.

Accessing the Command

 command bar: **audit** transparent: **'audit** menu bar: **File | Drawing Utilities | Audit** ribbon: **Home | File | Audit** : **comandName Prompts you in the command bar:** Fix any errors detected? [Yes/No] <No>: **(Type Y or N)** 55 objects audited Total errors found during audit 0, fixed 0

Command Options

Option	Description
Yes	Fixes errors, if BricsCAD finds any.
No	Searches and reports errors in the drawing database, but does not repair them.

Procedures

- To analyze the integrity of the current drawing (1.19.8)
- To repair a drawing (1.19.8)

Related Commands

ProxyInfo (6.24.66) - displays a information about proxy entities, contained in the current drawing, in a dialog box. Recover (6.26.3) - recovers damaged drawings. RecoverAll (6.26.4) - recovers a drawing with all nested XRef drawings, each drawing is saved with .BAK copy and .ADT report.

6.5 Ai

6.5.1 Ai_DeSelect

(6.2981 on page 6079) Deselects all selected entities.

Figure 6.165

Accessing the Command

command bar: **ai_deselect** : **ai_deselect Reports in the command bar:** Everything has been deselected

Command Options

No options.

Related Commands

Ai_SelAl (6.5.13) - selects all entities in the current space Select (6.27.16) - selects entities through a variety of methods

Figure 6.166

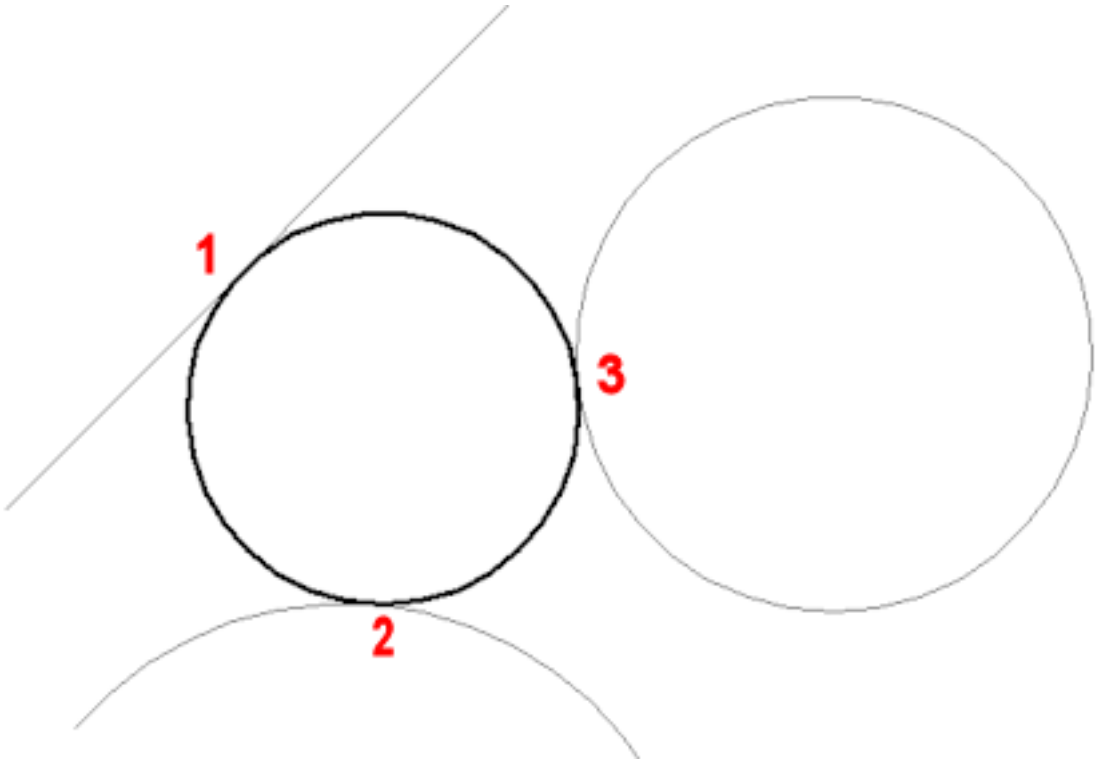
6.5.2 Ai_CircTan

(6.2981 on page 6079) Draws a circle tangent to three entities.

Accessing the Command

command bar: **ai_circtan** transparent: **'ai_circtan** : **ai_circtan Prompts you in the command bar:** Enter Tangent spec: **(Select a line, circle, arc, polyline segment, xline or ray)** Enter second Tangent spec: **(Select a line, circle, arc, polyline segment, xline or ray)** Enter third Tangent spec: **(Select a line, circle, arc, polyline segment, xline or ray)** (6.167 on the following page)

Figure 6.167



Tutorial: Click here (1.24.1) to watch

Command Options

Option	Description
Enter Tangent spec	Select one of the following entities: • Line • Polyline segment • Polyarc • Circle • Arc • Xine • Ray When the entity is ineligible, the program responds, "No tangent found for selected point."
Enter second Tangent spec	Select a second entity
Enter third Tangent spec	Select a third entity

Related Commands

Circle (6.9.12) - draws circles by several methods.

Figure 6.168

6.5.3 AiDimFlipArrow

(6.2981 on page 6079) Flips individual arrows of a dimension.

Accessing the Command

command bar: **aidimfliparrow** menu: **Dimension | Flip dimension arrowhead** toolbar: **Dimensions |** : **aidimfliparrow Prompts you in the command bar:** Select entities: **(Click the extension or dimension line nearest to the dimension arrow you want to flip)** (6.169) The arrow flips to the other side of the extension line. (6.170 on the next page)

Figure 6.169

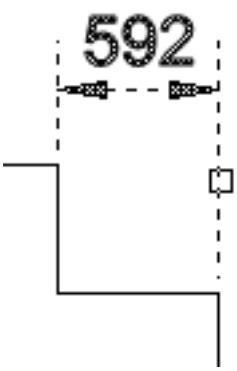


Figure 6.170

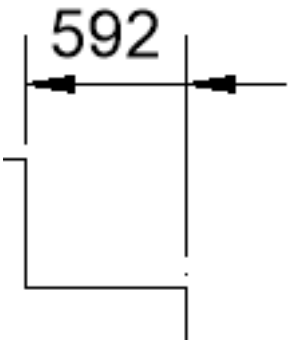


Command Options

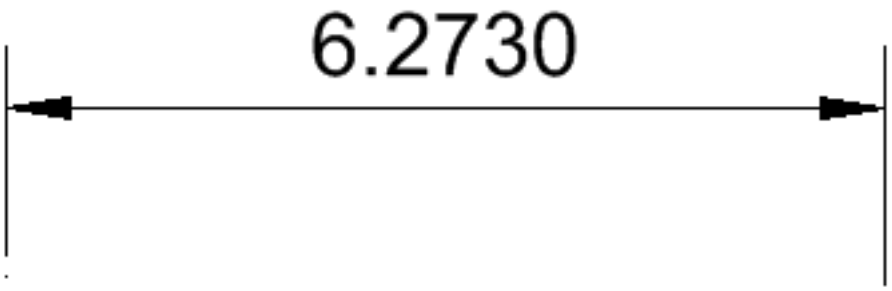
Option	Description
Select entities:	Click the extension line of the dimension arrow you want to flip. Even though the prompt is plural (entities), this command flips only one arrowhead at a time. It flips the one closest to the pick point along the dimension or extension line.

Related Commands

DimLinear (6.11.12) - places linear dimensions in drawings: horizontal, vertical, and rotated. DimAligned (6.11.3) - places aligned dimensions. DimDiameter (6.11.9) - places diameter dimensions. DimRadius (6.11.16) - places radius dimensions. DimAngular (6.11.4) - places angular dimensions. DimEdit (6.11.11) - changes the wording and angle of dimension text; changes the angle of extension lines.

Figure 6.171

Figure 6.172



6.5.4 Ai_Dim_TextAbove

(6.2981 on page 6079) Moves dimension text above the dimension line. **Note:** This command makes drawings compatible with the design standard of Japan. (6.172)

Accessing the Command

command bar: **ai_dim_textabove** transparent: **'ai_dim_textabove** : **ai_dim_textabove Prompts you in the command bar.** Select entities: **(Select one or more dimensions)** Entities in set: 1 Select entities: **(Select more dimensions, or else press Enter to end the command)** The program moves the text above the dimension line.

Command Options

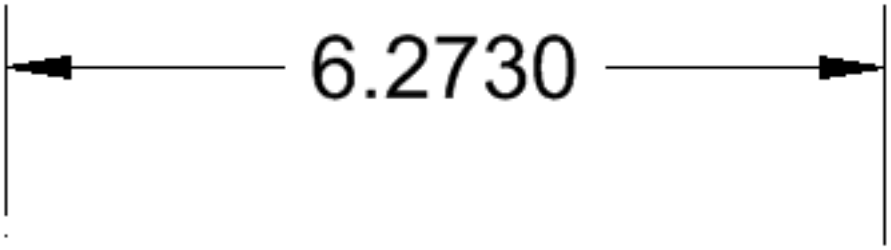
Option	Description
Select entities	Selects the dimensions whose text should be move above the dimension line: • Select one or more dimensions • Enter **all** to select all entities in the drawing; the program filters out ineligible ones • Press **Enter** to end entity selection

Related Commands

AiDimFlipArrow (6.5.3) - flips individual arrows of a dimension. Dim (6.11.1) - places and edits dimensions at the 'Dimensioning command:' prompt. DimEdit (6.11.11) - changes the wording and angle of dimension text; changes the angle of extension lines. DimTEdit (6.11.23) - changes the position of dimension text. DdEdit (6.10.13) - edits dimension text. DimStyle (6.11.19) - creates and edits dimension styles through the Drawing Explorer. DimOverride (6.11.15) - overrides the values of the current dimension style.

Figure 6.173

Figure 6.174



6.5.5 Ai_Dim_TextCenter

(6.2981 on page 6079) Centers dimension text in the dimension line. **Note:** This command makes drawings compatible with the design standard of many countries. (6.174)

Accessing the Command

command bar: **ai_dim_textcenter** transparent: **'ai_dim_textcenter** : **ai_dim_textcenter Prompts you in the command bar:** Select entities: **(Select one or more dimensions)** Entities in set: 1 Select entities: **(Select more dimensions, or else press Enter to end the command)** The program moves the text in the dimension line and centers it.

Command Options

Option	Description
Select entities	Selects the dimensions whose text should be centered in the dimension line: • Select one or more dimensions • Enter **all** to select all entities in the drawing; the program filters out ineligible ones • Press **Enter** to end entity selection

Related Commands

Ai_Dim_TextAbove (6.5.4) - centers dimension text on the dimension line Dim (6.11.1) - Creates multiple dimension types in a single workflow. DimEdit (6.11.11) - changes the wording and angle of dimension text; changes the angle of extension lines. DimTEdit (6.11.23) - changes the position of dimension text. DdEdit (6.10.13) - edits dimension text. DimStyle (6.11.19) - creates and edits dimension styles through the Drawing Explorer. DimOverride (6.11.15) - overrides the values of the current dimension style.

Figure 6.175

6.5.6 Ai_Dim_TextHome

(6.2981 on page 6079) Moves dimension text to the positive defined by the dimension style.

Accessing the Command

command bar: **ai_dim_texthome** transparent: **'ai_dim_texthome** : **ai_dim_texthome Prompts you in the command bar:** Select dimensions to restore text to default position: **(Select one or more dimensions)** Entities in set: 1 Select dimensions to restore text to default position: **(Select more dimensions, or else press Enter to end the command)**

Command Options

Option	Description
Select dimensions to restore text to default position	Selects the dimensions whose text should be moved to the located defined by the dimension style: • Select one or more dimensions • Enter **all** to select all entities in the drawing; the program filters out ineligible ones • Press **Enter** to end entity selection

Related Commands

Dim (6.11.1) - Creates multiple dimension types in a single workflow. DimEdit (6.11.11) - changes the wording and angle of dimension text; changes the angle of extension lines. DimTEdit (6.11.23) - changes the position of dimension text. DdEdit (6.10.13) - edits dimension text. DimStyle (6.11.19) - creates and edits dimension styles through the Drawing Explorer. DimOverride (6.11.15) - overrides the values of the current dimension style.

Figure 6.176

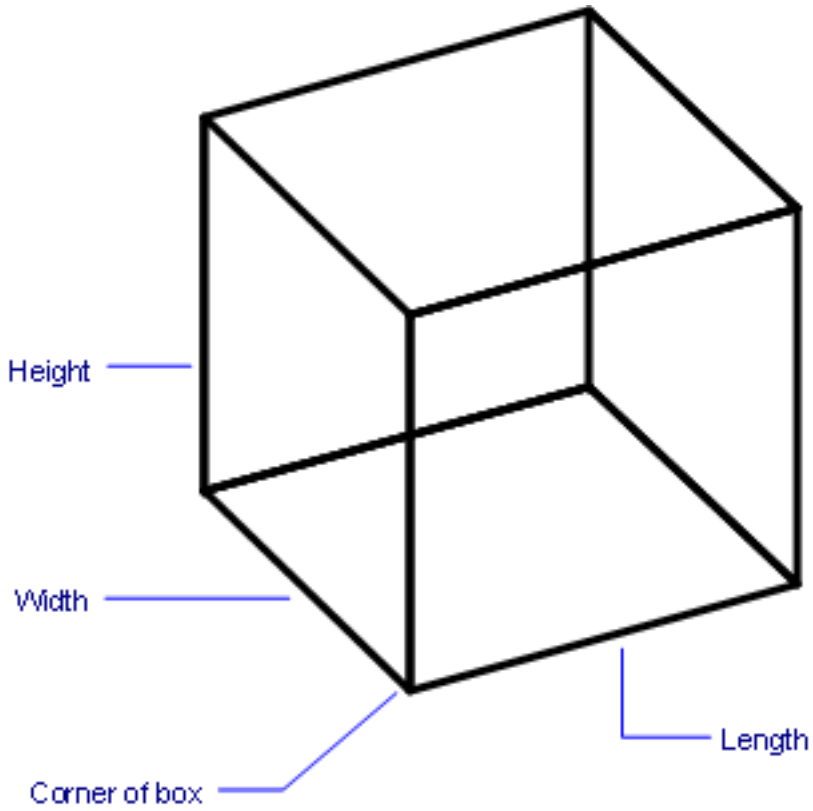
6.5.7 Ai_Box

(6.2981 on page 6079) Draws 3D boxes from polyface meshes.

Accessing the Command

command bar: **ai_box** menu bar: **Model | Meshes | Box** toolbar: **Meshes |** ribbon: **Model | Meshes | Box** : **ai_box Prompts you in the command bar.** Corner of box <0,0,0>: **(Pick a point, or enter coordinates)** Length of side of box: **(Pick a point, or enter a length)** Set width of box or [Cube]: **(Pick a point, enter a width, or type C)** Height of box: **(Enter a height)** Rotation angle for box <0>: **(Enter a rotation angle, or press Enter for none)** (6.177 on the facing page)

Figure 6.177



Command Options

Option	Description
Corner of box	Specifies the lower-left corner of the box.
Length of side of box	Specifies the length of one side, along the positive x-direction.
Width of box	Specifies the width of one side, along the positive y-direction.
Height of box	Specifies the height of one side, along the positive z-direction.
Rotation angle for box	Specifies the counterclockwise rotation angle about the corner (initial pick point).
Cube	Draws a box with all sides of equal length.

Grips Editing

Mesh-formed boxes can be edited directly through grips:

1. Select the box. Notice that it has several grips.
2. Drag a grip to stretch the adjacent faces.

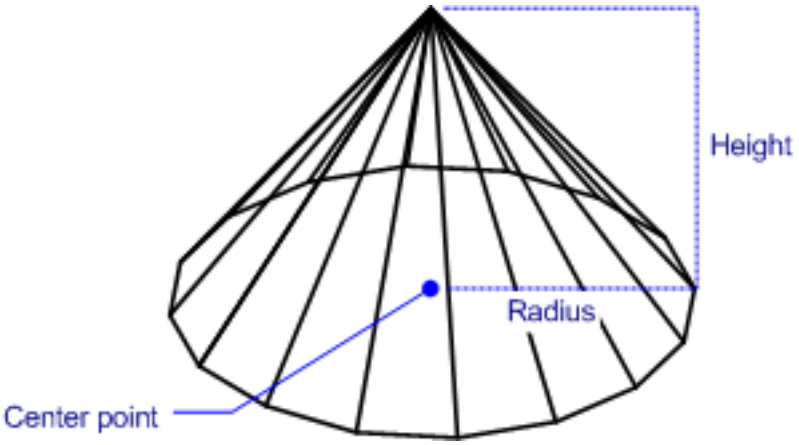
6.5.8 Ai_Cone

(6.2981 on page 6079) Draws 3D cones as polyface meshes, with round or elliptical bases

Accessing the Command

command bar: **ai_cone** menu bar: **Model | Meshes | Cone** toolbar: **Meshes |** ribbon: **Model | Meshes | Cylinder | Cone** : **ai_cone Prompts you in the command bar:** Elliptical/Divisions/<Center of base of cone> <0,0,0>: **(Pick a point, enter x,y,z coordinates, or else enter an option.)** Diameter/<Radius of base>: **(Pick a point, enter coordinates, or type D)** Apex/<Height of cone>: **(Pick a point, enter coordinates, or type A)** (6.180)

Figure 6.180



Command Options

Option	Description
Center of base of cone	Specifies the center point of the cone's base: • Pick a point • Enter x,y,z coordinates
Radius of base	Specifies the radius of the cone's base.
Height of cone	Specifies the height of the cone (in the z direction); enter a negative number to draw the cone upside down.

(6.181)

Option	Description
Apex	Specifies x,y,z coordinates for the top of the cone as an alternative to specifying the height. Prompts you: **Apex of cone - (specify the top of the cone by pointing or entering a height)**
Diameter	Specifies the diameter of the cone's base; prompts you: **Diameter of base - (specify the diameter by picking a point or entering a value)**
Divisions	Changes the number of isolines used to simulate the cone's curved surface. Prompts you: **Number of divisions - (change the number of isolines from the default of 1)**
Elliptical (6.183 on page 3506)	Specifies that the cone should have an elliptical base. Prompts you: 1. **Center specifies the center of the ellipse. First end of ellipse axis - (specify the endpoint of one ellipse axis.)** 2. **Second end of ellipse axis - (specify the other endpoint of the first axis)** 3. **Other axis - (specify the length of the other (second) axis)**

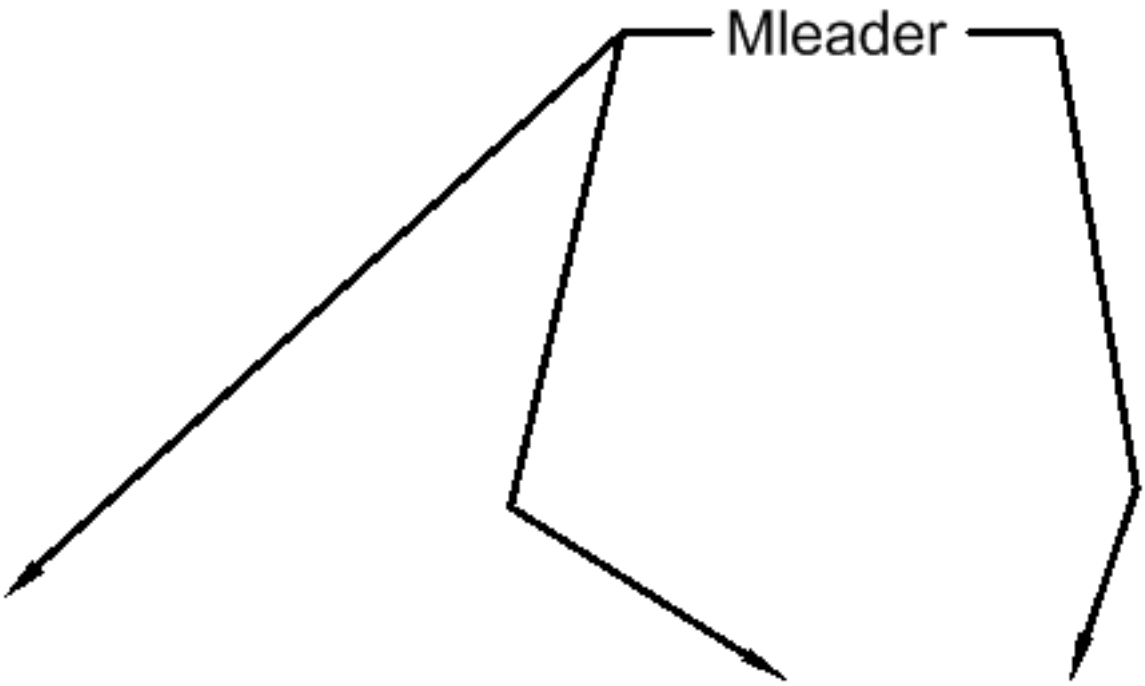
Figure 6.190



6.5.10 AiMLeaderEditAdd

(6.2981 on page 6079) Adds and removes leader lines from a multileader entity. (6.190)

Accessing the Command

command bar: **aimleadereditadd** : **aimleadereditadd Prompts you in the command bar.** Select a multileader: **(Choose a multi-line leader)** Specify leader arrowhead location or [Remove leaders]: **(Pick a point to locate the vertex the new leader)** Specify next point: **(Pick a point to locate the arrowhead)** Specify leader arrowhead location or [Remove leaders]: **(Enter an option, or else press Enter to end the command)**

Command Options

(Pick a point to locate the vertex the new leader)

Option	Description
Select a multileader	Selects the multiline to which you wish to add leaders, or remove them
Specify leader arrowhead location	Pick a point to locate the vertex the new leader; prompts you: 1. **Specify next point - (Pick a point to locate the arrowhead)** 2. **Specify leader arrowhead location or [Remove leaders] - (enter an option)** • Pick a another point to locate another new leader • Press **R** to remove leaders • Press **Enter** to end the command

Remove leaders	Selects the leaders to remove; prompts you: 1. **Select leaders to remove or [Add leaders] - (select one or more leaders to remove)** 2. **Select leaders to remove or [Add leaders] - (enter an option)** • Choose one or more leaders to remove • Press **A** to add leaders • Press **Enter** to end the command The leaders are not removed until you end the command.

Related Commands

MLeader (6.21.19) - creates multileader entities using the current multileader style. MLeaderEditExt (6.21.23) - adds and removes leader lines, adds and removes vertices from a multileader entity. MLeaderStyle (6.21.24) - Creates and manages multileader styles in the Drawing Explorer dialog box.

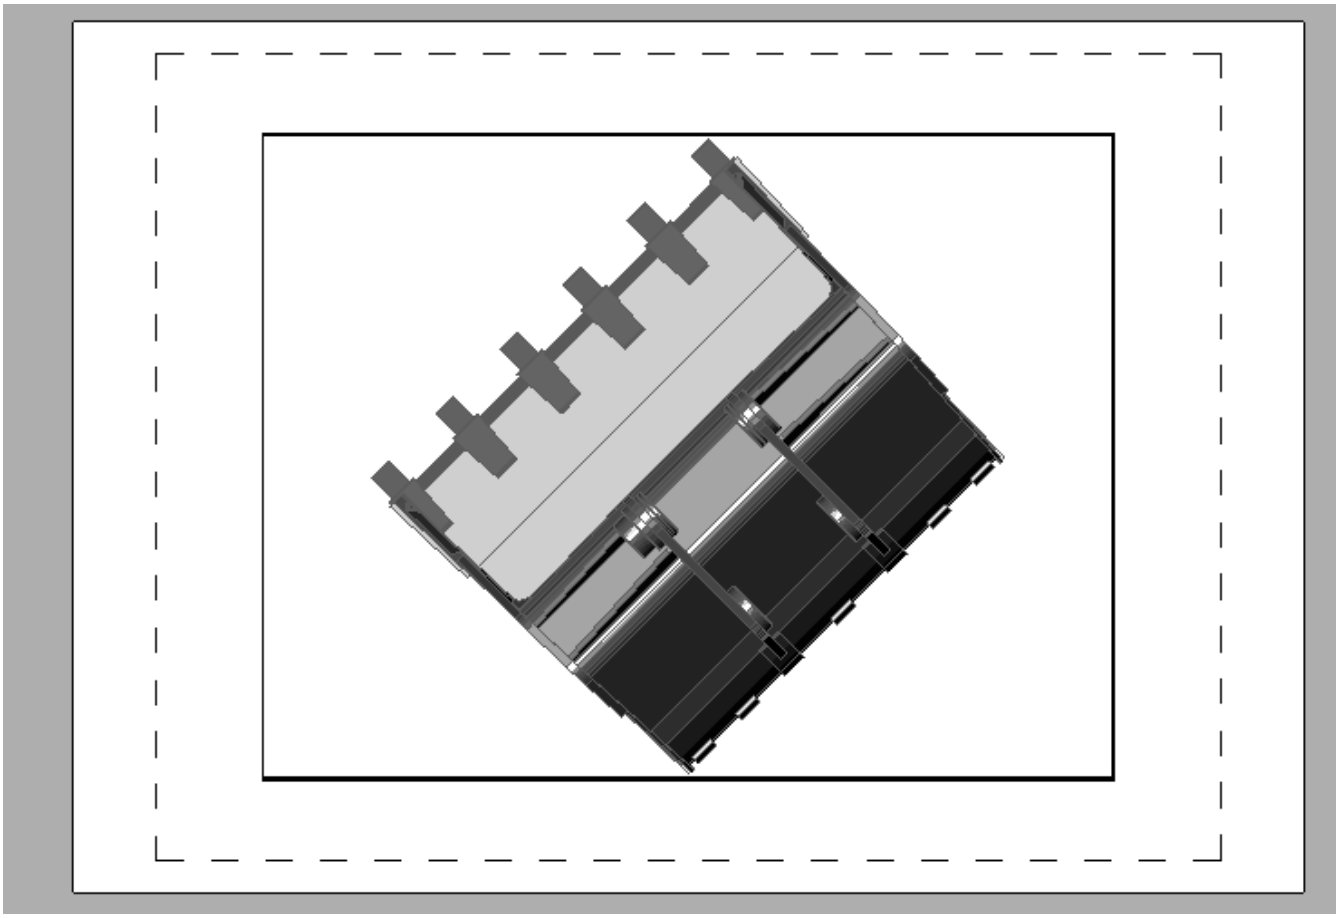
Figure 6.192



6.5.11 Ai_Fms

(6.2981 on page 6079) Switches from model tab to the first layout tab, and then goes into model space (short for "floating model space"). (6.192)

Accessing the Command

command bar: **ai_fms** transparent: **'ai_fms** : **ai_fms** Displays no prompts in the command bar:

- When in Model tab, switches to the first layout tab, and then goes into model space (viewport)
- When in a layout tab, goes into model space (viewport)

Command Options

No options.

Related Commands

ChSpace (6.9.13) - Moves entities from paper space to model space and vice versa. MSpace (6.21.32) - switches to model space. MView (6.21.37) - creates viewports in paper space.

Figure 6.193

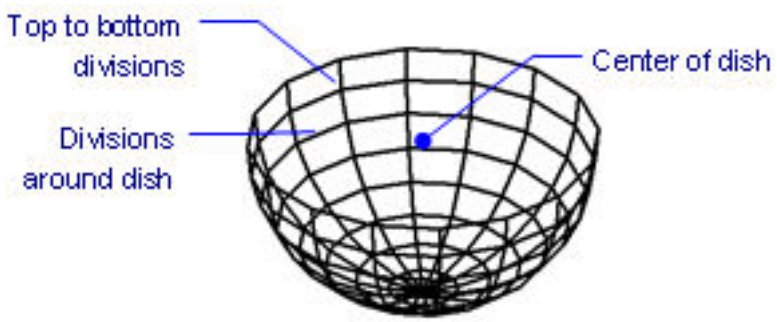
6.5.12 Ai_Dish

(6.2981 on page 6079) Draws the bottom half of spheres as 3D polyface meshes.

Accessing the Command

command bar: **ai_dish** menu bar: **Model| Meshes | Dish** toolbar: **Meshes |** ribbon: **Model | Meshes | Cylinder | Dish** : **ai_dish Prompts you in the command bar:** Center of dish: **(Pick a point or enter coordinates)** Set radius of dish or [Diameter]: **(Pick a point, enter x,y,z coordinates, or enter a value)** Number of divisions around dish <16>: **(Enter a number, or press Enter to keep the default value)** Number of top-to-bottom divisions <8>: **(Enter a number, or press Enter to keep the default value)** (6.194)

Figure 6.194



Command Options

Option	Description
Center of dish	Specifies the center point of the dish's open end; the end is drawn on the current x,y-plane.
Radius of dish	Specifies the radius of the dish.
Number of divisions around dish	Changes the number of horizontal isolines used to simulate the dish's curved surface.
Number of top-to-bottom divisions	Changes the number of vertical isolines from the default of 8.
Diameter (6.196 on the facing page)	Specifies the diameter of the dish. Prompts you: **Diameter of dish - (specify the diameter by pointing or entering a value.)**

Grips Editing

Mesh-formed dishes can be edited directly through grips:

1. Select the dish. Notice that it has several grips.
2. Drag a grip to stretch the adjacent faces.

(6.2981 on page 6079) This command is obsolete. It still exists for backward compatibility only. Please use Edgesurf (6.13.2) instead.

Figure 6.199

6.5.15 Ai_Pyramid

(6.2981 on page 6079) Draws a variety of pyramids and tetrahedrons as 3D polyface meshes. **Note:** To draw a pyramid from a 3D solid, use the Pyramid (6.24.64) command.

Accessing the Command

command bar: **ai_pyramid** menu bar: **Model | Meshes | Pyramid** ribbon: **Model | Meshes | Box | Pyramid** **toolbar: Meshes |** : **ai_pyramid Prompts you in the command bar:** First point for base of pyramid: **(Pick a point, or enter coordinates)** Second point: **(Pick another point, or enter coordinates)** Third point: **(Pick a third point, or enter coordinates)** Set last point for base or [Tetrahedron]: **(Pick the last point, enter coordinates, or type T)** Set apex of pyramid or [Ridge/Top]: **(Pick a point, or enter coordinates, or enter an option)** (6.2024 on page 5214) This command draws:

- Pyramids with four-sided bases and four sides; the base does not need to be an equilateral.
- Tetrahedrons with triangular base and three sides; the base can be scalene.
- Pyramids with pointed, ridged, or flat tops.

(6.201 on the facing page) To draw a rotated pyramid, specify the angle during the Apex option.

Figure 6.200

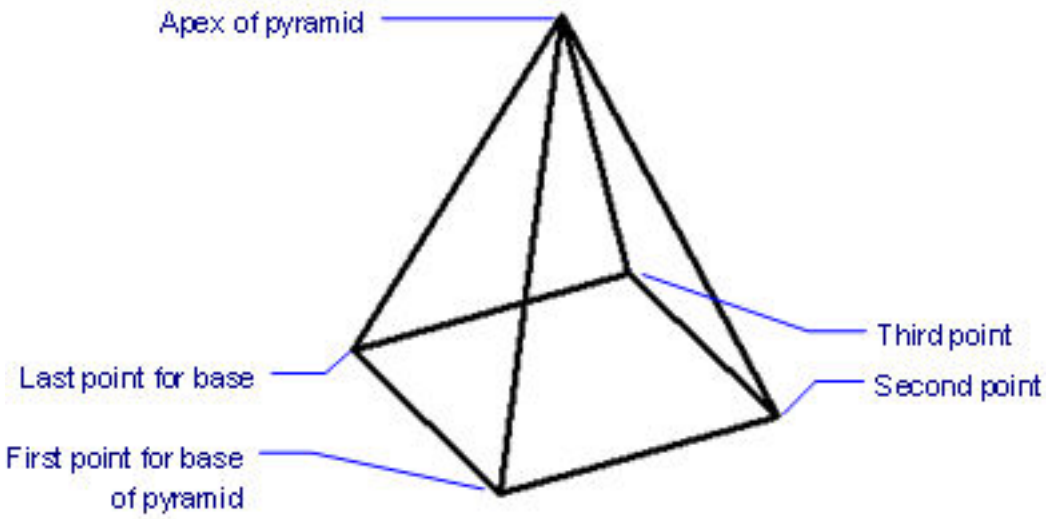

Figure 6.201

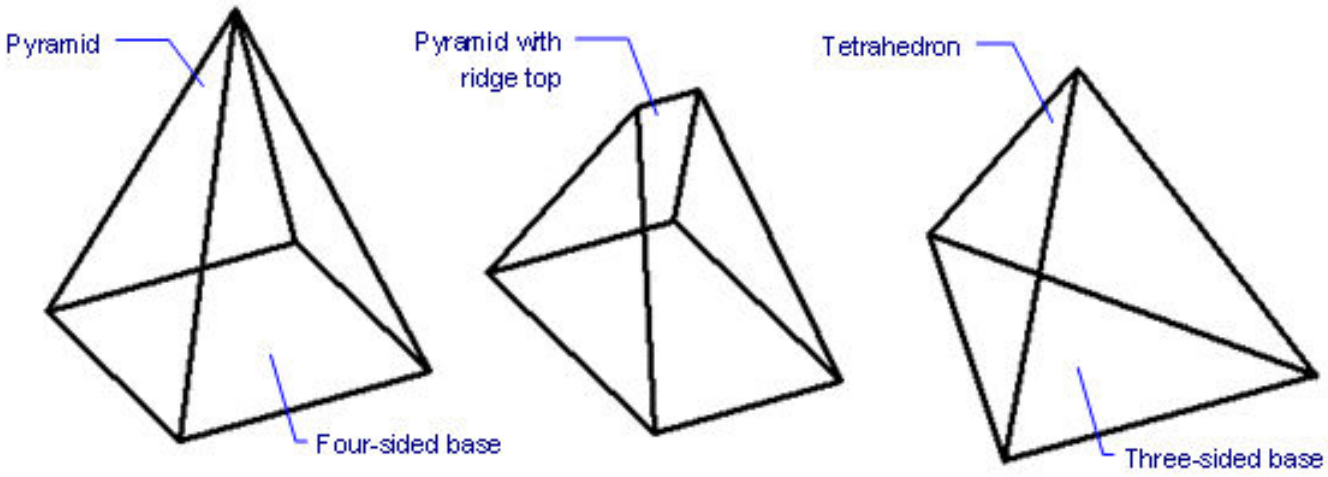

Command Options

Option	Description
First point for base of pyramid	Specifies the first corner of the pyramid's base.
Second point	Specifies the second corner of the base.
Third point	Specifies the third point of the pyramid's base, or the last point for a tetrahedron's base.
Last point for base	Specifies the fourth point for the pyramid's base.
Apex of pyramid	Specifies the height and angle of the pyramid; draws a pointy top.
Tetrahedron (6.203 on the next page)	Draws tetrahedrons; prompts you: **Apex of tetrahedron - (specify the top of the tetrahedron.)**
Ridge (6.204 on page 3524)	Draws a ridge at the top of the pyramid. Prompts you: 1. **Start of ridge - (specifies the height and location of one end of the ridge.)** 2. **End of ridge - (specifies the height and location of the other end of the ridge.)**
Top surface (6.205 on page 3524)	Draws a flat surface at the top of the pyramid; prompts you: 1. **First point on top surface of pyramid - (specifies the starting corner of the pyramid's flat top.)** 2. **Second point - (specifies the next corner.)** 3. **Third point - (specifies the third corner for pyramid, and the last corner for a tetrahedron.)** 4. **Last point of top surface - (specifies the fourth corner for the pyramid.)**

Grips Editing

Mesh-formed pyramids can be edited directly through grips:

1. Select the pyramid. Notice that it has one grip at each vertex.
2. Drag the grip to move the adjacent faces.

Figure 6.212

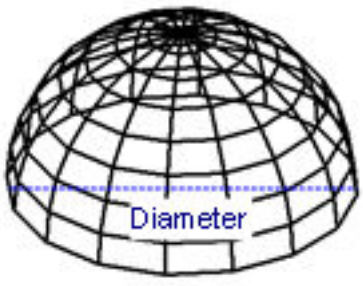

Figure 6.213

6.5.20 Ai_Torus

(6.2981 on page 6079) Draws tori (donut shapes) as 3D polyface meshes.

Accessing the Command

command bar: **ai_torus** menu bar: **Model | Meshes | Torus** toolbar: **Meshes |** ribbon: **Model | Meshes | Cylinder | Torus** : **ai_torus Prompts you in the command bar:** Center of whole torus: <0,0,0> **(Pick a point, or enter coordinates)** Set Radius of whole torus or [Diameter]: **(Specify the radius, or type D)** Set radius of body of torus [Diameter]: **(Specify the radius, or type D)** Segments around body of torus <16>: **(Type a value or press Enter to accept the default number)** Segments around whole torus <16>: **(Type a value or press Enter to accept the default number)**

Command Options

Option	Description
Center of whole torus	Specifies the center of the torus; you can press Enter to accept the default coordinates.
Radius of whole torus	Specifies the overall radius of the torus; note that the distance is measured to the center of the tube (body).
Radius of body of torus	Specifies the radius of the torus body, or tube. It is not necessary for the body radius to be smaller than the whole radius.
Diameter	Specifies the diameters of the whole torus and/or body.
Segments around body of torus	Specifies the number of segments of the circles around the body of torus.
Segments around body whole torus	Specifies the number of segments of the circles around the whole torus.

Grips Editing

Mesh-formed torus surfaces can be edited directly through grips:

1. Select the torus. Notice that it has one grip at each vertex.
2. Drag the grip to move the adjacent faces.

Command Options

Option	Description
Block	Select a block from the drawing whose attributes you want to edit: 1. Do one of the following: • Click the **Block** droplist, then select a block in the list. • Click the **Select Block** button (). The Block Attribute Manager dialog box temporarily closes to let you select a block in the drawing; prompts you: **Select a block** - pick one block in the drawing 2. Select an attribute from the Attribute list to edit.
Attribute list	Choose an attribute from the list to edit it: (6.221 on the facing page) • - moves the attribute up the list • - moves the attribute down the list • - deletes the attribute from the block
Attribute tab	Click the **Attribute** tab to edit the definition of the selected attribute: (6.222 on the next page) See the **AttDef (6.4.31)** command for the meaning of these options.
Properties tab	Click the **Properties** tab to edit the properties of the selected attribute: (6.223 on the facing page)
Text Options tab	Click the **Text Options** tab to edit the text properties of the selected attribute: (6.224 on the next page) See the **Style (6.27.55)** command for the meaning of these options.
Apply button	Applies the changes to the block definition, and keeps the dialog box open; choose another block whose attributes you wish to edit.
Sync button	Applies the changes to all instances of the same block in the drawing.
OK button	Saves the changes you made, and then closes the dialog box.
Cancel button	Undoes all changes you made, and then closes the dialog box.

Related Commands

AttDef (6.4.31) - defines attributes through a dialog box. -AttDef (6.4.32) - defines attributes through the command bar. AttDisp (6.4.33) - toggles the display of attribute text. AttEdit (6.4.34) - edits attribute values and properties. -AttExt (6.4.35) - extracts attributes from drawings to data files through the command bar. AttRedef (6.4.36) - redefines a block and updates associated attributes. AttSync (6.4.37) - synchronizes attribute definitions in all block references of a specified block definition. Block (6.6.11) and -Block (6.6.12) - create blocks from attribute definitions and entities. DataExtraction (6.10.4) - exports entity properties, block attributes and drawing information to a an external file. EAttEdit (6.13.1) - edits attribute values and most properties. Explode (6.13.16) - reduces attributes to tags. Insert (6.17.13) - inserts blocks and prompts for attribute values through a dialog box. -Insert (6.17.14) - insert blocks and prompts for attribute values through the command bar. InsertAligned (6.17.15) - inserts blocks repeatedly, and inserts mirrored blocks. Properties (6.24.54) - edits attribute values and properties.

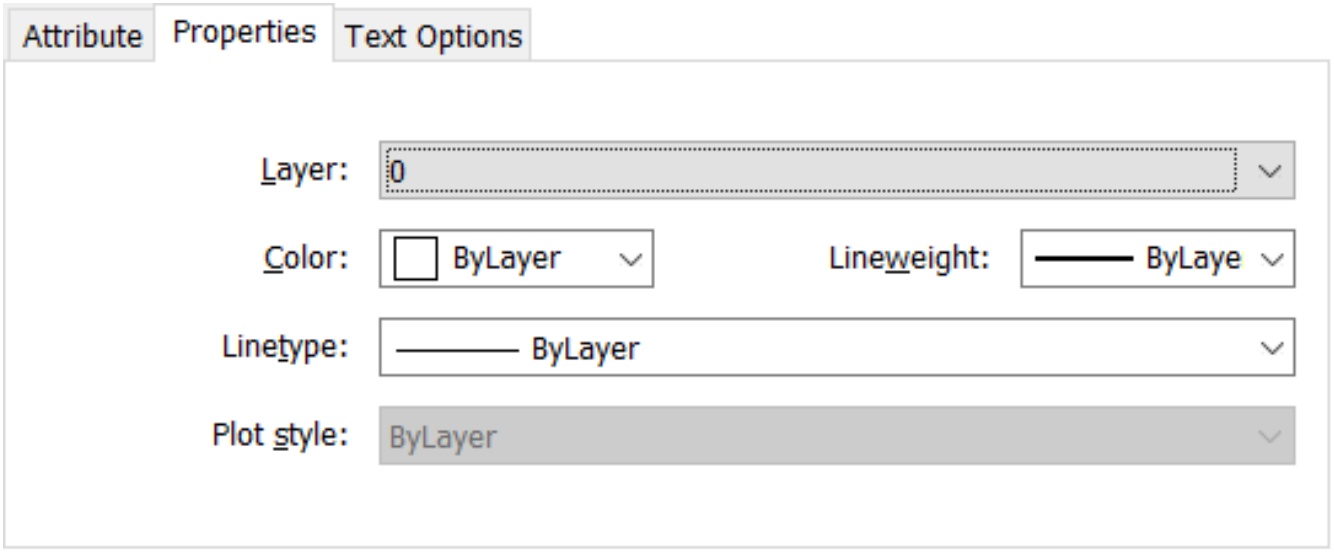

Figure 6.224

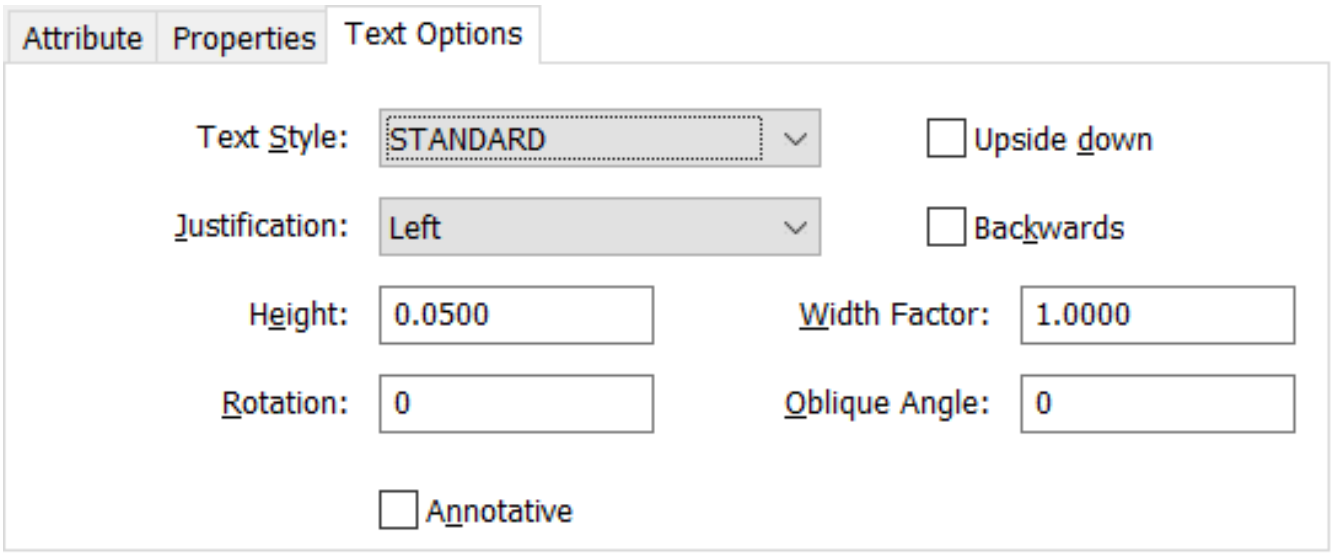

Figure 6.225

6.6.2 Base

(7.3 on page 6132) Changes the drawing's base (insertion) point for when it inserted into other drawings, usually as a block or external reference.

Accessing the Command

 command bar: **base** transparent: **'base** alias: **ba** menu bar: **Settings | Base Point** toolbar: **Settings |**  ribbon: **Settings | Base Point** : **base Prompts you in the command bar:** Base point for inserting this drawing <0.0000,0.0000,0.0000>: **(Enter x,y,z coordinates to relocate the base point for the drawing.)**

Command Options

Option	Description
Base point for inserting this drawing	Specifies x,y,z coordinates. The coordinates of the base point are in the current UCS. When this drawing is inserted into another drawing, these coordinates specify the insertion point, whether this drawing is inserted as a block or as an external reference. This allows the inesrted drawing to match the destination drawing.

Related Commands

-Insert (6.17.14) - inserts DWG drawing files into the current drawing through the command bar. Insert (6.17.13) - inserts DWG drawing files into the current drawing through a dialog box. WBlock (6.33.1) - writes all or part of the drawing to a DWG file. XRef (6.13.23) - inserts DWG files as external references.

Figure 6.226

6.6.3 Background

(7.3 on page 6132) Sets a background for the current viewport, such as gradient colors and images.

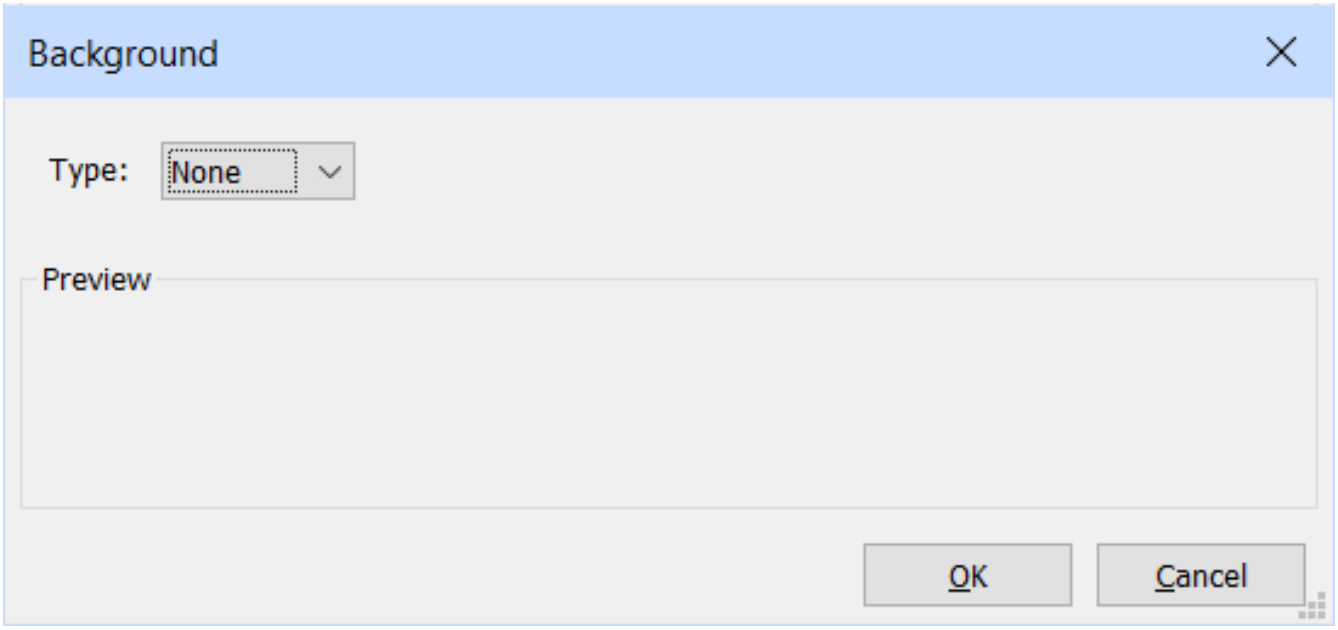
Accessing the Command

 command bar: **background** transparent: **'background** alias: **backgrounds** This command has an effect only

- When the **Perspective** variable is on
- In model space.

: **background** Displays a dialog box: (6.227 on the following page) Choose a **Type** from the droplist, and then select options. Click **OK** when done. The background appears in the viewport. Backgrounds are viewport-specific, so you can have a different type of background in every viewport.

Figure 6.227



Command Options

None Options	Description
Type = None	Displays the default background in model space, which depends on the **Perspective** variable: **Off** - background is the color specified by the **BkgColor** variable, most often black or white; the Background command has no effect **On** - two-color gradient that simulates the ground with sky; the colors are specified by variables that begin with Gradient-, such as GradientColorTop. (6.228 on page 3546)
Solid Options	**Description**
Color	Type = **Solid** sets a single color for the background of the current viewport. (6.229 on page 3547) **Color** button opens the Color (6.9.19) dialog box: 1. Select a color from the dialog box, either an index color or a true color. 2. Click **OK** to close the Color dialog box. The Preview area shows the color. 3. Click **OK** to close th Background dialog box. The background color changes to the new color.
Gradient Options	**Description**
	Type = **Gradient** sets a two- or three-color for the background of the current viewport.
Rotate	Specifies the angle at which to rotate the gradient; this option, however, does not work.
Colors	Choose the number of colors for the gradient: **Two** - displays a two-color gradient; click the **Top** and **Bottom** buttons to choose the colors from the Color (6.9.19) command's dialog box. (6.230 on page 3548) **Three** - displays a three-color gradient; click the **Top**, **Middle**, and **Bottom** buttons to choose the colors from the Color (6.9.19) command's dialog box. (6.231 on page 3549)
Image Options	**Description**
	Type = **Image** sets an image, such as a photograph, for the background of the current viewport. (6.232 on page 3550)

Image Settings	Specifies the path to the raster (image) file used for the background; click the **Browse** button () to select a BMP, GIF, JPG/JPEG, or PNG file. Until you select a file, none of the other options in the dialog box are available to you.
Position	Positions the image in the viewport; chose from: • **Center** - centers the image in the viewport (6.233 on page 3551) • **Stretch** - stretches small images to fit the size of the viewport (6.234 on page 3551) • **Tile** - repeats small images a sufficient number of times to fill the viewport (6.235 on page 3552) As you choose an option, the Preview window shows the result.
Lock aspect ratio	This option is available only when the **Sliders Adjust** option is set to "Scale." • **On** - maintains the image's aspect ratio; the x and y sliders move together • **Off** - allows the image to be distored; the x and y sliders move independently of each other
Sliders adjust	Determines the function of the two slides: • **Offset** - move the image in the viewport • **Scale** - resizes the image; allows you to make the image the same size as the viewport
X and Y sliders	Adjust the offset and/or the scale of the image in the viewport: • **X** - move the slider left and right, or else enter a value • **Y** - move the slider up and down, or else enter a value You can use both the Offset and the Scale sliders to adjust the image's position and size in the viewport.
Reset	Resets the offset and scale to the default values: • **Offset** - default = 0 • **Scale** - default = 1

Tutorial: Backgrounds for visualizing your 3D models Click here (1.20.1) to watch

Related Commands

GradientBkgOff (6.15.24) - switches the gradient background color of the current viewport off. Restores the default view background. GradientBkgOn (6.15.21) - restores the default gradient background of the current viewport. MatchPerspective (6.21.7) - matches the current model space perspective view with a background image by selecting 3 or more matching point pairs. Render (6.26.21) - generates a photorealistic rendering using materials and lights through a dialog box. -Render (6.26.35) - generates a photorealistic rendering using materials and lights through the command bar. View (6.31.2) - creates and sets named views through the Drawing Explorer.

Figure 6.236

6.6.4 Bclose

(6.2981 on page 6079) Closes a Block Edit session and saves or discards the changes.

Accessing the Command

 or  **Keyboard**: bclose **Toolbar**: Block Edit **bclose: Prompts you:** Enter option [Save/Discard block editing changes] <Save>: **(Choose an option.)**

Command Options

Option	Description
 Save	Save the changes and close the Edit Block session.
 Discard	Discard the changes and close the Edit Block session.

Related Commands

Bedit (6.6.7) - Edits the blocks' entities in a temporary drawing session, using the local coordinate system of the block.

Figure 6.237

6.6.5 BHatch

(6.2981 on page 6079) Fills closed areas with repeating patterns or gradated colors; displays the Hatch and Gradient dialog box.

Accessing the Command

command bar: **BHatch :bhatch** Displays a dialog box. See the Hatch (6.16.3) and Gradient (6.15.20) commands.

Related Commands

Boundary (6.6.15) and -Boundary (6.6.16) place a polyline boundary inside closed areas. Hatch (6.16.3) - place hatch patterns through a dialog box. -BHatch (6.6.6) and -Hatch (6.16.1) - places hatch patterns through the command bar. HatchGenerateBoundary (6.16.5) - generates a boundary around a hatch or gradient fill. Properties (6.24.54) - changes the properties of hatch patterns. Settings (6.27.25) - specifies the default parameters for hatch patterns. Solid (6.27.45) - draws 3- and 4-side solid-filled areas.

Figure 6.238

6.6.6 -BHatch

(6.2981 on page 6079) Fills closed areas with repeating patterns; displays prompts at the command bar.

Accessing the Command

command bar: **-bhatch** : **-bhatch** Prompts you in the command bar. See the -Hatch (6.16.1) command.

Related Commands

Boundary (6.6.15) and -Boundary (6.6.16) place a polyline boundary inside closed areas. BHatch (6.6.5) and Hatch (6.16.3) - place hatch patterns through a dialog box. -Hatch (6.16.1) - places hatch patterns through the command bar. HatchGenerateBoundary (6.16.5) - generates a boundary around a hatch or gradient fill. Properties (6.24.54) - changes the properties of hatch patterns. Settings (6.27.25) - specifies the default parameters for hatch patterns. Solid (6.27.45) - draws 3- and 4-side solid-filled areas.

Figure 6.239

6.6.7 BEdit

(6.2981 on page 6079) Edits the entities that make up blocks in a temporary drawing session called the Block Editor, which uses the local coordinate system of the block. Optionally creates a new block.

Accessing the Command

Keyboard: **bedit** Menu: **Tools | Edit Block** Toolbar: **Block Edit** Quad Tab: **Edit** Ribbon Tab | Panel: **Home | Blocks and Insert | Blocks :bedit** Displays a dialog box: (6.240 on the next page)

To edit an existing block, do the following:

1. Select a block in the list, then double click or click the OK button. The Edit Block session starts. The **Block Edit** toolbar displays: (6.242 on the facing page)
2. Edit the block.
3. Do one of the following:
   - On the **Block Edit** toolbar:
     - : Save the changes and close the Edit Block session.
     - : Discard the changes and close the Edit Block session.
   - Execute the BCLOSE (6.6.4) command.

To create a new block, do the following:

1. Type a name in the **Block to create or edit** field.
2. The Edit Block session starts. The **Block Edit** toolbar displays: (6.242 on the next page)
3. Create the block entities.
4. Do one of the following:
   - On the **Block Edit** toolbar:
     - : Save the changes and close the Edit Block session.
     - : Discard the changes and close the Edit Block session.
   - Execute the BCLOSE (6.6.4) command.

Figure 6.240

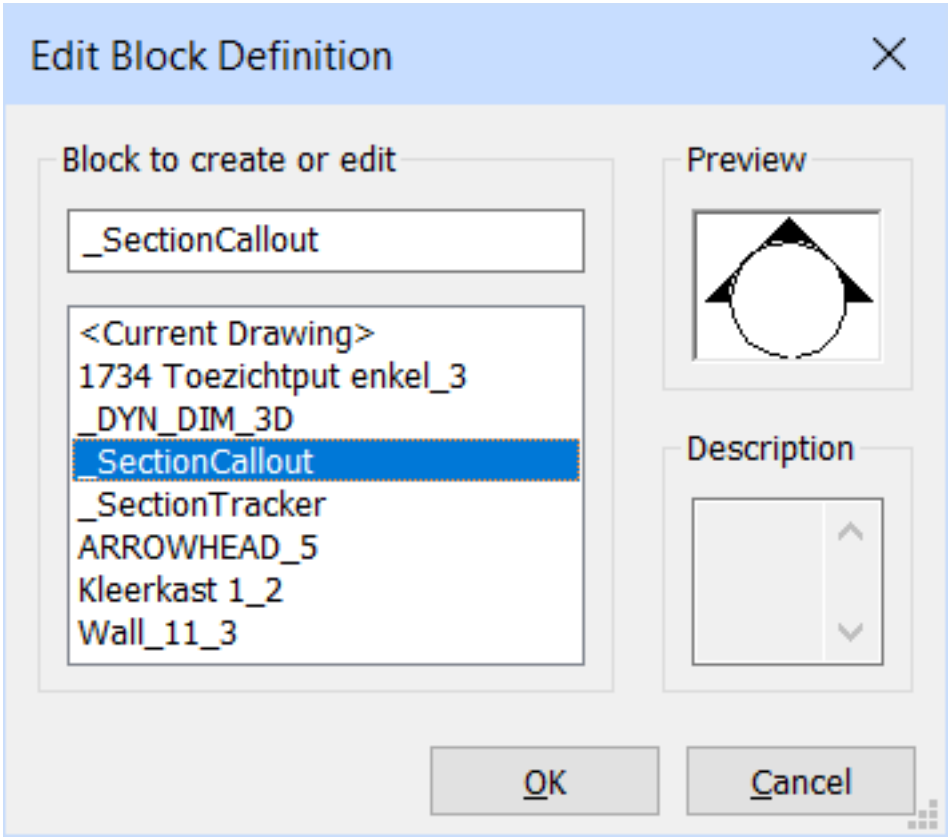

Figure 6.241

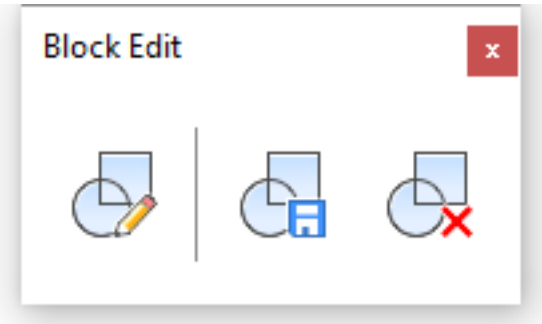

Figure 6.242

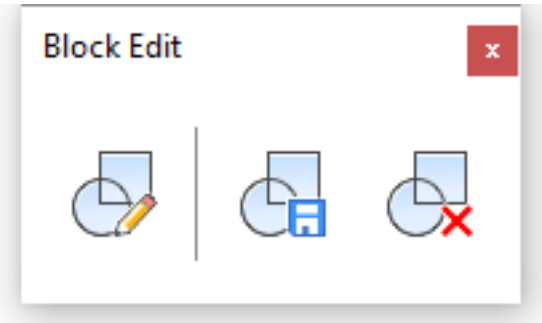


Related Commands

Bclose (6.6.4) - closes a Block Edit session and saves or discards the changes. Block (6.6.11) - groups entities into a block (symbol), which can be reused in drawings. BlockIcon (6.6.17) - creates and updates preview bitmaps of blocks and stores them in the drawing. BSaveAs (6.6.14) - saves a copy of the block definition being edited in the drawing or as a separate drawing. RefEdt (6.26.13) - edits block references and externally-referenced drawings through a dialog box.

Figure 6.243

6.6.8 -BEdit

(6.2981 on page 6079) Prompts for a block name at the command line, and then opens the Block Editor environment

Accessing the Command

Keyboard: **-bedit :-BEdit Prompts you:** Block name or ? to list existing blocks: **(Enter the name of a block, or else enter ? to see the list of block names in the current drawing)**

Command Options

Option	Description
Block name	Enter the name of a block; or enter an unused name to create a new block
? to list existing blocks	Lists the names of blocks in the drawing; prompts you: **Block(s) to list [* for all]: (Use wildcards, such as ? and *, to specify the block names to list)** Enter * to see the names of all blocks in the current drawing.

Procedures

<links to other articles in the BricsCAD, BricsCAD BIM or BricsCAD Mechanical sections.>

Related Commands

BEdit (6.6.7) - opens the Block Editor environment through a dialog box. BClose (6.6.4) - closes the Block Editor environment, optionally saving the changes. BlockIcon (6.6.17) - creates and updates preview bitmaps of blocks and stores them in the drawing. BSaveAs (6.6.14) - saves a copy of the block definition being edited in the drawing or as a separate drawing.

Figure 6.244

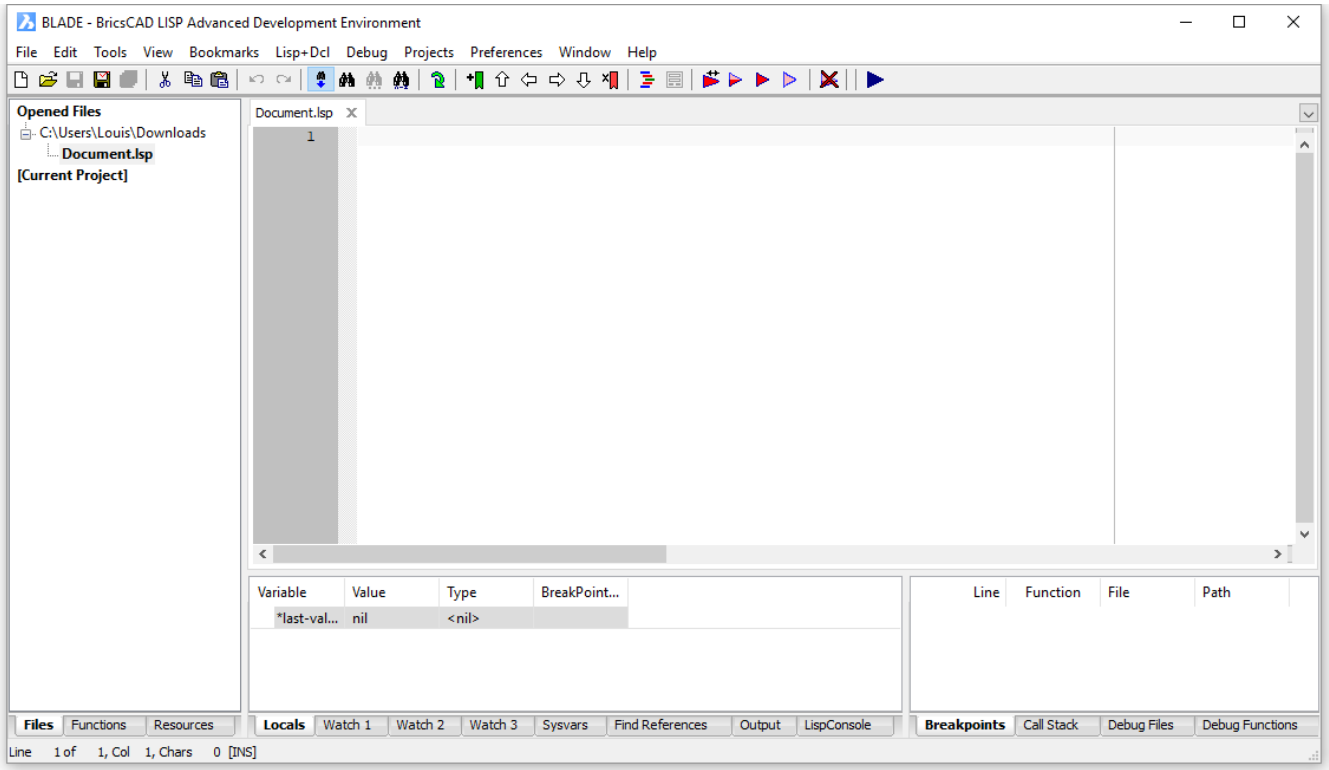
6.6.9 Blade

(6.2981 on page 6079) Opens the interactive environment for editing and debugging LISP applications (short for "BricsCAD LISP advanced development environment").

Accessing the Command

command bar: **blade** transparent: **'blade** : **blade** Displays BLADE - BricsCAD LISP Advanced Development Environment dialog box: (6.2830 on page 5928)

Figure 6.245



Command Options

No command options.

Related Commands

AddInMan (6.4.3) - loads and unloads VBA functions through a dialog box. AppLoad (6.4.17) - selects external routines to load when BricsCAD starts. Netload (6.22.3) - loads a .NET application. VbaLoad (6.32.2) loads VBA projects. VbaMan (6.32.4) - manages VBA projects. VbaNew (6.32.5) - starts a new VBA project. VbaRun (6.32.6) and -VbaRun (6.32.7) - runs VBA macros. VbaIde (6.32.1) - opens the VBA integrated development environment. VbaUnload (6.32.9) - unloads VBA projects. Security (6.32.8) - depending on the selected security level (Low, Medium or High) VBA macros are allowed to run automatically or not.

Figure 6.246

6.6.10 Blipmode

(7.3 on page 6132) Toggles the display of blips that are made as you pick points in the drawing.

Accessing the Command

command bar: **blipmode** transparent: **'blipmode** alias: **bm** : **blipmode Prompts you in the command bar:** Blipmode is currently off: ON/Toggle/<Off>: **(Enter an option)** (6.783 on page 4033) Examples of blips made when the user picks points in the drawing.

Figure 6.247

Command Options

Option	Description
ON	Turns on the display of blips. Use the Redraw command to erase blips from the screen.
Toggle	Turns on blip mode, if off; turns off, if on.
Off	Turns off the display of blips.

Related Commands

Redraw (6.26.9) - removes blips from the screen. Settings (6.27.25) - specifies the default parameters for blip-mode.

Command Options

Option	**Description**
Name	Specifies the name of the block.
Description	(optional) Describes the block.
Base Point Options	**Description**
Specify On-Screen	Specifies the block's base point, the point at which it will be inserted into drawings with the **Insert** (**6.17.13**) command. Choose how you want to specify the base point's coordinates: • **On** - you will be prompted later to define the base point after you click the **OK** button; the Pick Point button and X, Y, Z fields are grayed out (unavailable) • **Off** - click the Pick Point button, or else enter x, y, z coordinates in the X, Y, Z fields.
 Pick point	Pick a point in the drawing for the block's base point: 1. Click the **Pick point**  button. 2. The Block Definition dialog box temporarily closes, and the program prompt you to specify the base point on screen: **Insertion point for new block or [Annotative] - (pick a point, or else enter x,y,z coordinates, and then press Enter.)**
X, Y, Z	Enter x, y, z coordinates for the base point in the X, Y, and Z fields. The z coordinate is usually optional.
Entities Options	**Description**
Specify On-screen	The Entities section selects the entities that make up the block. Choose how you want to select the entities: • **On** - you will be prompted later to select the entities after you click the **OK** button; the Select Entities button is grayed out • **Off** - click the Select Entities button

 Select Entities

Select one or more entities in the drawing:

1. Click the **Select Entities**  button
2. The Block Definition dialog box temporarily closes, and the program prompt you to specify the base point on screen:

Select entities for block - **(select one or more entities using a selection method) Select entities for block** - **(select more entities, or else press Enter to return to the dialog box)** Optionally, include Reference Curves (6.26.15) in the selection which allows to automatically align a block during insertion. Once entities are selected, decide what happens to them once they are turned into a block. Choose an option:

- **Retain** - selected entities are retained as entities, and the block definition is created in the drawing
- **Convert to block** - selected entities are converted to a block
- **Delete** - selected entities are deleted after the block definition is created

The Convert to Block option is the most efficient one.

Behavior Options

Annotative

Description

Sets the annotative property of the block. This kind of block should be created when the annotation scale in model or paper space is 1:1. By being annotative, the block automatically scales itself according to the current annotation scale factor. Choose whether you want block to follow annotative scaling:

- **On** - block will scale itself to whatever annotative scale is in effect; the Scale Uniformly option is grayed out (unavailable)
- **Off** - block follows the scale factor you give the block during the **Insert** (**6.17.13**) command

Match block orientation to layout

Determines if annotative blocks match the orientation of the layout:

- **On** - annotative blocks display upright, regardless of the orientation of the viewport
- **Off** - annotative blocks match the orientation of the viewport

Scale Uniformly	Determines if blocks can be scales non-uniformly. This option is not available to annotatively-scaled blocks. Choose one: • **On** - X, Y, and Z scale factors of blocks are the same as one another; this prevents blocks from being distorted • **Off** - blocks can be inserted with different X, Y, and Z scale factors; this is useful for unit blocks that are meant to become a variety of objects, such as differently sized table tops
Allow Exploding	Determines if users can explode the block after it is inserted. When a block is exploded, it loses its block status, and the individual entities can be edited. (To edit the entities of an unexploded block, use the **BEdit (6.6.7)** command.) Choose one: • **On** - block can be exploded after being inserted, with the **Explode (6.13.16)** command • **Off** - blocks cannot be exploded; you can change this property with the **Explorer (6.13.11)** command, Blocks section.
Settings Option	**Description**
Block Unit	Scales the block correctly when the block definition is inserted in a drawing whose units are different from the drawing in which the block was created. More specifically, in which the **INSUNITS** variable differs. 1. Click the Block Unit droplist. 2. Choose a unit from the list (6.250 on the next page)
OK	Closes the dialog box, and if necessary prompts you at the command line for the base point and the entities to include in the block, then saves the block definition in the drawing.
Cancel	Exits the dialog box without saving the block definition; no block is created.

Procedures

- General procedure to create a block (1.30.6)
- To create a block in a drawing (1.30.6)
- To create a block using the Blocks Explorer (1.30.6)
- To save a block to a separate file (1.30.6)

Related Commands

BEdit (6.6.7) - edits blocks -Block (6.6.12) - groups entities into a block (symbol). Blockify - automatically detects equally shaped solids in a model and replaces them by block references. Searches the drawing for an identical set of entities (2D and 3D) and replaces them by block references. Optionally replaces block patterns by arrays. CopyBase (6.9.58) - copies entities to the Clipboard with a base point. ExpBlocks (6.13.11) - opens the Blocks section of the Drawing Explorer dialog. Insert (6.17.13) - inserts blocks and prompts for attribute values through a dialog box. -Insert (6.17.14) - insert blocks and prompts for attribute values through the command bar. InsertAligned (6.17.15) - inserts blocks repeatedly, and inserts mirrored blocks. Properties (6.24.54) - edits attribute values and properties. ReferenceCurves (6.26.15) - creates reference geometry to automatically align a block during insertion. WBlock (6.33.1) - writes blocks and other drawing parts to files on disk through a dialog box. -WBlock (6.33.3) - writes blocks and other drawing parts to files on disk through a dialog box.

Figure 6.251

6.6.12 -Block

(7.3 on page 6132) Groups entities into a block (symbol).

Accessing the Command

command bar: -**Block** alias: **-b** : -**block Prompts you in the command bar:** Name for new block or [? to list existing blocks(?)]: **(Enter a name, or ?)** Insertion point for new block or [Annotative]: **(Pick a point, or enter x,y coordinates)** Select entities for block: **(Select one or more entities)** Select entities for block: **(Select more entities, or press Enter to exit command)**

Command Options

Option	Description
Name for new block	Specifies the name of the block.
? to list existing blocks	Lists the names of blocks already in the drawing, so that you don't use an existing name by accident. Prompts you: **Block(s) to list [* for all]** - **(use wildcards to specify groups of names, or else press Enter to display all names.)** The program provides this report: **Defined blocks. "BSWITCH" "CONNECT" "DOMESW" "ELECTRIC" "FUSE40"** User Blocks (5), External References (0), Dependent Blocks (0), Unnamed Blocks (0) When the list of block names is long, press **F2** to see it in the Text window. If you enter an existing name, the program ask you if you want to redefine the block: **The block ground already exists. Do you want to redefine it? [Yes/No] <No>** - **(enter an option)**: • **Yes** - changes the block definition to the new set of entities you select in the next steps. **Caution:** all instances of this block name will be changed! • **No** - exits the command

Insertion point for new block	Specifies the block's base point, the point at which it will be inserted into drawings with the Insert command. Prompts you: **Insertion point for new block or [Annotative]** - **(enter an option)**: • **Insertion point** - pick a point in the drawing, or else enter x,y, and z coordinates • **Annotative** - specifies that the block will follow annotative scaling; prompts you: **Create annotative block[Yes/No] <Yes>** - **(enter an option)**: • **No** - avoids making the block annotative • **Yes** - gives the block the annotative property, and then goes on to the following prompt: **Orient relative to sheet in paper space viewports[Yes/No] <No> - (determines if annotative blocks match the orientation of the layout)**: • **On** - annotative blocks display upright, regardless of the orientation of the viewport • **Off** - annotative blocks match the orientation of the viewport The Z coordinate is optional, and is usually left at 0.
Select entities for block	Selects the entities that make up the block; you may use any selection method, including entity snaps and windowed selection. Repeats the command: **Select entities for block** - **(press Enter to finish selecting entities and to exit the command.)** Optionally, include Reference Curves (6.26.15) in the selection which allows to automatically align a block during insertion. The entities disappear from view, but are now part of the block; use the **Oops (6.23.7)** command to return the entities to the drawing.

Procedures

- General procedure to create a block (1.30.6)
- To create a block in a drawing (1.30.6)
- To create a block using the Blocks Explorer (1.30.6)
- To save a block to a separate file (1.30.6)

Related Commands

BEdit (6.6.7) - edits blocks Block (6.6.11) - groups entities into a block (symbol), which can be reused in drawings. Blockify - Automatically detects equally shaped solids in a model and replaces them by block references. Searches the drawing for an identical set of entities (2D and 3D) and replaces them by block references. Optionally replaces block patterns by arrays. CopyBase (6.9.58) - copies entities to the Clipboard with a base point. Insert (6.17.13) - inserts blocks and prompts for attribute values through a dialog box. -Insert (6.17.14) - insert blocks and prompts for attribute values through the command bar. InsertAligned (6.17.15) - inserts blocks repeatedly, and inserts mirrored blocks. ReferenceCurves (6.26.15) - creates reference geometry to automatically align a block during insertion. WBlock (6.33.1) - writes blocks and other drawing parts to files on disk through a dialog box. -WBlock (6.33.3) - writes blocks and other drawing parts to files on disk through a dialog box.

Figure 6.252

6.6.13 Blockify

(6.2981 on page 6079) Automatically detects equally shaped solids in a model and replaces them by block references. Searches the drawing for an identical set of entities (2D and 3D) and replaces them by block references. Optionally replaces block patterns by arrays. Youtube

Accessing the Command

Keyboard: **blockify** Menu: **Tools** Quad Tab**: Modify** Ribbon Tab | Panel: **Inserts | Blocks : blockify Prompts you:** Select source entities or [match Equal solids/match existing Blocks/Settings/selection options (?)] <match Equal solids>: **(Select entities or choose an option.)** Enities selected: XX Select source entities or [Settings/selection options (?)]: **(Select more entities or press Enter.)** Select block insertion point or [use Default point] <use Default point>: **(Identify a point or press Enter to accept the default insertion point.)** Select search space or [Entire drawing/selection options (?)] <Entire drawing>: **(Select the area of the drawing to be searched or press Enter to search the entire drawing.)** Specify block name or <ENTER to use default name>: **(Type a name or press Enter to accept the default name.)** Duration of finding similar groups: XX sec Number of block inserts: YY

Command Options

Option	Description
Select source entities	Compose a set of entities (2D and/or 3D). BricsCAD will then search the drawing for identical sets and replace them by a newly created block definition. Select the entities, then press Enter. Prompts you: **Select block insertion point or [use Default point] <use Default point>:** • **Select insertion point**: Specify a point. • **Use default point**: The insertion point is set automatically. Prompts you: **Select search space or [Entire drawing/selection options (?)] <Entire drawing>:** • **Select search space**: Select the entities to search for indentical sets. • **Entire drawing**: The entire drawing is search for identical sets. Prompts you: **Specify block name or <ENTER to use default name>:** • **Specify block name**: Type a name for the block. • **Default name**: The default block names are Block, Block 1, Block 2, ...
Match equal solids (1)	Searches the drawing (or the selection) for equally shaped solids and replace them by newly created block definitions. In case a solid matches an existing block definition, the replacing block reference points to that block definition.
Match existing block definitions	Searches the drawing (or the selection) for 2D geometry matching existing block definitions.

Settings	Opens the Settings dialog on the Blockify settings (see below under Settings).

(1) This option is not available in the Lite license level.

Settings

The BLOCKIFYMODE system variable defines the behavior of the BLOCKIFY and PARAMETRICBLOCKFY commands. Depending on the value of the system variable, some prompts or options are not available: **Select insertion point:** available only if **Use default clock insertion point** is not checked. **Select search space:** available only if **Use entire drawing as search space** is not checked. **Specify block name:** available only if **Use default block name** is not checked. (6.1829 on page 5035)

Bitcode	Option	Description
1	Use entire drawing as search space	Controls whether you are prompted to select the part of the drawing to be searched. • **OFF**: You are prompted to select the part of the drawing to be searched. • **ON**: The entire drawing is searched. Suppresses the **Select search space** prompt.
2	Use default block insertion point	Controls whether you are prompted to define the block insertion point. • **OFF**: You are prompted to define the block insertion point. • **ON**: The default insertion point is used. Suppresses the **Select insertion point** prompt.

Figure 6.253

Blockify settings	0x002F (47)
1	☑ Use entire drawing as search space
2	☑ Use default block insertion point
4	☑ Use default block name
8	☑ Replace patterns by arrays (BLOCKIFY only)
16	☐ Use block references as array base elements (BLOCKIFY only)
32	☑ Compare geometry only

BLOCKIFYMODE

Blockify settings

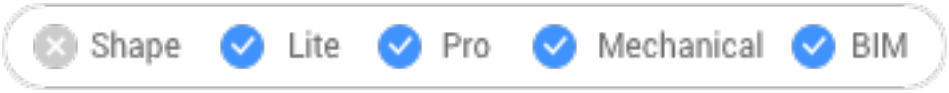
Defines the behavior of the BLOCKIFY and PARAMETRICBLOCKIFY commands

4	Use default block name	Controls whether you are prompted to specify the block name. • **OFF**: You are prompted for the block name. • **ON**: The default block name is used. Suppresses the **Specify block name** prompt.
8	Replace patterns by arrays	Applies to the BLOCKIFY command only. Controls whether patterns are replaced by arrays. • **OFF**: No arrays are created. • **ON**: Patterns of created blocks are replaced by arrays.
16	Use block references as array base elements	Applies to the BLOCKIFY command only. Controls whether the base element of the array is a block or the source entities. • **OFF**: The source entities are the base element of arrays. • **ON**: The created block is the base element of arrays.
32	Compare geometry only	Controls whether entity properties are compared or not. • **OFF**: Matching entities must have the same properties such as color, layer, etc. • **ON**: Entity properties are ignored.

Related Commands

-Block (6.6.12) - Groups entities into a block (symbol). Block (6.6.11) - Groups entities into a block (symbol) through a dialog box. ExpBlocks (6.13.11) - opens the Blocks section of the Drawing Explorer dialog Overkill (6.23.14) - Deletes duplicate entities and overlapping lines, arcs, and polylines, and unifies partly overlapping or contiguous ones; optionally moves duplicates to a dedicated layer. Combines duplicate blocks; optionally purges duplicate block definitions. ParametricBlockfiy (6.24.9) - automatically replaces equally shaped sets of solids, matching a selected parametric block or a set of parametrized solids in a model, by parametric block references.

Figure 6.254



6.6.14 BSaveAs

(6.2947 on page 6049) Saves a copy of the block definition being edited in the drawing or as a separate drawing. The command is valid only when executing the BEDIT (6.6.7) or -BEDIT (6.6.8) (block edit) commands.

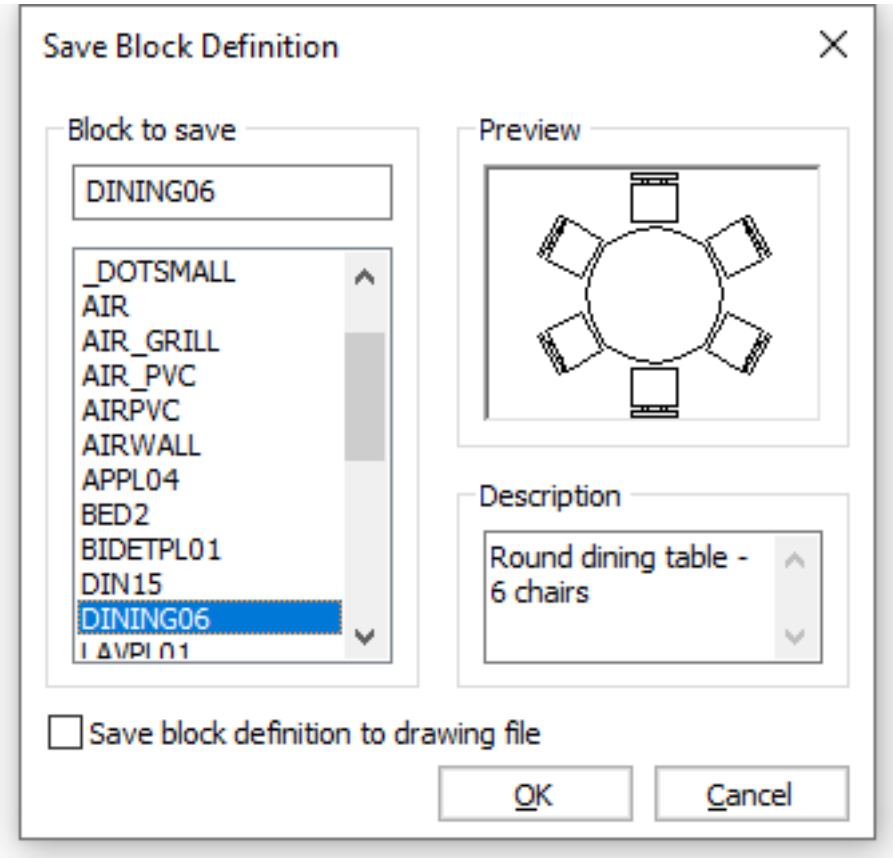
Accessing the Command

Keyboard: **bsaveas : BSAVEAS**

If launched when executing the BEDIT command, displays a dialog box: (6.255 on the following page)

If launched when executing the -BEDIT command, prompts you: Block name or ? to list existing blocks: **(Type a name.)** Save definition to drawing file? [Yes/No] <No>: **(Press Enter to save the block definition in the current drawing;k choose Yes, then press Enter to save to a drawing file.)**

Figure 6.255



Command Options

Option	Description
Block to save	Defines the block name. Do one of the following: • Type a name. • Keep the current name to redefine the block.
Save block definition to drawing file	Allows to save the block as a separate drawing file. When selected, a File dialog displays. Do the following: • Select a folder. • Accept the drawing name or type a new name. • Click the **Save** button on the File dialog.
OK	Saves a copy of the block definition.
Cancel	Exits the command without saving.

Related Commands

BEdit (6.6.7) - edits blocks. -BEdit (6.6.8) - prompts for a block name at the command line, and then opens the Block Editor environment Block (6.6.11) - groups entities into a block (symbol), which can be reused in drawings. SaveAs (6.27.3) - saves drawings in DWG drawing, DWT template, and DXF interchange formats; always displays a dialog box. WBlock (6.33.1) - writes blocks and other drawing parts to files on disk through a dialog box.

Figure 6.256

6.6.15 Boundary

(6.2981 on page 6079) Creates a polyline that forms a boundary around closed areas, through a dialog box.

Accessing the Command

command bar: **boundary** aliases: **bo, bpoly** menu bar: **Draw | Boundaries | Boundary Polyline** toolbar: **Draw | Boundaries|**  ribbon: **Draw | Draw | Polygons | Boundary** : **boundary** Displays a dialog box: (6.257 on the following page) Choose options, and then click **OK**.

Command Options

Boundaries	Description
Pick points in boundary	Specifies the closed areas in which to place the boundary; temporarily dismisses the dialog box, and then prompts you at the command bar: **Pick a point to define a boundary or hatch area or [Select entities/Undo]:** - **(enter an option)**: • **Pick a point to define a boundary or hatch area** - pick a point inside an area closed by entities (ignore the reference to hatch area) • **Select entities** - allows you to select individual entities forming a closed area • **Undo** - un-selects the last selected entities **Notice** that BricsCAD highlights draws the boundary, allowing you to preview it. The prompt repeats, allowing you to choose additional areas, entities, or undo the selection. When done selecting areas, press Enter return to the dialog box.
Boundary tolerance	Determines the largest gap that can exist in the boundary for the program to consider the area closed; enter a value: • 0 - no gaps allowed to exist
Boundary set	Specifies where BricsCAD should search for entities that make up the boundary. Select an option from the droplist: • **Current Viewport** - searches all entities in the current viewport • **Existing Set** - searches only the current selection set for possible boundaries
New	Creates a new selection set of entities that make up the boundary; temporarily dismisses the dialog box, and then prompts you at the command bar: **Select entities** - **(use any selection method to choose one or more entities)** The prompt repeats, allowing you to choose additional entities. When done selecting entities, press Enter to return to the dialog box.
Retain Boundaries as	Specifies how to handle the boundary entity; currently, the only option is to make the boundary out of a polyline, and then retain the boundary after you exit the dialog box.

Islands	Determines how the boundary search algorithm treats "islands", boundaries that are found inside the boundary. (6.259 on page 3582) Choose one: • **Nested** - the program treats every island as a boundary  • **Outer** - the program creates a boundary of only the outermost entities  • **Ignore** - the program creates one boundary, like the Outer option; the Ignore option means only something for hatches and gradients, not boundaries 

Procedures

- Drawing polylines (1.25.12)
- Creating boundary polylines (1.25.12)

Grips Editing

Boundaries can be edited directly through grips:

1. Select the boundary. Notice that it has many grips.
2. Drag a grip to stretch the boundary.

(6.258 on the facing page)

Related Commands

BHatch (6.6.5) and Hatch (6.16.3) - place boundaries and hatch patterns through a dialog box. -BHatch (6.6.6) and -Hatch (6.16.1) - places boundaries and hatch patterns through the command bar. -Boundary (6.6.16) creates a polyline boundary inside closed areas through the command bar. GenerateBoundary (6.15.14) - Creates closed polylines from faces of 3D solids as well as the boundaries detected when the Enable Boundary Detection open of SELECTIONMODES is activated. HatchGenerateBoundary (6.16.5) - generates a boundary around a hatch or gradient fill. Properties (6.24.54) - changes the properties of hatch patterns. Region (6.26.18) - creates boundary-like regions. XEdges (6.34.4) - creates 2D linear entities (lines, arcs, circles, ellipses, elliptical arcs and splines) from the edges of 3D solids, 3D solid faces, surfaces, etc. and regions.

Figure 6.259

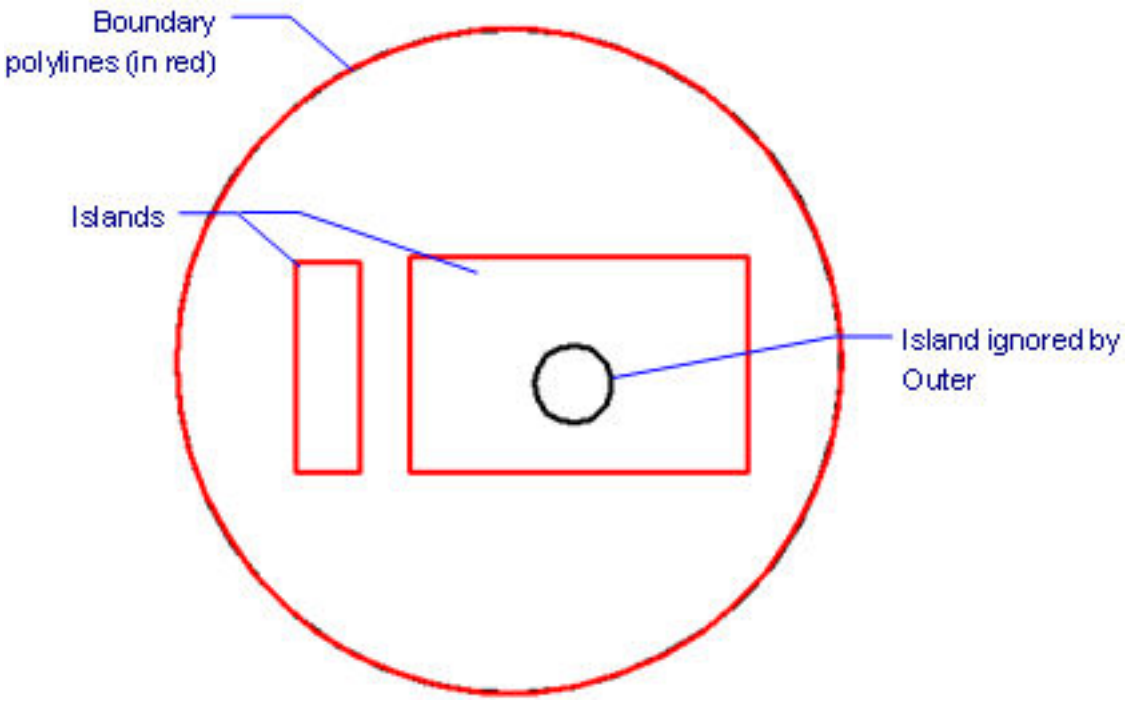

Figure 6.260

6.6.16 -Boundary

(6.2981 on page 6079) Creates a polyline boundary inside closed areas, through the command bar.

Accessing the Command

command bar: **-Boundary** alias: **-bo** : **-boundary Prompts you in the command bar:** Internal point or [Advanced/Undo]: **(Pick a point inside a closed area, or type A)** Internal point or [Advanced/Undo]: **(Pick a point inside another closed area, enter A, or press Enter to end the command)**

Command Options

Option	Description
Internal point	Specifiers the area by picking a point inside a closed area: **Internal point or [Advanced/Undo]** - **(enter an option)**: • **Internal point** - pick a point in the drawing that you hope is an enclosed area, or else enter x,y coordinates. The prompt repeats until you press Enter. • **Advanced** - switches to advanced mode; see below • **Undo** - un-selects the last selected entities When the program cannot find an enclosed area around your pick point, it reports: Selecting everything visible... Valid hatch boundary not found. Adjust the gap tolerance value if the boundary should be considered closed.
Advanced Options	**Description**
Advanced	Entering **a** for the Advanced option produces the following prompt: **[Boundary/Island/eXit] <eXit>** - **(enter an option)** • **Boundary** - jumps to the options for specifying the boundary; see below • **Island** - jumps to the options for specifying how islands should be treated; see below • **eXit** - returns to the "Internal point or [Advanced/Undo]" prompt
Boundary	Specifies where the program should search for the entities making up the boundary: **Specify boundary set [New/Everything] <Everything>:** - **(enter an option)**: • **New** - starts a new boundary selection process; prompts you "Select entities" • **Everything** - uses all entities in the current viewport for the boundary

Island	Determines whether islands are hatched over or not; prompts you: **Do you want Island Detection? [Yes/No/Outer only] <Yes>:- (enter an option)**: • **Yes** - places the boundary entity at the outermost area, as well as around all islands • **No** - islands are ignored; boundary is created of the outermost area only • **Outer only** - ignores innermost areas; boundary is created between outermost area and islands (6.262 on page 3586)
eXit	Returns to the previous prompt.

Procedures

- Drawing polylines (1.25.12)
- Creating boundary polylines (1.25.12)

Grips Editing

Boundaries can be edited directly through grips:

1. Select the boundary. Notice that it has many grips.
2. Drag a grip to stretch the boundary.

(6.261 on the next page)

Related Commands

BHatch (6.6.5) and Hatch (6.16.3) - place boundaries and hatch patterns through a dialog box. -BHatch (6.6.6) and -Hatch (6.16.1) - places boundaries and hatch patterns through the command bar. Boundary (6.6.15) places a polyline boundary inside closed areas through a dialog box. GenerateBoundary (6.15.14) - Creates closed polylines from faces of 3D solids as well as the boundaries detected when the Enable Boundary Detection open of SELECTIONMODES is activated. HatchGenerateBoundary (6.16.5) - generates a boundary around a hatch or gradient fill. Properties (6.24.54) - changes the properties of boundaries. Region (6.26.18) - creates boundary-like regions. Settings (6.27.25) - specifies the default parameters for boundaries. XEdges (6.34.4) - creates 2D linear entities (lines, arcs, circles, ellipses, elliptical arcs and splines) from the edges of 3D solids, 3D solid faces, surfaces, etc. and regions.

Figure 6.262

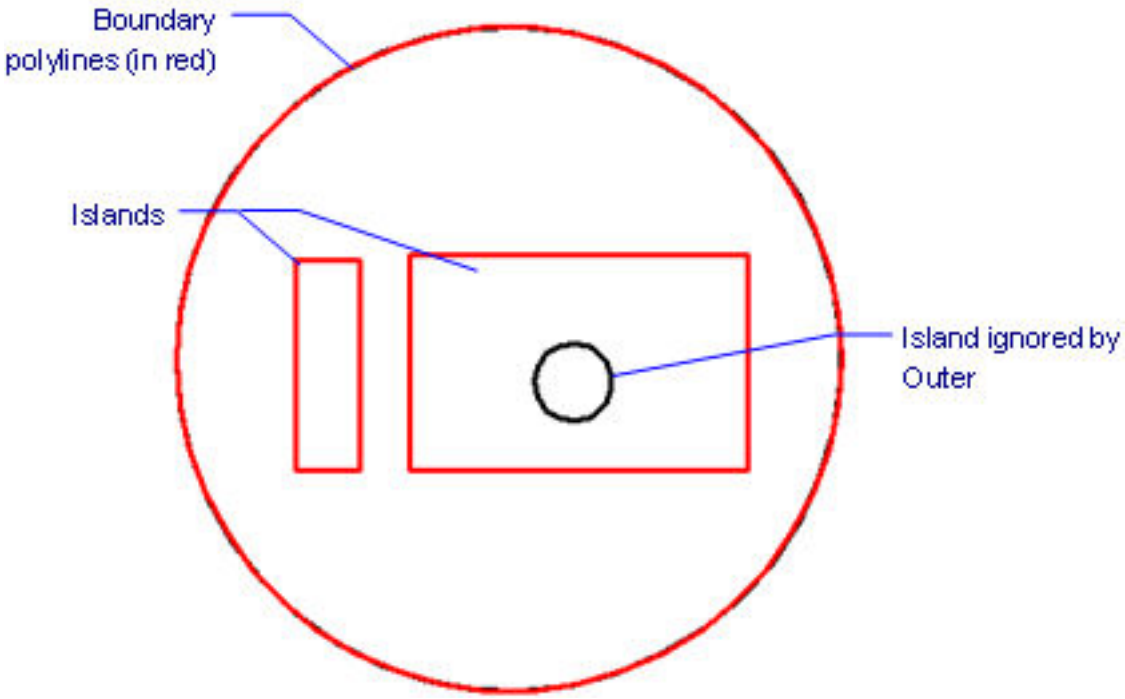

Figure 6.263

6.6.17 BlockIcon

(6.2981 on page 6079) Creates and updates preview bitmaps of blocks and stores them in the drawing.

Accessing the Command

Keyboard: **blockicon : blockicon Prompts you:** Enter block names <*> **(Type block names or press Enter to update/create icons for all blocks in the drawing;.)**

Command Options

Title	Description
Enter block names	Type the name(s) of the block(s) to be processed. Separate block names by commas. You can use wild cards (? or *).

Related Commands

BEdit (6.6.7) - edits the entities that make up blocks in a temporary drawing session called the Block Editor. Optionally creates a new block.

Figure 6.264

6.6.18 Box

(7.3 on page 6132) Creates 3D boxes:

- Classic: box is drawn from a 3D polyface mesh.
- Other license levels: box is drawn as a 3D solid.

Accessing the Command

 command bar: **box** menu bar: **Model | 3D Solids | Box** toolbar: **3D Solids |**  ribbon: **Solid | Create | Primitive | Box** : **box Prompts you in the command bar;** in the Classic version, the prompts follow those of the **Ai_Box (6.5.7)** command: Set corner of box or [Center] <0.00,0.00,0.00>: **(Pick a point, or enter an option)** Set opposite corner or [Cube/Length)]: **(Pick another point, or enter an option)** Height of box [2Point]: **(Pick two points, or enter a height)** (6.265 on the facing page) If Dynamic Dimensions (1.21.9) are active, you can enter the dimensions in the dynamic dimensions entry fields, as illustrated below. (6.266 on the next page)

Figure 6.265

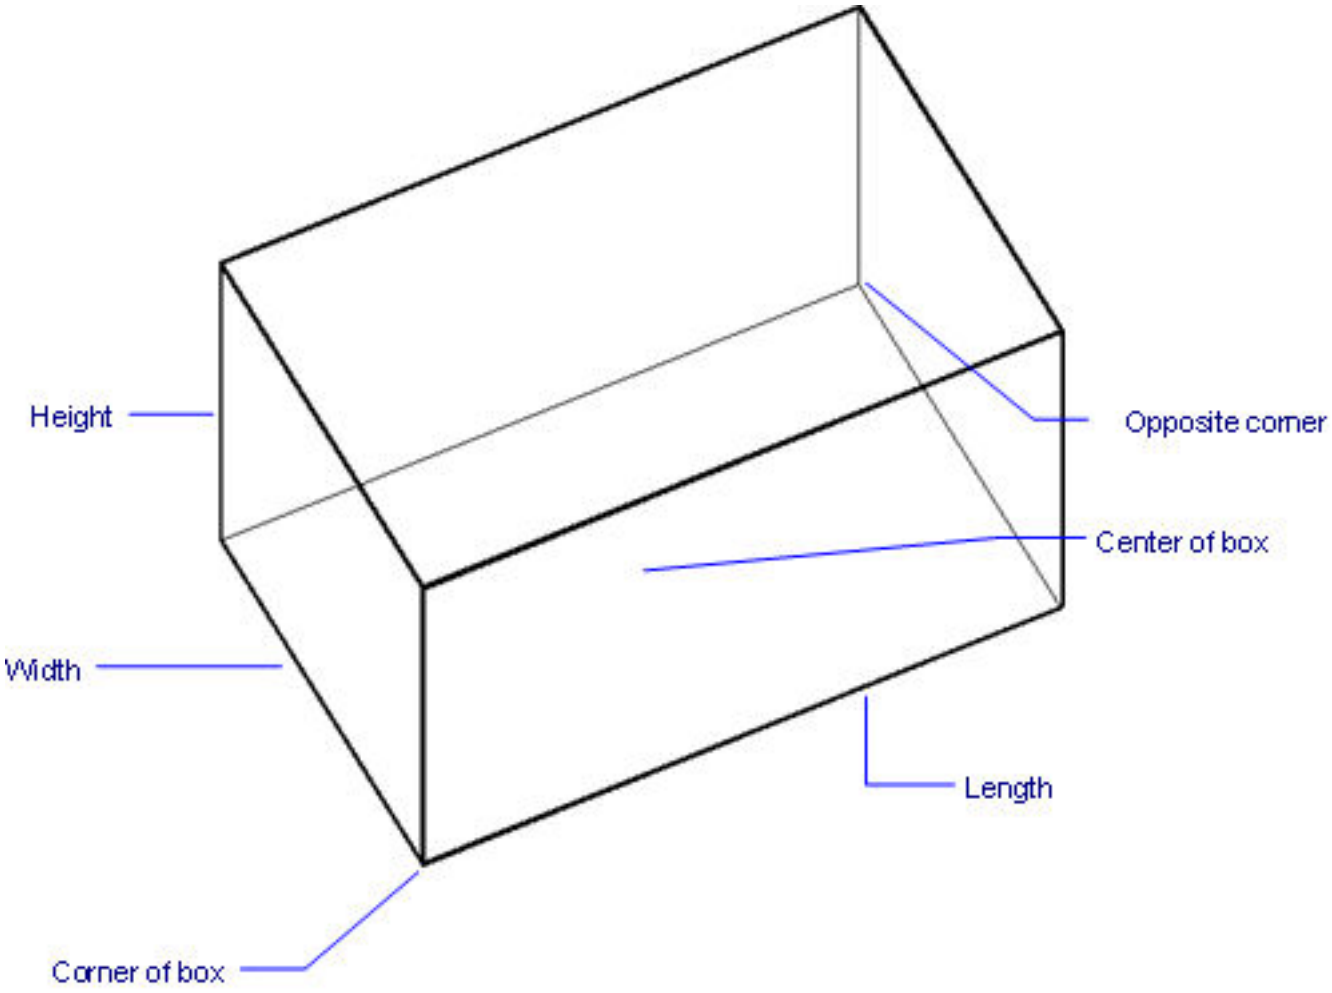

Figure 6.266

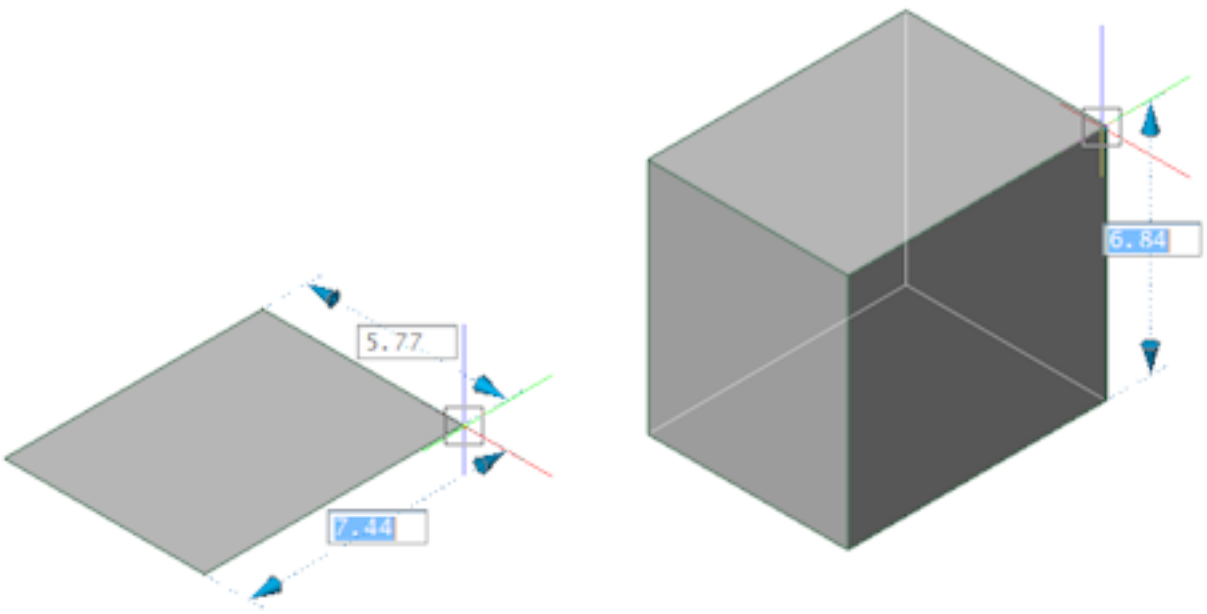


Command Options

Option	Description
Corner of box	Specifies one corner of the box's base. Enter x,y,z coordinates or pick a point in the drawing. Press Enter to reuse the previously-entered coordinates.
Center	Specifies the center of the box's base; prompts you: **Center <1,2,3>** - **(Enter x,y,z coordinates, pick a point in the drawing, ore press Enter to accept the previously-used coordinates.)**
Cube	Specifies a box with three sides of equal length; prompts you: **Length of sides of cube <6>** - **(enter a length, or pick two points, or press Enter to accept the previously-used length.)** The command ends at this point, drawing the cube box.
Length of side	Specifies the length of each side: • **Length of side of box <3>** - **(specify the length in the x direction, pick a point, or press Enter to accept the previously-used length)** • **Width of box <2>** - **(specify the length in the y direction, or pick a point, or press Enter to accept the previously-used width)** • **Height of box <1>** - **(specify the length in the z direction, or pick a point, or press Enter to accept the previously-used height)** You may enter negative values to draw the box in the downward directions.
Set opposite corner	Specifies the opposite corner of the box's base; enter x,y,z coordinates or pick a point in the drawing
Height of box	Specifies the height of the box; enter an option: • **Height of box** - **(specify the height, or pick a point to indicate the height)** • **2Point** - **(pick two points in the drawing)**

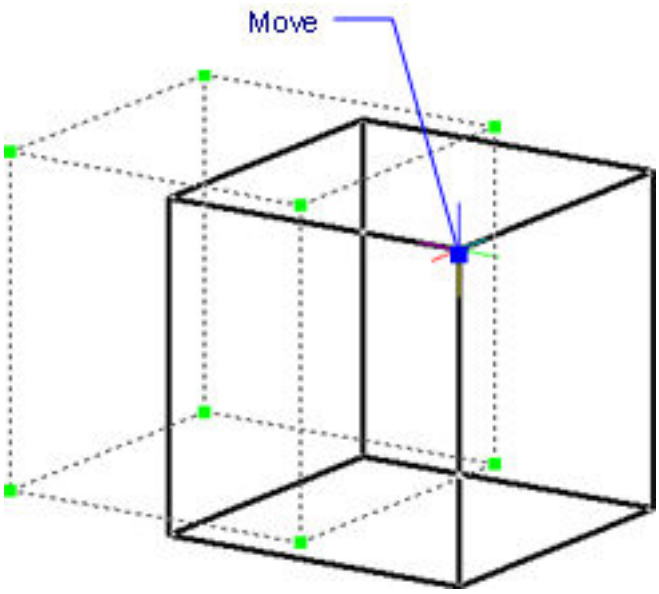
Grips Editing

Boxes can be edited directly through grips:

1. Select the box. Notice that it has many grips.
2. Drag any grip to move the box. (All eight grips perform the same function: move.)

(6.267 on the facing page)

Figure 6.267



Related Commands

Cone (6.9.46) - creates 3D cones as solid models. Cylinder (6.9.49) - creates 3D cylinders as solid models. Extrude (6.13.25) - extrudes 2D entities into 3D solid models. Interfere (6.17.17) - creates 3D volumes of intersecting 3D solid models. Intersect (6.17.20) - removes volumes not in common between two solid models. MassProp (6.21.2) - reports the mass properties of 3D solid models and 2D regions. Pyramid (6.24.64) - creates a pyramid as a 3D solid (Pro and Platinum). Creates a pyramid as a polyface mesh (Classic) Revolve (6.26.45) - revolves 2D entities into 3D solid models. Section (6.27.11) - creates 2D regions from 3D models. Slice (6.27.40) - cuts 3D solids into two parts. SolidEdit (6.27.42) - edits the bodies, faces, and edges of 3D models. Sphere (6.27.50) - creates 3D balls as solid models. Subtract (6.27.58) - removes one solid model from a second. Torus (6.29.29) - creates 3D donuts as solid models. Union (6.30.6) - joins two or more solid models into a single entity. Wedge (6.33.6) - creates 3D wedges as solid models.

Figure 6.268

6.6.19 Browser

(7.3 on page 6132) Opens the default Web browser.

Accessing the Command

command bar: **browser** alias: **url** : **browser Prompts you in the command bar:** Enter URL <http://bricsys.com>: **(Enter address of a Web page or press Enter to open the Bricsys website)**

Command Options

Option	Description
Enter URL	Specifies a location on the Internet, such as www.bricsys.com. After you press Enter, your Web browser opens to that page. (URL is short for "universal resource locator.")

Related Commands

OnWeb (6.23.6) - opens the Bricsys home page in your computer's default Web browser. Mail (6.21.1) - attaches the current drawing to a message in the default email client.

Figure 6.269

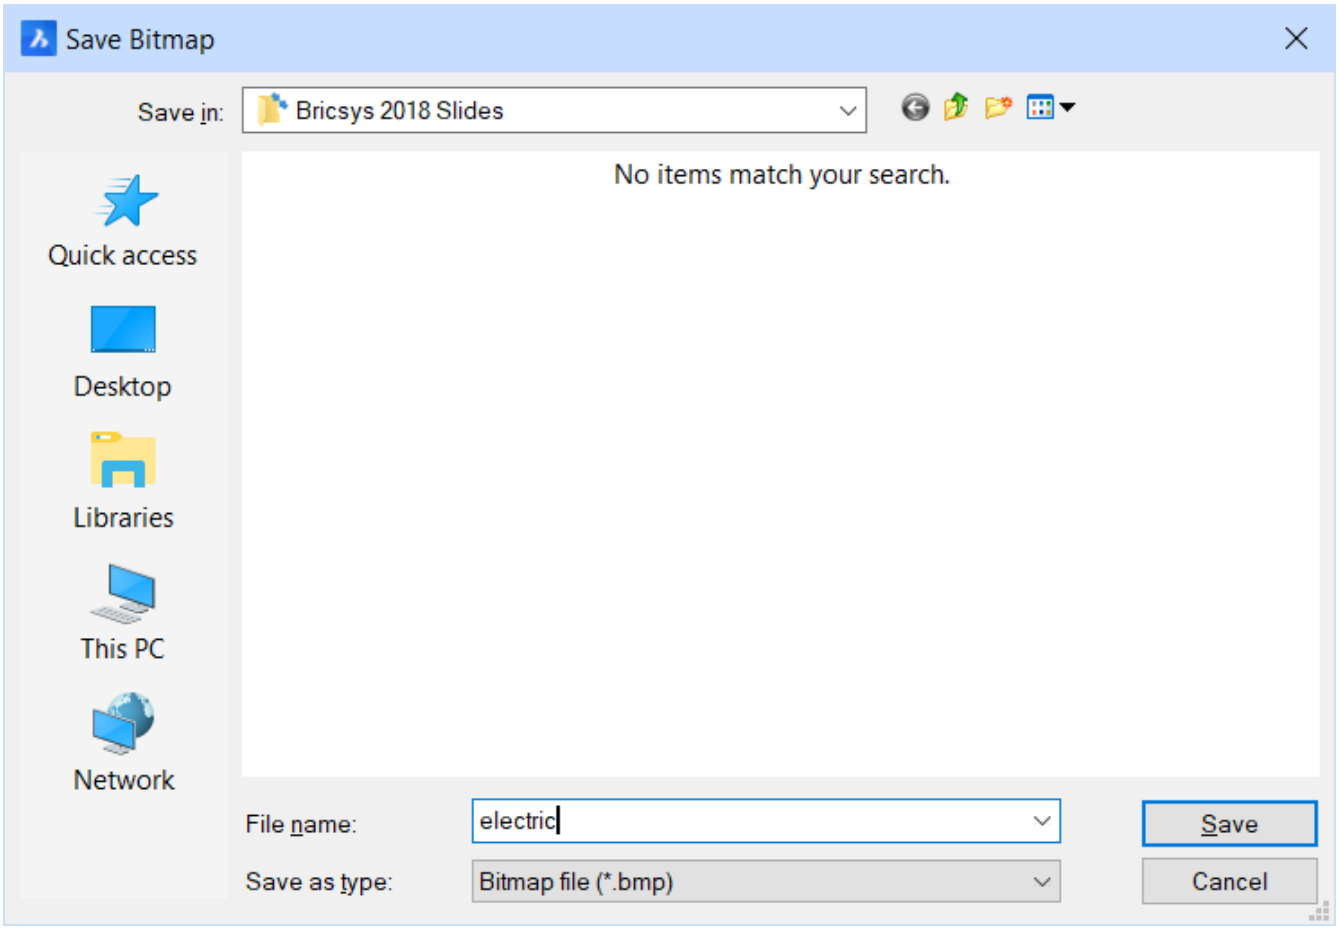
6.6.20 BmpOut

(7.3 on page 6132) Exports the current viewport as a BMP (bitmap or raster) file.

Accessing the Command

command bar: **bmpout** menu bar: **File | Export**, and then choose BMP from the File of Type droplist : **bmpout** Displays a dialog box: (6.270 on the next page)

Figure 6.270



Command Options

Option	Description
Save in	Selects the folder and drive in which to save the file.
File name	Specifies the name of the file.
File of type	Specifies the format in which to save the image.
Save	Saves the content of the current viewport as a raster image.

Related Commands

Export (6.13.18) - exports drawings in BMP, DWF, DXF, DWT, PDF, WMF, EMF, SLD, and older DWG formats. MSlide (6.21.31) - exports drawings in WMF, EMF, and SLD formats. WmfOut (6.33.12) - exports drawings in WMF, EMF, and SLD formats.

Figure 6.271

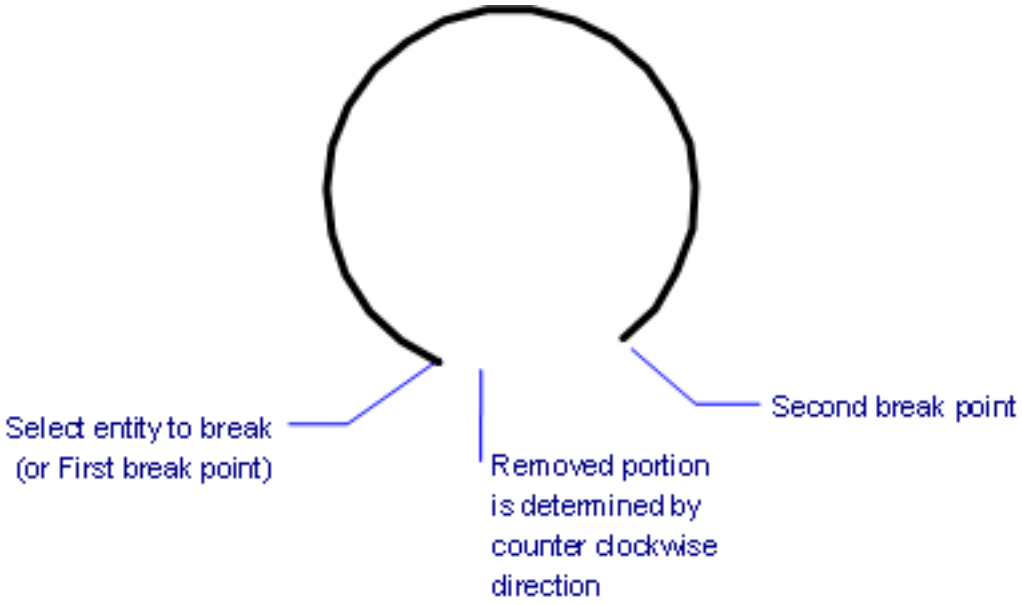
6.6.21 Break

(7.3 on page 6132) Removes a portion of an entity.

Accessing the Command

 command bar: **break** alias: **br** menu bar: **Modify | Break** toolbar: **Modify |**  ribbon: **Change | Modify | Break** : **break Prompts you in the command bar.** Select entity to break: **(Pick an entity)** Select second breakpoint or [First break point/@]: **(Pick a point on the entity or enter an option)** (6.272 on the next page)

Figure 6.272



Command Options

Option	Description
Select entity to break	Selects the entity to break; only one entity may be selected. The pick point is also the first break point, unless you use the **First break point** option.
First break point	Specifies the start of the portion of the entity to remove.
Second break point	Specifies the end of the broken out section. On arcs and circles, the break occurs in the counter-clockwise direction from first to second break points.
@	Specifies that the first and second break points are at the same location on the entity. The selected entity is broken into two connected parts.

Procedures

- To break an entity (1.32.32)

Related Commands

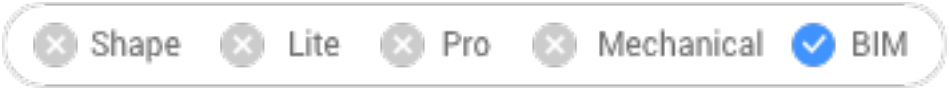
DimBreak (6.11.17) - breaks dimension lines, extension lines and leaders at locations where they cross other entities. Join (6.18.1) - joins lines, LW polylines, 2D polylines, 3D polylines, circular arcs, elliptical arcs, splines and helixes at their common endpoints.. PEdit (6.24.24) - joins lines and arcs into a single polyline. Trim (6.29.35) - cuts entities where they cross other entities.

6.7 BIM (Building Information Modeling)

6.7.1 PointCloudProjectSection

(6.493 on page 3778) Automatically generates 2D a raster image with optional contour lines from a defined section box.

Figure 6.273



Accessing the Command

Commandline: **POINTCLOUDPROJECTSECTION** Ribbon: Panel: **Insert|Pointclouds – Pointclouds Project Section** Toolbar: **Pointclouds : PointCloudProjectSection Prompts you in the command bar:** Select section volumes to project [selection options (?)]: **Select the section volume to project and press Enter**. **Specify the options in the Wall Detection Options dialog and click OK.**

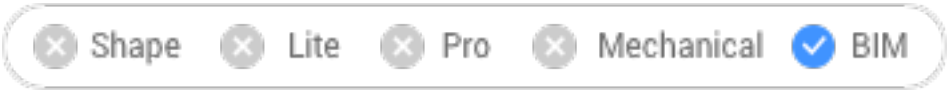
Command Options

Option Description The following parameters control 2D line drawings. Detect walls When "OFF" only a raster image is created. When "ON" lines representing walls will be generated with the raster image. **Search area** Select Distance from plane to detect walls in a given radius from a plane. This option is often used to generate vertical sections. Select Across the volume to detect all the walls in the point cloud. This option is often used to generate floor plans. **Wall distance** Only available when Distance from plane is selected. Controls the search area for the wall detection. **Gap tolerance** A bigger value will result in a bigger search area for the algorithm to draw lines. A higher tolerance is needed in grainier models. Gaps smaller than the specified value will be closed. **Angular tolerance** Controls the angular tolerance of the generated lines. More angular tolerance will result in pronounced right angles. Useful for perpendicular plans. Generated lines with an angle smaller than the specified value will be merged. **Minimum length** Controls the minimum length of a generated line. Lines with a length smaller than the specified value will not be generated. **The following parameters control the generated raster image. Pixel size** Controls the pixel size of the generated image. Pixel size is in model units. A higher pixel size generates a lower resolution, with a faster result. **Attach projection to** Determines where the resulting image is generated. **Same .dwg** will make the projection in the same file, **New .dwg** will create a new .dwg file. You can overwrite a previous file or create a new one. **Project resolution** Choose Finest or Adaptive. **Finest** will produce a sharp and detailed background picture. While **adaptive** is less detailed and softer, it's quicker because fewer points need to be rendered. **Attachment point** Determines the insertion point for the generated image. **In-place:** the lines and image will be placed in the same location and orientation as the sectionplane. **X-Y Plane:** the section will be aligned with X_Y axis. The section can be edited in Topview, as any regular 2D drawing. This is practical for vertical sections. **Over-write old projection file** When "ON", the existing projection file will be overwritten.

Related Commands

PointCloud (6.24.31) - opens the Drawing Explorer to the Point Cloud section; converts, loads, and unloads point cloud file attachments. PointCloudAlign (6.24.67) - rotates the point cloud to optimally align it with the X and Y axes. PointCloudDetectFloors (6.7.4) - generates volume sections for each floor found in a point cloud representing a building. PointCloudFitPlanar (6.7.2) - creates 3d geometry based on the point cloud as a planar surface or solid.

Figure 6.274



6.7.2 PointCloudFitPlanar

(6.493 on page 3778) Searches a point cloud for a dense set of points and creates a planar surface or a solid. The command can be executed in model view or in a bubble view. Double click the bubble you want to start the command in.

Accessing the Command

Commandline: **POINTCLOUDFITPLANAR** Ribbon: **Insert | Pointclouds – Pointclouds Fit Planar** Toolbar: **Pointclouds Prompts you in the command bar:**

When started in a Bubble view : POINTCLOUDFITPLANAR [Bubble viewer] Please select a point. Press ESC to cancel. Select point in bubble viewer or switch bubble [Switch]: **(When you move the cursor over a surface a red spot (plane) and a green line (normal of the plane) indicate a surface is detected. Click to select.)** 
Select point in bubble viewer or switch bubble [Switch]:DonePoint 1: The detected plane highlights in the bubble view. (6.287 on page 3609) BricsCAD reports the details of the detected surface. Accept, Decline, Switch Mode (contour) (CTRL), Switch Bubble, Undo, or Shift+Click for rapid selection [Accept/Decline/Mode/Bubble/Undo] <Accept>: **(Press Enter or choose an option.)** 1 surface(s) were successfully created. The highlight color of the detected plane plane turns to green in the bubble view. (6.288 on page 3609) Select point in bubble viewer or switch bubble [Switch]: **(Move the cursor over another plane, then click to select.)** Select point in bubble viewer or switch bubble [Switch]:DonePoint 2: The detected plane highlights in the bubble view. (6.289 on page 3610) BricsCAD reports the details of the detected surface. Accept, Decline, Switch Mode (contour) (CTRL), Switch Bubble, Undo, or Shift+Click for rapid selection [Accept/Decline/Mode/Bubble/Undo] <Accept>: **(Press Enter or choose an option.)** 1 surface(s) were successfully created. The highlight color of the detected plane plane turns to green in the bubble view. (6.290 on page 3610) [Bubble viewer] Please select a point. Press ESC to cancel. Select point in bubble viewer or switch bubble [Switch]: **(Repeat the previous steps to create more surfaces or close the bubble view, then press Esc to stop.)**

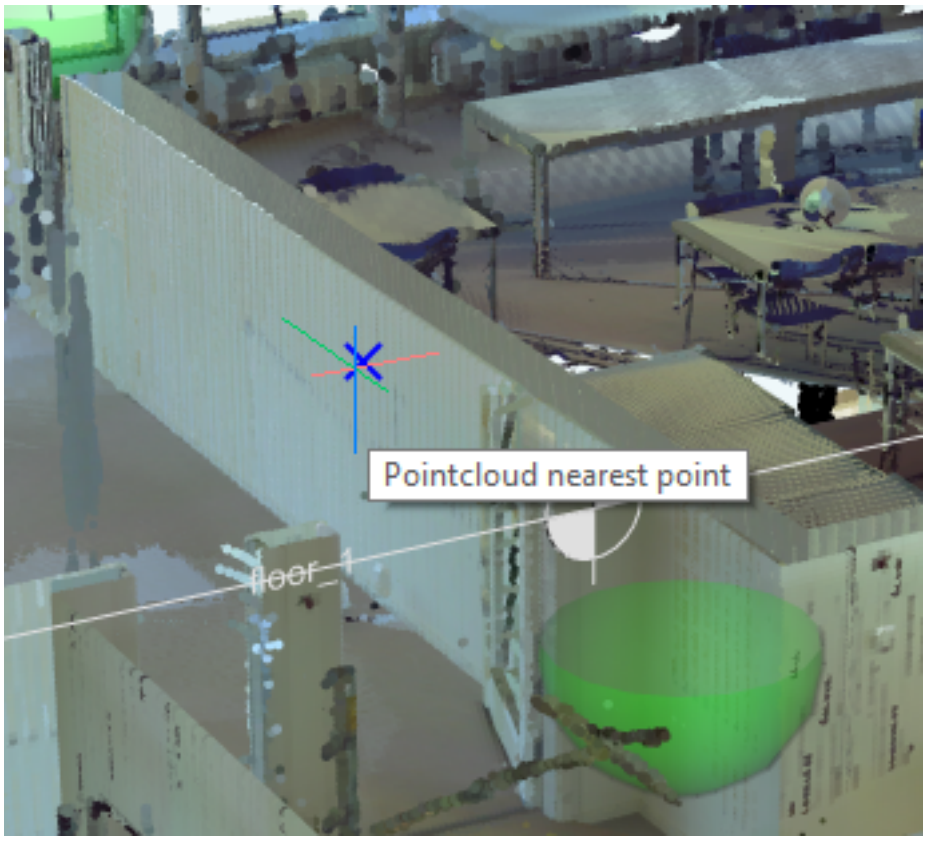
Figure 6.278

When started in Model view **Note**: Set the Pointcloud Nearest 3D entity snap (1.21.16) first. **: POINTCLOUDFITPLANAR** Select point cloud point in model view: **(Click to select a point.)** (6.291 on page 3612) Determining plane. BricsCAD reports the details of the detected surface. Accept, Decline, Switch Mode (contour) (CTRL) or Shift+Click for rapid selection [Accept/Decline/Mode/Undo] <Accept>: Press the Ctrl-key to switch (6.292 on page 3614) (6.293 on page 3614) (6.297 on page 3616) Rectangle mode Contour mode Solid mode **(Press Enter to accept the surface or solid or choose an option.)** 1 surface(s) were successfully created. Select point cloud point in model view: **(Click to select a point or press Esc to stop.)**

Figure 6.279



Command Options

Option	Description
Accept	Creates the highlighted surface on the current layer.
Decline	Declines the highlighted surface and nothing is created.
Switch Mode	Switches between Rectangular, Contour and Solid mode. • **Contour mode**: creates a surface to accommodate cut outs for voids, such as doors and window openings. (6.295 on page 3615) • **Rectangle mode**: creates a rectangular shape from the bounding rectangle of the plane around a region of planar points. (6.296 on page 3616) • **Solid mode**: creates a solid. This option is available in Model view only, if a dense area is detected in a plane that is parallel to the detected surface. (6.297 on page 3616)

Shift+ Click	Allows to add surfaces to the current selection. Prompts you: • In Model view: Select point cloud point in model view. • In bubble view: Select a point on an adjacent intersecting plane to adjust extents. Surfaces that share an edge will be joined according to the current value of the **PlaneFitTolerance** property of the point cloud. You can edit the value of this property in the **Misc** properties in the Properties panel.
Undo	Removes the most recently added surface from the current selection. Use the **Decline** option to remove the surface that was selected first.
Bubble	Allows to switch bubbles. Prompts you: Select a bubble to switch: Click a bubble in Model view. Bubble xx activated. Image: C:..\PointCloudCache\<pointcloud ID>\Bubbles\<bubble ID>

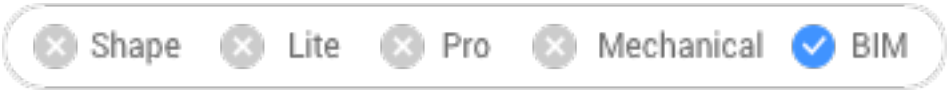
View Rotation (1.23.7)

Figure 6.301



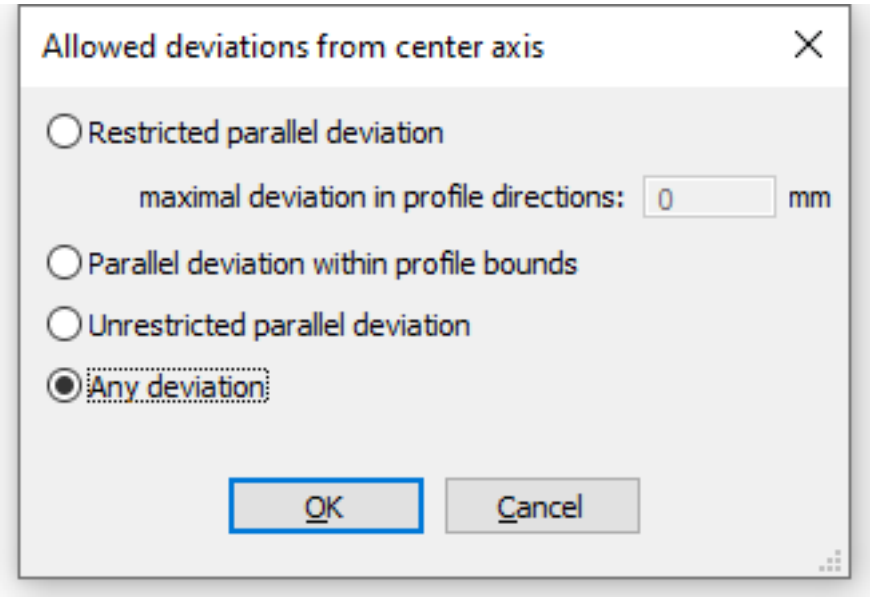
6.7.6 BimAnalyticalModel

(6.493 on page 3778) Creates an analytical model from a fully classified BIM model.

Accessing the Command

Commandline: **BIMANALYTICALMODEL : BimAnayticalModel** Displays a dialog box: **(6.302 on the next page) (You can choose the deviation in the Allowed deviations from center axis window) You are prompted:** Choose next action [Visual settings/ Recalculate/ Export and exit/ eXit] : **(Choose an option.)**

Figure 6.302



Command Options

Option	Description
Visual settings	Opens the Visual settings window. (6.303 on page 3623) In this window, you can check and uncheck different features of axes and nodes to highlight (in yellow) the axes and nodes that match these features. You can also change the size of the disks representing the nodes.
Recalculate	Propagates the effect of a local change further, allowing modifications in the complete model. It will launch a global solution that again tries to minimize rigid links, respecting the changes you made.
Export and exit	Exports the model to an IFC or CIS/2 file and exit the command. In the Settings dialog, find **Structural Analysis Model** options and choose the export format of the analytical model.
Exit	Exits the command.
Undo (ctrl-z)	Undoes the previous operation.
Option menu entities	Calls the options menu of the selected entities by hovering over an element in the selection or by right-clicking on it.

Allowed deviations from the center

Option	Description
Restricted parallel deviation	Axes remain parallel to the center axis and within the specified distance from the center axis in both profile directions. You can specify the distance in the window.
Parallel deviation within profile bounds	Axes remain parallel to the center axis and do not exceed profile bounds.
Unrestricted parallel deviation	Axes remain parallel to the center axis, but can be placed outside the profile bounds if this is useful to avoid node splits or rigid links.
Any deviation	The main axes remain parallel to the center axis, but tilted axes (with respect to vertical and main horizontal directions) can be allowed to deviate from parallel if it useful to avoid node splits and rigid links. Other axes can move outside of profile bounds.

Options in an axis

Option	Description
Select connected nodes	Selects the nodes connected to the axis.
Remove	Removes the axis.
Connect to node	Connects the axis to a chosen node. **You are prompted:** Select the node to connect to axes [Ok]
Disconnect from node	Disconnects the axis from a chosen node. **You are prompted:** Select node to disconnect from axes [Ok]
Add restrictions	Adds a restriction on the axis. The restriction you can add depends on the restrictions that are already imposed. If there are no restrictions yet, you can add the following restrictions: • Parallel to the centerline • Inside profile bounds • To closest midplane • To closest base position • To center • No length extension
Relax restrictions	Relaxes a restriction on the axis. The restriction you can relax depends on the restrictions that are imposed. Mostly these will be the restrictions that you can relax: • Inside profile bounds • Outside profile bounds • Non-parallel • Allow length extension

Procedures

Creating an analytical model with strict deviation settings (2.7.1) Creating an analytical model with the least restrictive deviation settings (2.7.1) Export an analytical model (2.7.1)

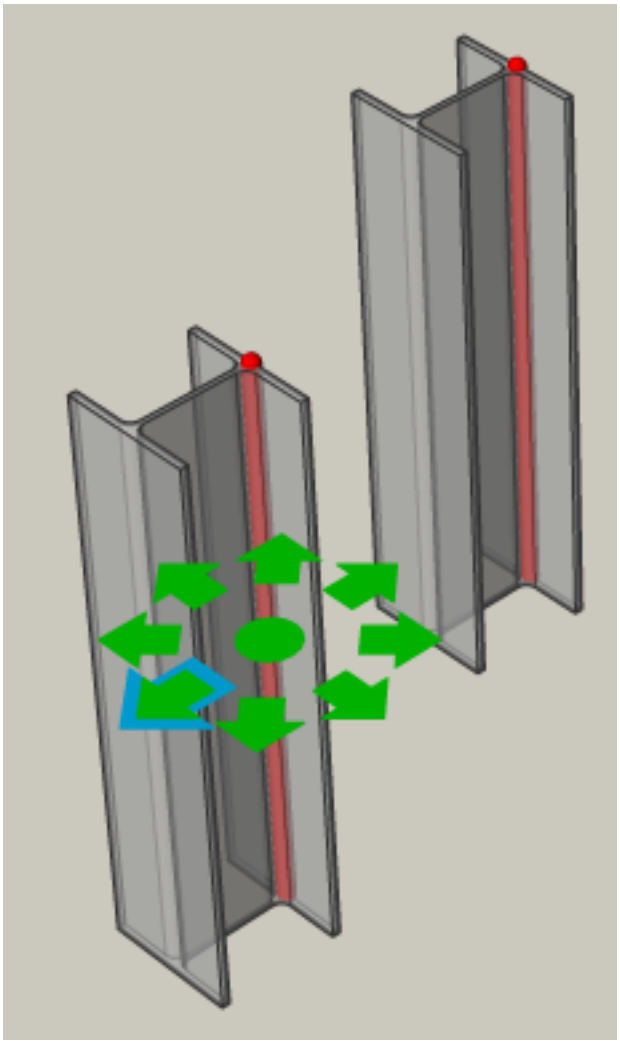
6.7.7 BimAddEccentricity

(6.1726 on page 4955) Allows to control the relative position of the axis of a linear solid.

Accessing the Command

Commandline: **BIMADDECCENTRICITY** Quad: **Model | Add Eccentricity** Ribbon: **Home | Structure/HVAC | Add Eccentricity** Toolbar: **BIM Toolbar | BIM Structural** : **BimAddEccentricity Prompts you in the command bar:** Select several entities/subentities: **(Select a linear solid.)** Entities in set: 1 Select several entities/subentities: **(Select more linear solids or press Enter.)** (6.305 on the facing page) Choose base location [Accept] <Accept>: **(Click a new location; type a location or press Enter.)**

Figure 6.305



Command Options

Option	Description
Click the widget	Click one of the nine locations, then right click to confirm.
Type a location	The options are: • **TR**: Top Right • **TM**: Top Middle • **TL**: Top Left • **MR**: Middle Right • **C**: Center (resets the axes of the selection set to the default location) • **ML**: Middle Left • **BR**: Bottom Right • **BM**: Bottom Middel • **BL**: Bottom right

Procedures

Add eccentricity to linear solids (2.5.1) Altering the axis of profiles Use modeling tools to create a structural steel model (2.5.20) Use the modeling tools to create a more detailed connection (2.5.20)

Related Commands

BimApplyProfile (6.7.10) - applies a profile to linear entities and linear solids. BimLinearSolid (6.7.29) - creates linear solids. BimProfiles (6.7.26) - opens the profiles library in the current project and the referenced library. BimRecalculateAxis (6.7.51) - recalculates the axis of linear building elements and repositions it back on the center line of a linear element.

Figure 6.306

6.7.8 BimAttachComposition

(6.1726 on page 4955) Attaches a BIM composition to solids.

Accessing the Command

 Commandline: **BIMATTACHCOMPOSITION** Quad: **Bim | Attach Composition** Ribbon:

- **Home | Classify | Attach Composition**
- **Data | Attach |** Attach Composition

: **BimAttachComposition** Prompts you in the **command bar:** Enter composition name or [Dialog/Entity/deTach] <Dialog>: **(Press Enter or select an option.)** The **Compositions** dialog box displays. See BLCompositions (6.7.57) for more information about the dialog. Select a composition in the **In Project** or the **In-Library** list: Double-click the composition or click the **Select** button on the **Compositions** dialog box. Select entities to attach composition: **(Select solids.)** Entities in set: 3 Select entities to attach composition: **(Select more solids or press Enter.)** Choose the reference face and press Enter.

Command Options

Option	Description
Entity	Applies the composition of an existing solid. Prompts you: **Select other entities to get composition - (select to copy the composition from.). Select entities to attach composition - (Select a solid.)** Entities in set: 1 Select entities to attach composition: **Select entities to attach composition - (Select more solids or press Enter.) Choose reference face [Accept] - (Press Enter to accept the current reference face or choose a reference option.)**

	Allows to control the reference face* when attaching a multiply composition or a single-ply composition with a fixed thickness. • Click the widget to flip the reference face to the opposite face of the solid. • Move the cursor over the widget then choose an option in the menu. (6.307 on the facing page) – **Flip composition**: reverses the order of the plies of a multiply composition. – **Redefine reference face**: allows you to choose a face as the reference face Prompts you: **Select reference face** - select a face of the solid. **Select opposing face** - select the opposite face. C**hoose reference face [Accept]** - press Enter to accept the reference face. – **Align by reference face**: use the selected face as the reference face (default) – **Align by center**: use the center face of the wall as the reference face Click the **Flip composition** option to reverse the ply order of asymmetric multiply compositions. (6.308 on the next page) (6.309 on page 3630) * Reference face: defines the position of the exterior ply of multiply compositions (2.7.4). **Note:** Hit the TAB key to select an obscured face.
Detach	Allows to detach a composition, while keeping the BIM classification, as different from the Unclassify option of the BIMCLASSIFY (6.7.12) command, which removes all BIM data.
Compositions panel (1.15.7) 	Drag a composition from the Compositions panel onto a single solid or a selection of solids.

Procedures

Creating a new Composition (2.7.4) Editing a Composition (2.7.4) Modifying the Thickness of a ply (2.7.4) Copying Compositions (2.7.4) Deleting Compositions (2.7.4)

Related Commands

Bimflip (6.7.20) - Flips the starting face from which the layers of a composition are set out. BimProjectInfo (6.7.32) - Opens the BIM Project Info dialog box. BimUpdateThickness (6.7.62) - Re-applies the overall thickness of a composition to the solid. BimSetReferenceFace (6.7.46) - Defines a reference and an opposing face to control the ply layout of a composition. BLCompositions (6.7.57) - Opens the compositions library in the current project and the referenced library. BLMaterials (6.7.58) - Opens the physical materials library in the current project and the referenced library. BimClassify (6.7.12) - Classifies an entity as a Building Element and get a name and an internal GUID (= globally unique identifier). LevelOfDetail (2.3.6) - Changes the visibility of a solid's composition in your model.

Figure 6.307

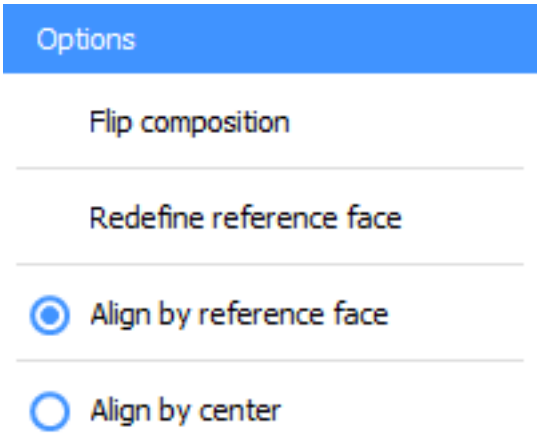


Figure 6.308

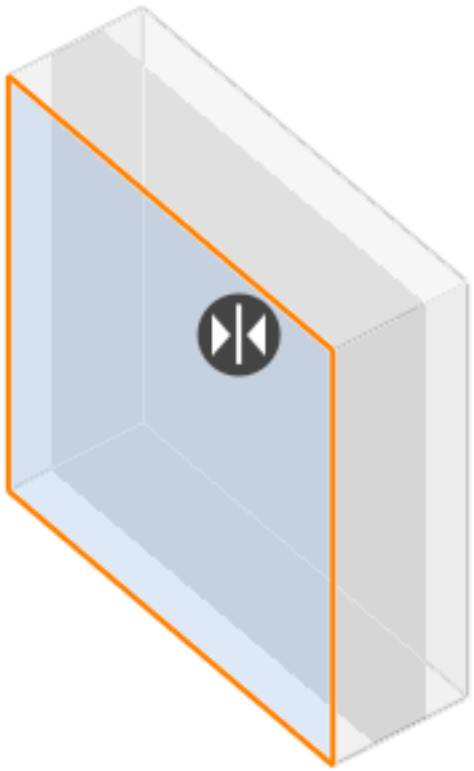

Figure 6.309

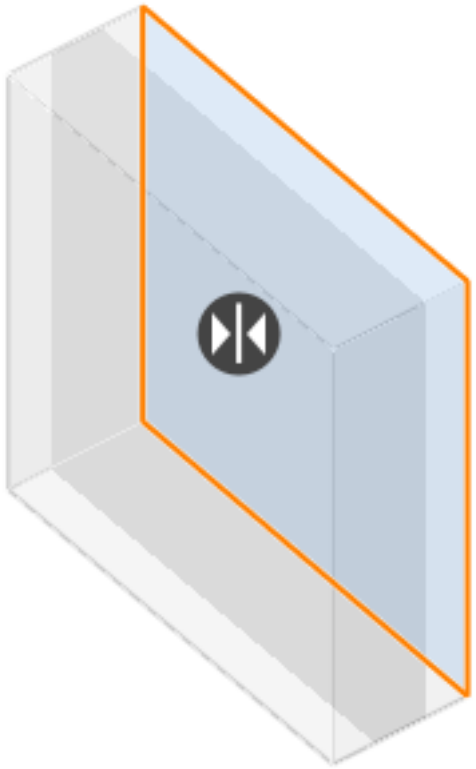

Figure 6.310

6.7.9 BimAttachSpatialLocation

(6.1726 on page 4955) Allows to attach or remove a spatial location to a selection of entities.

Accessing the Command

Commandline: **BIMATTACHSPATIALLOCATION** Quad: **BIM | Attach Spatial Location** Ribbon: **Home | Classify | Attach | Attach spatial location** Toolbar: **BIM Databases | Spatial locations** : **BimAttachSpatialLocation Prompts you in the command bar*:** Locations: 1. Building-2 2. Building-2 - Floor 0 3. Building-2 - Floor 1 ... * It might be necessary to press the F2 function key to open the Prompt History (6.29.16) window. Enter location number or [Auto attach locations/Unattach current location] <Auto attach locations>: **(Enter a location number or choose an option.)** Select entities to update: **(Select the entities you want to attach a spatial location to.)** Entities in set: xx Select entities to update: **(Select more entities or press Enter.)** The spatial location has been assigned to xx element(s).

Command Options

Option	Description
Auto attach locations	Allows to automatically assign a spatial location; prompts you: **Select entities to update - (select the entities to be processed.) Entities in set: xx Select entities to update - (select more entities or press Enter.) Building 'Building': <Existed> The spatial location has been assigned to yy element(s). Skipped: zz element(s).** If necessary, new building(s) and stories are created in the Building and Story Manager (6.7.63) dialog box.
Unattach current locations	Allows to remove the current spatial location from a selection set; prompts you: **Select entities to update - (select the entities to be processed.) Entities in set: xx Select entities to update - (select more entities or press Enter.) The spatial location has been removed from xx element(s).**

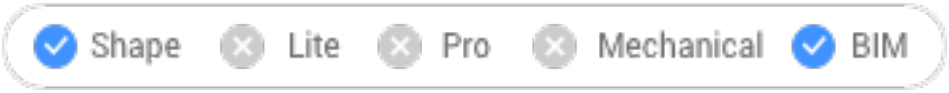
Procedures

Assigning a building and story to a building element (2.7.16)

Related Commands

BimClassify (6.7.12) - classifies an entity as a Building Element and get a name and an internal GUID (= globally unique identifier). Bimify (6.7.23) - analyzes the model and runs automatic classification and spatial location assignment for the entire model. BimSpatialLocations (6.7.63) - opens the Buildings & Stories manager. This explorer allows to create and edit site, buildings and stories.

Figure 6.311



6.7.10 BimApplyProfile

(6.586 on page 3851) Applies a profile to linear entities and linear solids.

Accessing the Command

Commandline: **BIMAPPLYPROFILE** Quad: **Model | Apply Profile** Ribbon: **Home | Classify | Attach | Attach Profile** Toolbar: **BIM Toolbar | BIM Structural** : **BimApplyProfile Prompts you in the command bar:** Select path(s) [selection options (?)]: **(Select a linear entity* or linear solid.)** Entities in set: 1 Select path(s) [selection options (?)]: **(Select more linear entities or linear solids or press Enter.)** Entities in set: 2 Select profile [LIbrary/selection options (?)] <LIbrary>: **(Select a profile entity in the drawing or press Enter to display the Profiles dialog box.)** Apply profile? [Ok/Quarter turn/Rotate/Delete clippings] <Ok>: **(Press Enter to apply the profile or choose an option.)** *Lines, polylines, arcs, circles, elliptical arcs, ellipses and helixes are accepted. Open and closed splines are accepted only if they have default tangents and are not self-intersecting.

Command Options

Option	Description
Selection options (?)	Allows to select a selection method. See the SELECT (6.27.16) command.
Select profile	Allows to select a profile in the model: • Click a closed 2D entity or a region in the model. • Click an existing linear solid.
Library	Opens the **Profiles (6.7.26)** dialog box. Select a profile, then click the **Select** button.
OK	Applies the profile to the selection.
Quarter Turn	Rotates the profile 90° counter clockwise.
Rotate	Allows to rotate the profile about a user defined angle; prompts you: **Rotation angle <90>** - **(type a value)**. Positive values rotate the profile counter clockwise.
Delete Clippings	Removes all clippings from the selected linear solid(s).

Procedures

Applying a profile to linear solids (2.5.1) Applying profiles to an already existing line or solid (2.5.14) Using the MEP Modeling tools to draw and connect profiles (2.5.14) Using the MEP Modeling tools to alter profiles (2.5.14)

Related Commands

BimAddEccentricity (6.7.7) - Allows to control the relative position of the axis of a linear solid. BimLinearSolid (6.7.29) - Creates linear solids. BimProfiles (6.7.26) - Opens the profiles library in the current project and the referenced library. BimFlowConnect (6.7.19) - Creates a connection between flow segments, such as pipes or HVAC ducts.

Figure 6.312

6.7.11 BimAutoMatch

(6.1726 on page 4955) Matches the composition, properties or parameters of example entities to all similar entities in your project. **Note:** This command works best when the project is Bimified. (6.7.23) E.g: You have attached a specific composition to a wall and a floorslab in the project. Instead of attaching the composition to all the similar walls and floor slabs 1 by 1, you can use this command to do it for you. BimAutoMatch finds similarities based on the type of element, interior/exterior property, orientation, spatial location, amount of windows in a wall and already defined properties. It will not overwrite already defined properties, unless no unmodified entity can be found and the user specifies a source entity.

Accessing the Command

Commandline: **BIMAUTOMATCH** Quad: **Model | Automatch** Ribbon: **Home | Classify | Auto Match : BimAutoMatch Auto Match Dialogbox displays:** (6.313) **(Choose the options you want to automatch and click Autocomplete or External file.)**

- When there are unmodified or unclassified entities in the drawing and there is only one building, nothing is prompted.
- When choosing 'Autocomplete' with multiple buildings in the drawing, following is prompted. **Prompts you in the Command bar:** Select building to apply style on [All/Building/0 for building-2/1 for building-3/...]: **(Select an option.)**

Option	Description
All	All the buildings will be taken into account while doing AutoMatch.
Building	AutoMatch is only applied as if 'Building' was the only building in the drawing.
0 for building-2	AutoMatch is only applied as if 'building-2' was the only building in the drawing.
1 for building-3	AutoMatch is only applied as if 'building-3' was the only building in the drawing.
...	All building names, available in the current drawing, are listed here.

- When choosing 'External file' with multiple buildings in both drawings, following is prompted. **Prompts you in the Command bar:** Select building to detect style from [Building/0 for building-2/1 for building-3/...]: **(Select an option.)**

Option	Description
Building	'Building' is taken as source building to detect the style from.
0 for building-2	'building-2' is taken as source building to detect the style from.
1 for building-3	'building-3' is taken as source building to detect the style from.
...	All building names, available in the external source file, are listed here.

Prompts you in the Command bar: Select building to apply style on [All/Building/0 for building-2/1 for building-3/...]: **(Select an option.)**

Option	Description
All	The chosen style is applied onto all buildings in the destination drawing.
Building	The chosen style is applied onto 'Building'.
0 for building-2	The chosen style is applied onto 'building-2'.
1 for building-3	The chosen style is applied onto 'building-3'.
...	All building names, available in the current drawing, are listed here.

When all entities have compositions, following is prompted to let you use automatch to overwrite certain compositions. **Prompts you in the Command bar:** Select composition Style Example: **(Select an entity with a composition attached to it, from which you want to copy the composition.)**

- When all entities in the drawing have the same customized property, following is prompted to let you use automatch to overwrite certain values of this property. **Prompts you in the Command bar:** Select solids with Bim Properties to do AutoMatching from: **(Select an entity with a customized value of a property, from which you want to copy the property.)**
- When all windows have customized parameters, following is prompted to let you use automatch to overwrite certain parameters. **Prompts you in the Command bar:** Select Window Style: **(Select a window in your drawing, from which you want to copy the parameters.)**
- When all stairs have customized parameters, following is prompted to let you use automatch to overwrite certain parameters. **Prompts you in the Command bar:** Select stairs as source for automatch: **(Select a stair in your drawing, from which you want to copy the parameters.)**

Before	After
Every type of element has one entitity with the correct composition. (6.314 on page 3637)	All elements are given the correct composition. (6.315 on page 3637)

Command Options

Option	Description
Compositions	Check this option if you want the composition of your entities to be copied. If there are entities without a composition in your drawing Automatch will match them with the other compositions in your drawing, based on type, spatial location and orientation of the entity, as well as on the 'Is external'-property. If all entities have compositions, you can overwrite some by choosing a source entity. AutoMatch will then copy this source's composition to the rest of the valid entities.

BIM Properties	Check this option if you want the BIM properties of entities to be copied. If there are entities with unchanged properties in your drawing AutoMatch will match the properties, based on BIM type, composition and spatial location of the other entities in your drawing. If every entity has a changed property, you can overwrite it by choosing a source entity. AutoMatch will then copy this source's property to the rest of the valid entities. Some general BIM properties will never be copied along: • GUID • Composition • Profile • SpatialLocation • IsExternal Some beam and column related BIM properties will never be copied along: • GeomHash • PathString • XAxis • YAxis • ZAxis • ProfileName • EndPoint • StartPoint • Valid • InstancePropertySets Some window and door related BIM properties will never be copied along: • Name • SubtractAllSolids • Translucency • OverallWidth • OverallHeight Some slab related BIM properties will never be copied along: • RoomBounding Some room related BIM properties will never be copied along: • Number • RoomArea • RoomRepresentation Some stair related BIM properties will never be copied along: • StairType • NumberOfRisers • NumberOfTreads

Window Parameters	Check this option if you want the parameters of a window to be copied. If there are unchanged windows in your drawing AutoMatch will match the properties, based on width, height, type, spatial location and orientation of the windows and type and composition of the entities they are in. If every window has changed parameters, you can overwrite some by choosing a source window. AutoMatch will then copy this source's parameters to the rest of the valid windows. Some window parameters will never be copied along: • W (= width of the window) • H (= height of the window)
Stair Parameters	Check this option if you want the parameters of a stair to be copied. If there are unchanged stairs in your drawing AutoMatch will match the properties, based on number of treads, number of risers, height, width, length and type of the stair. If every stair has changed parameters, you can overwrite some by choosing a source stair. AutoMatch will then copy this source's parameters to the rest of the valid stairs. Some stair parameters will never be copied along: • Height_Staircase • Stair_Width • Length_Staircase

Option	Description
Autocomplete	Matches all chosen options for entities in the open drawing with similar entities in the open drawing.
External file	Matches all chosen options for entities in the chosen drawing with similar entities in the open drawing.

Procedures

Using autocomplete in one file (2.7.2) Using autocomplete with an external file (2.7.2)

Related Commands

Bimify (6.7.23) - Analyzes the model and runs automatic classification and spatial location assignment for the entire model. Creates new buildings and/or stories and rooms if necessary. Optionally creates plan sections and elevations. MatchProp (6.21.18) - Copies the properties and styles from one entity and then applies them to one or more other entities, with control over which properties are copied (short for "match properties"). BimAttach-Composition (6.7.8) - Attaches a BIM composition to solids.

Figure 6.314

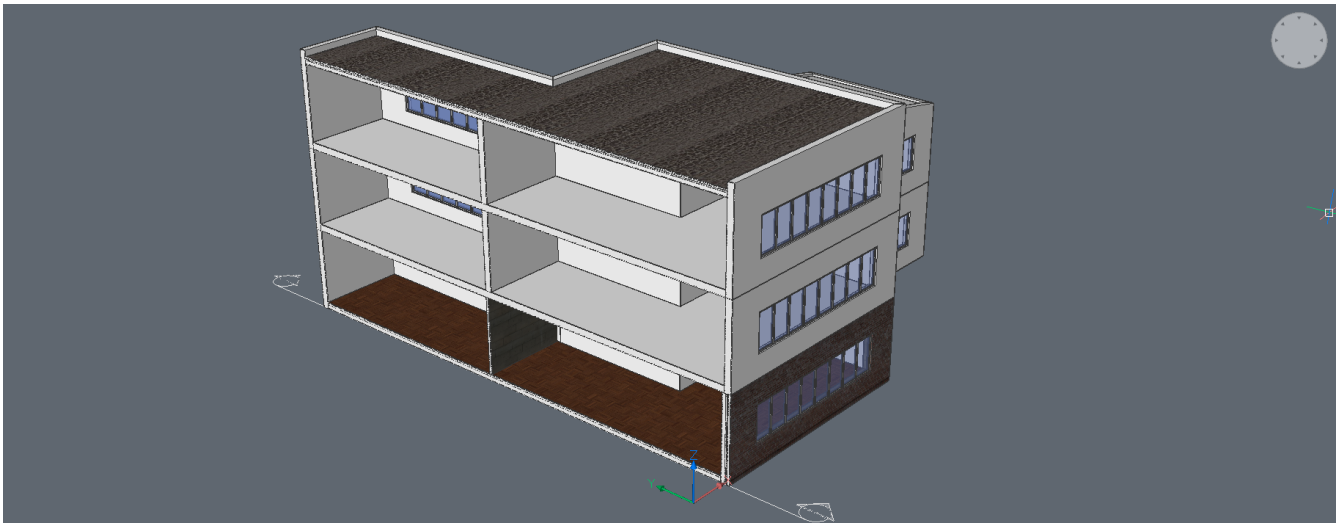


Figure 6.315

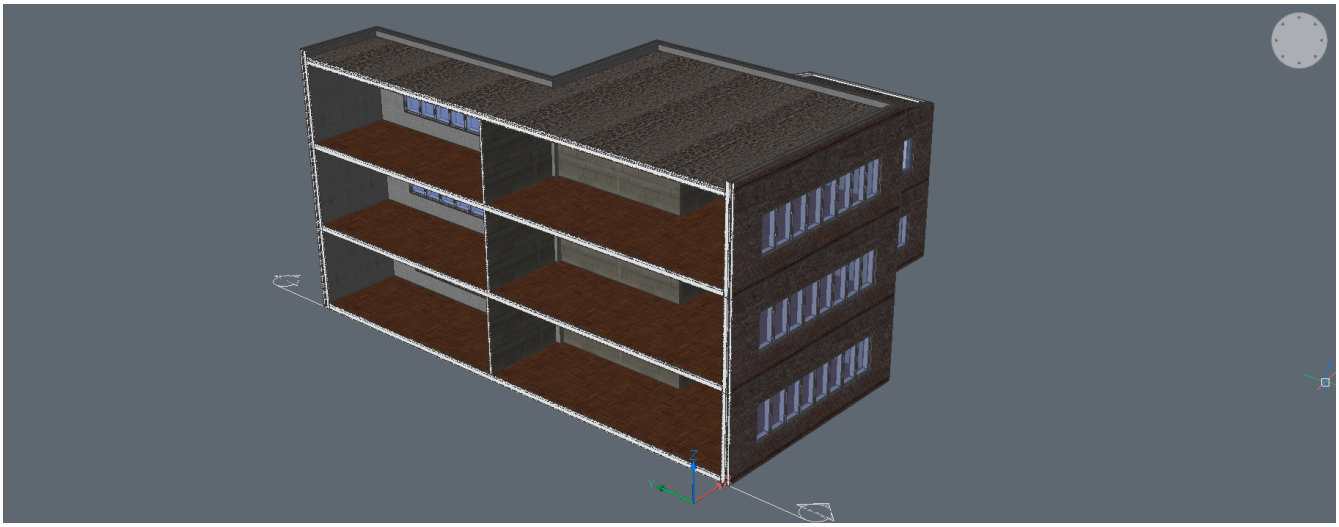

Figure 6.316

6.7.12 BimClassify

(6.1726 on page 4955) Classifies an entity and get a name and an internal GUID (= globally unique identifier). Any dwg entity can be given a classification.

Accessing the Command

Commandline: **BIMCLASSIFY** Quad: **BIM** Ribbon: **Home | Classify | Classify As ...** Toolbar: **BIM Toolbar | BIM Classify** : **BimClassify Prompts you in the command bar:** Classify entities as [Wall/Column/Slab/Beam/wIndow/Door/sPace/Building/Story/Element/Xref/Other/Auto/Unclassify] <Other>: **(Select an option.)** Select entities to classify <Drawing>: **(Select one or more entities or press Enter to classify the drawing.)**

Command Options

Option	Icon	Description
Wall		Classifies the selection as walls. Attaching a Wall composition (6.7.8) to a solid automatically classifies the solid as a wall.
Column		Classifies the selection as columns.
Slab		Classifies the selection as slabs. Attaching a Slab composition (6.7.8) to a solid automatically classifies the solid as a slab.
Beam		Classifies the selection as beams.
Window		Classifies the selection as windows.
Door		Classifies the selection as doors.
Space		Classifies 2D and 3D entities as spaces. (IFC Spatial Structure Element) Converts BIM rooms to BIM spaces.
Building		Classifies 3D entities as buildings (IFC Spatial Structure Element)
Story		Classifies 3D entities as stories (IFC Spatial Structure Element)

Building Element		Classifies the selection as unspecified building elements.
Xref		Classifies the selection as External References.
Other		Allows to classify the selection or convert the selection to a block and classify the block reference. Displays a dialog box: (6.317 on page 3643) Do the following: • (option) Type a search string in the **Search** field to filter the available element types. • Select a building element type. • (option) Check the **Convert to block ...** option and type a name in the **Block name** field. • Click the **OK** button.
Auto		Automatically classifies the selected entity or entities. This is the same as running Bimify (6.7.23).
Unclassify		Removes all BIM data from the selected entities.
Drawing		Classifies the entire drawing.

Definitions

Type	Description
	Building Core Elements
Wall	Vertical construction that subdivides spaces. Example: separation wall, bearing wall, interior wall
Beam	Structural member that carries loads between or beyond points of support, usually narrow in relation to its length and (nearly) horizontal. Example: I-beam, L-beam, T-beam, double T-beam
Column	Structural member of slender form, usually vertical, that transmits to its base the forces, primarily in compression, that are applied to it. Example: Doric column, Ionic column, Corinthian column
Slab	Component of the construction that normally encloses a space vertically. The slab may provide the lower support (floor) or upper construction (roof slab) in any space in a building Example: floor slab, roof slab
Stair	Construction comprising a succession of horizontal stages (steps or landings) that make it possible to pass on foot to other levels. Example: stairs, escalator, spiral staircases interrupted with landings

Stair Flight	Assembly of building components in a single "run" of stair steps (not interrupted by a landing). The stair steps and any stringers are included in this object. Example: stairs, escalator, spiral staircases NOT interrupted with landings
Ramp	Inclined way or floor joining two surfaces at different levels. Example: Slope/Ramp interrupted with landings
Ramp Flight	Inclined slab segment, normally providing a human circulation link between two landings, floors or slabs at different elevations. Example: Slope/Ramp NOT interrupted with landings
Railing	The railing is a frame assembly adjacent to human circulation spaces and at some space boundaries where it is used instead of walls or to complement walls. It is designed to aid humans, either as an optional physical support, or to prevent injury by falling. Example: handrail, balustrade, grab bar, guard rail
Curtain Wall	Exterior wall of a building which is an assembly of components, hung from the edge of the floor/roof structure rather than bearing on a floor.
Roof	Construction enclosing the building from above. Example: flat roof, gable roof, gambrel roof, hip roof
Building Element	The building element comprises all elements that are primarily part of the construction of a building. Example: structural and space separating system like walls, beams, doors
Site	A defined area of land, possibly covered with water, on which the project construction is to be completed.
BIM XReference	The identification of information that is not explicitly represented in the current model or in the project database. Such information may be contained in classifications, documents or libraries within the external source.
Grid Axis	An individual axis that is defined in the context of a design grid. The axis definition is based on a curve of dimensionality 2. Example: X-axis, Y-axis, Z-axis
Grid	A planar design grid defined in 3D space used as an aid in locating structural and design elements. Example: rectangular grid, radial grid, triangular grid
Annotation	A graphical representation within the geometric context of a project, that adds a note or meaning to the objects of the project. Example: additional line drawings, text, dimensioning, hatching,...
Building Architecture Elements	
Window	Construction for closing a (near) vertical opening in a wall or pitched roof that will admit light and may admit fresh air. The window is a building element that is predominately used to provide natural light and fresh air. A window consists of a lining and one or several panels. Example: skylights, light domes, swinging, pivoting, sliding, or revolving panels and fixed panels
Door	Construction for closing an opening. The door is a building element that is predominately used to provide controlled access for people and goods. A door consists of a lining and one or several panels. Example: hinged, pivoted, sliding, revolving, folding doors
Covering	A covering is an element which covers some part of another element and is fully dependent on that other element. Example: wall claddings, floorings, suspended ceilings, finish trim, base molding
Furnishing Element	Generalization of all furniture related objects. Example: closet, table, chair, bed

Opening	Represents a void within any element that has physical manifestation. Example: opening for a door, opening for a window
	Building Service Elements
Distribution Control Element	The occurrence elements of a building automation control system that are used to impart control over elements of a distribution system. It senses elements and measures changes in the controlled variable such as temperature, humidity, pressure, or flow. Example: thermostat
Distribution Port	The occurrence of a specialized port for use within the context of distribution elements. Example: A gas-powered hot water heater may have three ports: GAS, DOMESTICCOLDWATER, and DOMESTICHOTWATER. The heater is a member of two systems (GAS and DOMESTICCOLDWATER), and hosts one system (DOMESTICHOTWATER) at the corresponding port.
Distribution Flow Element	The occurrence elements of a distribution system that facilitate the distribution of energy or matter, such as air, water or power. Example: ducts, pipes, wires, fittings
Distribution Chamber Element	A place at which distribution systems and their constituent elements may be inspected or through which they may travel. Example: sump, trench
Energy Conversion Device	The occurrence of a device used to perform energy conversion or heat transfer and typically participates in a flow distribution system. Example: boiler, chiller, or a cooling coil
Flow Fitting	The occurrence of a junction or transition in a flow distribution system. Example: elbow, tee, a junction box in an electrical distribution system
Flow Controller	The occurrence of elements of a distribution system that are used to regulate flow through a distribution system. Example: damper, valve, switch, relay
Flow Moving Device	The occurrence of an apparatus used to distribute, circulate or perform conveyance of fluids, including liquids and gases, and typically participates in a flow distribution system . Example: pump, fan
Flow Segment	A flow segment is a section of a distribution system that typically has only two ports. Example: section of a duct, pipe, conduit, etc.
Flow Storage Device	Device used for the temporary storage of a fluid such as a liquid or a gas, the voltage potential induced by the induced electron flow. Example: tank, battery
Flow Terminal	The occurrence of a permanently attached element that acts as a terminus or beginning of a distribution system. A terminal is typically a point at which a system interfaces with an external environment. Example: air outlet, drain, water closet, sink
Flow Treatment Device	Device used to change the physical properties of the medium, flow treatment types (or the instantiable subtypes) may be exchanged without being already assigned to occurrences. Example: air, oil or water filter, duct silencer
Flow Connection Point	The connection point is used to describe the geometric constraints that facilitate the physical connection of two objects at a point.
	Building Structure Elements
Member	Structural member designed to carry loads between or beyond points of support. It is not required to be load bearing. The orientation of the member (being horizontal, vertical or sloped) is not relevant to its definition. Example: diagonal element of a truss construction

Footing	A part of the foundation of a structure that spreads and transmits the load directly to the soil. Example: wall footing, stepped footing, sloped footing, raft footing
Pile	A slender timber, concrete, or steel structural element, driven, jetted, or otherwise embedded on end in the ground for the purpose of supporting a load. A pile is also characterized as deep foundation, where the loads are transfered to deeper subsurface layers. Example: pile foundation
Reinforcing Bar	A steel bar, usually with manufactured deformations in the surface, used in concrete and masonry construction to provide additional strength. Example: reinforced concrete
Reinforcing Mesh	A series of longitudinal and transverse wires or bars of various gauges, arranged at right angles to each other and welded at all points of intersection. Example: reinforced concrete floor slab
Tendon	A steel element used to impart pre-stress to concrete when the element is tensioned. Example: wire, cable, bar, rod, strand
Tendon Anchor	A tendon anchor is the end connection for tendons in pre-stressed or post-tensioned concrete.
Plate	A Plate is a planar and often flat part with constant thickness. A plate can be a structural part carrying loads between or beyond points of support, however it is not required to be load bearing. The location of the plate (horizontal, vertical or sloped) is not relevant to its definition.
Discrete Accessory	A discrete accessory is a representation of different kinds of accessories included in or added to elements. Example: visible steel corbel (corbel system made from steel components protruding from the master element), corner fixing plate (fixing plate attached to the corner of an element), steel plate (steel plate used as an accessory in a joint)
Fastener	Representations of fixing parts which are used as fasteners to connect or join elements with other elements. Example: jointing mortar, glue, weld
Mechanical Fastener	Fasteners connecting building elements mechanically. Example: bolt, screw, nail, nut, washer, rivet

Procedures

Classifying entities (2.7.3) Creating a simple window (2.5.5)

Related Commands

BimAttachComposition (6.7.8) - Attaches a BIM composition to solids. BimProperties (6.7.38) - Allows to create, edit and delete property definitions in a dialog box, and to organize properties in property sets. BimSpatialLocations (6.7.63) - Opens the Buildings & Stories manager. This explorer allows to create and edit site, buildings and stories. Bimify (6.7.23) - Analyzes the model and runs automatic classification and spatial location assignment for the entire model. Export (6.13.18) - Exports drawings in a variety of vector and raster formats, including *.ifc.

6.7.13 BimCopy

(6.504 on page 3789) Creates copies from the planar faces of 3D solids, and the sides and ends of linear solids.

Accessing the Command

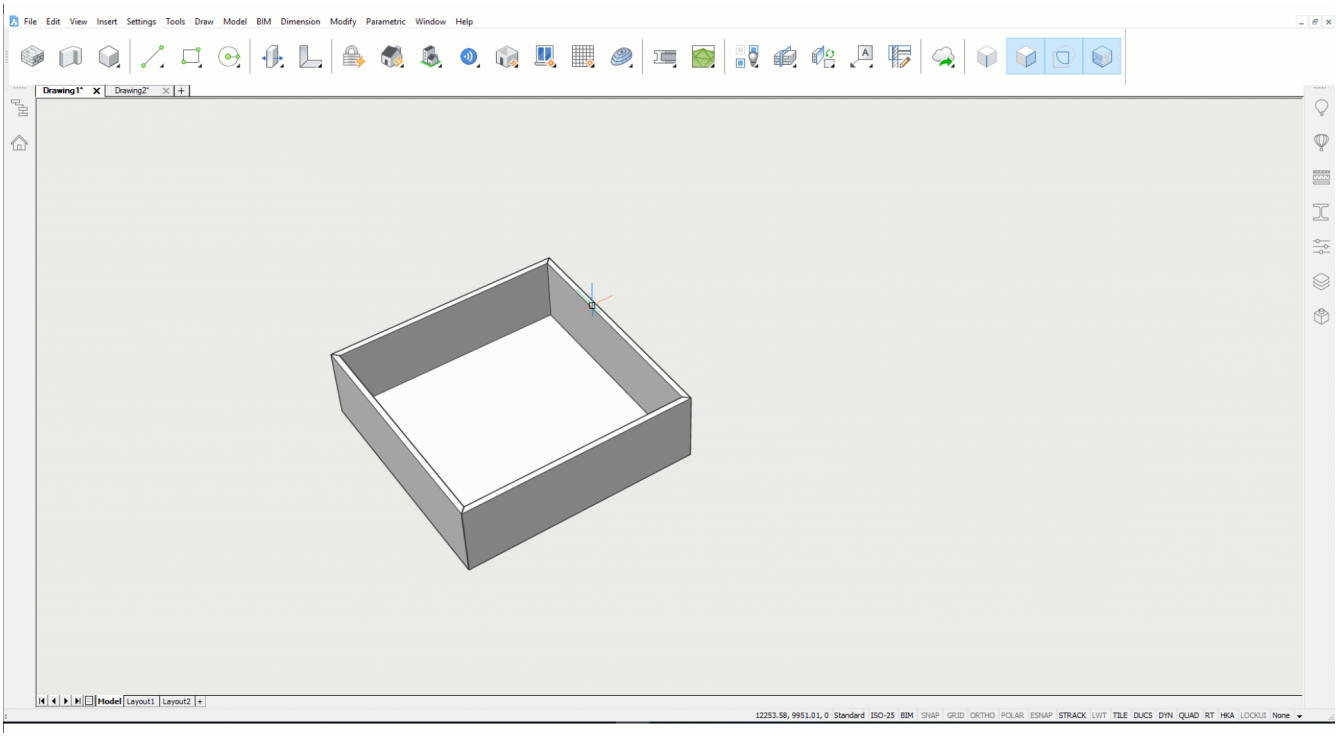
Commandline: **BIMCOPY** Quad: **Model tab | BIM copy** Ribbon: **Home | Modify | BIM copy** Toolbar: **BIM Manipulate Toolbar | BIM copy : BimCopy** Move the solid, specify a distance in the dynamic dimension field, and right-click to create a single copy. **Prompts you in the command bar:** Copy mode: single copy (in the Prompt History window) **Prompts you in the command bar:** Specify distance to create copy or switch to [Copy/Repeat/Number/Accept] <Accept>: **(Enter the distance value to make a copy of the solid at the specified distance or use one of the available options in the command bar)**

Command Options

Option	Description
Copy	Creates copies of the planar faces of 3D solids, and the sides and ends of linear solids.
Repeat	Repeats the copy using the same displacement. Move the cursor in the displacement direction. The further you move away from the source solid, the more copies are created. Click when the desired number of copies displays.
Number	Creates a number of copies you want to have in your model; prompts you: **Specify number of repeated copies: (specify the number of entities you want to create in the dynamic dimension field and press Enter to accept it.)**
Accept	Accepts the current distance you entered in the dynamic dimension field. This is the default option. Either press Enter to use this option or type A in the command line.

The following animated gif shows how to use bimcopy for 3D solids and linear solids. (6.319 on the facing page)

Figure 6.319



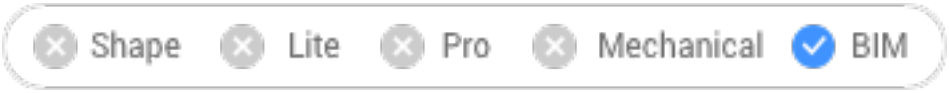
Procedures

Creating a parallel copy of a solid (2.5.4) Creating a partial copy of a solid (2.5.4)

Related Commands

Copy (6.9.35) - makes copies of entities.

Figure 6.320



6.7.14 BimCreateDetail

(6.493 on page 3778) Creates a detail and saves it in the library.

Accessing the Command

Commandline: **BIMCREATEDETAIL : bimcreatedetail** A dialog displays: (6.321 on the facing page) Click the **Select Reference Solids** button. The **Create Detail** dialog closes. **Prompts you:** Select reference solids. These will not be copied, but used to match other locations. [selection options (?)]: **(Select one or more solids, then press Enter.)** The **Create Detail** dialog displays with feedback about the detail creation: (6.322 on the next page) Click the **Select Details** button. The **Create Detail** dialog closes. Prompts you: Optional. Select detail objects (solids, block references, faces, edges,...) to be copied. [selection options (?)]: **(Select one or more detail objects, then press Enter).** The **Create Detail** dialog displays with feedback about the detail creation: (6.323 on the facing page) Click the **Select Sections** button. The **Create Detail** dialog closes. **Prompts you**: Select one section. [selection options (?)]: **(Select a BIM section,)** The **Create Detail** dialog displays with feedback about the detail creation: (6.324 on page 3648) Type a **name** for the detail. Select a **category** in the drop-down list or type a name to create a new category. Detail categories are subfolders of the Details **folder** which is defined by the **DETAILSPATH** system variable. By default this is **C:\ProgramData\Bricsys\Details**. Click the **Create** button. (6.325 on page 3648) **Prompts you**: Blue: detail area. Purple: reference contact area. Accept? [Accept/Reject/Inflate first] <Accept>: **(Press Enter, or choose an option.)** The **Save Detail** dialog displays: (6.326 on page 3649) Do the following:

- (option) Click Pencil icon on the detail thumbnail to adjust the image. The Save Detail dialog closes, then adjust (Move, Zoom, Rotate) the view. **Prompts you**: Accept thumbnail frame [Ok]: **(Press Enter.)**
- (option) Add **Tags** to the detail that can be used to find the detail in the Details Panel (2.9.9).
- (option) Expand the automatically generated **Reference solid tags** that are assigned to each reference solid and delete unwanted tags.
- (option) Expand the automatically generated **General tags** and delete unwanted tags.

Click the **Save** button. A *.dwg file is created in a subfolder of the details folder, which is defined by the **DETAILSPATH** system variable. By default this is **C:\ProgramData\Bricsys\Details**. Detail categories are subfolders of the Details folder.

- The detail name is the *.dwg file name.
- Reference solids sit on the REFERENCE_SOLIDS layer.
- Detail objects sit on the DETAIL_OBJECTS layer
- The section entity (if present) sits on the DETAIL_SECTION layer.

Command Options

Option	Description
Inflate First	Expands the sensitive zone to include similar solids which are not connected yet in the model. The edges of the initially detected detail are moved outward over a specified distance. Prompts you: **Enter inflation distance: (Type a value).**

Procedures

Defining the detail volume (2.9.2) Use modeling tools to create a structural steel model (2.5.20) Adjusting Details (2.9.9) BIM Ply Editing (2.7.8)

Related Commands

BimParametrizeDetail (6.7.28) - Generates parameters for a detail in order to easily change dimensions, angles, etc. BimPropagate (6.7.30) - Maps details (solids, holes, finishing geometry, ...) related to selected base solids to similar base solids in the model and optionally outlines the detail in a grid. BimPropagateCorner (6.7.31) - Propagates details connected to three planar base solids (i.e., corners). BimPropagateEdges (6.7.44) - Propagates a detail along the edge of a planar solid; can be used to propagate railings, gutters, borders, wall caps, etc. BimPropagateLinear (6.7.33) - Propagates connections between linear elements (beams, columns, pipes, ducts and their connections to walls and slabs). BimPropagatePattern (6.7.34) - Propagates a single element on a flat surface to multiple locations and grids; can be used to propagate lights, light switches, windows, air diffusers, etc. BimPropagatePlanar (6.7.36) - Propagates connections between planar elements (walls/slabs/roofs).

Figure 6.327

6.7.15 BimCurtainWall

(6.1726 on page 4955) Creates a curtain wall, as a block, from the face of a 3D Solid.

Accessing the Command

Commandline: **BIMCURTAINWALL** Quad: **Select Face | Model** Ribbon: **Home | Create | Curtain Wall** Toolbar: **BIM Toolbar | BIM Curtain Wall : BimCurtainwall Prompts you:** Select a face: **(If no face was selected before running the command: select the face of a solid or surface.)** Create grid or [Length U panels/Length V panels/Number U panels/Number V panels]: **(Press Enter or choose an option.)** (6.511 on page 3798) Change parameters or accept [Accept/Width/Depth/Glass thickness/Connections type] <Accept>: **(Press Enter to create the curtain wall using the current values or choose an option.)** (6.329 on page 3653) Delete defining entities? [Yes/No] <Yes>: **(Press Enter or choose an option.)** This prompt only displays when the value of the DELOBJ (1.17.10) system variable is **-1** or **-2**.

Figure 6.328

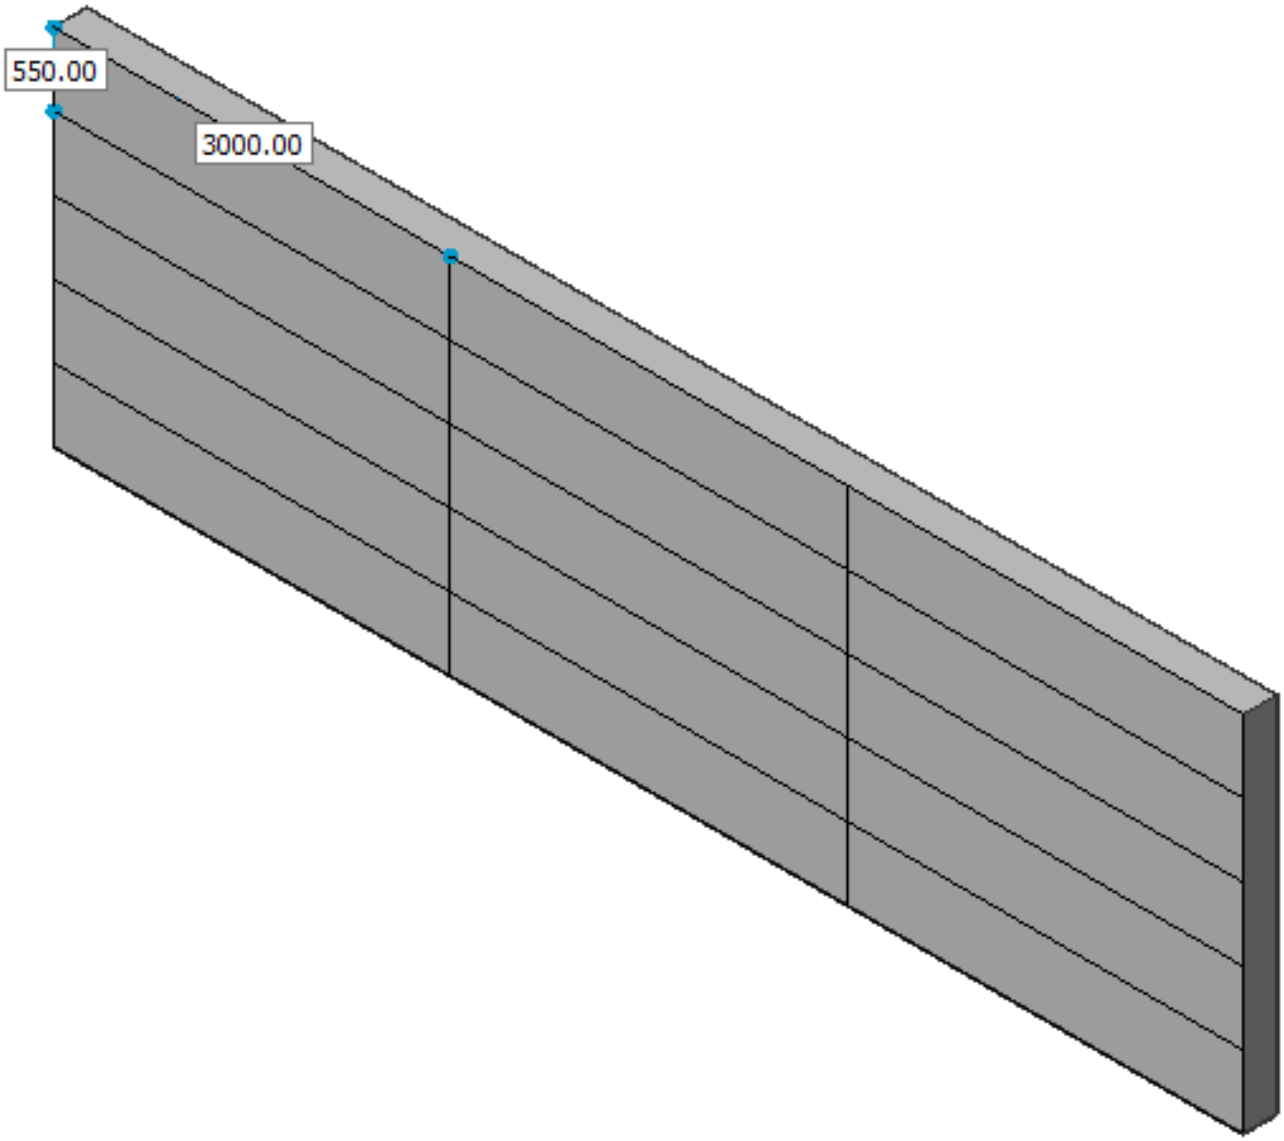

Figure 6.329

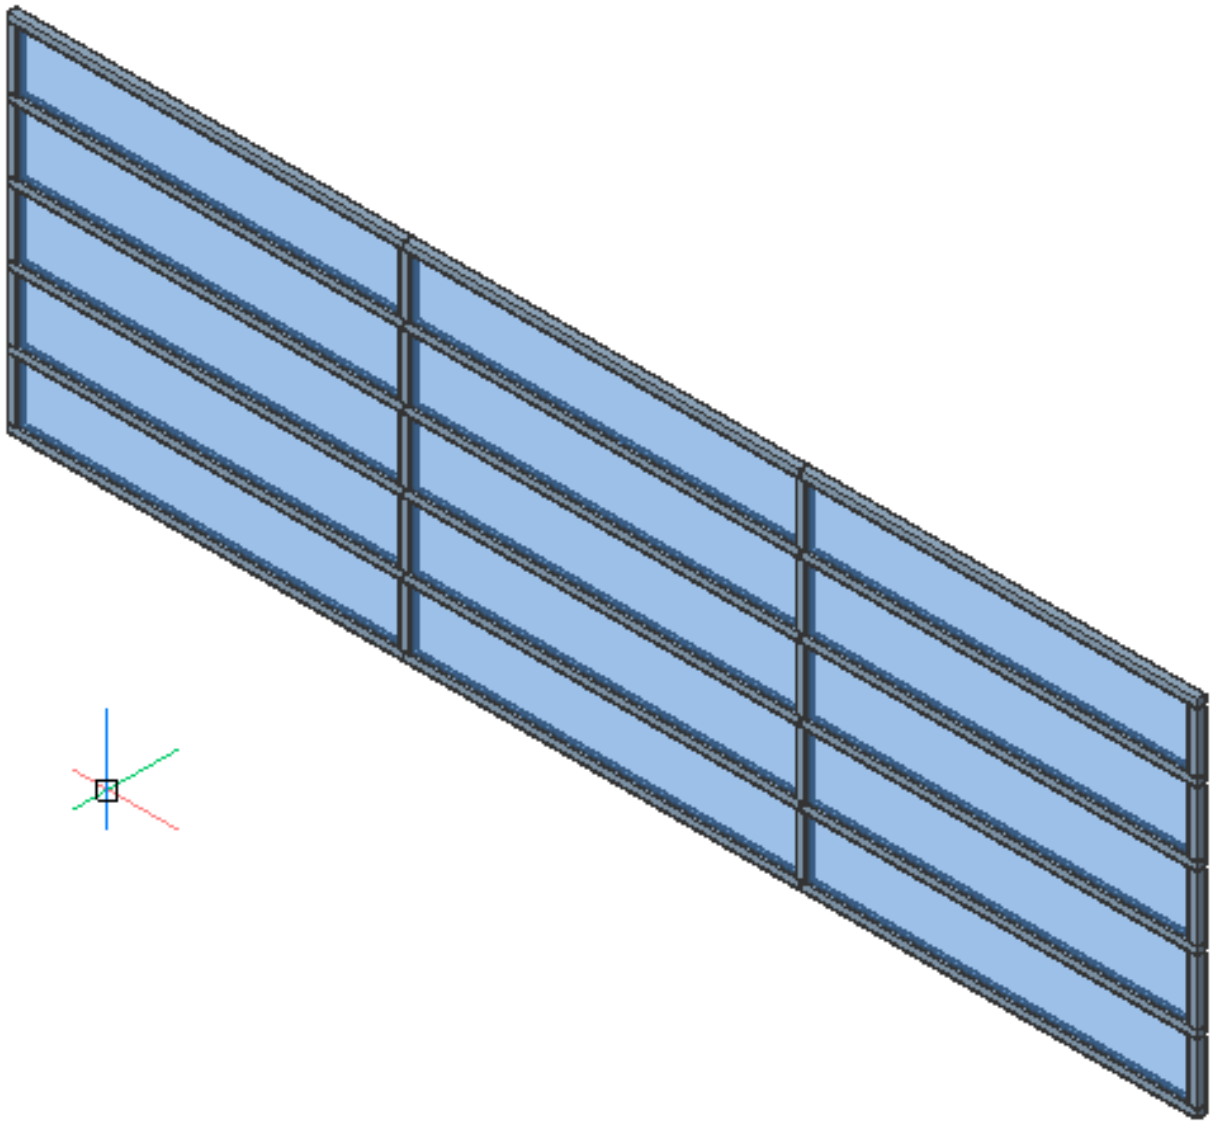

Command Options

Option	Description
Grid Options	
Length U panels	Sets the length of the panels in U direction (height). Prompts you: **U grid length <550>: (Type a value or press Enter.)**
Length V panels	Sets the length of the panels in V direction (width). Prompts you: **V grid length <3000>: (Type a value or press Enter.)**
Number U panels	Number of panels in U direction (rows). Prompts you: **U grid size <5>: (Type a number or press Enter.)**
Number V panels	Number of panels in V direction (columns). Prompts you: **V grid size <3>: (Type a number or press Enter.)**
Parameter options	
Width	Defines the width of the curtain wall frame, mullions and transoms. Prompts you: **Frame width <60.000000>: (Type a value or press Enter.)**
Depth	Defines the depth of the curtain wall frame, mullions and transoms. Prompts you: **Frame depth <60.000000>: (Type a value or press Enter.)**
Glass thickness	Defines the thickness of the glass panels. Prompts you: **Glass thickness <20.000000>: (Type a value or press Enter.)**
Connections type	Defines the type of the connections between horizontal and vertical mullions Prompts you: **Choose the type for the connections [sTraight/Smooth/Nodes] <sTraight>: (Choose an option or press enter to accept the default.)** Choose one of the following: • **Straight:** (6.330 on the next page) • **Smooth** (6.331 on the facing page) • **Nodes** (6.332 on page 3656)
Delete defining entities	Whether the selected source entity is retained or deleted depends on the value of the DELOBJ (1.17.10) system variable: • 0 : retained • 1 or 2 : deleted • -1 or -2 : You are prompted: **Delete defining entities? [Yes/No] <Yes>:**

Procedures

Creating a curtain wall (2.5.9) Creating a curtain wall from a free form surface (2.5.9)

Related Commands

BimWindowCreate (6.7.55) - Creates a fully parametric window or opening based on a closed contour. Panelize (6.7.60) - Creates a grid on the face of a 3D Solid as a block.

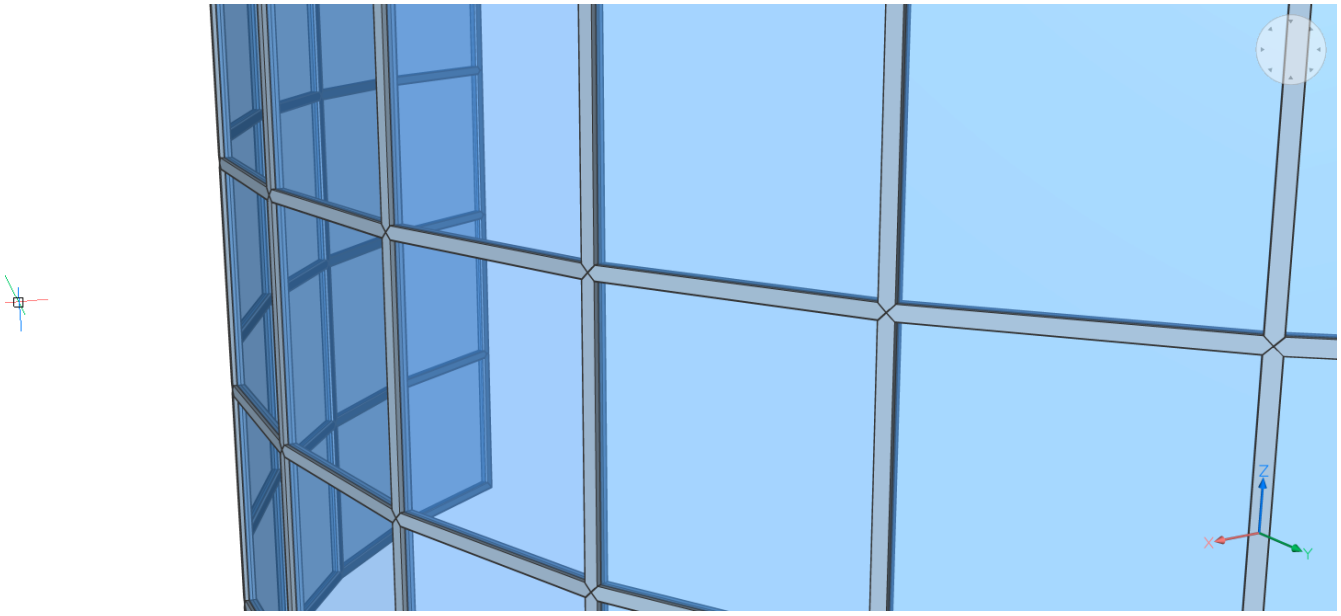

Figure 6.332

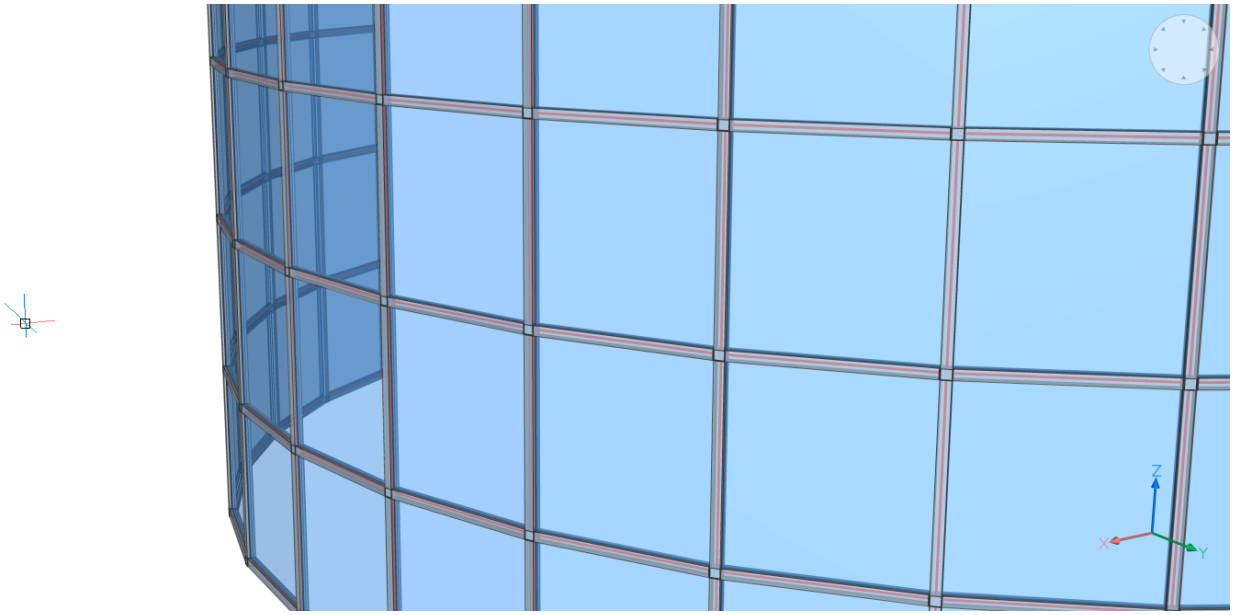

Figure 6.333

6.7.16 BimDecompose

(6.1726 on page 4955) Decompose compositions into their seperate plies.

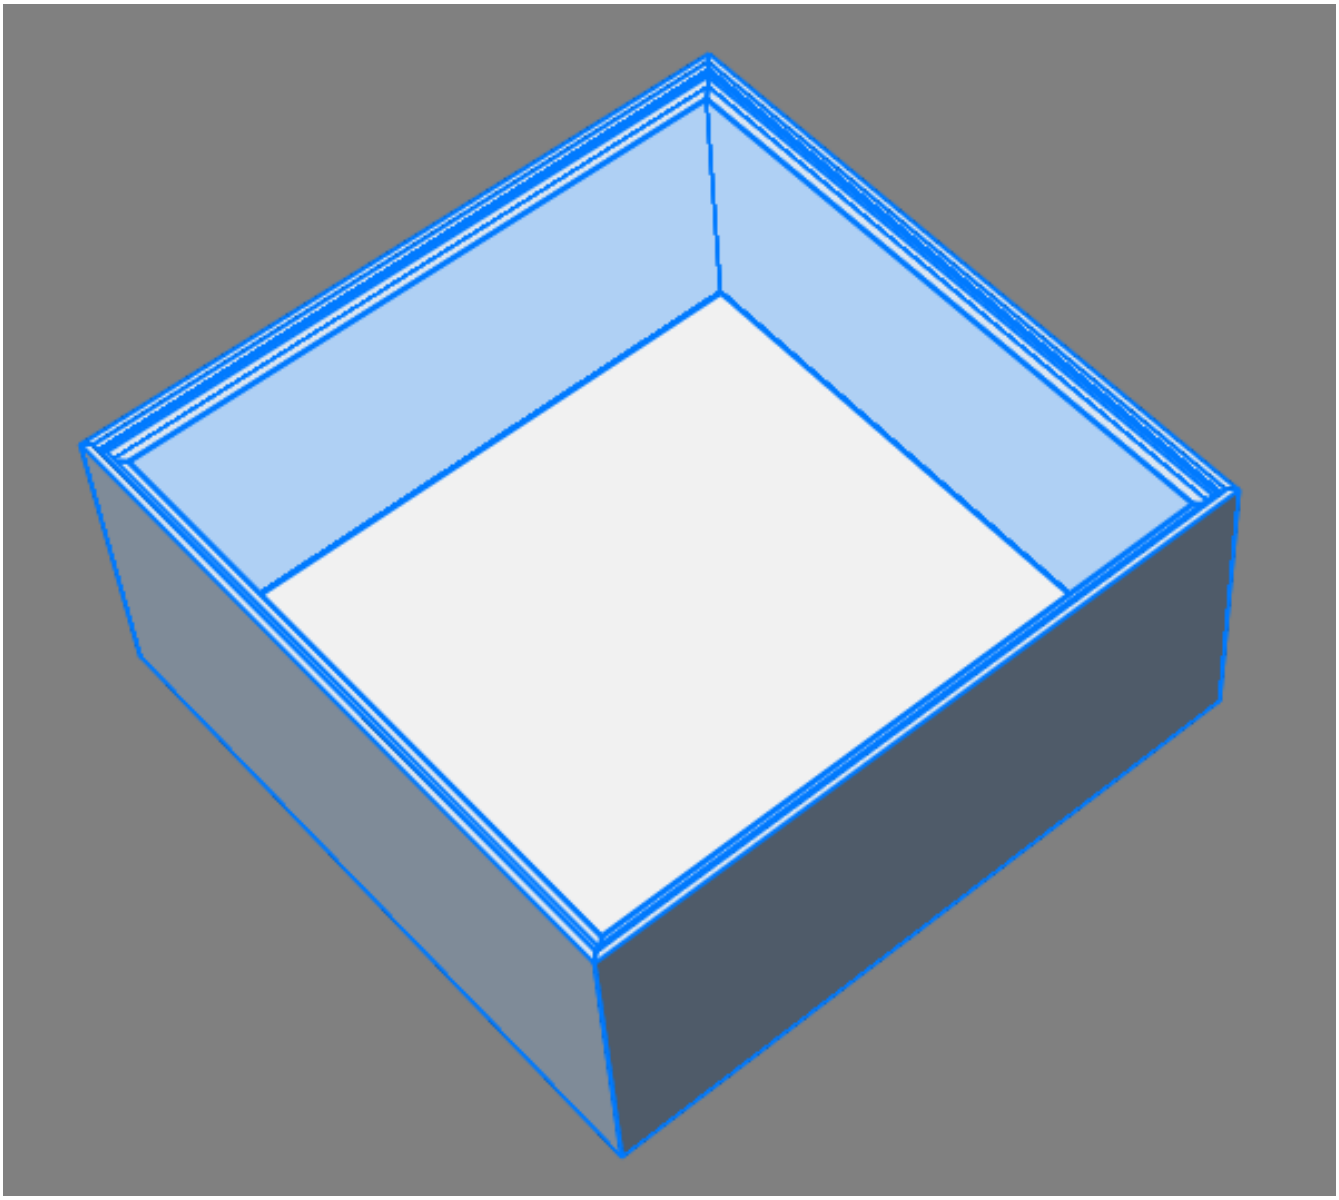
Accessing the Command

Commandline: BIMDECOMPOSE : BimDecompose You are prompted: Select BIM solid to decompose: **(Select the compositions that you want to decompose and press Enter.)** (6.334 on the next page) The solids are now decomposed into their seperate plies, which are put into one block. Each ply has inherited the BIM data of the original solid. You can see this in the **Structure Browser**.

Before	After
(6.335 on page 3660)	(6.336 on page 3660)

If you now want to manipulate the plies, you can use the BEdit (6.6.7) command.

Figure 6.334



Procedures

Manipulating the composition plies (2.7.8) Ply Editing (2.7.4)

Related Commands

BimAttachComposition (6.7.8) - Attaches a BIM composition to solids. BEdit (6.6.7) - Edits the entities that make up blocks in a temporary drawing session called the Block Editor, which uses the local coordinate system of the block. Optionally creates a new block.

6.7.17 BimExport

(6.1726 on page 4955) Obsolete. Use Export (6.13.18) instead and select file type *.ifc.

6.7.18 BimDrag

Obsolete The command has been renamed. See Drag (6.10.38).

Figure 6.338

6.7.19 BimFlowConnect

(6.1726 on page 4955) Creates a connection between flow segments, such as pipes or HVAC ducts.

Accessing the Command

Commandline: **BIMFLOWCONNECT** Quad: **Model** Ribbon: **Home | Modify | Connect | FlowConnect** Toolbar: **BIM Toolbar | BIM Connect : BimFlowConnect Prompts you:** Select solids to connect: **(Select one or more flow segments*.)** Entities in set 1: Select solids to connect: **(Select more flow segments* or press Enter.)** * When more than 2 flow segments are selected, the axes of the selected segments must be coplaner. When multiple coplanar segments are selected, the connections are created. When 2 non coplaner solids are selected: Apply connection or switch to the next alternative [Switch] <Accept>: **(Press Enter to accept the connection or press the Ctrl-key for alternative connection(s))**

Command Options

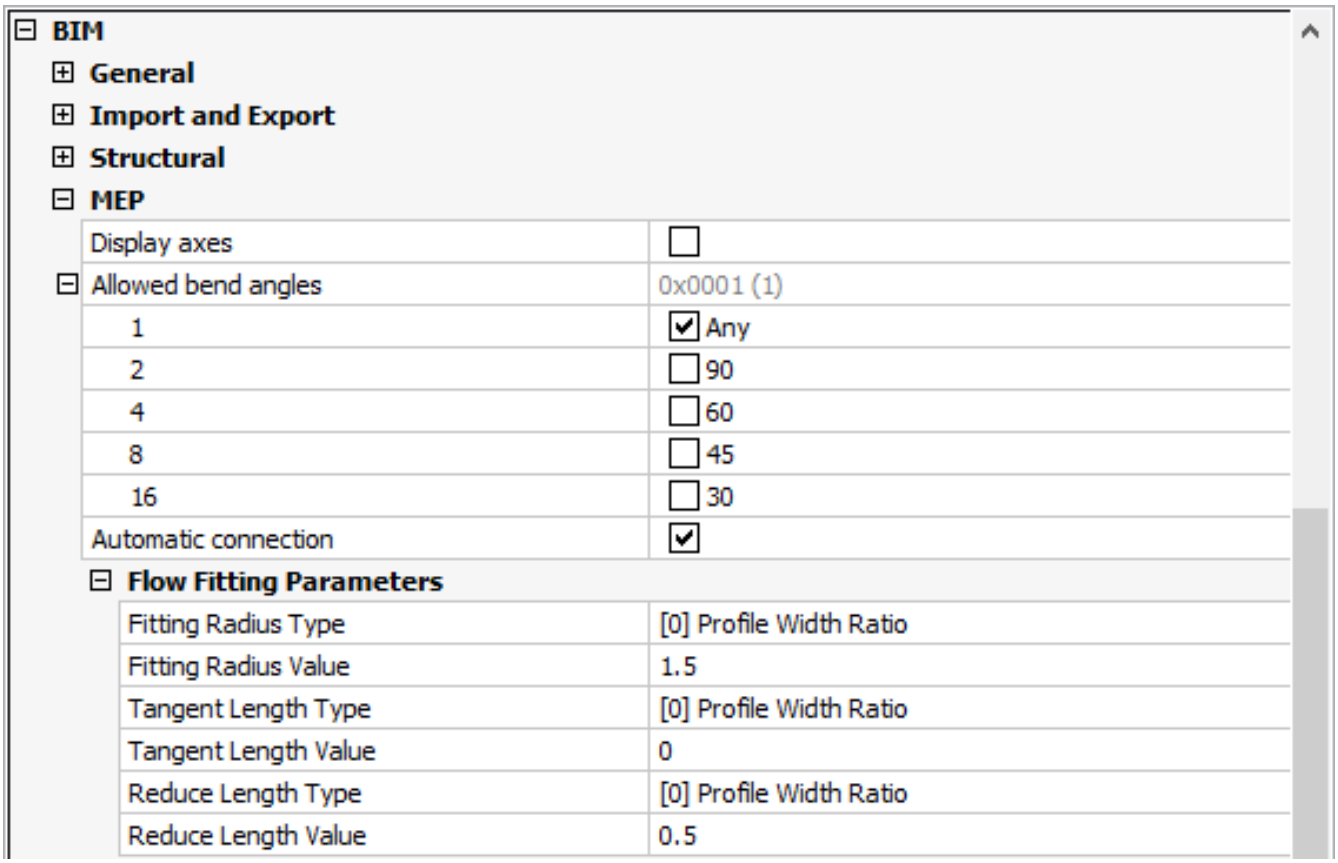
Option	Description
Switch	Switches between possible connections. **Type s + Enter or** tap the **Ctrl-key** to cycle the various alternatives. Alternatives for circular flow segments: (6.340 on the following page) (6.341 on page 3665) Alternatives for rectangular flow segments: (6.342 on page 3665) (6.343 on page 3665) (6.344 on page 3665)
Reducers	When the section of the selected flows is different, reducer elements are inserted. (6.345 on page 3666) (6.346 on page 3666)

User Preferences

The creation of bends and reducers is controlled by user preferences (1.17.10). (6.339 on the next page)

Display axes	Displays a red axis of the profile.
Allowed bend angles	Defines which angles are used for MEP bends. • **Any**: allows to connect any two ducts, • **90**, **60**, **45**, **30**: specifies which bend angles are allowed.
Automatic connection:	If set, APPLYPROFILE and LINEARSOLID commands automatically create bends when creating multiple flow segments in the same same workflow.
Flow Fitting parameters	These parameters control the creation of bends and reducers. • Fitting Radius: radius of the bend; more precisely the radius sweep path of the bend. (6.347 on page 3667) • Tangent Length: length of the straight part at the end of a bend. (6.348 on page 3667) • Reduce Length: Length of a reducer element which connects two different profiles. For each of the flow fitting parameter you can choose between a relative value (Profile Width Ratio) or an absolute value.

Figure 6.339



Procedures

Using the MEP Modeling tools to draw and connect profiles (2.5.14) Connecting different segments to each other (2.5.14)

Related Commands

Drag (6.10.38) - Moves 3D solids perpendicular to a selected face by dragging that face. Optionally preserves connections to other solids. BimStructuralConnect (6.7.61) - Connects structural profile solids such as beams and columns. LConnect (6.20.19) - Creates an L-connection between solids. TConnect (6.29.9) - Connects solid faces to other solids.

6.7.20 BimFlip

(6.504 on page 3789) Flips the starting face from which the layers of a composition are set out. Mirrors an insert (e.g. a window or door) left/right or flips it inside/outside.

Accessing the Command

 Commandline: **BIMFLIP** Quad: **Model | Solids, Inserts** Ribbon: **BIM | Flip** : **BimFlip Prompts you in the command bar:** Select BIM entity to flip: **(Select a wall, slab or an insert)** Entities in set: 1 Select BIM entity to flip: **(Select more walls, slabs or inserts, or press Enter.)** If the selection contains no inserts: Done on xx object(s). The result is visible in drawings generated by the BimSectionUpdate (6.7.43) command if a multi-layered composition is attached to the sectioned solid.

(6.350 on the next page)	(6.351 on the facing page)
Before	After

If the selection contains at least 1 insert: Flip insert(s) Left-right/In-out <Left-right>: **(Press Enter to flip left-right or type I and press Enter to flip inside-outside.)**

Command Options

Option	Description
Select BIM entity to flip	The **BimFlip** command accepts inserts, walls or slabs. Solids that have no BIM classification (6.7.12) yet, cannot be selected. The command only succeeds for solids that meet both of the following conditions: • have a BIM composition (6.7.8) attached. • are in a calculated BIM section (6.7.54). BricsCAD reports the number of solids that could not be flipped: '... failed on xx object(s)'
Left-right 	Mirrors the insert about a vertical axis in the face of the solid.
In-out 	Flips the insert to the opposite face of the solid.

Related Commands

BimAttachComposition (6.7.8) - Attaches a BIM composition to solids. BimClassify (6.7.12) - Classifies an entity as a Building Element and get a name and an internal GUID (= globally unique identifier). BimUpdateThickness (6.7.62) - Re-applies the overall thickness of a composition to the solid. BimSection (6.7.54) - Creates a BIM section entity. BimSectionUpdate (6.7.43) - Exports or updates the result of a BIM section in a drawing. BimSetReferenceFace (6.7.46) - Defines a reference and an opposing face to control the ply layout of a composition.

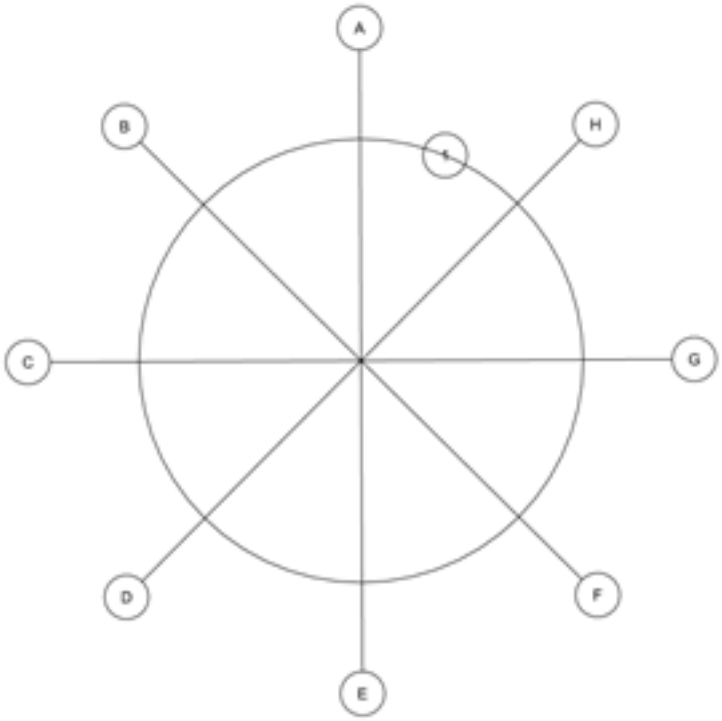

Figure 6.358

6.7.22 BimInsert

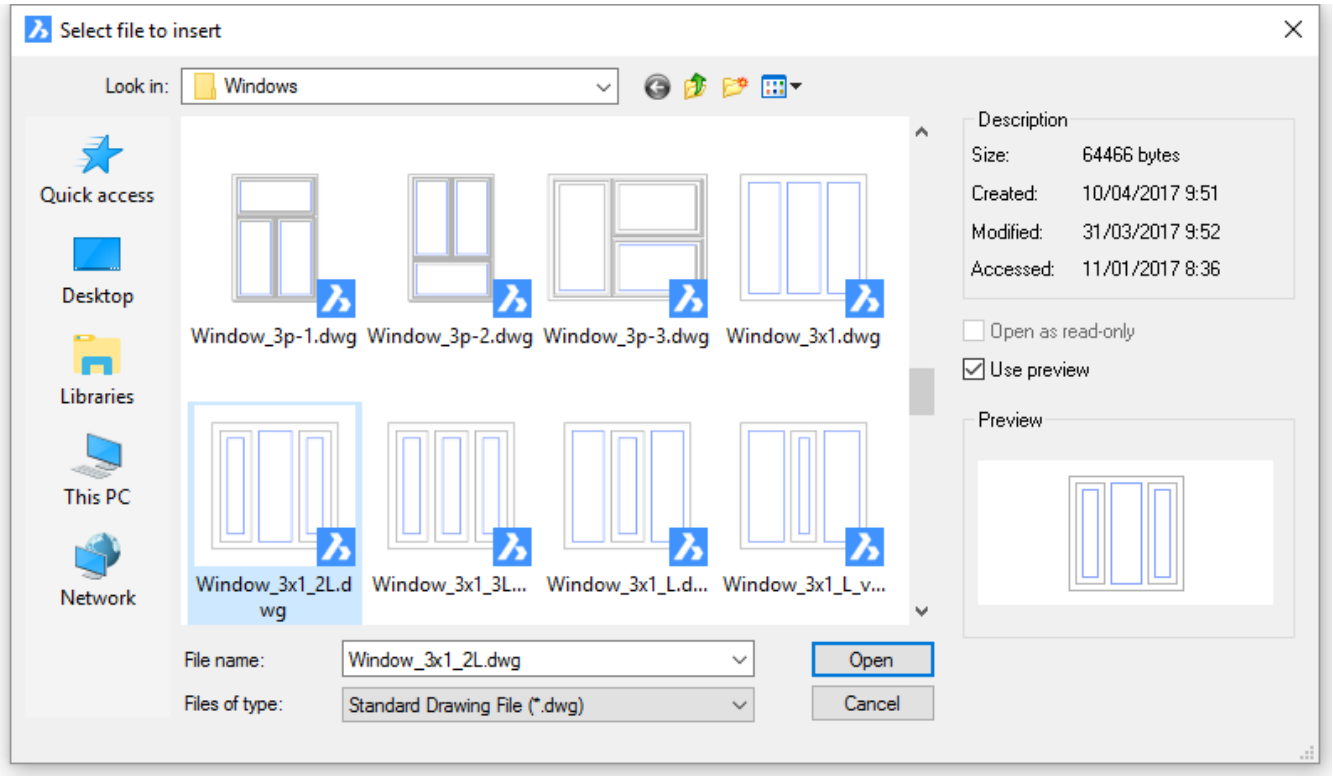
(6.504 on page 3789) Inserts a window or door in a solid. Inserts a copy of a window or door in a solid. Inserts a RFA* file as a BIM component into the current drawing. **The command is deprecated. Use BMINSERT (6.8.16) instead.** Make sure Dynamic UCS (DUCS (1.15.2)) and Dynamic Dimensions (DYN (1.15.2)) are active. * RFA import is a work-in-progress. Some general guidelines about the current V19 RFA import functionality are:

- RFA files older than 2015 are not supported.
- Files from 2015 to 2020 are imported correctly. Currently, you can import; extrusions, blends, revolutions, and sweeps.
- Only the geometry of the family is imported without parameters or properties.

Accessing the Command

Command bar: **biminsert** Menu bar: **BIM| BIM Insert** Toolbar: **BIM |** Quad: **BIM |** : **BimInsert** Displays a File dialog box: (6.359 on the following page) Select a window or door to insert, then double click or click the **Open** button. Select insertion point or [Edit inserted entity] : **(Move the cursor over a solid; the face under the cursor highlights: The UCS aligns dynamically with the selected face; if the edge by which the cursor enters the solid is horizontal or vertical, the X-axis of the UCS is horizontal, otherwise the X-axis is aligned with the edge; the Z-axis is perpendicular to the face of the solid. Specify point to insert.)** Hit the Ctrl-key to switch between Select insertion (6.7.22) point and Edit inserted entity (6.7.22) mode.

Figure 6.359



Command Options

Option	Description
Select insertion point (6.606 on page 3873)	Allows to specify the insertion point. Hit the Ctrl-key to switch to Edit inserted entity (6.7.22) mode. From the middle of each edge of the placement rectangle dynamic dimensions display to the nearest parallel edge on the face of the solid. Press the TAB key to cycle the fields. Type a value in the dynamic dimension fields, then press the TAB key, to lock the field which then turns red. Only one of two parallel dimensions can be locked. If a dimension value is entered, and the other, parallel dimension was already locked, it will be unlocked.. Press Enter or click to insert the selected block. (6.607 on page 3873) 1. Locked field 2. Current field 3. Unlocked fields 4. Unlocked fields
Edit inserted entity (6.608 on page 3873)	Allows to specify the width and height of the placement rectangle of the insert. Prompts you: **Edit [Height/Width/Done] <Height>:** Two dynamic dimension fields show the current width and height of the placement rectangle. (6.609 on page 3874) Type a value in the current dynamic dimension field, then press the TAB key to switch to the other field. Hit the Ctrl-key to switch to Select Insertion Point (6.7.22) mode.

Procedures

Inserting windows or doors (2.5.19) Editing the parameters of an insert (2.5.19) Using distance fields (2.5.19) Using Push/Pull to move an insert (2.5.19) Copying an insert on the wall face (2.5.19)

Command Options

Option	Description
Discipline	Determines to what discipline the model belongs to. This improves the accuracy of the automatic classification. • Auto Detect: an AI algorithm determines the discipline automatically. • Architectural: The model is classified as an architectural model. • Structural: The model is classified as a structural model. • MEP: The model is classified as a MEP model. • Mixed Model: The model can't be assigned to 1 discipline and is perceived as a mixed model.
Classification	See BimClassify (6.7.12). • Solids: Classifies 3D Solids as walls, slabs, ... • Block References: Classifies blocks as windows, doors, ...
Structural/MEP Profiles	Assigns columns, beams, members or flow segments profiles that are available in BricsCAD profile library. If no match can be found for a profile element in the standard library, Bimify creates a new custom profile in the project's library.
Spatial Information	Assigns spatial locations (6.7.63) (buildings and floors) Creates spaces (6.7.45). Detects external walls and sets the property Wall Common / Is External = ON.
Sections	Creates BIM Section (6.7.54) entities. Sections: Creates a plan section for each floor. Elevations: Creates four elevations (Front, Back, Left and Right).

Procedures

Bimify your entire drawing (2.9.1) Bimify a selection of your BIM Model (2.9.1)

Related Commands

BimAttachSpatialLocation (6.7.9) - Allows to attach or remove a spatial location to a selection of entities. BimClassify (6.7.12) - Classifies an entity as a Building Element and get a name and an internal GUID (= globally unique identifier). BimSpace (6.7.45) - Creates BIM space entities. BimSection (6.7.54) - Creates a BIM section entity. BimSpatialLocations (6.7.63) - Opens the Buildings & Stories manager. This explorer allows to create and edit site, buildings and stories.

Figure 6.366

---------- BimDbRoom ------------------------------------------  Handle: 2E3
---------- BimDbWindow ----------------------------------------  Handle: 648  Material:   GUID: {D459
---------- BimDbWindow ----------------------------------------  Handle: 5CF  Material:   GUID: {1930
```

Figure 6.367

6.7.25 BimMultiselect

(6.504 on page 3789) Selects linear solids with coplanar and/or parallel axes.

Accessing the Command

Commandline: **BIMMULTISELECT** Ribbon: **Home | Structure/HVAC | Multiselect**
: **BimMultiSelect Prompts you in the command bar.** Select single entity/subentity: **(Select a solid or a solid face.)** Select type of selection [all Coplanar axes/coplAnar and parallel axes/all Parallel axes] <Accept>: **(Choose an option or press Enter to accept selection of the highlighted linear solids.)** If a face of a linear solid is selected, the corresponding faces of the linear solids with coplanar/parallel axes are selected.

Command Options

Option	Description
All coplanar axes	Selects all solids of which the axis is coplanar with the axis of the selected solid. (6.368 on the next page)
Coplanar and parallel axes	Selects all solids of which the axis is coplanar and parallel with the axis of the selected solid. (6.369 on the following page)
All parallel axes	Selects all solids of which the axis is parallel with the axis of the selected solid. (6.370 on page 3685)

Related Commands

DmSelect (6.12.28) - Selects edges and faces of 3D solids or surfaces based on their geometric properties. SelectAlignedFaces (6.27.17) - Selects all faces in a model which are coplanar with a selected face. SelectAlignedSolids (6.27.19) - Selects all solids in a model of which a face is coplanar with a selected face. SelectConnectedFaces (6.27.21) - Selects all faces in a model which are connected to a selected face. SelectConnectedSolids (6.27.27) - Selects all solids in a model which are connected to a selected face.

- **Name:** Type a name
- **Size:** Indicate the size of the profile.
- **Shape:** Do the following:
  - Select a shape. (6.379 on page 3691)
  - Click the **Pick Profile in Model** button ( ). Prompts you: **Pick a profile** - the **Profiles** dialog box temporarily closes to let you select a closed 2D entity or the boundary entities of an enclosed area.
    - For standard profiles, fill out the properties grid for the selected profile: (6.380 on page 3691)
    - For a **CustomShape** profile, optionally click the buttons at the bottom of the profile preview to rotate or to mirror the profile. (6.381 on page 3692)
  - Click the **Set Profile Offset** button ( ). (6.382 on page 3692) The default status of the **Profile offset behavior** is set in the **ProfileOffsetBehavior** user preference. Define the offset and click the **Apply** button.

Deletes the selected profile

Allows to import profile definitions. Launches the BIMPROJECTINFO (6.7.32) command: Displays the **BIM Project Info** dialog. To import profile definitions:

1. Click the **Import** button on the **BIM Project Info** dialog. A file dialog displays.
2. Select the CSV Library files (*.csv) file type.
3. Select the *.csv file to import.
4. Double click or click the **Open** button.

In the **\Support\Bim\Profiles** folder of the Roamable Root folder (1.17.2) you can find:

- templates_of_mostly_used_profiles.csv
- profile_parameters.pdf

(6.383 on page 3692)

Select a profile and right click to display the context menu:

- **New Profile:** Creates a new profile.
- **Duplicate:** Creates a new profile as a duplicate of the selected profile.
- **Delete:** Deletes the selected profile.
- **Copy to Project:** Copies the selected profile to the Project library.

Edit a custom profile	Select the profile in the **In Project** list and edit the properties. When the axis offset () is edited and the profile is already applied to one or more linear solids, you are prompted to: • **Apply** the profile to the solid(s). • **Detach** the profile from the solid(s). • **Cancel** the editing operation and keep the original profile.

Related Procedures

Applying profile to linear solids (2.5.1) Use modeling tools to create a structural steel model (2.5.20) Use the modeling tools to create a more detailed connection (2.5.20)

Related Commands

BimAddEccentricity (6.7.7) - Allows to control the relative position of the axis of a linear solid. BimApplyProfile (6.7.10) - Applies a profile to linear entities and linear solids. BimLinearSolid (6.7.29) - Creates linear solids. BimRecalculateAxis (6.7.51) - Recalculates the axis of linear building elements and repositions it back on the center line of a linear element. BLCompositions (6.7.57) - Opens the compositions library in the current project and the referenced library.

6.7.27 BimPatch

(6.1726 on page 4955) Allows to replace part of a generated section. The command is valid in model space only.

Important Note: BIMPATCH cuts out part of geometry and replaces it by a block reference. In this cutting process, entity da

Accessing the Command

Commandline: **BIMPATCH** Toolbar: **BIM Toolbar | BIM** : **BimPatch Prompts you in the command bar:** Specify start point of rectangle (in Model Space): **(Specify a point.)** Specify end point of rectangle: **(Specify a point or use the dynamic dimension fields to specify the dimensions of the rectangle).**

Note	If BricsCAD responds: 'Cannot apply patch: no intersection points found' set the GENERATEASSOCVIEWS system variable ON. Lookup the variable in the Settings (1.17.10) dialog under Dimensions or type GENERATEASSOCVIEWS in the command bar and choose ON.

A cut-out is generated as a nested block in the BIM section. BIM patch blocks are named Patch1, Patch2, .. The rectangular boundary of a BIM patch is placed on layer BIMPATCH_BOUNDARY. Launch RefEdit. (6.26.13) (6.385 on the following page) Select the BIM Patch in the **Reference Name** tree, then click the **OK** button. The **Reference Edit** dialog box closes. Edit the BIM Patch. Use RefClose (6.26.12) to save the changes in the BIM Patch. When the corresponding BIM section is updated, BricsCAD will check if the generated section result within that rectangle is identical to the result which was generated at the time the BIM patch was created:

- If not, then the user edited BIM patch is preserved but the boundary is colored red.
- If it is, the user edited BIM patch is preserved.

(6.386 on page 3695) Intersection points and endpoints of curves originating from 3d objects are used to find the position of a BIM patch rectangle. When objects are modified or moved in the 3d model in such way that the position of these intersection points change, but the geometry inside the BIM patch rectangle is not affected, then BricsCAD will relocate the user edited BIM patch.

6.7.28 BimParametrizeDetail

(6.1726 on page 4955) Generates parameters for a detail in order to easily change dimensions, angles, etc. Make sure you run this command in the detail file and not in a project. Detail files are saved in the folder, and its subfolders, which is defined by the DETAILSPATH system variable. By default this is C:\ProgramData\Bricsys\Details\.

Accessing the Command

Commandline: **BIMPARAMETRIZEDETAIL : BimParametrizeDetail** No prompts. The parameters and constraints can be edited in the Mechanical Browser (6.8.32).

Procedures

Parametrize and Edit a Wall-Slab Connection Detail (2.9.8) Parametrize and Edit a Structural Steel Connection (2.9.8) Propagate a Detail in a Project (2.9.8) Parametrizing a component automatically (2.5.21) Changing the parameters and constraints in the parameters manager (2.5.21)

Related Commands

BimCreateDetail (6.7.14) - Creates a detail that can be saved in the library. Parametrize (6.24.7) - Adds constraints and parameters to pure geometric models. ParametersPanelOpen (6.24.10) - Opens the Parameters Panel. ParametersPanelClose (6.24.8) - Closes the Parameters Panel. MechanicalBrowserOpen (6.8.32) - Opens the Mechanical Browser panel. SmParametrize (6.28.23) - Creates a consistent set of 3D constraints for a selected sheet metal part. Recognizes rectangular array of holes on flanges. DcAligned (6.10.6) - Constrains the distance between two points. DcAngular (6.10.7) - Constrains the angle between two lines or linear polyline segments; the total angle of an arc or an arc polyline segment; or the angle between three points on entities. DcConvert (6.10.18) - Converts an associative dimension to a dimensional constraint. DcDiameter (6.10.8) - Constrains the diameter of a circle or an arc. DcHorizontal (6.10.10) - Constrains the horizontal distance (X-distance) between two points with respect to the current coordinate system. DcLinear (6.10.12) - Constrains the horizontal distance (X-distance) or vertical distance (Y-distance) between two points with respect to the current coordinate system. DcRadius (6.10.11) - Constrains the radius of a circle or an arc. DcVertical (6.10.15) - Constrains the vertical distance (Y-distance) between two points with respect to the current coordinate system.

6.7.29 BimLinearSolid

(6.586 on page 3851) Creates a chain of linear solids.

Accessing the Command

Commandline: **BIMLINEARSOLID** Quad: **Model** Ribbon: **Home | Structure/HVAC | Linear Solid** Toolbar: **BIM Toolbar | BIM Or** drag a profile from the **BIM Libaries - Profiles** panel onto the graphic screen. : **BimLinearSolid Prompts you in the command bar:** Set start point or [Follow/Rectangular/Circular/Library/select in Model/adJust profile] <Last point>: **(Pick a point or choose an option.)** Set next point or [Angle/Length/Undo/Quarter turn/Rotate/choose other Profile/adJust profile]: **(Pick a point or choose an option.)** Set next point or [Angle/Length/Undo/Quarter turn/Rotate/choose other Profile/adJust profile]: **(Pick more points, or choose an option, or press Enter to stop.)**

Command Options

Option	Description
Last point	Press Enter to use the most recently specified point.
Follow	Draws the next linear solid at the same angle as the previous one. **Length of line** - **(specify the length of the linear solid.)**
Rectangular	Switches to a default rectangular profile.
Circular	Switches to a default circular profile.
Library	Opens the Profiles (6.7.26) dialog box. Select a profile, then click the Select button on the Profiles dialog box. Returns to the previous prompt.
Select in model	Allows to select a profile in the model; prompts you: **Pick a profile** - **(Do one of the following)**: • Click a closed 2D entity or a region in the model. • Click an existing linear solid. Returns to the previous prompt.
Adjust profile	Allows to adjust the dimensions of the default rectangular and circular profile; prompts you: For rectangular profile: **Width of rectangle <250> [Height]** - **(Type a value or press Enter to accept the current value.) Height of rectangle <120> [Width]** - **(Type a value or press Enter to accept the current value.)** For circular profile: **Radius of circle <100>** - **(Type a value or press Enter to accept the current value.)** Returns to the previous prompt.
Angle	Draws at a user-specified angle and distance; prompts you: **Angle of line** - **(specify the angle (measured counter-clockwise from the positive x-axis)). Length of line** - **(specify the length of the linear solid.)**
Length	Draws at a user-specified distance and angle; prompts you: **Length of line** - **(specify the length of the linear solid.) Angle of line** - **(specify the angle (measured counterclockwise from the positive x-axis)).**
Undo	Erases the last linear solid.
Quarter turn	Rotates the profile 90° counter clockwise.

Rotate	Allows to rotate the profile by a user defined angle: prompts you: **Angle to rotate profile** - **(specify the rotation angle.)** Positive values rotate the profile counter clockwise.
Choose other profile	Allows to use a different profile for the next linear solid; prompts you: **Choose a profile [Rectangular/Circular/Library/select in Model]** - **(choose an option; see above.)**
Adjust profile	Prompts you to pick a profile for the next linear solid in the model: **Pick a profile** - **(Do one of the following):** • Click a closed 2D entity or a region in the model. • Click an existing linear solid.

Procedures

Creating a single linear solid (2.5.1) Applying profile to linear solids (2.5.1) Add eccentricity to linear solids (2.5.1) Recalculate the axis of linear building elements (2.5.1) Making a structural connection to linear solids (2.5.1) Using the MEP Modeling tools to draw and connect profiles (2.5.14) Using the MEP Modeling tools to alter profiles (2.5.14)

Related Commands

BimAddEccentricity (6.7.7) - Allows to control the relative position of the axis of a linear solid. BimApplyProfile (6.7.10) - Applies a profile to linear entities and linear solids. BimProfiles (6.7.26) - Opens the profiles library in the current project and the referenced library.

BimPropagate (6.7.30) - Maps details (solids, holes, finishing geometry, ...) related to selected base solids to similar base solids in the model and optionally outlines the detail in a grid. BimPropagateCorner (6.7.31) - Propagates details connected to three planar base solids (i.e., corners). BimPropagateEdges (6.7.44) - Propagates a detail along the edge of a planar solid; can be used to propagate railings, gutters, borders, wall caps, etc. BimPropagateLinear (6.7.33) - Propagates connections between linear elements (beams, columns, pipes, ducts and their connections to walls and slabs). BimPropagatePlanar (6.7.36) - Propagates connections between planar elements (walls/slabs/roofs).

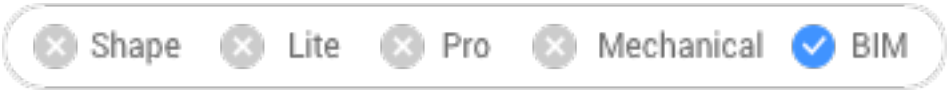
Procedures

Propagate a Detail in a project (2.9.9)

Related Commands

BimPropagateCorner (6.7.31) - Propagates details connected to three planar base solids (i.e., corners). BimPropagateEdges (6.7.44) - Propagates a detail along the edge of a planar solid; can be used to propagate railings, gutters, borders, wall caps, etc. BimPropagateLinear (6.7.33) - Propagates connections between linear elements (beams, columns, pipes, ducts and their connections to walls and slabs). BimPropagatePattern (6.7.34) - Propagates a single element on a flat surface to multiple locations and grids; can be used to propagate lights, light switches, windows, air diffusers, etc. BimPropagatePlanar (6.7.36) - Propagates connections between planar elements (walls/slabs/roofs). BimCreateDetail (6.7.14) - Creates a Detail that can be saved in the library.

Figure 6.421



6.7.36 BimPropagatePlanar

(6.493 on page 3778) Propagates connections between planar elements (walls/slabs/roofs).

Tutorial: How to use Propagate Planer Click here (2.8.5) to watch

Accessing the Command

Commandline: **BIMPROPAGATEPLANAR** Ribbon: **Home | Classify | Propagate Planar** Toolbar: **BIM Toolbar | BIM Propagate : bimpropagateplanar Prompts you:** Select planar solids to connect. [selection options (?)]: **(Select a planar solid.)** Entities in set: 1 Select planar solids to connect. [selection options (?)]: **(Select a planar solid.)** Entities in set: 2 Select planar solids to connect. [selection options (?)]: **(Select more solids or press Enter.)** Select detail objects (solids or faces) to be extruded along the connection (optional). [selection options (?)]: **(Select detail objects or press Enter.)** Propagate detail as an extrusion of this 2D section? [Yes/No/Inflate first/Save detail/save detail to Library] <Yes>:**(Choose an option or press Enter.)** Choose next action [apply All/Cancel] <apply All>: **(Press Enter to apply the selected suggestions.)**

Command Options

Option	Description
Inflate first	Expands the sensitive zone (left) to include similar solids which are not connected yet (right) in the model (right). The edges of the initially detected detail are moved outward over a specified distance. Prompts you: **Enter inflation distance: (Type a value).** (6.422 on page 3727) (6.423 on page 3727)
Save Detail	A File dialog displays. You are prompted to specify a file name to save the detail.
Save Detail to Library	The **Save Detail** dialog displays. See the BIMCREATEDETAIL (6.7.14) command.

Apply All	 : Selected suggestion. Click to switch to not selected.  : The detail will be applied, but there are several alternatives. Hovering over the icon to cycle between alternatives  : The detail will be applied, but interferences were detected  : Not selected suggestion. Click to switch to selected.  : Location of the original detail. Hover over the icon for more information. Click to apply original detail by adapted extrusion. (6.424 on page 3728) Use window selection to select multiple widgets (): • Click the left mouse button then move the mouse to the right to select all widgets inside the selection window. • Click the left mouse button then move the mouse to the left to select all widgets inside or overlapping the selection window. • Keep the Shift-key down while window selecting to unselect widgets. Click one of the selected widgets to modify the state of the entire selection set.

Procedures

The five flavors of BimPropagate (2.9.2) Propagating a wall-slab connection (2.9.5) Propagating a column-beam connection (2.9.3) Propagating columns on top of a slab (2.9.4) Propagating a wall cap (2.9.6) Propagate a corner (2.9.7) Propagate a Detail in a Project (2.9.8)

Related Commands

BimPropagate (6.7.30) - Maps details (solids, holes, finishing geometry, ...) related to selected base solids to similar base solids in the model and optionally outlines the detail in a grid. BimPropagateCorner (6.7.31) - Propagates details connected to three planar base solids (i.e., corners). BimPropagateEdges (6.7.44) - Propagates a detail along the edge of a planar solid; can be used to propagate railings, gutters, borders, wall caps, etc. BimPropagateLinear (6.7.33) - Propagates connections between linear elements (beams, columns, pipes, ducts and their connections to walls and slabs). BimPropagatePattern (6.7.34) - Propagates a single element on a flat surface to multiple locations and grids; can be used to propagate lights, light switches, windows, air diffusers, etc.

Command Options

Option	Description
Namespace	Properties exist in a namespace. Three namespaces are available: The **IFC2x3** and **Quantity** namespaces are read-only. • **Id**: Not eiditable • **Label**: Not eiditable • **Visible**: If set to YES, the properties are visible in the Properties panel (1.15.4). **User**: Allows to create user defined properties. (6.428 on page 3734) • **Id**: Name of the userspace. This field is not editable. • **Label**: The label of the namespace is used in the properties tree. If the Label field is empty, then the Id is used instead. • **Visible**: Defines whether the namespace properties are visible in the Properties panel (1.15.4).
(6.429 on page 3735) **User namespace**	Allows filtering the property tree. Type a search string in the field. Only properties of which the **Id** or the **Label** contains the search string display. The properties tree is filtered as you type.

Add Property Set	Allows adding a property set in the current namespace. Click the **Add Set** button to add a new property set. (6.430 on page 3735) Do the following: • Type a name in the **Id** field. • Type a name in the **Label** field. The **Label** name appears in the properties tree. If the **Label** field is empty, the **Id** name displays. • **Per Instance**: Allows to enable/disable user-defined properties, on a per-entity basis. When set, the **BIM/Entity property sets** property is available in the Properties panel when a BIM entity is selected. To enable the **Per Instance** property, do the following: – Click the **BIM/Entity property sets** property in the Properties panel. – Click the Browse (...) button. The **Enable per-instance property set** dialog displays: (6.431 on page 3736) • Check the **User** namespace, then click the **OK** button. **Visible**: Defines whether the properties in the property set are visible in the Properties panel (1.15.4). **Categories**: Select the building elements the property set applies to. All entities which are such classification get the properties in this property set assigned automatically. Available categories and building elements are the same as in the BimClassify (6.7.12) command. (6.432 on page 3737) Expand a category, then check building elements. Click a category checkbox to select all building elements in that category Click the **All** button to select all building elements in all categories. Click the **None** button to uncheck all building elements in all categories
Add Property	Allows adding a property to the currently selected property set. Select a property set in the properties tree, then click the **Add Property** button to add a new property. Do the following: • Type a name in the **Id** field. • Type a name in the **Label** field. The **Label** name appears in the properties tree. If the **Label** field is empty, the **Id** name displays. • (optional) Type a description in the **Description** field. • Set the property **Type**. The options are: **Boolean**: an ON or OFF value. **Integer**: a whole number between -2147483648 and 2147483647. **Real**: an approximation of a real number. **String:** a sequence of characters, can be both numbers and letters. • **Enum**: allows you to define a fixed number of possible values for custom BIM properties. These values can be selected in a drop-down list in the Properties panel. Optionally, check the Mapping option to add a description for each value. (6.433 on page 3738)

Add Value	Allows to add a set of values for a property set. Select a property set in the properties tree, then click the **Add Value** button to add a new value. Do the following: • Type a name in the **Id** field. • Type a name in the **Label** field. The **Label** name appears in the properties tree. If the **Label** field is empty, the **Id** name displays. • (optional) Type a description in the **Description** field. • Set the value **Type**. The options are: **Boolean**: an ON or OFF value. **Integer**: a whole number between -2147483648 and 2147483647. **Real**: an approximation of a real number. **String:** a sequence of characters, can be both numbers and letters. • **Formula**: Type a value, according to the selected value type. • When the value type is **Real**: – **Measure**: Sets the dimension of the value: length, area or volume. – **Formula**: Type a formula to calculate the value. You can use the syntax of the Formula field of the corresponding BIM entity type in the Quantity namespace to compose a formula.
Remove	Deletes the selected item.

Procedures

Using the BIM properties dialog box (2.7.11) Assigning classification codes to the BIM (2.7.10)

Related Commands

BimExport (6.7.17) - Saves a BIM model as an IFC file for use with IFC-certified applications. BimClassify (6.7.12) - Classifies an entity as a Building Element and get a name and an internal GUID (= globally unique identifier). BimTag (6.7.59) - Creates associative tags in generated BIM section drawings for the corresponding building entities in a 3D BIM model.

6.7.39 BimPython

(6.493 on page 3778) Allows Python Scripting and Querying of a BIM model. **Note**: This is feature is in beta state. Whilst beta features are new and exciting, there could still be bugs and/or rough edges left to iron out. Therefore, please be aware of the risk when trying out them as things might not go as expected.

Accessing the Command

Keyboard: **BIMPYTHON : BimPython** If the **BimActivatePython** user preference is not set, prompts you: Would you like to activate Python [No] <Yes>: **(Press Enter.)** Displays a File dialog box. Select a Python script file (*.py) then double click or click the **Open** button. The Python script is executed. BricsCAD reports the output in the command line panel.

If the **BimActivatePython** user preference is already set: Displays a File dialog box. Select a Python script file (*.py) then double click or click the **Open** button. The Python script is executed. BricsCAD reports the output in the command line panel.

Command Options

Option	Description
File name	Specifies the name of the file.
Files of type	Specifies the file type to show in the Import File dialog box: • **PY** - program file or script written in Python Programming Language
Open	Executes the Python script and returns a result or output in the command line panel.

Procedures

Using Python scripts (2.7.9)

Related Commands

Script (6.27.9) - loads and runs SCR script files through a dialog box.

Figure 6.435

6.7.40 BimQuickBuilding

(6.1726 on page 4955) Use QuickBuilding to quickly transform massing solids into buildings.

Accessing the Command

Commandline: **BIMQUICKBUILDING** Quad: **BIM** Ribbon: **Modeling > Building Elements : BimQuickBuilding**
Prompts you: Select solids [selection options (?)]: **(Select a solid.)** Entities in set: 1 Select solids [selection options (?)]: **(Select more solids or press Enter.)** Do the selected solids represent [Buildings/Spaces]: **(Choose an option.)** Enter desired story height (mm) or [BuildingRequirementFile/Spatiallocations]: **(Type a value or choose an option.)**
The building is created in a new drawing.
BricsCAD reports:

```
Area information : Outer surface area: 11239.114 m² Total projection area : 1107.528 m² Footprint area :
```

Command Options

Option	Description
Enter desired story height (mm)	For equal story heights: type a value For different story heights e.g. type: **2x4000,*3000,1x5000**, which results in two stories of 4000mm, a top story of 5000mm, in-between stories of 3000mm.
BuildingRequirementFile	Use a .txt file to configure the story heights of the building. For instance a text line for 1 story configuration can be: **Space: Name='Level_1_NameBuilding', Area=7%, 'Floor-to-Floor Height'=2500 mm Count=2** You can configure the values for multiple stories.
SpatialLocation	Use the Spatial Structure as input for subdividing the building. The spatial locations information (like story heights) is used for making the new building. See Spatial Locations (2.7.16) for more information.

Procedures

Top-Down workflow (2.5.13) Bottom-up workflow (2.5.13) SpatialLocations as input (2.5.13)

Related Commands

BimQuickDraw (6.7.41) - quickly create and edit rectangular and L-shaped rooms and buildings. BimSpatialLocations (6.7.63) - opens the Buildings & Stories manager which allows to create and edit the site, buildings and stories.

Figure 6.436

6.7.41 BimQuickDraw

(6.504 on page 3789) Use QuickDraw to quickly create and edit rectangular and L-shaped rooms and buildings.

Tutorial: How to use Quickdraw Click here (2.4.26) to watch

Accessing the Command

Commandline: **BIMQUICKDRAW** Quad: **Model | Quickdraw** Ribbon: **Home | Create | Quickdraw** Toolbar: **BIM Toolbar | BIM : BimQuickdraw** The layout of the QuickDraw cursor represents the room being created: Left to right: placed freely, aligned with one existing walls, aligned with two existing walls. (6.437) (6.438 on the next page) (6.439 on the following page) **Prompts you:** Current settings: Floor to Floor distance: 3250, Wall Width: 250, Slab Thickness: 250, Auto Adopt Sizes: On Select first point or [quickdraw Settings]: **(Select a point to define the first corner of the room or choose an option*.)** Select second point: **(Select the a point to define the opposite corner of the room.)** * floor**H**eight, wall**W**idth, slab**T**ickness, auto**A**doptsizes: these QuickDraw command options are hidden in the command prompt, and can be chosen only by typing the capitalized letter in the command line or by clicking the option in the Prompt Menu (1.15.6) if the Show Hidden Options flag of the PromptMenuFlags (1.17.10) user preference is set. (6.440 on the next page)

Figure 6.437

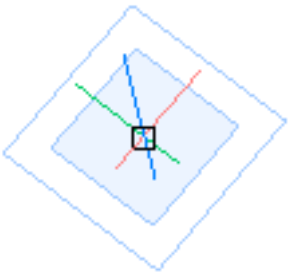

Figure 6.438

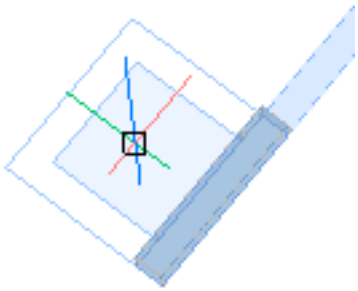

Figure 6.439

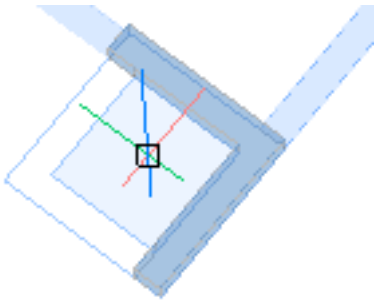

Figure 6.440

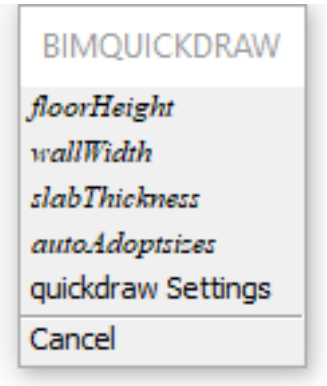

Command Options

Option	Description
Floor to Floor Distance (Floor Height)	Sets the floor to floor distance. The value is saved to the FLOORTOFLOORDISTANCE system variable and will be used until set differently. Default value = 3250 mm The height of the exterior walls = Floor to Floor Distance. The height of interior walls = Floor to Floor Distance - Slab Thickness
Wall Width	Sets the width of the walls being created. The width is saved to the WALLWIDTH system variable and will be used until set differently. Default value = 250 mm
Slab Thickness	Sets the slab thickness of the room. The thickness is saved to the SLABTHICKNESS system variable and will be used until set differently. Default value = 250 mm.
Select first point	Defines the first corner of a room. The layout of the QuickDraw cursor indicates the alignment with existing walls and distances from existing solids. Depending on the layout of the QuickDraw cursor: • Default cursor: Click a point. (6.441 on page 3745) • Aligned with one exiting wall; distance from one existing solid: (6.442 on page 3745) – Type a value in the dynamic distance field. – Click a point to accept the alignment • Aligned with two existing walls; distances from two existing solids. (6.443 on page 3745) – Type a value in the distance field, then press the TAB key and type a value in the second dynamic distance field. Optionally press the TAB key to adjust the value in the first distance field. Press Enter to accept the distances. – Click to accept the alignment. **Note:** The dynamic distance dimensions are independent of the snapping in the BimQuickDraw. It is possible to have the cursor snapping in one or two directions, while there are no dynamic dimensions visible. (6.444 on page 3746)

Select second point	Defines the opposite corner of a room. When creating the exterior walls of a building, do one of the following: (6.445 on page 3746) • Click a point. • Type a value in the distance field, then press the TAB key and type value in the second distance field. Optionally press the TAB key to adjust the value in the first distance field. Press **Enter** to accept the distances. When creating rooms: (6.446 on page 3747) • Click a point. • Type a value in the distance field, then press the TAB key and type value in the next distance field. Optionally press the TAB key again to type a value in the next distance field, thus overriding the value in the first distance field. If necessary, keep pressing the TAB key to adjust the distances, then press Enter to accept. Snap to existing walls: • You can snap to (the extents of) existing walls to set the second point. (6.447 on page 3748) • It is also possible to snap to gridlines. (6.448 on page 3749)
Auto adopt sizes	Allows to copy the wall width and height from an existing wall, thus overriding the current value of the WALLWIDTH system variable. Prompts you: **Auto adopt sizes On/OFF <On>** - **(choose an option.)** • **ON**: The width and height are copied from the highlighted wall when you place the QuickDraw cursor against a wall to specify the first corner of a new room. When two walls of different height or width highlight (corner), the dimensions of the wall that highlights first are copied. • **OFF**: The values of the FLOORTOFLOORDISTANCE and WALLWIDTH system variables are used. Default value = ON
(6.449 on page 3749) Add Story	Hover the cursor over the icon () to see the options: •  Full copy of the top floor. •  Copies the slab and the outer walls of the top floor. •  Finish the building with flat roof. Click an icon to add a new story or to finish the building with a flat roof.

Figure 6.441

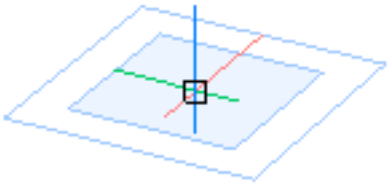

Figure 6.442

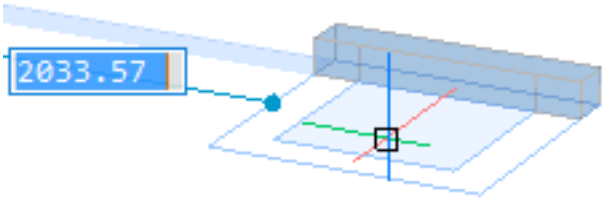

Procedures

Setting the Quickdraw system variables (2.5.22) Creating an L-shaped house (2.5.22) Creating a Story and a Roof (2.5.22) Using Quickdraw starting from a 2D lay-out (2.5.22)

Related Commands

PolySolid (6.24.65) - Creates wall-like or pitched roof 3D solids. BimConnect (6.20.19) - Creates an L-connection between minor faces of two solids. BimRoom (6.7.42) - Creates BIM Room entities. BimStair (6.7.47) - Creates stairs between 2 floor slabs.

6.7.42 BimRoom

(6.1726 on page 4955) The BIMROOM command is obsolete and has been replaced by the BIMSPACE (6.7.45) command. You can still open BIM rooms, but it is not possible to create new BIM rooms or update their geometry. Use the **Space** option of the BIMCLASSIFY (6.7.12) command to convert a BIM room to a BIM space.

Figure 6.451

6.7.43 BimSectionUpdate

(6.1726 on page 4955) Exports or updates the result of a BIM section in a drawing.

NOTE	The GENERATEASSOCATTRS (Generate associative attributes) system variables controls the generation of associative data on 3D solids during modeling. When set to On, 3D solids contain associative data from the moment of creation. This allows BIMSECTIONUPDATE to produce drawings for which dimensions and tags can be automatically updated when the 3D model has been modified.

Accessing the Command

 Commandline: **BIMSECTIONUPDATE** Quad: **Select Section Object | Model | Generate Section** Ribbon: **Annotate | Generate Sections | Update Section** Toolbar: **BIM Toolbar | BIM Section Update** : **BimSectionUpdate**

To create or update BIM sections when in a BIM 3D model Open the BIM 3D model. Launch the BimSectionUpdate command. **Prompts you in the command bar:** Select BIM section entity to generate or BIM section result to update: **(Select a BIM section entity or a BIM room*.)** Entities in set:1 Select BIM section entity to generate or BIM section result to update: **(Select more BIM section entities or BIM rooms, or press Enter.)** Bricsys reports:

```
 xx section(s) were generated
C:\BricsCAD\Villa\Section Plane (1)
...
C:\BricsCAD\Villa\Section Plane (xx)
```

*BIM rooms can be selected if the interior elevations have been created by the Interior (6.7.54) option of the BimSection (6.7.54) command.

To update a BIM section drawing Open the BIM section drawing. Launch the BimSectionUpdate command. **Prompts you in the command bar:** Select BIM section entity to generate or BIM section result to update: **(Either select a section in Model Space or a viewport in a Paper Space layout.)** Entities in set:1 Select BIM section entity to generate or BIM section result to update: **(Either select a section in Model Space or a viewport in a Paper Space layout; or Press Enter.)**

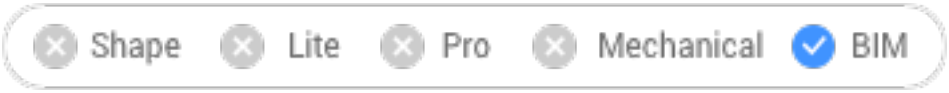
Procedures

To Update a BIM Section (2.13.13)

Related Commands

BimPatch (6.7.27) - Allows to replace part of a generated section. BimSection (6.7.54) - Creates a BIM section entity. BimSectionOpen (6.7.49) - Opens the drawing file related to a BIM section entity; or the 3D BIM model related to a BIM section drawing. SectionPlane (6.27.18) - Creates a section entity that creates sections of 3D solids. SectionPlaneSettings (6.27.12) - Defines the properties of a section plane entity in the Drawing Explorer - Section Planes dialog. SectionPlaneToBlock (6.27.13) - Saves the selected section plane to a 2D cross section / elevation block or a 3D cutaway section block. BimTag (6.7.59) - Creates associative tags in generated BIM section drawings for the corresponding building entities in a 3D BIM model.

Figure 6.452



6.7.44 BimPropagateEdges

(6.493 on page 3778) Propagates a detail along the edge of a planar solid; can be used to propagate railings, gutters, borders, wall caps, etc.

Tutorial: How to use Propagate Edges Click here (2.8.6) to watch

Accessing the Command

Commandline: **BIMPROPAGATEEDGES** Ribbon: **Home | Classify | Propagate Edges** Toolbar: **BIM Toolbar | BIM Propagate : BimPropagateEdges Prompts you:** Select planar reference solid to which the edge detail is related. The detail will be copied to edges of similar solids. [selection options (?)]: **(Select a planar solid (1).)** Entities in set: 1 Select planar reference solid to which the edge detail is related. The detail will be copied to edges of similar solids. [selection options (?)]:: **(Select more planar solids or press Enter.)** Select detail objects to be copied. These should be solids or faces that are parallel to an edge of the reference solid. [selection options (?)]: **(Select the detail object(s) (2).)** Entities in set: 1 (6.453 on the facing page) Select detail objects to be copied. These should be solids or faces that are parallel to an edge of the reference solid. [selection options (?)]:: **(Select more detail objects or press Enter.)** (6.454 on the next page) Blue: detail area to be copied. Purple: reference contact area. Accept? [Yes/No/Inflate first/Save detail/save detail to Library] <Yes>: **(Press Enter or choose an option.)** Propagate to edges with similar orientation only? [Yes/No] <Yes>: **(Press Enter or choose an option.)** Choose location of detail relative to edge: [Outside reference solid/Inside reference solid] <Outside reference solid>: **(Press Enter or choose an option.)** Searching for similar connections Creating the suggestions Showing 6 application details Resolving conflicts and extensions Duration start BIMPROPAGATE: 0.930000 Showing 6 visible suggestions of total 6. (6.455 on page 3754) Accept or reject suggestions by clicking on the tick. Then [Apply/Cancel] <Apply>: **(Press Enter to propagate the detail along all selected edges.)** Applying all 6 visible suggestions. (6.456 on page 3754)

Figure 6.453

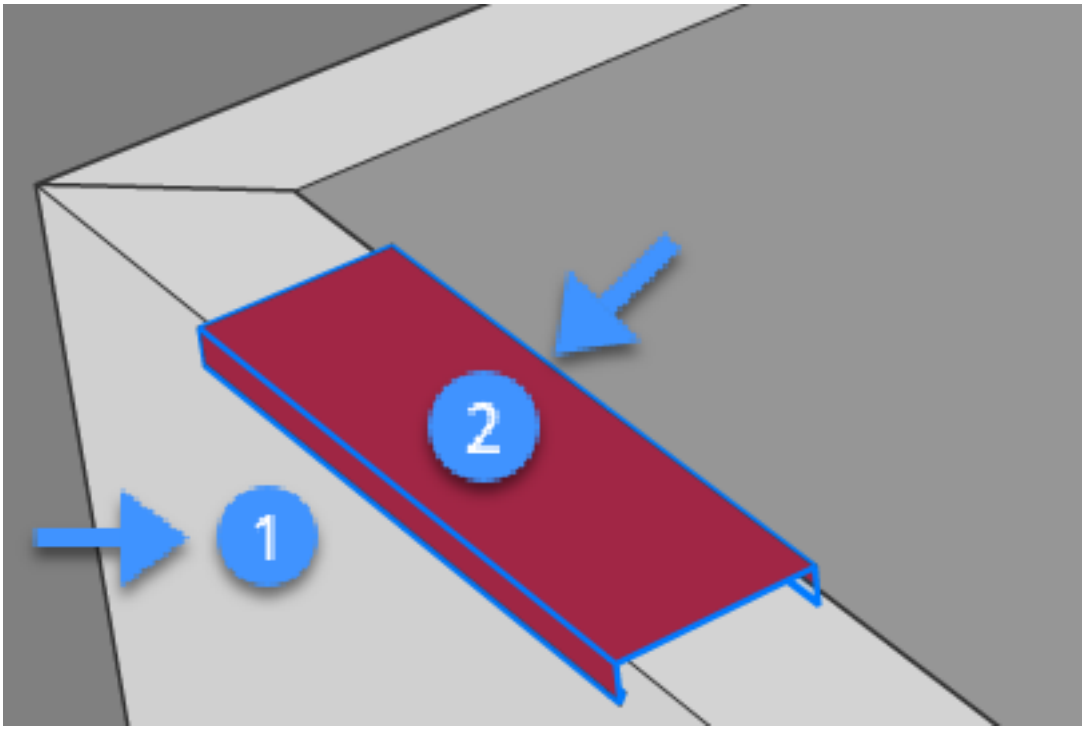


Figure 6.454

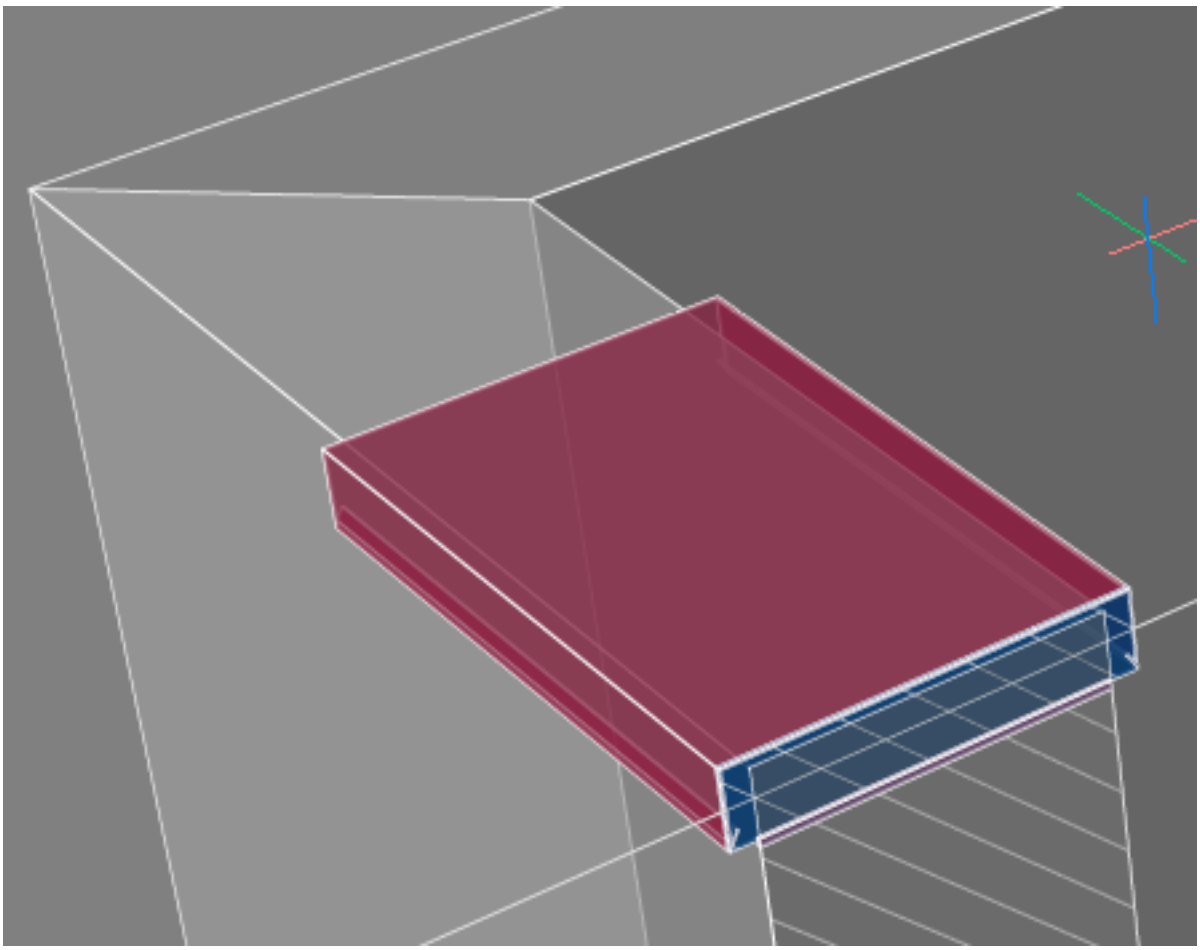

Figure 6.455

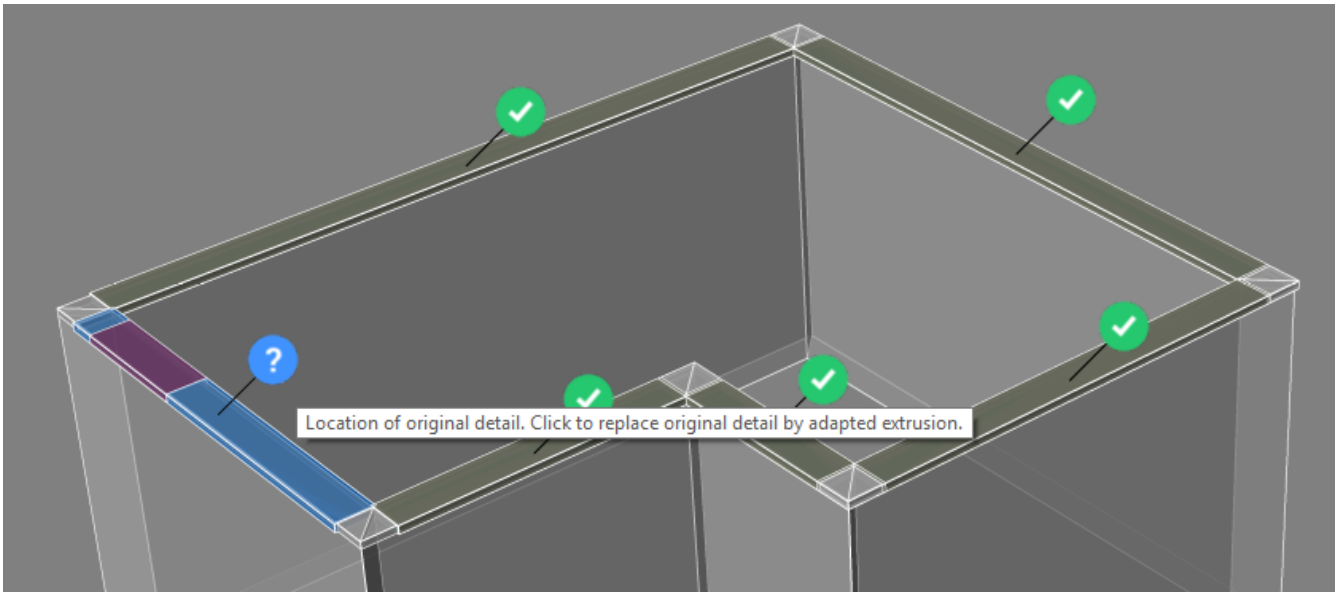

Figure 6.456

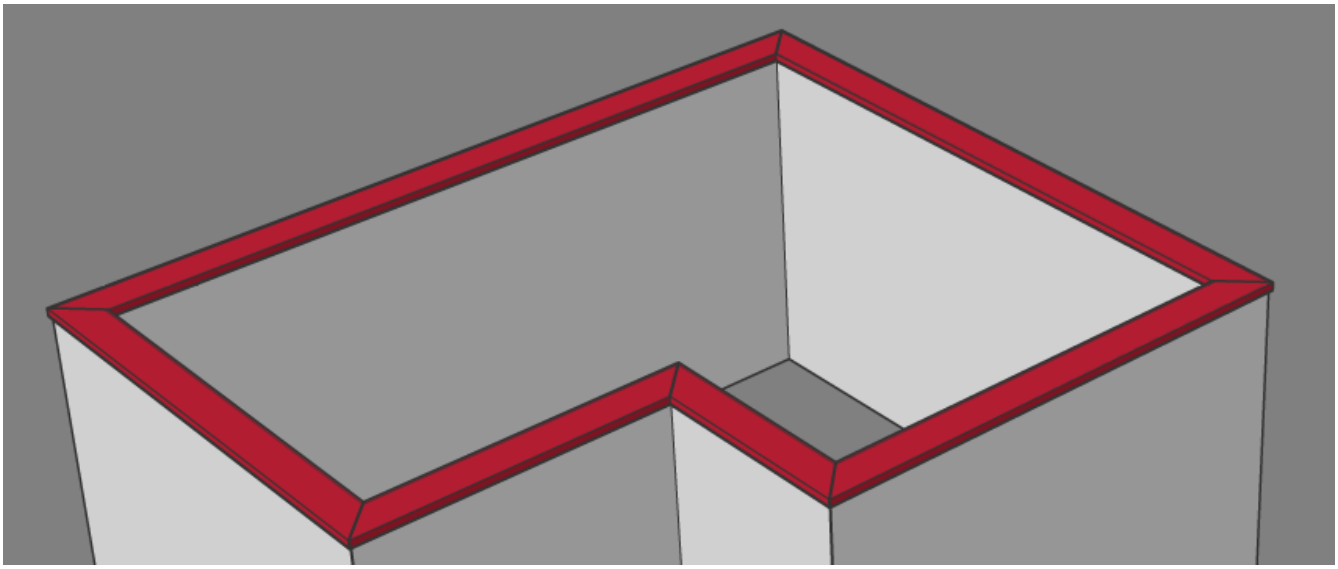


Command Options

Option	Description
Inflate first	Expands the sensitive zone to include similar solids which are not connected yet. The edges of the initially detected detail are moved outward over a specified distance. Prompts you: **Enter inflation distance: (Type a value).**
Propagate to edges with similar orientation only	**Yes**: Only edges with similar orientation are selected. In the above example only the horizontal top face of the walls are selected. **No**: All minor faces of similar planar solids are selected. In the above example also the bottom face of the walls would be selected.
Choose location of detail relative to edge:	**Inside**: The propagated detail is placed inside the base solids; the volume of the detail is subtracted from the base solids. **Outside**: The propagated detail is placed outside the base solid; the volume of the base solids is not modified.
Save Detail	A File dialog displays. You are prompted to specify a file name to save the detail.
Save Detail to Library	The **Save Detail** dialog displays. See the BIMCREATEDETAIL (6.7.14) command.
Apply All	Accept or reject suggestions by clicking on the tick. See the Apply option in the BIMPROPAGATE (6.7.30) command.

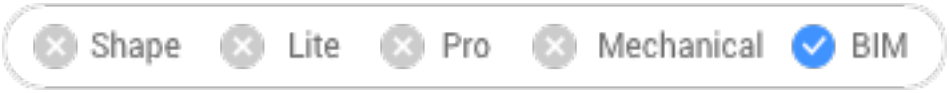
Procedures

The five flavors of BimPropagate (2.9.2) Propagating a wall-slab connection (2.9.5) Propagating a column-beam connection (2.9.3) Propagating columns on top of a slab (2.9.4) Propagating a wall cap (2.9.6) Propagate a corner (2.9.7) Propagate a Detail in a Project (2.9.8)

Related Commands

BimPropagate (6.7.30) - Maps details (solids, holes, finishing geometry, ...) related to selected base solids to similar base solids in the model and optionally outlines the detail in a grid. BimPropagateCorner (6.7.31) - Propagates details connected to three planar base solids (i.e., corners). BimPropagateLinear (6.7.33) - Propagates connections between linear elements (beams, columns, pipes, ducts and their connections to walls and slabs). BimPropagatePattern (6.7.34) - Propagates a single element on a flat surface to multiple locations and grids; can be used to propagate lights, light switches, windows, air diffusers, etc. BimPropagatePlanar (6.7.36) - Propagates connections between planar elements (walls/slabs/roofs).

Figure 6.457



6.7.45 BimSpace

(6.493 on page 3778) Creates BIM Space entities from enclosed boundaries.; optionally or edits spaces. Note: The **Space** option of the BIMCLASSIFY (6.7.12) command converts any 2D or 3D entity into a BIM Space entity.

Accessing the Command

 Create space  Edit space Keyboard: **bimspace** Menu: **BIM | Space** Toolbar: **BIM Spaces** Quad Tab: **BIM** Ribbon Tab | Panel: **Data | Spaces : bimspace Prompts you:** Pick a point inside the space or [Edit]: **(Pick a point inside an enclosed area defined by space bounding entities*.)** The footprint of the space highlights. Click to create the space. The BIM Space is created using the following Footprint representation. A label is created at the geometric center of the space. Optionally, select the space and edit its properties in the Properties (1.15.4) panel. * Space bounding entities: (3D solids or linear 2D entities), which are classified as a BIM entity (6.7.12) and having the Space Bounding property set to Yes. If the Centerline property property of a space bounding solid is Yes, the center of the solid is used as the space boundary. The height of the space is defined by:

- The top face of the highest bounding entity.
- The DefaultSpaceHeight user preference, when all bounding entities are 2D linear entities,

Command Options

Option	Description
Edit 	Launches the Edit mode:. Prompts you: **Select a space to update its bounding elements [selection options (?)]** - Select a BIM space. The bounding entities of the selected space highlight. **Select to add or remove space bounding elements [selection options (?)] <Accept>:** Do the following: • To remove space bounding entities: Hover over a bounding entity entity, then click. (6.458 on the next page) • To add space bounding entities: Hover over a BIM entity, then click. (6.459 on page 3758) • Press Enter to accept the changes. The current space bounding entities highlight. A warning icon displays next to the space tag indicating that the space is out of date and must be updated. (6.494 on page 3778) Launch the BIMUPDATESPACE (6.7.53) command to update the space. If the **Update Method** property of the space is **Manually** () the space cannot be updated by the BIMUPDATESPACE command. You must set the property to **Automatic** in the Properties panel first. (6.495 on page 3779)

Space Properties

Space Properties	A BIM Space corresponds to an IfcSpace, and has all IFC properties listed under **Space Common** in the Properties panel. The **BIM** properties of a space are: • **Representation**: Click the field to set the represenation. Footprint: Space stamp only. Solid: Transparent 3D solid. The height of the solid is copied from the surrounding wall solids. • **Status**: Click the field to set the status or run the BIMUPDATESPACE (6.7.53) command. Up to date Out of date: An exclamation mark icon displays next to the space stamp. • **Name**: Sets the name of the space, also visible on the space stamp. • **Description**: Describes the space. • **Building**: Click the field, then select a building (see BIMSPATIALLOCATIONS (6.7.63)). • **Story**: Click the field, then select a story (see BIMSPATIALLOCATIONS (6.7.63)). • **Interior Elevations**: Controls the display of Interior Elevations. If interior elevations are not created yet for the space the property is disabled. See BIMSECTION (6.7.54) for more information. **Custom properties**: You can create additional properties using the BIMPROPERTIES (6.7.38) command.

Procedures (related procedure from BIM articles)

Defining a BIM Space (2.7.14) Creating a BIM Space from virtual boundaries (2.7.14) Bimify your entire drawing (2.9.1) Bimify a selection of your BIM Model (2.9.1)

Related Commands

BimUpdateSpace (6.7.53) - updates the geometry of a Space entity. Bimify (6.7.23) - Analyzes the model and runs automatic classification and spatial location assignment for the entire model. Creates new buildings and/or stories and spaces if necessary. BimTag (6.7.59) - Creates associative tags in generated BIM section drawings for the corresponding building entities in a 3D BIM model. BimQuickDraw (6.7.41) - Use QuickDraw to quickly create and edit rectangular and L-shaped spaces and buildings. BimQuickbuilding (6.7.40) – Generates a BIM building out of a massing solid, including levels, floors, walls, spatial locations, spaces etc. BimClassify (6.7.12) - classifies an entity as a Building Element and get a name and an internal GUID (= globally unique identifier).

6.7.46 BimSetReferenceFace

(6.1726 on page 4955) Defines a reference and an opposing face to control the ply layout of a composition. If one of the plies of the composition has a variable thickness, the reference and opposing face can be non-parallel. In this case the fixed thickness plies are set out starting from the reference face, and the remainder of the solid is filled by the variable ply. (6.463) (6.464)

Figure 6.464

Accessing the Command

Commandline: **BIMSETREFERENCEFACE : BimSetReferenceFace Prompts you:** Select reference face: **(Select the reference face of the solid.)**

- If the selected face is parallel to the opposing face: Opposing face(s) are detected [Select manually] <Accept>: **(Press Enter to accept the parallel face or typ S to manaully select the opposing face manually.)**
- If the selected face is not parallel to the opposing face: Select opposing face: **(Select a face.)**

Reference face was set. (6.465 on the facing page) (6.466 on the next page) Solids without composition Multiply composition assigned Reference faces are either wrong or not found (6.467 on page 3762) (6.468 on page 3762) Defining reference face (1) and opposing face (2) Attaching a composition (6.7.8) Reference faces highlight (6.469 on page 3763) Result

Command Options

Option	Description
Select manually	Allows to select the opposite face manually. Prompts you: **Select opposing face: (Select a face.)**

Related Commands

BimAttachComposition (6.7.8) - Attaches a BIM composition to solids. BimFlip (6.7.20) - Flips the starting face from which the layers of a composition are set out.

6.7.47 BimStair

(6.504 on page 3789) Creates stairs between 2 floor slabs or any empty space and it will create a stair – using the default floor-to-floor-distance as height.

Accessing the Command

Commandline: **BIMSTAIR** Quad: **Model | Stair** Ribbon: **Home | Create | Stair** Toolbar: **BIM Toolbar | BIM Quick Tools : BimStair Prompts you:** Select first step or [Quarter-turn/Flip/Stair settings]: **(Click to choose the start point of the first step or choose an option.)** Select second step or [Quarter-turn/Flip/U-shape type/Stair settings]: **(Select the end plane of the stairs or choose an option.)** The stairs display dynamically when you move the cursor. The type of stairs being created depends on the position of the cursor with respect to the position of the selected start point. Click to create the stairs. The staircase is created as a parametric block. The Stair Type property is assigned automatically. **Note:** Editing the Stair Type property in the Properties panel (1.15.4) does not affect the geometry of the staircase. You can edit the parameters of the stairs in the property set Parameters in the Properties panel.

Command Options

Option	Description
Select first step	Defines the start plane of the stairs. Do one of the following: • Move the cursor over a horizontal face of a solid. • Move the cursor over a void area to select the XY-plane of the current UCS.
Quarter-turn	Turns the direction of the stair cursor with 90 degrees. When the Hot Key Assistant (HKA field in the Status bar (1.15.2)) is ON, press the Ctrl key to turn the stair cursor with 90 degrees.
Flip	Turns the direction of the stair cursor with 180 degrees.
Select second step	Defines the end plane of the stairs. Defines the height of the staircase. Do one of the following: • Move the cursor over a horizontal face of a solid. The stair height is set to the difference between the Z-values of start plane and the end plane. • Move the cursor over a void area. If the first step was a horizontal face of a solid, then the stair height is set to the difference between the Z-values of start plane and the void area. If the first step was a void area as well, then the stair height is set to the current value of the FLOORTOFLOORDISTANCE system variable.

U-shape type	Switches between two different U-shape type stairs: • **Double-flight U-shaped stairs**, with a single rectangular landing solid bridging the perpendicular distance between both opposing stair flights, • **Triple-flight U-shaped stairs**, with two square landing solids between each pair of subsequent stair flights. When the Hot Key Assistant (HKA field in the Status bar (1.15.2)) is ON, press the Ctrl key to cycle the possible stair types with respect to the current position of the stair cursor.
Stair Settings	Sets the parameters of the stair. The Settings dialog box displays: (6.471 on the following page) • **Stair Width:** Default width of the stairs • **Preferred Tread Length:** Preferred tread length of the stairs • **Ideal Riser height:** Ideal riser height of the stairs • **Head Room:** Sets the minimum clearance for the opening to be created • **Step Thickness:** Thickness of the individual steps • **Nosing:** Horizontal distance of overlap between subsequent treads • **Final Tread Length:** Length of the final tread, this always in regards to the top tread of the stair • **Automatically flip/quarter-turn:** Turn on if you want to automatically flip or turn when you hover over the slab with your cursor and snap the blue StairCursor to the walls (the end of the arrow can then never be facing a wall) • **Final Tread:** Controls creation of a tread at the elevation of the top bounding slab For all properties, parameters will be created when creating the stair, driving the constraints of the parametric stair block. These parameters can then be changed individually afterward in the Parameters section of the Properties panel (1.15.4).

Parameters

Depending on the stair type, additional parameters are created.

Stair Type	Parameters

Figure 6.480

6.7.48 BimStretch

(6.1726 on page 4955) This command stretches the ends of linear solids while maintaining the connections that were previously made between the other linear solids in the overall structure.
BimStretch has two flavors, one to stretch structural connections, see Procedure 'Stretching Steel Structures' (2.5.20), and one to stretch MEP connections, see procedure 'Stretching Flow Segments' (2.5.14). To define which flavor BimStretch should use, it looks towards the classification of your elements:

- Stretching elements that are classified as Beam, Column, or Member will result in structural stretching.
- Stretching elements that are classified as Flow Segments will result in MEP stretching.

Before using BimStretch make sure that:

- 'Display sides and ends' is enabled.
- 'Display Axes' is enabled.
- Structural profiles are connected with StructuralConnect.
- MEP connections are connected with FlowConnect.

Accessing the Command

Before accessing the command, select the ends of the entities you want to stretch.  Commandline: **BIMSTRETCH** Quad: **BIMSTRETCH : BimStretch Prompts you in the command bar:** Enter new point [Base point/Copy/Undo/eXit]: **(click to the point you want to move the end to or enter a value and press Enter)**

Command Options

Option	Description
Base Point	Choose another base point to start the displacement from.
Copy	Instead of moving the entities, this option makes a copy of them in the new position.
Undo	Undo the last action.
Exit	Exit the command.

Procedures

Using BimStretch to modify Structural Steel (2.5.20) Using BimStretch to modify Flow Segments (2.5.14)

Related Commands

BimApplyProfile (6.7.10) - Applies a profile to linear entities and linear solids. BimLinearSolid (6.7.29) - Creates linear solids. BimProfiles (6.7.26) - Opens the profiles library in the current project and the referenced library. BimFlowConnect (6.7.19) - Creates a connection between flow segments, such as pipes or HVAC ducts. BimStructuralConnect (6.7.61) - Connects structural profile solids such as beams and columns. Drag (6.10.38) - Moves 3D solids perpendicular to a selected face by dragging that face. Optionally preserves connections to other solids. BimAddEccentricity (6.7.7) - Allows to control the relative position of the axis of a linear solid. BimRecalculateAxis (6.7.51) - Recalculates the axis of linear building elements and repositions it back on the center line of a linear element.

Figure 6.481

6.7.49 BimSectionOpen

(6.1726 on page 4955) Opens the drawing file related to a BIM section entity; or the 3D BIM model related to a BIM section drawing.

Accessing the Command

Commandline: **BIMSECTIONOPEN** Quad: **Select Section Object | Model | Open Model** Ribbon: **Annotate | Generate Sections | Open Section Model** Toolbar: **BIM Toolbar | BIM Section Update** : **BimSectionOpen**

To open the 3D BIM model related to a BIM section drawing **Prompts you in the command bar:** Select BIM section entity or BIM section results: **(Either select a section block in Model Space or a viewport in a Paper Space layout.)** Entities in set: 1 Select BIM section entity or BIM section results: **(Press Enter to open the 3D model.)**

To open the drawing file(s) related to a BIM section entity **Prompts you in the command bar:** Select BIM section entity or BIM section results: **(Select a BIM section entity.)** Entities in set: 1 Select BIM section entity or BIM section results: **(Select more BIM section entities, or press Enter.)**

Command Options

No options.

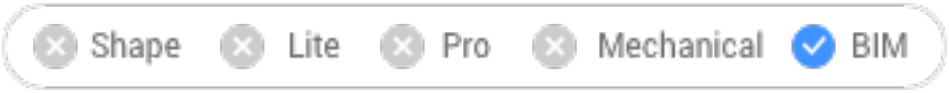
Procedures

Opening a generated drawing (2.13.13)

Related Commands

BimPatch (6.7.27) - Allows to replace part of a generated section. BimSection (6.7.54) - Creates a BIM section entity. SectionPlane (6.27.18) - Creates a section entity that creates sections of 3D solids. SectionPlaneSettings (6.27.12) - Defines the properties of a section plane entity in the Drawing Explorer - Section Planes dialog. SectionPlaneToBlock (6.27.13) - Saves the selected section plane to a 2D cross section / elevation block or a 3D cutaway section block. BimTag (6.7.59) - Creates associative tags in generated BIM section drawings for the corresponding building entities in a 3D BIM model. BimSectionUpdate (6.7.43) - Exports or updates the result of a BIM section in a drawing.

Figure 6.482



6.7.50 BimSetLoadBearingDirection

(6.493 on page 3778) Sets the loadbearing direction for BIM slab solids.

Accessing the Command

 Keyboard: **BIMSETLOADBEARINGDIRECTION** Quad Tab: **BIM** Ribbon Tab | Panel: **Structural/MEP | Modify : BimSetLoadBearingDirection Prompts you:** Select a slab [selection options (?)]:> **(Select a solid, classified as a slab.)** An icon displays in the center of the slab, indicating the current loadbearing direction(s). Click to change the load-bearing direction or [Accept]: **(Click the icon to cycle the various options. Right-click to accept.)**

Figure 6.488

6.7.52 BimSplit

(6.504 on page 3789) Automatically splits segmented solids into separated solids and allows to split a solid using a selection of cutting faces.

Accessing the Command

Commandline: **BIMSPLIT** Quad: **Select solid | Model | Split** Ribbon: **Home | Modify | Split Modeling | Modify | Split** Toolbar: **BIM Toolbar | BIM Connect** : **BimSplit Prompts you in the command bar:** Select solid for auto splitting or cutting faces for manual splitting: **(Select a 3D solid* or one or more faces**.)** Entities in set: 1 Select solid for auto splitting or cutting faces for manual splitting: **(Select more solids or faces or press Enter.)** Entity was split in 6 parts (*) To select a solid, make sure that the value of SelectionPreview is 2 or 3; hover over the solid, then hit the TAB key until the whole solid highlights and click. (**) To select a face, place the cursor over a face and click. Faces highlight one by one, regardless of the value of SelectionPreview or SelectionModes.

Note	Inserts, such as windows and doors, which existed in the split solid are removed.

Command Options

Select solid:

(6.489 on the following page) Solid selected ...	(6.490 on the next page) ... split into 6 separate solids

Select cutting faces:

(6.491 on page 3777) Two cutting faces selected ...	(6.492 on page 3777) ... split into 4 separate solids

Procedures

To split a solid automatically (2.5.17) To split a solid using cutting faces (2.5.17)

Related Commands

BimConnect (6.20.19) - Creates an L-connection between minor faces of two solids. Union (6.30.6) - Performs Boolean union operations on 3D solids and 2D regions; adds one to another to form a single entity. Slice (6.27.40) - Cuts a 3D solid with a plane into two parts. SolidEdit (6.27.42) - Edits 3D solids and 2D regions.

Command Options

No command options.

Related Commands

BimSpace (6.7.45) - creates BIM Space entities from enclosed boundaries.; optionally or edits spaces.

Figure 6.496

6.7.54 BimSection

(6.504 on page 3789) Creates a BIM section entity.

Accessing the Command

Commandline: **BIMSECTION** Quad: **Model | Define Section** Ribbon: **Home | Section** Toolbar: **BIM Toolbar | BIM Sections** : **BimSection** The Section Tracker is attached to the cursor. (6.497) The section plane (1) lies in the XY-plane of the current coordinate system (WCS or UCS). The view direction (2) is in the negative Z-direction of the current coordinate system. If Dynamic UCS (UCSDETECT (1.17.10)) is ON, the section plane aligns to the face of a 3D solid under the cursor. **Prompts you in the command bar.** Select a point to place section or [Detail/Interior/Scale/Reflected ceiling]: **(Specify a point.)** The section plane displays dynamically parallel to UCS XY-plane, through the cursor position. Specify distance: **(Type a distance* or specify a point.)** **Note:** it is recommended to have Dynamic Dimensions (1.21.9) (DYN) active, which allows to type the distance in the dynamic entry field. The section plane is defined through the point or at the specified offset from the first point. The section line is parallel to the X-axis of the UCS or dynamic UCS and through the point at the specified offset from the first point. Only the section line and the callouts of a BIM Section entity display. When highlighted or selected the section plane, section boundary and/or section volume display. The **Clip Display** property of the BIM Section entity is enabled by default. Double click the section line or a callout of a section to toggle **Clip Display** on/off. Multiple sections can have **Clip Display** on simultaneously. The **Clip Display** property can be saved in a model view (See the View (6.31.2) command). BIM section entities are created on the current layer. It is recommended to create a dedicated layer for BIM sections. Horizontal sections get the **Plan** section type, other sections get the **Section** section type, unless no geometry is cut by the section plane, then the section type is **Elevation** . The section type can be edited in the **Section Type** field on the **Properties Bar** . (6.498 on the next page)

NOTE	The GENERATEASSOCVIEWS (1.17.10) system variable controls whether VIEWSECTION produces 2D drawings which are persistently associated with the source 3D model. If GENERATEASSOCVIEWS is ON, associative dimensions are updated automatically when the 3D model is modified and BIMSECTIONUPDATE (6.7.43) is executed.

Figure 6.497

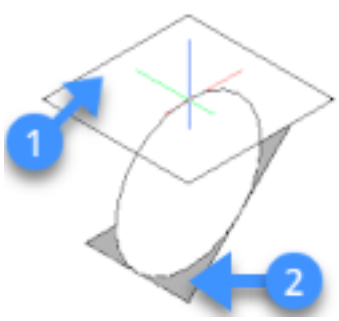

Figure 6.498

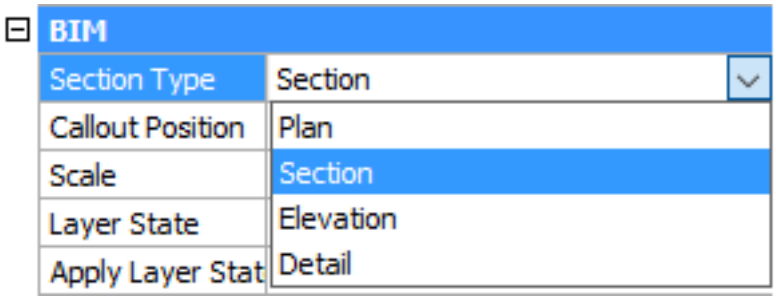

Command Options

Option	Description
Scale	Sets the **Scale** property of the viewport in the drawing file created by the BIMSECTIONUPDATE (6.7.43) command. The default **Scale** is saved through the **SectionScale** user preference. Default = 0.02. Prompts you: **Specify a scale for the viewport with the section result (0.000001 - 1000000.000000) <0.02>:** Do one of the following: • Press Enter to accept the default scale. • Type a value, then press Enter.
Detail	Creates a **Detail** section type. Prompts you: **Select first corner of the volume box base rectangle or [Based on an existing section/Scale]: (Specify a point, or choose an option.) Select the opposite corner of volume box base rectangle: (Do one of the following)**: • Specify a point. • Use the dynamic dimension fields to define the base rectangle. Hit the TAB key to switch between the dynamic dimension fields. **Select the height of volume box: (Do one of the following)**: • Specify a point. • Type a value in the dynamic dimension field.

Based on an existing section	Creates a **Detail** section type based on an existing section. The base rectangle of the detail section will be parallel to the section plane of the selected section. Prompts you: **Select an existing section plane as base - (Select a Bim section). Select first corner of the volume box base rectangle or [Based on an existing section/Scale]** - **(Specify a point, or choose an option.) Select the opposite corner of volume box base rectangle: (Do one of the following)**: • Specify a point. • Use the dynamic dimension fields to define the base rectangle. Hit the TAB key to switch between the dynamic dimension fields. **Select the height of volume box: (Do one of the following)**: • Specify a point. • Type a value in the dynamic dimension field.
Interior	Creates interior elevations and a floor plan of a space. Prompts you: **Select BIM Spaces to generate Interior Elevations** - **(Select a space)**. Entities in set: 1 **Select BIM Spaces to generate Interior Elevations** - **(Select more spaces or press Enter.)** Interior Elevations created for 1 BIM Space(s). The **BIM / Interior Elevations** property of the selected space(s) is set to ON. Use BimSectionUpdate (6.7.43) to update the interior elevations.
Reflected ceiling	Creates the plan of a ceiling projected onto the section plane. A reflected ceiling plan shows the size and location of light fixtures and other structures on the ceiling. Prompts you: **Select a point to place section or [Detail/Interior/Scale/Reflected ceiling] - (Specify a point).** The section plane displays dynamically parallel to UCS XY-plane, through the cursor position. **Specify distance** - **(Type a distance* or specify a point)**. The **Clip display** property of a reflected ceiling section is **Off** by default.

Grips Editing

BIM Section entities can be edited through grips. Select the entity. A section entity in **Plane** state has 3 grips. (6.499 on the facing page)

- 3: Start grip: allows to move the section and the position of the **Start** callout..
- 4: End grip: allows to modify the orientation of the section and the position of the **End** callout.
- 5: Center Grip: allows to move the section and the position of the **Mid** callout.
- 6: Click the arrow to flip the view direction.

In **Boundary** state, section entities have five more grips. (6.500 on the next page)

- 7: Midpoint grip: allows to move the section entity.
- 8: Corner grip: allows to deform the section boundary/volume.
- 9: Midpoint grip: allows to stretch the section boundary/volume.
- 10: Corner grip: allows to deform the section boundary/volume.
- 11: Midpoint grip: allows to stretch the section boundary/volume.

In **Volume** state, section entities have two more grips, compared to the boundary state.. (6.501 on page 3784)

- 12: Allows to move the top plane of the section entity.
- 13: Allows to move the bottom plane of the section entity.

Figure 6.499

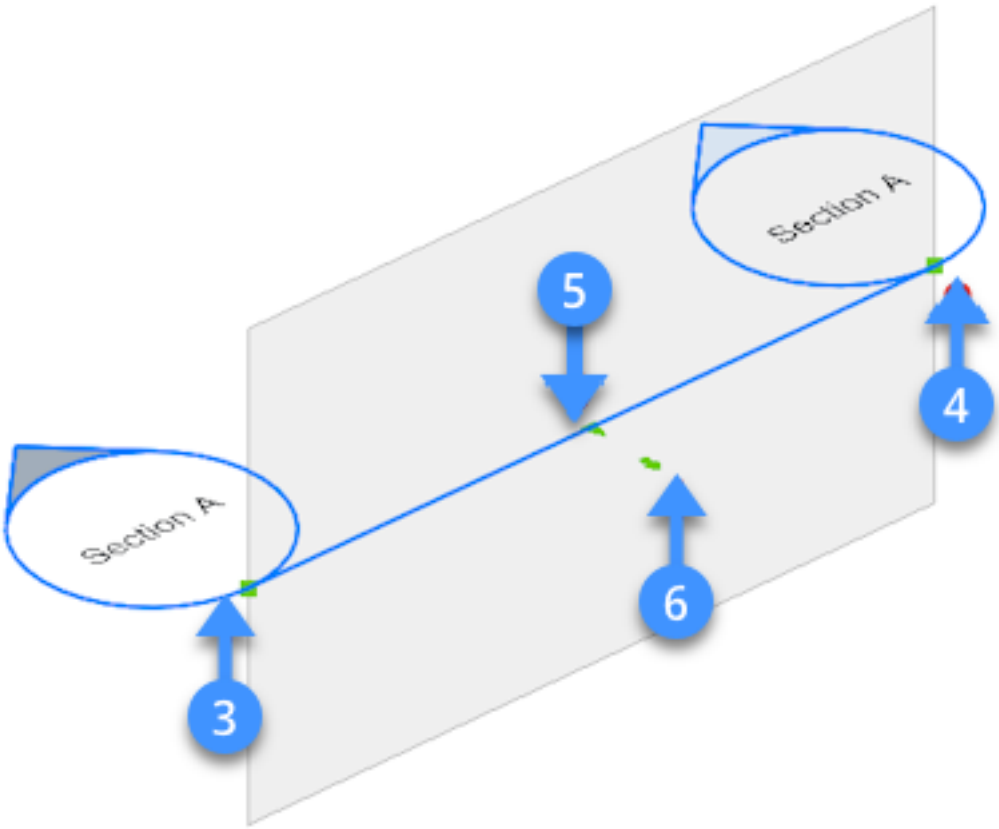

Figure 6.500

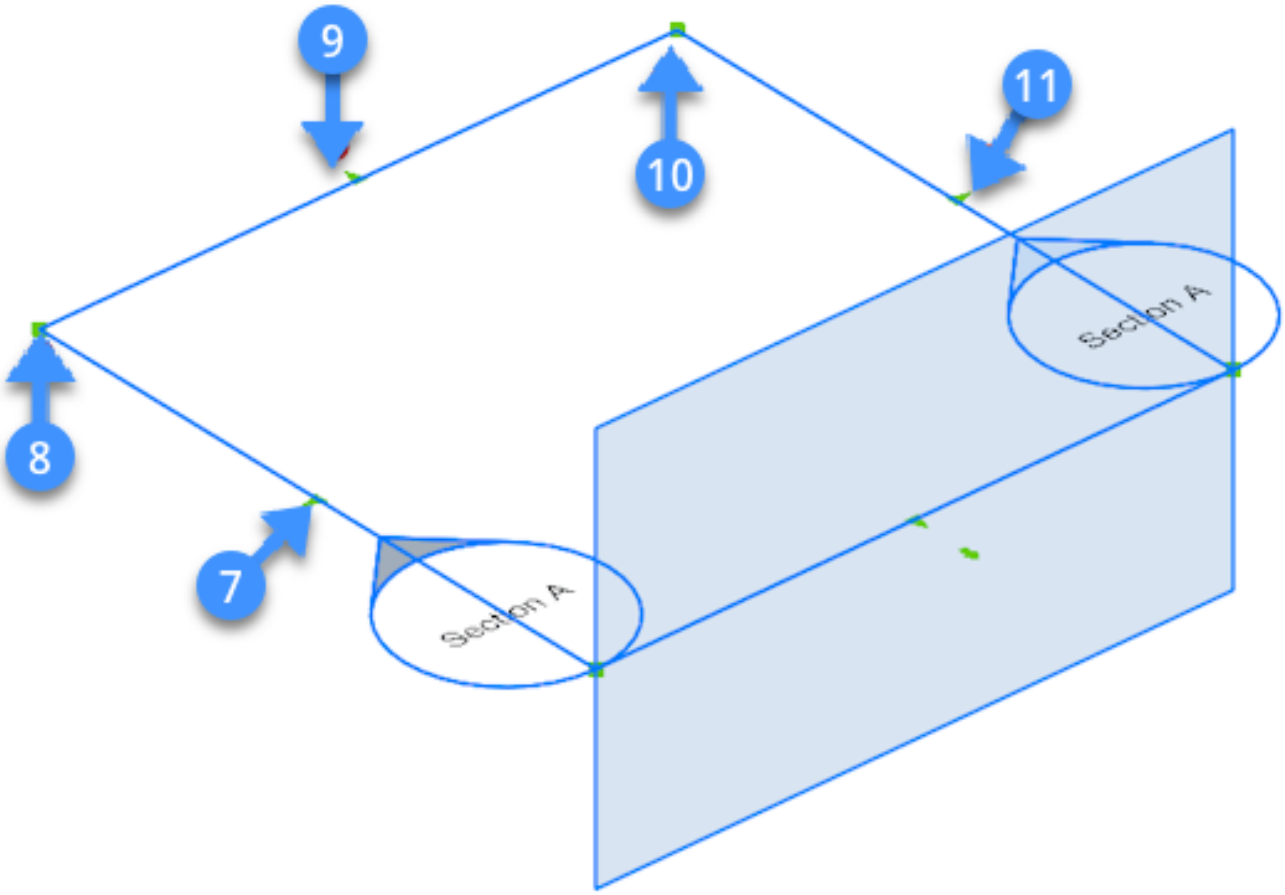

Figure 6.501

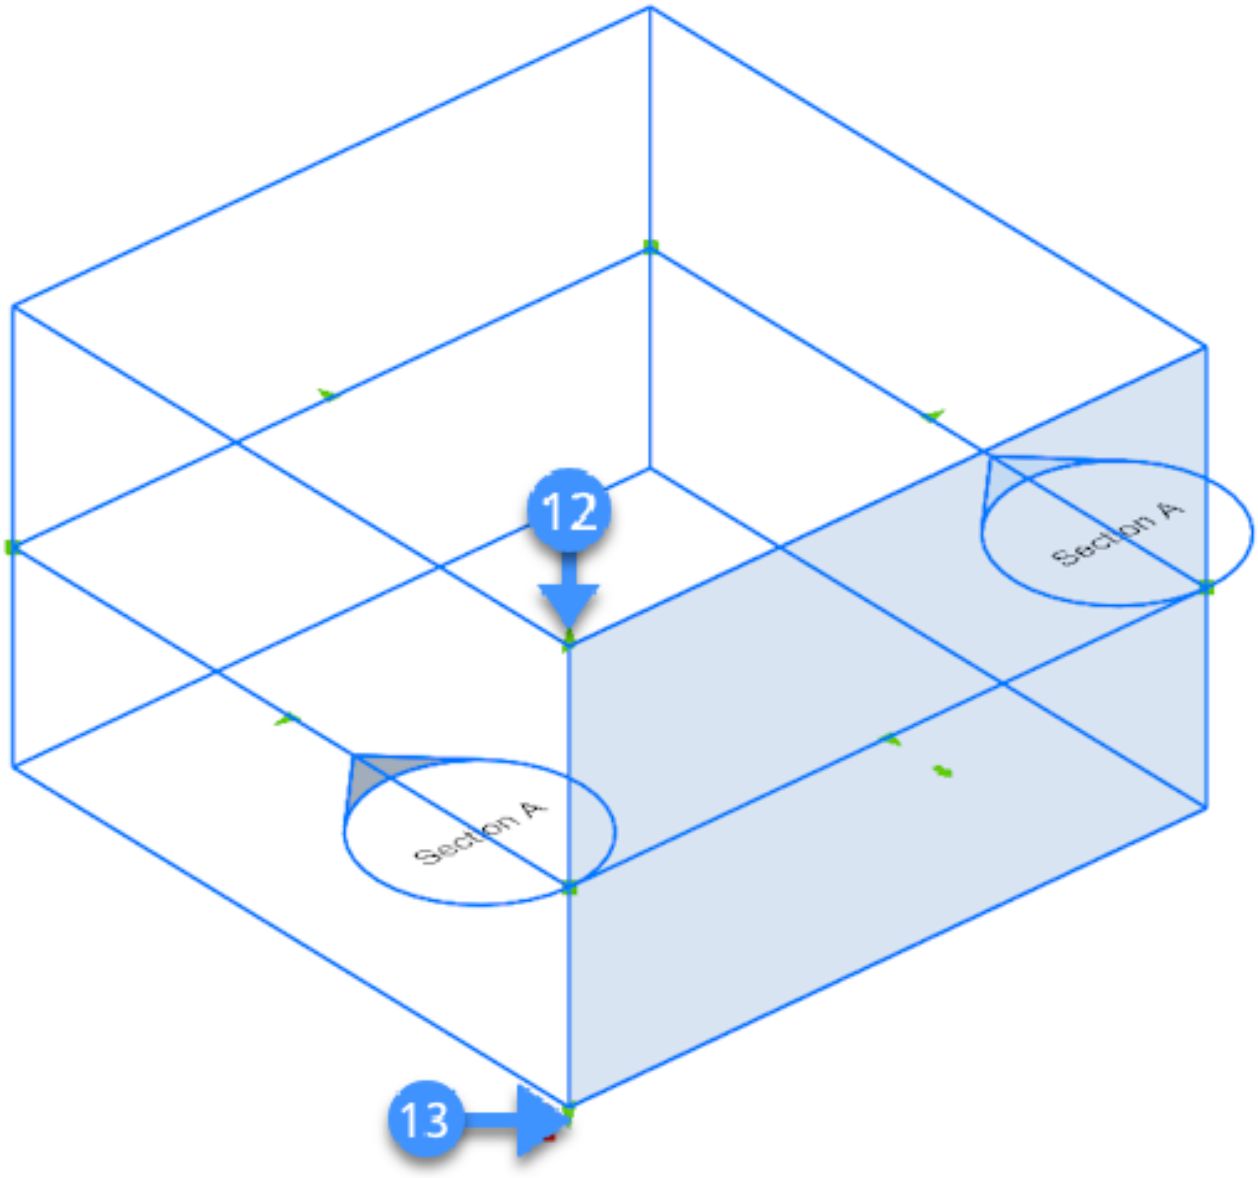


Procedures

Defining a section (2.13.1) Editing the default properties of a BIM Section (2.13.1) To toggle the clipped display property of a BIM section entity (2.13.1) Converting a section entity to a BIM section (2.13.1)

Related Commands

BimSectionOpen (6.7.49) - Opens the drawing file related to a BIM section entity; or the 3D BIM model related to a BIM section drawing. BimSectionUpdate (6.7.43) - Exports or updates the result of a BIM section in a drawing. ClipDisplay (6.9.22) - Toggles the Clip Display property of a section plane or a BIM section entity. Section (6.27.11) - Creates section planes of 3D solids; the results are region entities. SectionPlane (6.27.18) - Creates a section entity that creates sections of 3D solids. SectionPlaneSettings (6.27.12) - Defines the properties of a section plane entity in the Drawing Explorer - Section Planes dialog.

Figure 6.502

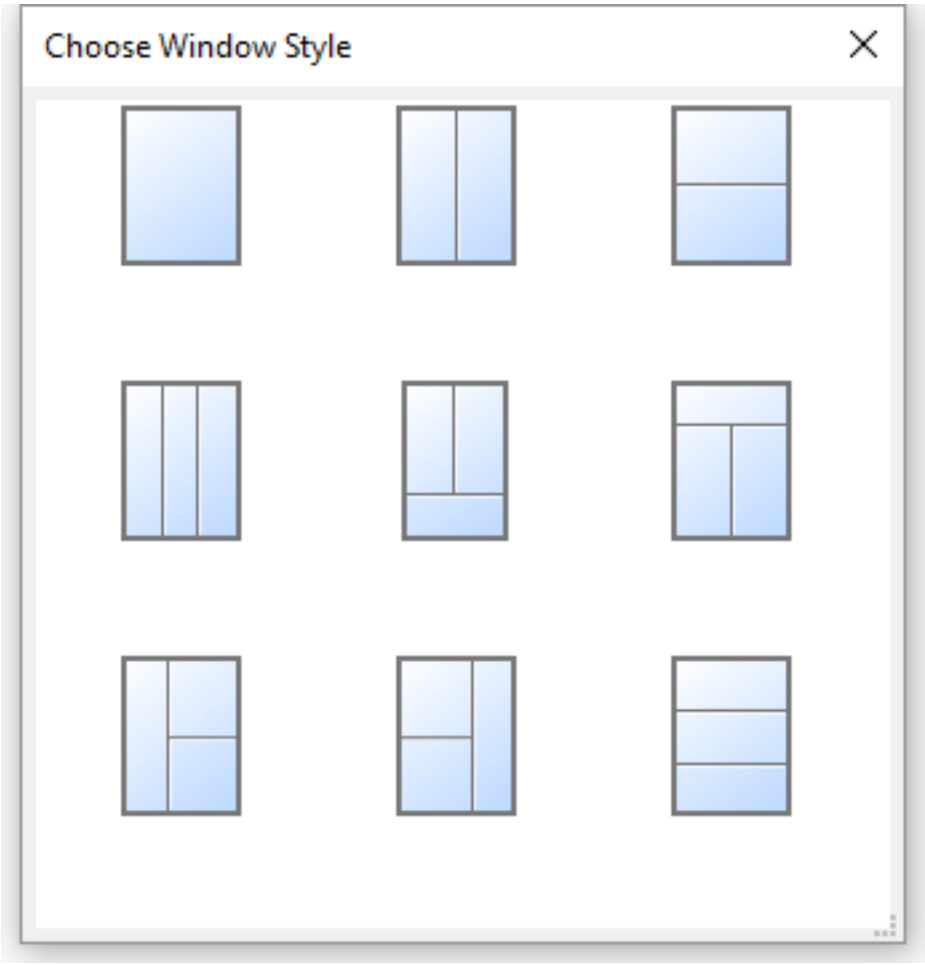
6.7.55 BimWindowCreate

(6.504 on page 3789) Creates a fully parametric window or opening based on a closed contour.

Accessing the Command

Commandline: **BIMWINDOWCREATE** Quad: **Select Boundary | Model | Create Window** Ribbon: **Home | Classify | Create Window Modeling | Building Elements | Create Window** Toolbar: **BIM Toolbar | BIM** : **BimWindowCreate Prompts you in the command bar:** Select profile (boundary, closed polyline or grid) to create [Window/Opening] <Window>: (**Select a closed entity or boundary and press Enter, or type 'O' to activate the opening option).** A Dialog box displays: (6.503 on the facing page) Pick a window style. The window(s) is (are) created using the selected style. A series of parameters is created, which can be edited in the Parameters section of the Properties (6.24.54) panel. Rectangular windows and openings have a W (Width) and H (Height) parameter.

Figure 6.503



Command Options

Option	Description
Select Profile	Select the source geometry for the window or opening. The options are: • **Boundary**: Uses a detected boundary. **Tutorial: How to detect boundaries in BricsCAD BIM** Click here to watch (2.4.4) • **Closed Polyline**: Uses an existing closed polyline. • **Grid**: Uses a BIM Grid entity. See the BimGrid (6.7.21) and the Panelize (6.7.60) commands.
Window 	Creates a BIM Window entity. An opening in the solid on which the profile entity lies is created automatically.
Opening 	Creates an opening in the solid on which the profile entity lies. The opening is created by a solid on the BIM_SUBTRACT layer. This layer is frozen by default. Thaw the layer to select the opening.

Procedures

Creating a parametric window using boundaries (2.5.2) Create windows based on a grid (2.5.2) Creating window openings (2.5.2)

Related Commands

BimCurtainWall (6.7.15) - Creates a curtain wall from the face of a 3D Solid as a block. BimInsert (6.7.22) - Inserts a window or door in a solid. Inserts a copy of a window or door in a solid. BimGrid (6.7.21) - Creates 2-dimensional rectangular and radial grids. BimWindowUpdate (6.7.56) - Updates the opening made by a window or door in a solid, in case the definition changed in such way that the opening was not correctly updated automatically. Panelize (6.7.60) - Creates a grid on the face of a 3D Solid as a block.

Figure 6.504

6.7.56 BimWindowUpdate

(6.504) Updates the opening made by a window or door in a solid, in case the definition changed in such way that the opening was not correctly updated automatically.

Accessing the Command

 Commandline: **BIMWINDOWUPDATE** Quad: **Select window | Model | Update window** Ribbon: **Modeling | Building elements | Update window** Toolbar: **BIM Toolbar | BIM | Create window** : **BimWindowUpdate Prompts you in the command bar:** Select windows to update: **(Select a window or door.)** Entities in set: 1 Select windows to update: **(Select another window or door or right click.)**

Command Options

No options.

Related Commands

BimInsert (6.7.22) - Inserts a window or door in a solid. Inserts a copy of a window or door in a solid. BimWindowCreate (6.7.55) - Creates a fully parametric window based on a closed contour.

Procedures

Adding physical materials (2.7.17) Editing a physical material (2.7.17) To copy materials between the Project and Library databases (2.7.17) Deleting physical materials (2.7.17)

Related Commands

BimProfiles (6.7.26) - opens the profiles library in the current project and the referenced library. BimProjectInfo (6.7.32) - opens the BIM Project Info dialog box. BLCompositions (6.7.57) - opens the compositions library in the current project and the referenced library.

Figure 6.509

6.7.59 BimTag

(6.1726 on page 4955) Creates associative tags in generated BIM section drawings for the corresponding building entities in a 3D BIM model. The command can be used on section viewports only. The GenerateAssocViews (1.17.10) system variable must be ON when generating or updating BIM tags.

Accessing the Command

A M Commandline: **BIMTAG** Quad: **Go to paper space | Draw | Tag** Ribbon: **Annotate | Leaders | Tag (Manually or Automatically)** Toolbar: **BIM Toolbar | BIM Tag** : **BimTag Prompts you in the command bar:** Select BIM section viewport [Manual]: **(Click the border of a Bim Section viewport.)** Tags are created automatically for all sectioned building entities in the selected viewport. The tags are created as multileader (6.21.19) entities using multileader styles in **_Section Tag.dwg**. The content of such multileader style is a block with attributes. Each attribute refers to a property of a BIM entity type. BIM entity types are linked to a multileader style in **_TagTypeToStyle.csv**. All source files sit in the **Bim/Sections** folder of the support folder (6.27.59), e.g.: **C:\Users\<UserName>\AppData\Roaming\Bricsys\BricsCAD\V18x64\en_US\Support\Bim\Sections.** If tags already exist in the selected viewport, **prompts you:** Tags already have been assigned to the section. Choose an update option [Update existing/update existing and add New/Regenerate all] <Regenerate all>: **(Press Enter to (re)generate all tags or choose an option.)**

Command Options

Option	Description
A Auto	Tags are created automatically for all sectioned building entities in the selected viewport.
M Manual	This option creates tags on background entities in sections and elevations. Prompts you: **Pick point on a sectioned BIM element [Auto/Current mleader style/change Tag type]** - **(Click a bim element). Place the tag [Next element]** - **(Pick a point to place the tag). Pick point on a sectioned BIM element [Auto/Current mleader style/change Tag type]** - **(Click a bim element or press Enter to stop).**
Current mleader style	Allows to use the current multileader style instead of the default style for the selected sectioned BIM element. See the MLEADERSTYLE (6.21.24) command. Prompts you: **Pick point on a sectioned BIM element [Auto/Default mleader styles]** - **(Click a bim element). Place the tag [Next element] - (Pick a point to place the tag). Pick point on a sectioned BIM element [Auto/Default mleader styles]** Do one of the following: • Keep clicking sectioned BIM elements to place more tags using the current multileader style. • Choose **Default mleader styles** to switch back to using the default style for the selected sectioned BIM element.

Change Tag Type	Allows to choose special tag types. Prompts you: **Choose tag type [Tag/cOmposition/Load-bearing directions/Spot-elevation] <Tag>** - **(Choose an option)** • **Composition**: Creates a tag with all materials of the composition of the sectioned BIM element. • **Load-bearing directions**: Inserts a loadbearing direction symbol when a line that is generated from a BiM Slab solid is selected, if the load bearing direction of the slab is assigned by the SETLOADBEARINGDIRECTION (6.7.50) command. • **Spot-elevation**: Inserts a tag that indicates the elevation of the identified point in elevations and vertical sections.
Update Existing	Updates the existing tags in the selected viewport. The position of relocated tag blocs is preserved.
Update Existing and Add New	Updates the existing tags in the selected viewport and adds new tags.
Regenerate All	Updates all tags in the selected viewport. Repositioned tag blocks are moved to their default location.

Procedures

Manually create a BIM tag (2.13.2) Automatically create BIM tags (2.13.2) Create composition tags (2.13.2) Adding a load bearing symbol in a plan section (2.7.12)

Related Commands

BmBalloon (6.8.2) - Creates associative balloon entities for assembly components in Model Space and for their generated views in a Paper Space layout. BimProperties (6.7.38) - Creates and manages property definitions in a dialog box. Organizes properties in property sets. BimRoom (6.7.42) - Creates BIM Room entities. BimSectionUpdate (6.7.43) - Exports or updates the result of a BIM section in a drawing. MLeader (6.21.19) - Creates multileader entities using the current multileader style. MLeaderEdit (6.21.22) - Adds leader lines to and removes leader lines from a multileader entity.

Figure 6.510

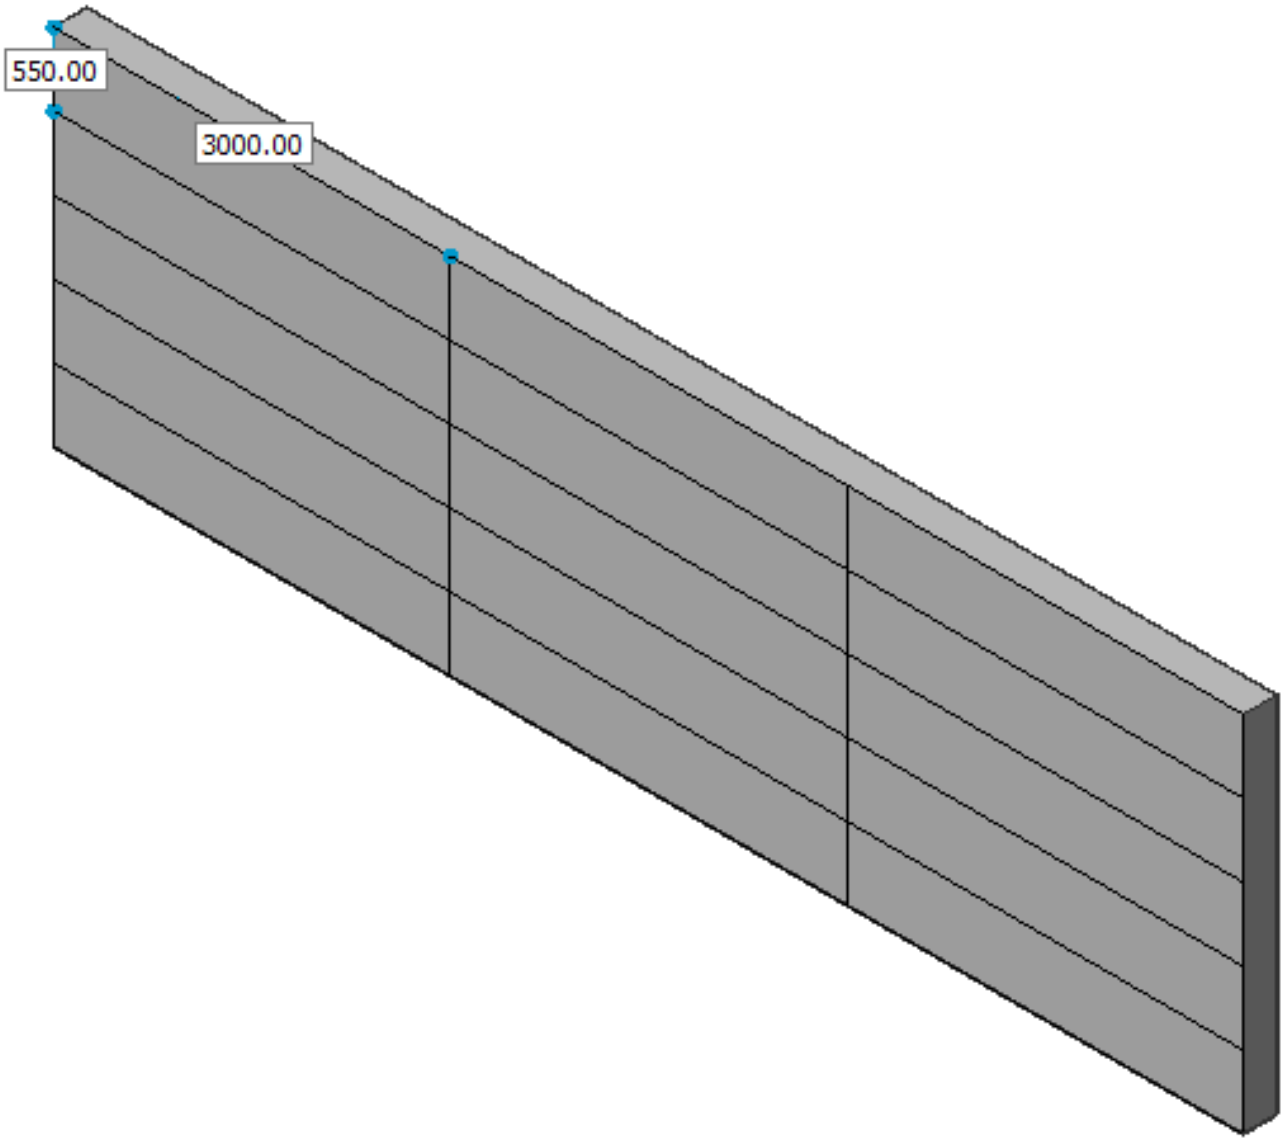
6.7.60 Panelize

(6.1726 on page 4955) Creates a grid on the face of a 3D Solid as a block.

Accessing the Command

 Commandline: **PANELIZE** Quad: **Select face | Model | Panelize** Ribbon: **Home | Curtain wall | Panelize Modeling | Curtain wall | Panelize** Toolbar: **BIM Toolbar | BIM Curtain wall : Panelize Prompts you:** Select face or set [Result]: **(Select the face of a solid)** Create grid or [Length U panels/Length V panels/Number U panels/Number V panels]: **(Press Enter or choose an option.)** (6.511 on the following page)

Figure 6.511



Command Options

Option	Description
Length U panels	Sets the length of the panels in U direction (height). Prompts you: **U grid length <550>: (Type a value or press Enter).**
Length V panels	Sets the length of the panels in V direction (width). Prompts you: **V grid length <3000>: (Type a value or press Enter).**
Number U panels	Number of panels in U direction (rows). Prompts you: **U grid size <5>: (Type a number or press Enter).**
Number V panels	Number of panels in V direction (columns). Prompts you: **V grid size <3>: (Type a number or press Enter).**

Procedures

Creating a curtain wall (2.5.9) Creating a curtain wall from a free form surface (2.5.9)

Related Commands

BimCurtainWall (6.7.15) - Creates a curtain wall from the face of a 3D Solid as a block. BimWindowCreate (6.7.55) - Creates a fully parametric window or opening based on a closed contour.

Figure 6.512

6.7.61 BimStructuralConnect

(6.1726 on page 4955) Connects structural profile solids such as beams and columns.

Accessing the Command

Commandline: **BIMSTRUCTURALCONNECT** Quad: **Select structural solids | Model | Connect Structural** (If solids are selected) Ribbon: **Structural/MEP | Modify | Connect structural** Toolbar: **BIM Toolbar | BIM Connect : BimStructuralConnect Prompts you:** Select solids to connect [selection options (?)]: **(Select one or more structural profile solids*.)** Entities in set: 1 Select solids to connect [selection options (?)]: **(Select more structural profile solids* or press Enter.)** * The axes of the selected solids must be coplanar. When 2 solids are selected:

- If an L-connection is created: Select base solid [Switch] <Accept>: **(Press Enter to accept the connection or choose an option.)**
- If a T-connection is created, no options are available.

When multiple solids are selected:

- If only L-connections are created: Select base solid [Switch] <Accept>: **(Press Enter to accept the connection or choose an option.)**
- If only T-connections, or a mixture of T-connections and L-connections are created, no options are available.

Command Options

Switch	Allows to choose between two butted L-connections: (6.1426 on page 4705)or (6.1427 on page 4706) or a mitered L-connection: (6.1428 on page 4706) or a touching (disconnected) connection. (6.1429 on page 4706) Prompts you: **Select base solid [Switch] <Accept>: (Type s then press Enter or tap the Ctrl-key)**. The connection between the solids changes. Press Enter to accept the selected connection. If the HOTKEYASSISTANT = ON, the the Hotkey Assistant indicates the currently selected L-connection type. (6.1430 on page 4706)

Settings

The DMCONNECTIONCUTTYPE system variable defines the connection type: Smooth or Planar.

(6.518 on page 3802) Smooth connection	(6.519 on page 3802) Planar connection

Procedures

Making a structural connection to linear solids (2.5.1)

Related Commands

Drag (6.10.38) - Moves 3D solids perpendicular to a selected face by dragging that face. Optional. BimFlowConnect (6.7.19) - Creates a connection between flow segments, such as pipes or HVAC ducts. preserves connections to other solids. LConnect (6.20.19) - Creates an L-connection between solids. TConnect (6.29.9) - Connects solid faces to other solids.

6.7.62 BimUpdateThickness

(6.1726 on page 4955) Re-applies the overall thickness of a composition to the solid.

Accessing the Command

Commandline: **BIMUPDATETHICKNESS** Quad: **Select solid | Bim | Update Thickness** : **BimUpdateThickness** **Prompts you in the command bar:** Select entities to update thickness: **(Select an entity.)** Entities in set: 1 Select entities to update thickness: **(Select an entity or press Enter.)** Do you want to update Symmetrical [Yes/No] <No>: **(Press Enter or choose an option.)** Thickness of x element(s) has been updated. Skipped: y element(s)*. * Only solids that need to be updated are processed.

Command Options

Title	Description
Symmetrical Update	Allows to update the thickness symmetrically or with respect to the reference face (See BimAttachComposition (6.7.8)). Prompts you: **Do you want to update Symmetrical [Yes/No] <No>:** • **No:** The thickness is updated with respect to the reference face. • **Yes:** The thickness is updated symmetrically. The position of the axis of the solid is preserved.

Procedures

Modifying the thickness of a solid (2.5.4)

Related Commands

BimAttachComposition (6.7.8) - Attaches a BIM composition to solids. Bimflip (6.7.20) - Flips the starting face from which the layers of a composition are set out.

Figure 6.521

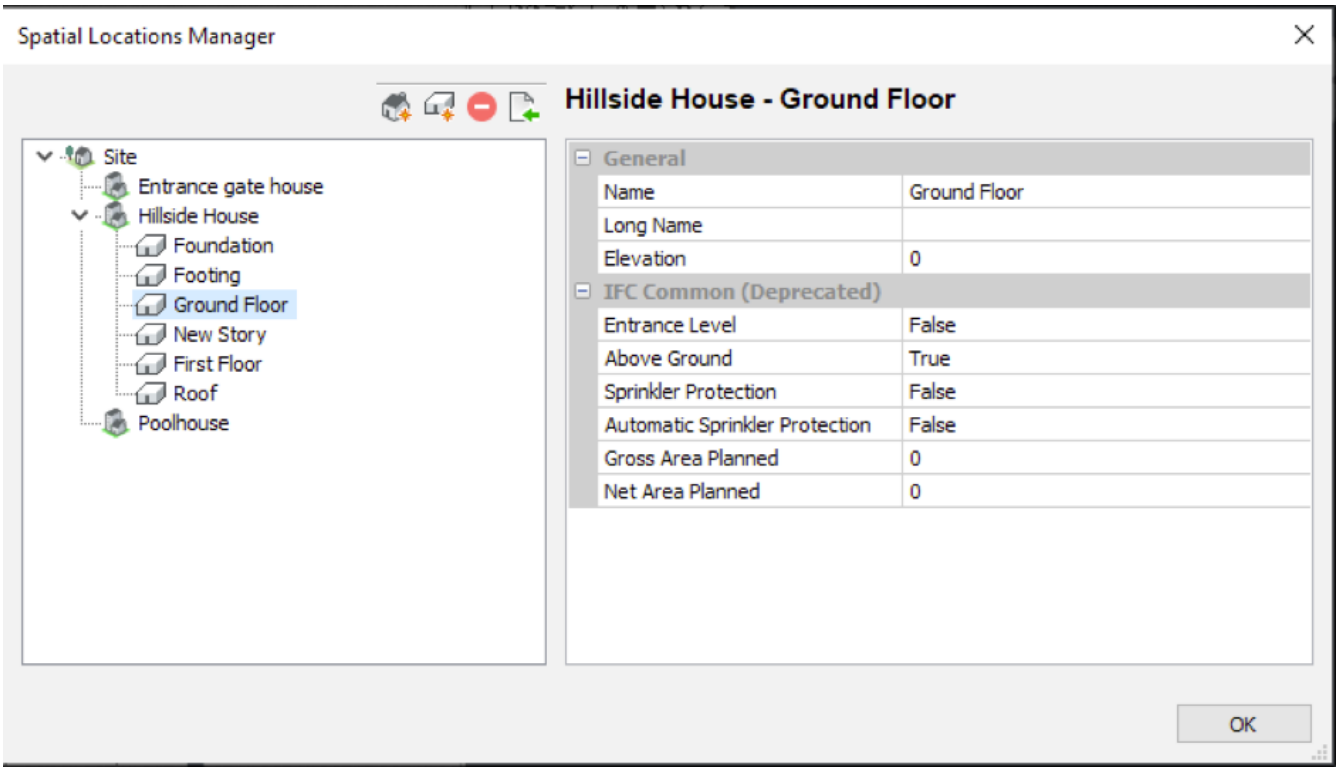
6.7.63 BimSpatialLocations

(6.1726 on page 4955) Opens the Buildings & Stories manager. This explorer allows to create and edit site, buildings and stories.

Accessing the Command

Commandline: **BIMSPATIALLOCATIONS** Quad: **BIM | Spatial Locations** Ribbon: **Home | Classify | Database | Spatial location** Toolbar: **BIM Toolbar | BIM** : **BimSpatialLocations** Displays a dialog box: (6.522 on the next page) Click the **Close** (X) button or the **OK** button to close the dialog box.

Figure 6.522



Command Options

Icon	Option	Description
	New Building	Adds a new building to the model. Fill out the properties grid: (6.523 on the following page)
	New Story	Adds a new story in the selected building. Fill out the properties grid: (6.524 on the next page)
	Delete	Deletes the selected building or story. An alert box displays: (6.525 on page 3807) Click the **Yes** button to delete the selected item.
	Import	Imports spatial locations from a text file. Displays a file dialog box. Select the *.txt file, then click Open or double click.

Procedures

Assigning a building and story to a building element (2.7.16) Viewing the building elements in the Structure browser (2.7.16)

Related Commands

BimAttachSpatialLocation (6.7.9) - Allows to attach or remove a spatial location to a selection of entities. BimClassify (6.7.12) - Classifies an entity as a Building Element and get a name and an internal GUID (= globally unique identifier). Bimify (6.7.23) - Analyzes the model and runs automatic classification and spatial location assignment for the entire model. BimRoom (6.7.42) - Creates Room entities.

6.7.64 BimWindowPrint

(6.1726 on page 4955) (Description of the command in 1 sentence)

Accessing the Command

(ICON) **Keyboard: Menu: Toolbar: Quad Tab: Ribbon Tab | Panel: -> On hold: separate task when ALL articles are ready. : CommandName** (Description of what to do: eg. for BimCopy: Move the solid, specify a distance in the dynamic dimension field, and right-click to create a single copy.) **(You are prompted)** (Place 'the prompt you' in the **(Bold)**-lettertype font in the **(paragraph)** text
What appears in the command bar, place it in the normal **paragraph** text.
The action itself you place in the (**Italic**)-letter type font in the **(paragraph)** text and between ()/ brackets.
It has to look like in the picture) **Eg: Prompts you in the command bar.** Description of what the Commandline asks you to do: eg. Specify distance to create copy or switch to [Copy/Repeat/Number/Accept] <Accept>: **(Enter the distance value to make a copy of the solid at the specified distance or use one of the available options in the command bar)** (insert IMAGE if necessary)

Command Options

Option	Description
eg. Copy	Creates copies of the planar faces of 3D solids, and the sides and ends of linear solids.
eg. Repeat	Repeats the copy using the same displacement. Move the cursor in the displacement direction. The further you move away from the source solid, the more copies are created. Click when the desired number of copies displays.

Note: in tables extra options should be in BOLD. Eg.:

Option	Description
Room Height	Sets the height of the room. The height is saved to the **Default Room Height** system variable and will be used until set differently. Default room height = 3000 mm The height of the exterior walls = Room Height + Slab Thickness. The height of interior walls = Room Height.

Option	Description
Click the widget	Click one of the nine locations, then right click to confirm.

Type a location	The options are: • **TR**: Top Right • **TM**: Top Middle • **TL**: Top Left • **MR**: Middle Right • **C**: Center (resets the axes of the selection set to the default location) • **ML**: Middle Left • **BR**: Bottom Right • **BM**: Bottom Middel • **BL**: Bottom right

Note: 'Prompted', 'prompts you', 'You are prompted' should be in paragraph, **the text that appears in the command line should be in bold** and **the Action you have to do in Italic**. Eg.:

Option	**Description**
Grid Options	
Length U panels	Sets the length of the panels in U direction (height). Prompts you: **U grid length <550>: (Type a value or press Enter.)**
Length V panels	Sets the length of the panels in V direction (width). Prompts you: **V grid length <3000>: (Type a value or press Enter.)**

Procedures

List of related procedures in the BIM articles. eg.: The five flavours of BimPropagate (2.9.2) General procedure (2.9.2)

Related Commands

List of related commands in the Command References. eg.: BimPropagateCorner (6.7.31) - Propagates details connected to three planar base solids (i.e., corners). BimPropagateEdges (6.7.44) - Propagates a detail along the edge of a planar solid; can be used to propagate railings, gutters, borders, wall caps, etc. BimPropagateLinear (6.7.33) - Propagates connections between linear elements (beams, columns, pipes, ducts and their connections to walls and slabs). BimPropagatePattern (6.7.34) - Propagates a single element on a flat surface to multiple locations and grids; can be used to propagate lights, light switches, windows, air diffusers, etc. BimPropagatePlanar (6.7.36) - Propagates connections between planar elements (walls/slabs/roofs).

Figure 6.527

6.7.65 BimUpdateRoom

(6.1726 on page 4955) The BIMUPDATEROOM command is obsolete and has been replaced by the BIMUPDATESPACE command. You can still open BIM rooms, but it is not possible to create new BIM rooms or update their geometry. Use the **Space** option of the BIMCLASSIFY (6.7.12) command to convert a BIM room to a BIM space.

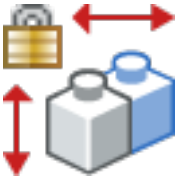
6.8 Bm (Mechanical)

6.8.1 BmConnect

(6.2582 on page 5709) Connects two Piping standard parts by creation of 3D constraints between their connection entities.

Figure 6.528

Access the Command



command bar: **bmconnect** menu bar: **Assembly | Connect StdParts** toolbar: Assembly | Connect StdParts ribbon:

- **Home | Assembly | Connect StdParts** (in **Insert Component** submenu)
- **Assembly | Modify | Connect StdParts** (in **Insert Component** submenu)

: **bmconnect Prompts you in the command bar:** Select two entities for connect [selection options (?)]: **(Select two standard parts of Piping category inserted either directly in your assembly or in a subassembly.)** (6.529 on the facing page) After selection of two Piping standard parts, the commands automatically creates proper set of 3D constraints to correctly connect the parts and maintain their relative position for any further modification of your assembly. (6.530 on the next page)

Figure 6.529

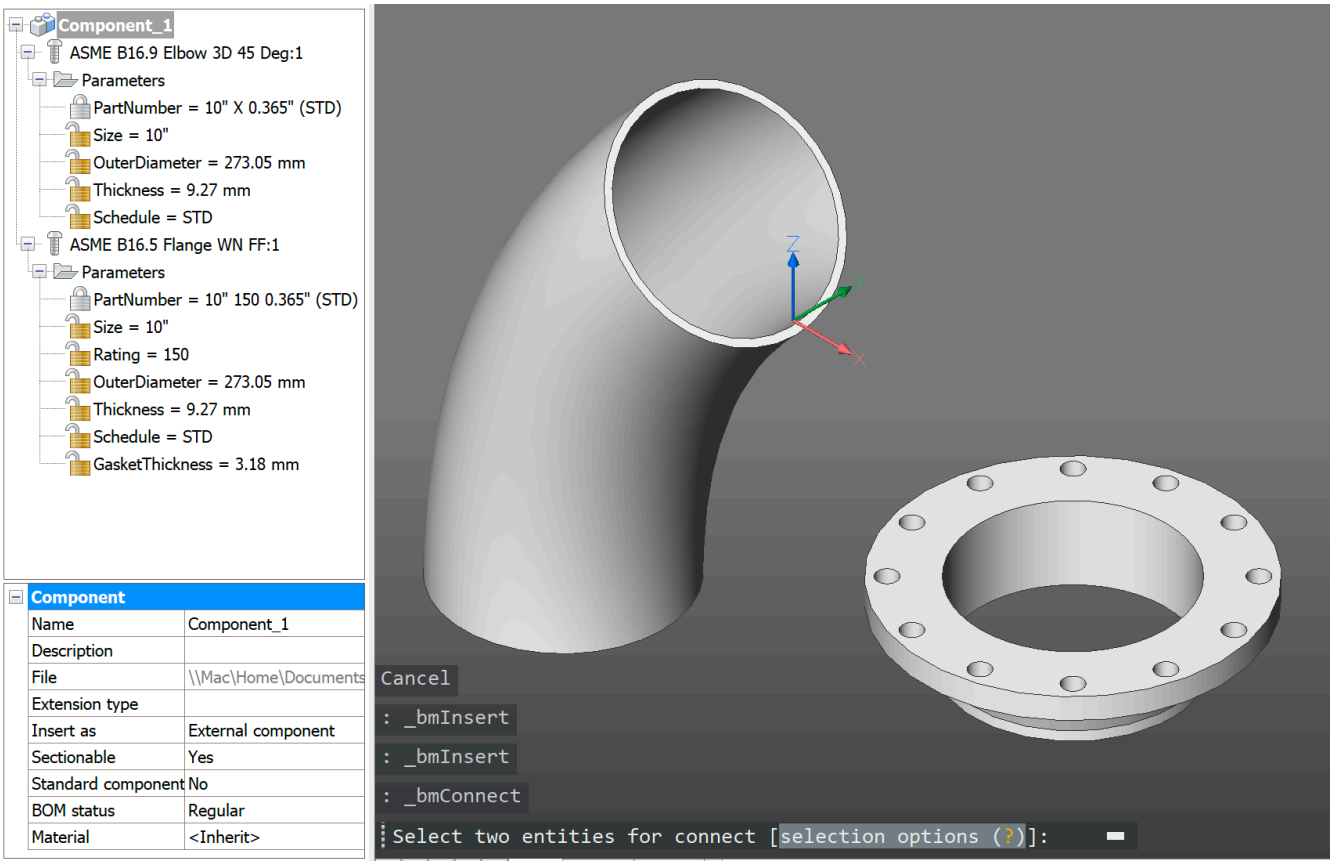


Figure 6.530

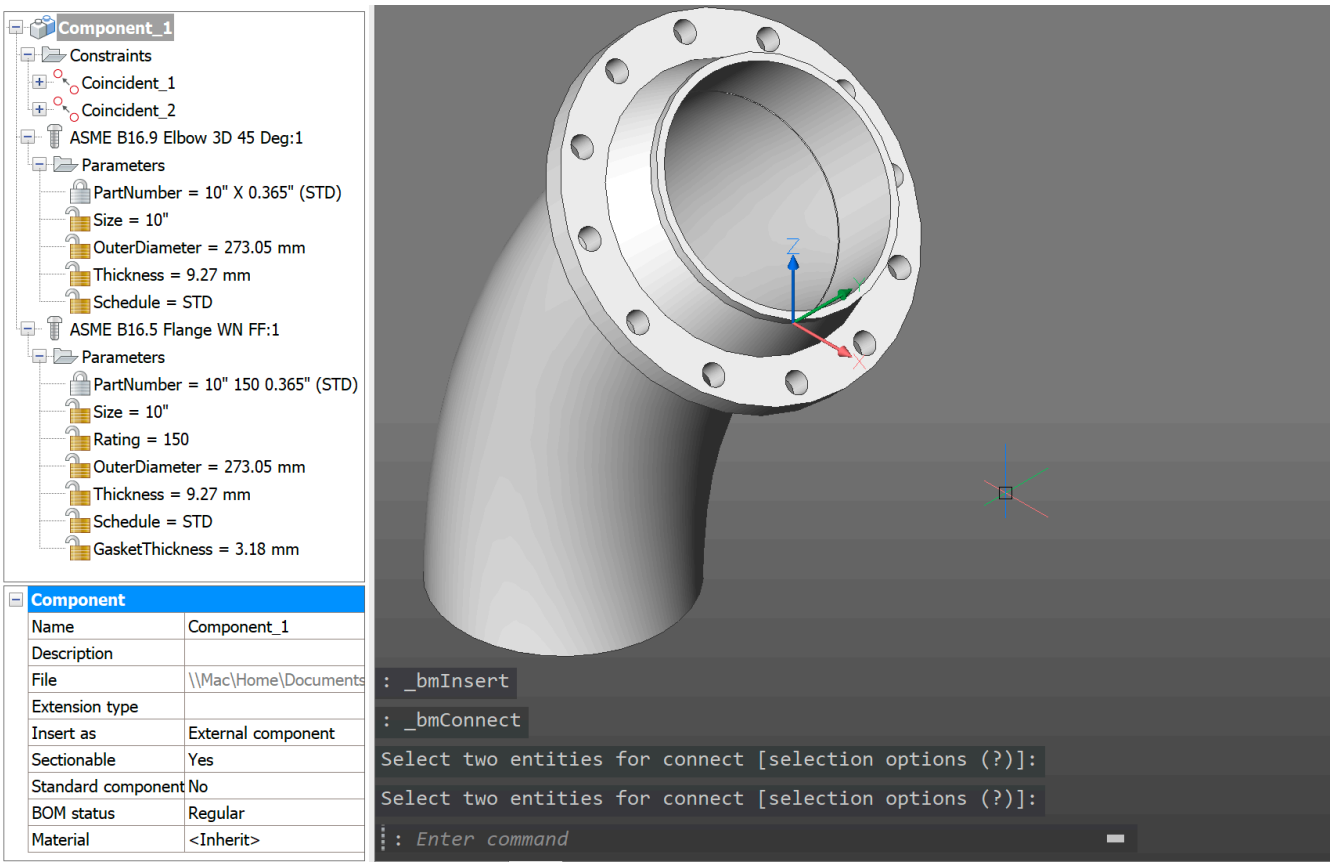


Related Commands

BmInsert (6.8.16) - inserts a component (a part or a subassembly) into your assembly.

Figure 6.531

6.8.2 BmBalloon

(6.2582 on page 5709) Creates associative balloon entities for assembly components in Model Space and for their generated views in a Paper Space layout. Each balloon contains an index of the component in the associated BOM-table created by BmBom (6.8.3) command.

Accessing the Command

command bar: **bmballoon** menu bar: **Assembly | Balloon** toolbar: **Assembly | Balloon** ribbon:

- **Home | Annotate | Balloon**
- **Assembly | Inquire | Balloon**
- **Annotate | Assembly | Balloon**

: bmballoon Prompts you in the command bar: Select a component insert [select Table/select Style/Auto mode]: **(Click a component insert.)** Pick point to place balloon: **(Define the location of the balloon.)** Select a component insert [select Table/select Style/Auto mode]: **(Click the next component or press Enter to stop.)**

NOTE	Balloons are created as Multileader (6.21.19) entities using the current Multileader style (6.21.24). Create a Multileader style with the **Content** set to **Block** and adjust the **Scale** property to control the size of the balloon frame.

Command Options

Option	Description
Select a component insert	Selects the component and sets the location of the arrowhead.
Pick point to place balloon	Locates the balloon; prompts you: Pick point to place balloon - pick a point. Hold down the SHIFT key to align the balloon with the previous one.
Select table	Allows to select a different BOM-table in case multiple BOM-tables exist in the layout. The most recently insert BOM-table is selected by default; prompts you: **Select a BOM table <Back>** - **(Select the BOM-table or press Enter to proceed with the currently selected BOM-table.)**
select Style	Allows to define the shape of the balloon; prompts you: **Choose balloon style**: - **(choose an option in command menu.)** (6.533 on page 3818) • (6.534 on page 3818) Circle • (6.535 on page 3818) No frame • (6.536 on page 3819) Underline • (6.537 on page 3819) Slot • (6.538 on page 3820) Box • (6.539 on page 3820) Hexagon • (6.540 on page 3820) Triangle • (6.541 on page 3821) Rhomb
	Predefined balloon styles from _BalloonStyles.dwg can be used, as well as any custom user-defined

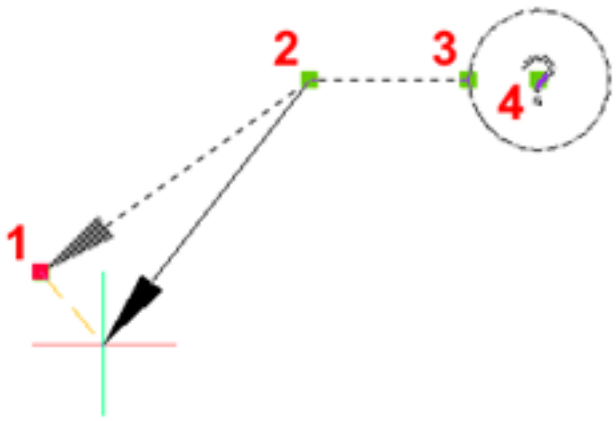
Auto mode	Allows automatic placement of balloons on all components in a particular drawing view. prompts you: **Select a viewport** [select other Table/choose balloon Style/placement Mode/Back]: • select other Table - Allows selecting a different BOM-table in case multiple BOM-tables exist in the layout. prompts you: Select a BOM table <Back> - Select the BOM-table or press Enter to proceed with the currently selected BOM-table; • choose balloon Style - choose an option in command menu; • placement Mode - allows select whether multiple balloons with the same values are generated or not. prompts you: Select placement mode <All> [Unique/All]: - controls whether multiple balloons with same values are generated or not. • Back - Returns to the previous prompt. Select first point [Circle]: - select the first point of a polyline or switch placement mode in command menu: (6.542 on page 3821) Align leaders along polyline: - select the next point of a polyline or press Enter to stop. (6.543 on page 3821): placement by the Polyline (6.544 on page 3822): placement by the Circle

Grips Editing

1. Select the balloon in the drawing. For a single segment balloon entity, four grips display: Endpoint (1), Vertex (2), Landing (3) and Text (4).
2. Drag the grips to perform the following actions:
   - Move the arrowhead (1) If move the arrowhead to a different component, the balloon automatically updates the position number according to the associated BOM-table. If the arrowhead hits a blank space, the question mark displays.
   - Move the landing and the balloon (2)
   - Edit the landing length(3)
   - Move the balloon (4)

(6.532)

Figure 6.532



Related Commands

BimTag (6.7.59) - creates associative tags in generated BIM section drawings for the corresponding building entities in a 3D BIM model. BmBom (6.8.3) - inserts a Bill of Materials (BOM) table in the current drawing. Ddedit (6.10.13) - edits single-line text, multi-line text, attribute definitions, and attribute text. DimReassociate (6.11.18) - reassociates or associates dimensions to entities or points on entities. MLeader (6.21.19) - creates multileader entities using the current multileader style. MLeaderEdit (6.21.22) - adds leader lines to and removes leader lines from a multileader entity. MLeaderStyle (6.21.24) - creates and manages multileader styles through the Drawing Explorer.

6.8.3 BmBom

(6.2582 on page 5709) Inserts a Bill of Materials (BOM) (3.7.11) table in the current drawing.

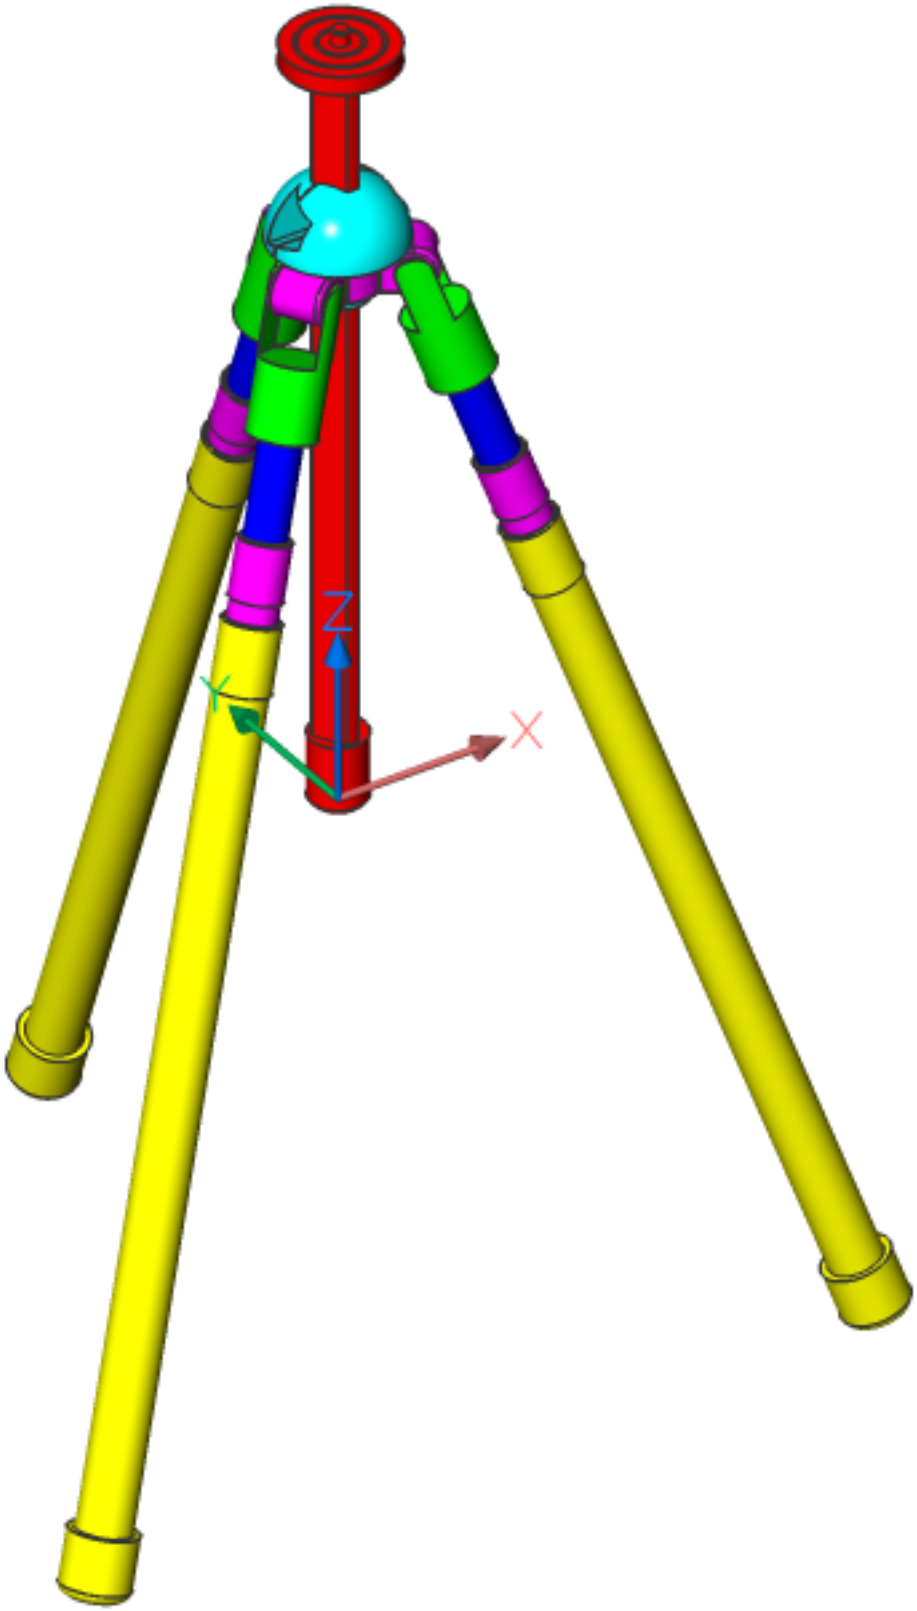
Access the Command

command bar: **bmbom** menu bar: **Assembly | Bill Of Materials** toolbar: Assembly | Bill Of Materials ribbon:

- **Home | Annotate | Bill Of Materials**
- **Assembly | Inquire | Bill Of Materials**
- **Annotate | Assembly | Bill Of Materials**

: **bmbom Prompts you in the command bar:** Insertion point [Name/Top level/Bottom level/Hierarchical/Load from template/Save as template/Configure]: **(Specify the insertion point or enter an option.)** (6.546 on the next page)

Figure 6.546



Command Options

Option	Description
Name	Prompts you: **Enter table name. Use <NAME> to refer the assembly name. <Default name>:** Type the name, then press Enter. Prompts you: **Insertion point [Name/Top level/Bottom level/Hierarchical/Load from template/Save as template/Configure]:** Specify the insertion point or enter an option.
Top level	Creates a BOM of the top-level components only. (6.547 on page 3827)
Bottom level	Creates a BOM of the subcomponents. (6.548 on page 3828) In contrast to the Top Level BOM, the base_assy component is broken up into the base and bracket components.
Hierarchical	View assembly subcomponents in a single BOM table. (6.549 on page 3828)
Load from template	Creates a BOM from a template. Opens a dialog: (**??** on page ??) **(Specify the template file)** • **Open** - Click to create a BOM using the selected template file. • **Cancel** - Click to cancel the command.
Save as template	Saves the current BOM configuration as a template. Opens a dialog: (**??** on page ??) **(Specify the template file)** • **Save** - Click to save the current configuration as a template. • **Cancel** - Click to close the dialog and cancel the command.

Configure

Configure adds additional columns to your BOM table: Description, Density, Volume, Mass, Material, Thickness, and Parameters (for parametric components). Prompts you: **Toggle columns [Description/dEnsity/Volume/Mass/parameterS/mAterials/Thickness/MO <Back>:**

- **Description**: adds a Description column.
- **Density**: adds a Density column.
- **Volume**: adds a Volume column.
- **Mass**: adds a Mass column.
- **Parameters**: If several inserts of the same parametric component exist in the assembly, they will be grouped in different BOM rows depending on the values of their parameters.
- **Materials**: adds a Material column.
- **Thickness**: adds a Thickness column. If a component is a sheet metal part, this column will show the thickness of the part. Otherwise, it will be empty.
- **More**: displays more configuration options. Prompts you: **Select action [Toggle column/Set sorting/column Properties/table sEttings/Back] <Back>:**
  - **Toggle column**: adds or removes columns from the BOM. Prompts you: **Enter the column number or name to toggle [add Formula field/Back] <Back>:**(Enter the number or the unique part of the name of the column to add/remove OR choose an option):
    - **Add formula field**: adds a formula field (3.7.11). Prompts you: **Enter the field name [Back] <Back>:** (Enter a formula using <> to refer to other columns or choose Back to return to the previous prompt)
    - **Back**: returns to the previous prompt.
  - **Set sorting**: sets the sorting mode (3.7.11) for the BOM. Prompts you: **Select sorting mode [Automatic/No sorting/Custom sorting/Back] <Automatic>:**
    - **Automatic**: sets the automatic sorting for the table. Prompts you: **Select action [Toggle column/Set sorting/column Properties/table sEttings/Back] <Back>:**
    - **No sorting**: disables the sorting of the BOM. Prompts you: **Select action [Toggle column/Set sorting/column Properties/table sEttings/Back] <Back>:**
    - **Custom sorting**: specifies the columns for sorting. Prompts you: **Select action [Toggle sorting column/Back] <Back>:**
      - **Toggle sorting column**: sets the

Integration with BOM manager

When the Bills of Materials manager (3.7.9) is open during BMBOM session, you can configure the BOM table with the command options or the BOM manager (3.7.9) tools. Some BOM manager (3.7.9) options will be locked during this mode.

Change the fixed corner

Press the **Tab** key to cycle the corners of the table. The table position will change to place the fixed corner under the cursor, thus helping to align the table with other objects in the drawing.

Related Commands

Table (6.29.2) - creates a table entity in the drawing through a dialog box. -Table (6.29.1) - creates a table entity in the drawing through the command bar. Tabledit (6.29.3) - edits texts in a table cell. BmBomPanelOpen (6.8.5) - opens the Bills of Materials manager (3.7.9) BmBalloon (6.8.2) - creates associative balloon entities for assembly components in Model Space and for their generated views in a Paper Space layout. BmExplode (6.8.10) - creates a block with an exploded representation of the current assembly and allows to insert this block at a user-defined location. BmMassProp (6.8.18) - computes mass properties for the current model using densities assigned its the components. BmUpdate (6.8.29) - reloads all referenced components from external files and updates BOM tables.

Command Options

Option	Description
Context menu	Right-click any line on the BOM grid (except the footer row). (6.556 on page 3838) • **Zoom to**: zooms to the corresponding component(s). • **Select**: removes the current selection and selects the corresponding component(s). • **Add to Selection**: adds all instances of the component to the current selection. • **Remove from Selection**: removes all instances of the component from the current selection. • **Remove highlighting**: clears highlighting from component(s). • **Clear selection**: clears the selection. • **Collapse**: in a hierarchical BOM, collapses the subassembly group(s). • **Expand**: in a hierarchical BOM, expands the subassembly group(s). • **Expand this level** - in a hierarchical BOM, expands all subassembly groups, at the same level as the current one. • **Collapse this level**: in a hierarchical BOM, collapses all subassembly groups, at the same level as the current one. • **Expand all**: in a hierarchical BOM, expands all subassembly groups. • **Collapse all:** in a hierarchical BOM, collapses all subassembly groups. • **Limit by this level**: in a hierarchical BOM, sets the current level as the maximal level for hierarchical BOM tables. • **Show all levels**: in a hierarchical BOM, removes the maximal level limit from hierarchical BOM tables.

Context menu

Right-click the column label. (6.557 on page 3838)

- **Add template column from selected**: opens a template column configuration dialog where the selected columns are automatically added to the template expression: (6.577 on page 3848) **(Specify the template expression, column title and unit)**
  - **OK:** adds a new template column.
  - **Cancel**: closes the dialog without adding a new column.
- **Edit column expressions**: for an evaluated column, opens the dialog to configure the expression: (6.576 on page 3848)**(Specify the expression, column title and unit)**
  - **OK**: adds a new template column.
  - **Cancel**: closes the dialog without adding a new column.
- **Delete column**: removes the selected column(s) from the table.
- **Footer**: opens a submenu: (6.579 on page 3849)
  - **No footer**: removes the footer from the selected columns.
  - **Sum**: displays the sum of each, selected column in the footer.
  - **Average value**: displays the average of each, selected column in the footer.
  - **Minimal value**: displays the minimum value of each, selected column in the footer.
  - **Maximal value**: displays the maximum value of each, selected column in the footer.
- **Sorting**: opens a submenu: (6.580 on page 3849)
  - **Automatic order**: sorts the table automatically.
  - **Natural order**: sorts the selected columns by the natural order of component instances in the document.
  - **Ascending order**: sorts the selected columns in ascending order.
  - **Descending order**: sorts the selected columns in descending order.
- **Aggregate function**: opens a submenu: (6.562 on page 3840)
  - **No function**: removes the aggregate function from the column.
  - **Sum**: sums the grouped values.
  - **Average**: finds the average value of grouped values.
  - **Minimum**: finds the minimal value of grouped values.
  - **Maximum**: finds the maximal value of grouped values.
  - **Concatenate**: concatenates all unique values in the group in ascending order.
  - **Concatenate with counts**: concatenates all unique values with their number of encounters in the group.

Opens the **Main menu**: (6.566 on page 3843)

- **New BOM**: opens a submenu: (6.567 on page 3844)
  - **Top level**: creates a new Top level BOM.
  - **Bottom level**: creates a new Bottom level BOM.
  - **Hierarchical**: creates a new Hierarchical BOM.
  - **Create from template**: opens the dialog to select the template file: (6.571 on page 3845) Select the BOM template file, double click or click the **Open** button.
    - **Open**: adds a new BOM table from the template file and closes the dialog.
    - **Cancel**: closes the dialog without creating a new BOM table.
  - **Copy the current table**: adds a new BOM table using the template of the current table.
- **BOM tables in the document**: opens a submenu: (6.569 on page 3844)
  - **Go to first table**: switches to the first BOM table in the document.
  - **Go to previous table**: switches to the previous BOM table in the document.
  - **Go to next table**: switches to the next BOM table in the document.
  - **Go to last table**: switches to the last BOM table in the document.
  - **<Name of the BOM>**: switches to the corresponding BOM table in the document.
- **Place/update BOM table**: starts the interactive placement of the table in the drawing. If the table is already in the drawing, this tool will update the table.
- **Export to CSV**: saves the content of the current table to a CSV file. Opens a dialog to select the location for the CSV file: (6.570 on page 3845) Specify the location and name for the CSV file.
  - **Open**: exports the BOM table to the selected CSV file and closes the dialog.
  - **Cancel**: closes the dialog. Does not export the table to a CSV file.
- **Replace from template**: replaces the current BOM configuration with the one from the template. Opens a dialog to select the template file: (6.571 on page 3845) Specify the BOM template file.
  - **Open**: adds a new BOM table from the template file and closes the dialog.
  - **Cancel**: closes the dialog. Does not create a new BOM table.
- **Save as template**: opens a dialog: (6.572 on page 3846) Specify the location of the BOM 3834 template file

(6.581 on page 3849)	Displays a list of all Bills Of Materials in the document.
	Click to update the content of the BOM panel.
	Click to place or update the associated table in the drawing. If there is no associated table, prompts you: **Select position for BOM table**: specify a point to insert the BOM table.
(6.582 on page 3849)	Displays the list of categories.
(6.583 on page 3849)	Displays the list of available columns. Partly type column's name and press **Enter** for autocompletion. Type a formula starting with "=" to denote a formula field. Click  or  to add the formula field to the table.
	Click to add the column after the selected one.
	Click to toggle the search string.
(6.584 on page 3849)	Type a string to search and press Enter. By default, the entire table is searched. To search (a) specific column(s), first select the column(s) before you search. Press **F3** to find the next result. Press **Ctrl+F3** to find the previous result. Use the  button to select all found parts.
	Click to find the previous result.
	Click to find the next result.
(6.585 on page 3850)	Type the name of the current Bill Of Materials. You can use <NAME> as a placeholder for the name of the current assembly. Press Enter, or exit the field to apply the changes.

Procedures

- To open or close a panel (1.15.7)
- To dock a panel (1.15.7)
- To dock a panel with respect to another docked panel (1.15.7)
- To stack panels in a tabbed panel (1.15.7)
- To add a new bill of materials (3.7.9)
- To set a custom filter for the bill of materials (3.7.9)
- To add new columns to the bill of materials (3.7.9)
- To save the bill of materials template. (3.7.9)

Related Commands

BmBom (6.8.3): inserts a Bill of Materials (BOM) table in the current drawing. MechanicalBrowserOpen (6.8.32): opens the Mechanical Browser panel.

Related Commands

MechanicalBrowserOpen (6.8.32) - displays the Mechanical Browser. BmRecover (6.8.24) - recovers a broken mechanical structure. BmUpdate (6.8.29) - reloads all referenced components from external files and updates BOM tables.

Figure 6.591

6.8.10 BmExplode

(6.2582 on page 5709) BmExplode creates a block with an exploded representation of the current assembly. You can insert this block at any given location. It supports two levels of the exploded representation: top and bottom. Top-level means that the assembly will be exploded down to top level components; Bottom-level means that the assembly will be exploded down to bottom level components. The steps to create an exploded representation are automatically completed and are displayed in the Mechanical Browser (3.3.2). You can add, delete and reorder the steps from the Mechanical Browser. Animate a single step of an explosion or the entire sequence.

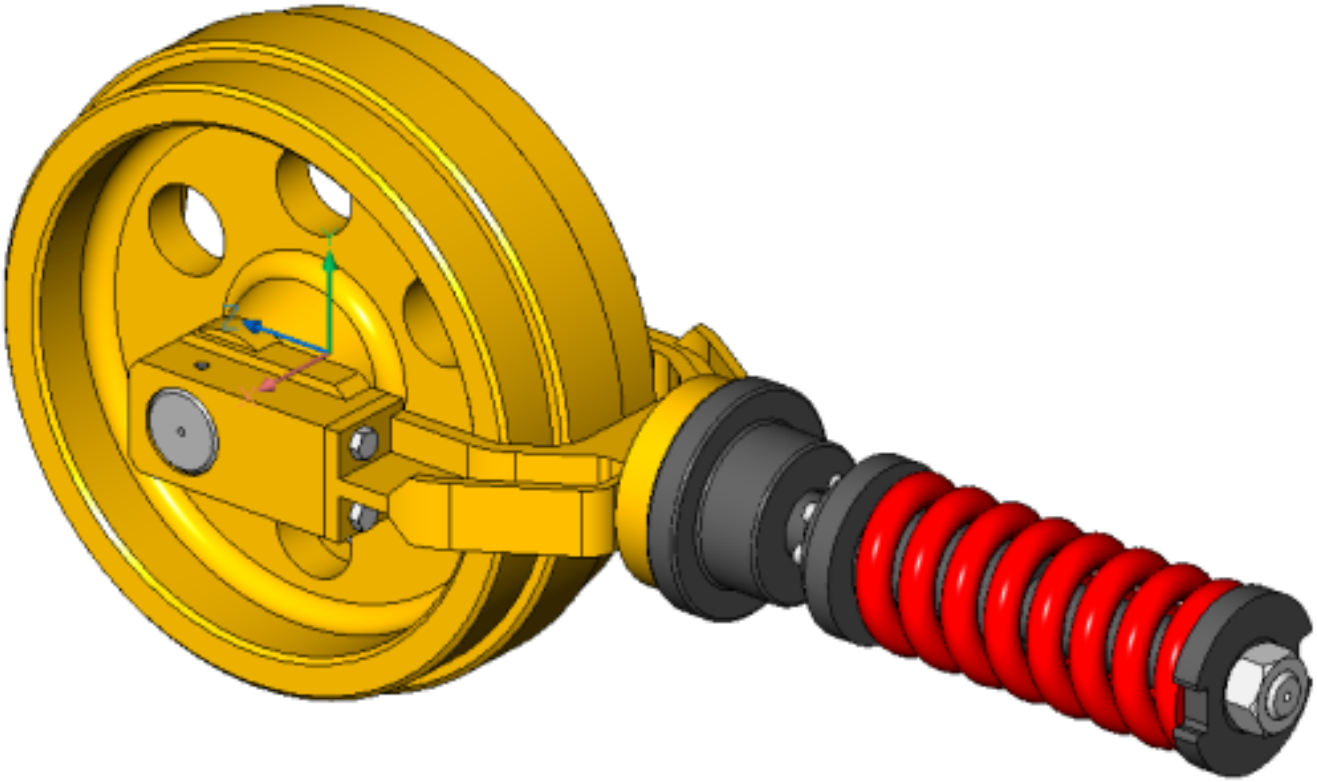
Accessing the Command

===ERROR WITH DOWNLOADED IMAGE=== command bar: **bmexplode** menu bar: **Assembly | Explode** toolbar: **Assembly | Explode** ribbon:

- **Home | Assembly | Explode**
- **Assembly | Tools | Explode**

: **bmexplode Prompts you in the command bar:** Select explosion algorithm [Table by types/Linear/Automatic/Manual/Settings <Manual>: **(Choose the algorithm or set the necessary options)** Select exploded view behaviour [Edit/Generate drawing views/Finish] <Finish>: **(Choose to further action)** (6.592 on the next page)

Figure 6.592



Command Options

Option	Description
Table by Types	Selects the Table by Types. The Table by Types algorithm groups identical parts on the same row and different parts on different rows. Prompts you: **Select exploded view behaviour** [Edit/Generate drawing views/Finish] <Finish>: - **choose an option or press Enter**. (6.593 on page 3859)
Linear	Automatically creates exploded representations of assemblies in a given direction, taking into account possible physical collisions between components. Prompts you: **Select axial entity or define axis by** [2Points/Xaxis/Yaxis/Zaxis] <2Points>: - **specify movement direction by using coordinate axis, linear edge or two arbitrary points** (6.594 on page 3860)

Automatic	Selects the Automatic algorithm, which will automatically determine the directions for each part, taking into account possible physical collisions between components. Prompts you: **Enter the minimal gap** [enable Leader follower/use Current projection for gap/Auto] <Auto>: - **choose an option, or enter the gap between parts, or press Enter.** • **Enable Leader follower** - enables the detection of parts that should move in a coherent manner. If enabled, parts that are inserted into other parts will follow the movement of the base parts they are inserted into. **This option is incompatible with use Current projection for gap option.** • **Use Current projection for gap** - enables the gap calculation with respect to the current camera orientation. It minimizes the probability that some parts will be hidden by other parts on a 2D view with the current camera orientation. **This option is incompatible with enable Leader follower option.** • **Auto** - enables automatic gap calculation.
Manual	===ERROR WITH DOWNLOADED IMAGE=== Selects the manual mode. This creates an exact copy of the assembly, ready to create a customized exploded view. (6.595 on page 3860) Prompts you: **Select exploded view behaviour** [Edit/Generate drawing views/Finish] <Finish>: - **choose an option or press Enter.**
Settings	Gives access to the command settings; Prompts you: **Select explode level or set block name** [Top/Bottom/set Name/BAck] - **choose an option**. • Top: If selected, the assembly will be exploded using only top-level components. (6.596 on page 3860) • Bottom: If selected, the assembly will be exploded down to bottom-level components. (6.597 on page 3861) • set Name: Set the name for the exploded representation; Prompts you: **Name for exploded block:** - **Type the name of the exploded representation.** If this name is already assigned to another exploded representation, a postfix will be added, starting from '_2.' • BAck: Returns to the previous prompt.
Edit	Opens the exploded representation for editing. Prompts you: **-bedit, Block name or ? to list existing blocks:** Manual_Top_2 **Use BCLOSE or the Block Edit toolbar to end the block edit session.**
Generate drawing views	Generates drafting views from an exploded representation. Prompts you: **Enter new or existing layout name to make current** <Layout1>: **- Enter the Layout name of the layout for the exploded representation**

Finish	Concludes the command

Procedures

Levels of the exploded representation (3.7.8) Selecting an algorithms (3.7.8) To create an exploded representation (3.7.8) To generate drawing views of the exploded representation (3.7.8) To update an exploded representation (3.7.8)

Related Commands

BmBalloon (6.8.2) - creates associative balloon entities for assembly components in Model Space and for their generated views in a Paper Space layout. BmBom (6.8.3) - inserts a Bill of Materials (BOM) table in the current drawing. BmExplodeMove (6.8.12) - creates a block with an exploded representation of the current assembly and allows to insert this block at a user defined location. Bedit (6.6.7) - opens the exploded representation for editing.

6.8.11 BmExternalize

(6.2673 on page 5786) Converts local components to external components.

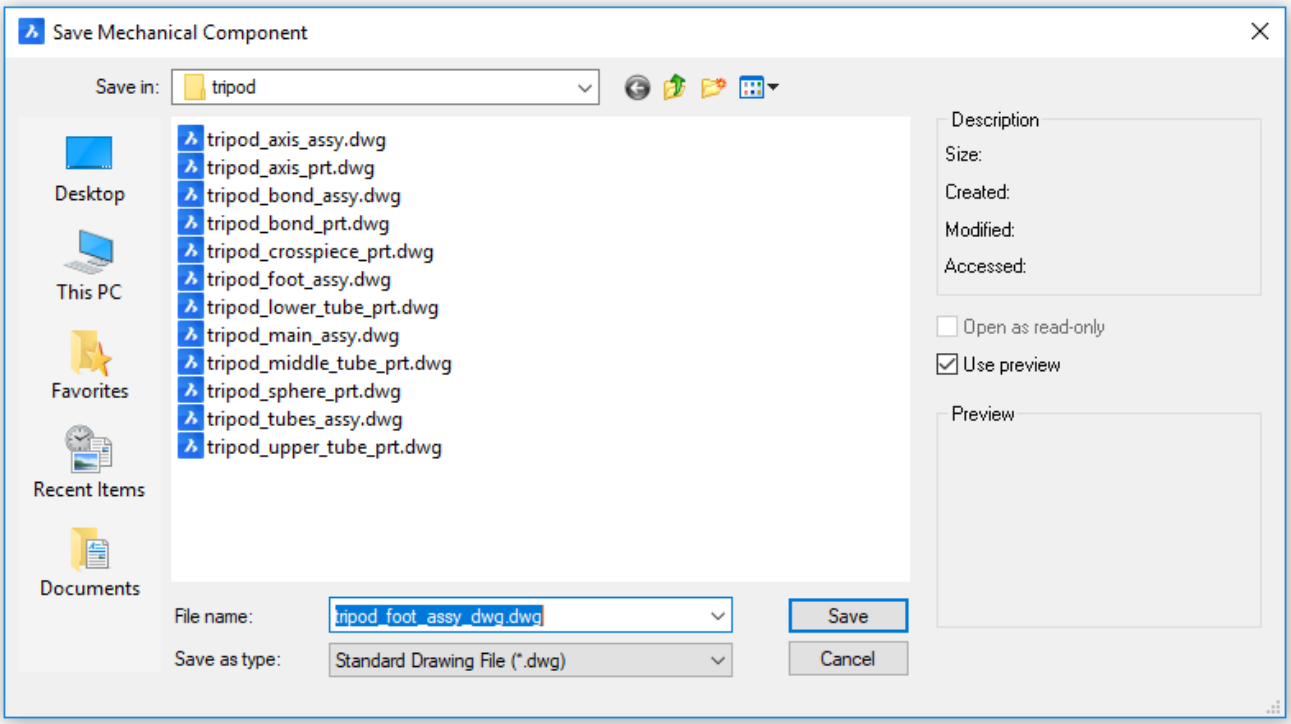
Accessing the Command

command bar: **bmexternalize** menu bar: **Assembly | Switch Component to External** toolbar: **Assembly | Switch Component to External** ribbon: **Assembly | Modify | Switch Component to External** Quad cursor menu: **Model | Switch Component to External** : **bmexternalize Prompts you in the command bar:** Select component instances [ASk for file names/Entire model] <Entire model>: **(Select a local component.)** Entities in set: 1 Select component instances [ASk for file names/Entire model] <Entire model>: **(Select a local component or press Enter.)** A file dialog displays: (6.599 on the facing page) Do one of the following:

- Press the **Save** button to accept the default name, which is the name of the selected local component.
- Type a name in the **File Name** field, then click the **Save** button.

This procedure is repeated for each of the selected local components.

Figure 6.599



Command Options

Option	Description
Entire Model	For each of the local components in the assembly a file dialog displays. Do one of the following: • Press the Save button to accept the default name, which is the name of the local component. • Type a name in the File Name field, then click the Save button.
Ask for file names	You can select to ask for file names of externalized components or generate them automatically. Prompts you: **Ask for file names of external components to be saved?** [Yes/No] <Yes>: • Yes: You are prompted to enter file names. • No: File names are generated automatically. Please note that some symbols used in component names cannot be used in file names. Such symbols will be automatically replaced with an underscore (_).

Procedures

Working with components and component inserts (1.30.25)

Related Commands

BmDissolve (6.8.8) - dissolves a mechanical component inserted in the current drawing. BmLocalize (6.8.17) - converts external components to local components. BmReplace (6.8.31) - replaces a component insert.

Figure 6.600

6.8.12 BmExplodeMove

(6.2582 on page 5709) BmExplodeMove moves selected parts to form an exploded representation in a given direction, taking into account possible physical collisions between components (similar to the Linear option of the BMEXPLODE (6.8.10) command). It also has an automatic mode. This determins the direction for each selected part automatically (similar to the Automatic option of the BMEXPLODE (6.8.10) command).

Accessing the Command

 command bar: **bmexplodemove** menu bar: **Assembly | Assembly Explode | Explode Move** toolbar: **Assembly | Explode Move** ribbon: **Assembly | Tools | Explode Move** : **bmexplodemove Prompts you in the command bar:** Select entities to explode [Automatic/Entire model] <Entire model>: **(Select the parts to be processed, or select Automatic option for enabling automatic mode.)**

If the Automatic option is chosen: Select entities to explode [Linear/Entire model] <Entire model>: **(Select the parts to be processed or select the Linear option for enabling linear explode mode. Press Enter to automatically create exploded representation of the selected parts.)**

Otherwise: Select base part <None>: **(Select the base component to remain stationary)** Select axial entity or define axis by [2Points/Xaxis/Yaxis/Zaxis] <2Points>: **(Specify movement direction by using coordinate axis, linear edge or two arbitrary points)**

Procedures

- Levels of the exploded representation (3.7.8)
- Selecting an algorithm (3.7.8)
- To create an exploded representation (3.7.8)
- To generate drawing views of the exploded representation (3.7.8)
- To update an exploded representation (3.7.8)
- To add trailing lines (3.7.8)

Related Commands

BmBalloon (6.8.2) - creates associative balloon entities for assembly components in Model Space and for their generated views in a Paper Space layout. BmBom (6.8.3) - inserts a Bill of Materials (BOM) table in the current drawing. BmExplode (6.8.10) - creates a block with an exploded representation of the current assembly and allows to insert this block at a user-defined location.

Figure 6.601

6.8.13 BmForm

(6.2673 on page 5786) BmForm creates a new mechanical component and inserts it into the current drawing. If necessary, run the BmMech (6.8.19) command first to initialize the mechanical structure in the current drawing.

Access the Command

command bar: **bmform** menu bar: **Assembly | Form Component** toolbar: **Assembly | Form Component** ribbon:

- **Home | Assembly | Form Component**
- **Assembly | Modify | Form Component**

Quad cursor menu: **Model | Form Component** : **bmform Prompts you in the command bar:** Select entities <Empty component>: **(Select a 3D solid.)** Entities in set: 1 If a history-based solid is selected, it prompts you: Selection set contains 3D solid/solids with recorded history. Confirm selection and purge history? <Yes>/No: **(Press Enter to accept the default option to include the X-Solid in a mechanical component.)** Select entities: **(Select a 3D solid or press Enter to stop selecting 3D solids.)** Enter external component base point or switch component type or choose template [Local/ External/ Template settings...] <0,0,0>: **(Specify a point or switch component type or choose a template.)** Name for new mechanical component <Component_1>: **(Specify a name, or press Enter to accept the default name.)** A new internal block, that contains the selected solid(s), is created and inserted as an internal reference in the current drawing. The selected solid(s) are removed from the current drawing.

Command Options

Option	Description
Create External component	Creates a new drawing, that contains the selected solid(s). The selected solid(s) are removed from the current drawing. The new drawing is inserted as an external reference in the current drawing. Displays a File dialog box: ===ERROR WITH DOWNLOADED IMAGE=== Select a folder, type a name in the File Name field and press the Save button.
Template settings...	Opens Settings dialog box (1.17.10) ===ERROR WITH DOWNLOADED IMAGE===

Related Commands

BmDissolve (6.8.8) - dissolves a mechanical component inserted in the current drawing. BmExternalize (6.8.11) - switches internal components to external components. BmInsert (6.8.16) - inserts an existing mechanical component into the current drawing. BmLocalize (6.8.17) - switches external components to internal components. bmXConvert (6.8.34) - converts X-Hardware solids in the current drawing to mechanical components.

Figure 6.602

6.8.14 BmHide

(6.2673 on page 5786) Hides a mechanical component inserted in the current drawing. The command affects the visibility of the selected inserts only. Hidden inserts will still be taken into account by commands such as BmBom, BmMassProp etc.

Accessing the Command

 command bar: **bmhide** menu bar: **Assembly Visualization | Hide** toolbar: **Assembly Visualization | Hide** ribbon: **Assembly l Modify | Hide** Quad cursor menu: **Model | Hide** : **bmhide Prompts you in the command bar:** Select insert or enter an option [Component name/Insert name]<Insert name>: **(Select an insert in the drawing or choose an option.)**

Command Options

Option	Description
Component name	Prompts you: **Component name**, all its inserts will be hidden: **Type the component name of the component insert(s) you want to hide.** All inserts of the specified component will be hidden.
Insert name	Prompts you: **Component insert name**, use / to separate names of nested inserts: **Type the insert name of the component insert you want to hide.** If you want to hide a nested component insert (subcomponent insert) first type the insert name of the parent component insert, then the component insert name separated by a slash (/)

Related Commands

MechanicalBrowserOpen (6.8.32) - displays the Mechanical Browser. BmShow (6.8.26) - shows a previously hidden mechanical component or subcomponent in the current drawing. BmVStyle (6.8.30) - applies a visual style to a mechanical component.

Figure 6.603

6.8.15 BmLink

(6.2673 on page 5786) Changes target 3D solids of component-based features (1.30.25).

Accessing the Command

command bar: **bmlink** menu bar: **Assembly | Link component** toolbar: **Assembly | Link component** ribbon: **Home | Assembly | Link component** Quad cursor menu: **Model | Link :bmlink Prompts you in the command bar:** Select component instances or [Change target 3d solids]: **(Select a component.)** Select target 3D solids or [Append/cleaR/Select all affected 3d solids] <Select all affected 3d solids>: **(Select target solids, choose an option, or press Enter.)** Select additional target 3D solids or [Change/cleaR/Select all affected 3d solids] <Select all affected 3d solids>: **(Select another target solids, choose an option, or press Enter.)**

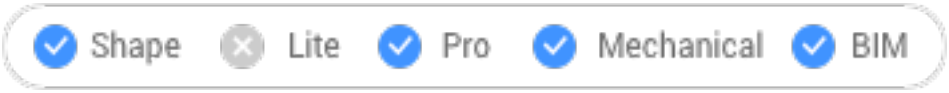
Command Options

Change target 3d solids Change	Allows you to choose the new set of target solids. Component-based features will be removed and new ones will be created for selected solids.
Append	Allows you to add new solids to set of target solids. Component-based features will be updated and new ones will be created for the selected solids.
cleaR	Allows you to remove the existed component-based features and their geometry (see BmUnlink (6.8.37)).
Select all affected 3d solids	This mode is similar to 'Change target 3d solids' but solids are chosen automatically. A solid will be chosen if any solids from BC_SUBTRACT (1.30.25) layer intersects it or if any other solid from the BC_UNITE (1.30.25) layer touches or intersects it.

Related Commands

BmInsert (6.8.16) - inserts an existing mechanical component or sheet metal form feature into the current drawing. BmUnlink (6.8.37) - breaks the connection between a component insert (e.g. a Window) and a 3D solid (e.g. a Wall) retaining the opening.

Figure 6.604



6.8.16 BmInsert

(6.604) Inserts sheet metal form features, and mechanical and BIM components. Inserts an RFA* file as a BIM component in the current drawing. The source drawing of the component is not affected. A virtual component is created, which represents the drawing in the assembly. * RFA import is a work-in-progress. Some general guidelines about the RFA import functionality are:

- RFA files older than 2015 are not supported.
- Files from 2015 to 2020 are imported correctly. Currently, you can import; extrusions, blends, revolutions, and sweeps.
- Only the geometry of the family is imported without parameters or properties.

Access the Command

BIM Workspace  **Insert BIM Component** menu bar: **BIM| Insert BIM Component** toolbar:

- **Bim | Insert BIM Component**
- **BIM Windows | Insert BIM Component**

ribbon:

- **Home | Create | Insert BIM Component**
- **Modeling | Building elements | Insert BIM Component**

Mechanical Workspace  **Insert Component**  **Insert Form Feature** ===ERROR WITH DOWNLOADED IMAGE=== **Smart Insert** menu bar:

- **Assembly | Insert Component**
- **Sheet Metal | Insert Form Feature**

toolbar:

- **Assembly | Insert Component**
- **Sheet Metal | Insert Form Feature**

ribbon:

- **Home | Assembly | Insert Component**
- **Assembly | Modify | Insert Component**
- **Sheet Metal | Modify | Insert Form Feature**

Library Panel The command is launched automatically when dragging a component from the Library panel (6.20.23) into the drawing. : **BMINSERT**

BIM Workspace A File dialog box displays. The default component folders sit in a subfolder of the BricsCAD installation folder: BIM components: ..\UserDataCache\Support\en_US\Bim\Components. ===ERROR WITH DOWNLOADED IMAGE=== Do the following:

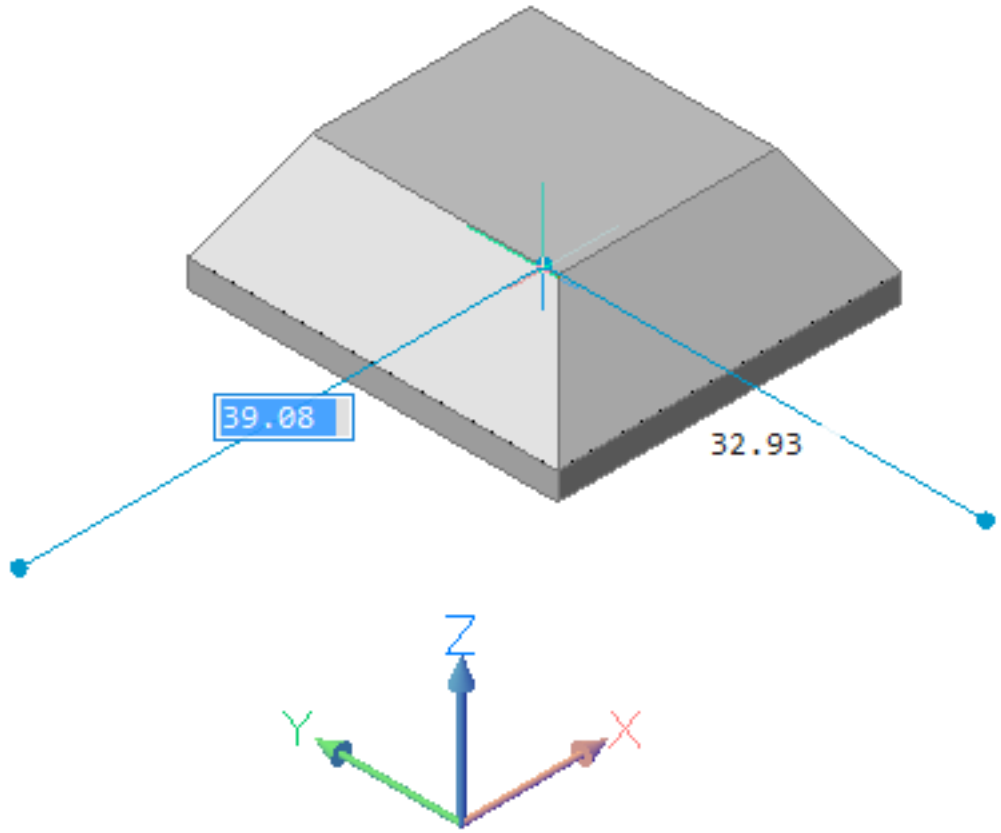
1. Select a component.
2. Double click or click the **Open** button.
3. The parameters of the selected component display in the Properties (1.15.4) panel. ===ERROR WITH DOWNLOADED IMAGE===
4. Optional: edit the parameters.

Prompts you in the command bar: Select insertion point or [Edit inserted entity/Rotate component/set Base point/Name/insertion Type/Flip/mUltiple/Change target 3d solids] <0, 0, 0>: **(Specify the insertion point or choose an option.)** Move the cursor over a solid; the face under the cursor highlights: The UCS aligns dynamically with the selected face. If the edge by which the cursor enters the solid is horizontal or vertical, the X-axis of the UCS is horizontal otherwise, the X-axis is aligned with the edge, the Z-axis is perpendicular to the face of the solid. Specify point to insert. Hit the Ctrl-key to switch between **Select insertion point** and **Edit inserted entity** mode.

Select insertion point (6.606 on page 3873)	Allows to specify the insertion point. From the middle of each edge of the placement rectangle, dynamic dimensions display to the nearest parallel edge on the face of the solid. Press the TAB key to cycle the distance fields. Type a value then press the TAB key, to lock the field and jump to the next field. Once locked, the field turns red. Only one of two parallel dimensions can be locked. If a dimension value is entered and the other, parallel dimension was already locked, it will be unlocked. Press Enter or click to insert the selected component. (6.607 on page 3873) 1. Locked field 2. Current field 3. Unlocked field 4. Unlocked field
Edit inserted entity (6.608 on page 3873)	Allows to specify the width and height of the placement rectangle of the component. This option is only available if the **W** (width) and/or **H** (height) parameters are defined in the component source drawing. Prompts you: **Edit [Height/Width/Done] <Height>:** Two dynamic dimension fields display the current width and height of the placement rectangle. (6.609 on page 3874) Type a value in the current dynamic dimension field, then press the TAB key to switch to the other field. Press the Ctrl-key to switch to **Select Insertion Point** mode.

Mechanical Workspace A File dialog box displays. The default component folders sit in a subfolder of the BricsCAD installation folder: ..\UserDataCache\Support\en_US\DesignLibrary ===ERROR WITH DOWNLOADED IMAGE=== Select a mechanical component drawing, then double click or press the **Open** button. The parameters of the selected component display in the Properties (1.15.4) panel. ===ERROR WITH DOWNLOADED IMAGE=== Optionally, edit the parameters. The component is attached to the cursor with its origin point. Dynamic dimensions display X and Y coordinates to the origin of the current coordinate system. (6.605 on the following page) **Prompts you in the command bar:** Select insertion point or [Edit inserted entity/SMART insert/Rotate component/set Base point/Name/insertion Type/Flip/mUltiple/Change target 3d solids] <0, 0, 0>: **(Specify the insertion point or choose an option.)**

Figure 6.605



Command Options

Option	Description
Edit inserted entity	Allows to edit the parameters of the selected insert. Prompts you: **Enter parameter name or [FINISH] <FINISH>: Press F2 to open the Prompt History (6.29.16) window.** (6.621 on page 3884) Type the name of a parameter. Prompts you: **Enter expression < 30.00 >:** - **Type a value, then press Enter.** Prompts you: **Enter the parameter name or press ENTER to finish:** - **Type the name of a parameter or press Enter.** The insert is updated. Parameters can also be edited in the Properties (1.15.4) panel: ===ERROR WITH DOWNLOADED IMAGE===

Smart insert	Allows to automatically connect a Piping standard part to an existing Piping standard part by creating a proper set of 3D constraints between them and by copying expressions for the parameters of existing inserted part to the new part. Prompts you: **Select entity to insert to or [switch Back/Rotate component/Flip/mUltiple/selection options (?)]:** - Hover over a Piping standard part to automatically connect the new part with it: ===ERROR WITH DOWNLOADED IMAGE=== ===ERROR WITH DOWNLOADED IMAGE=== You can hover over directly inserted Piping standard part as well as nested ones (contained in subassemblies). The part being inserted is resized automatically by copying the values of its parameters from the part under the cursor. Click to insert the part. The command automatically creates a set of 3D constraints between them. You can combine the Smart insert mode with the Flip, Multiple, and Rotate options. Press the Ctrl-key to switch between the regular, Edit, and Smart insert modes: ===ERROR WITH DOWNLOADED IMAGE===
Rotate component	Allows to define the rotation angle of the component. Prompts you: **Specify rotation angle of the insert:** - **Enter the rotation angle.** (6.611 on page 3874)
set Base point	Allows to specify a different base point to insert the component. Prompts you: **New base point <0,0,0>:** - **Specify a new base point.** The new base point is attached to the cursor.
Name	Allows to define the insert name of the component. Prompts you: **Component insert name <DefaultName>:** - **Type the insert name for the component.**
insertion type	Allows to specify the insertion type: Local or External Prompts you: **Specify component type [Local/External] <External>:** - **Choose an option.**
Flip	Inserts the selected insert in the opposite face of the parent solid.

Multiple	Allows to insert multiple copies of the same component or create an array. Prompts you: **Select insertion point or [Edit inserted entity/Rotate component/set Base point/Name/insertion Type/Flip/mUltiple/Change target 3d solids] <0, 0, 0>:** Optionally, choose an option, then do one of the following: • Select multiple insertion points. Press Enter to stop inserting more copies. • **Array** - creates an associative array of components. Prompts you: **Specify base point for the array:** - Specify a point. **Enter columns spacing or set [Direction]:** - Specify a distance or choose Direction. **Enter the distance between rows or set [Single row/Rectangular/Direction]:** - Specify a distance or choose an option. **Select an end point for creating the array:** - Move the cursor to dynamically define the extents of the array, then click a point. **Accept resulting array or edit [Base point/Columns/Rows] <Accept>:** - Press Enter to accept the array or choose an option.
Change target 3d solids	Allows to choose solids to which the component-based feature will be applied. Prompts you: **Select target 3D solids or [cleaR/Select all affected 3d solids] <Select all affected 3d solids>: - Select target solids, choose an option, or press Enter.** • **Clear**: No solids will be affected by the component being inserted. • **Select all affected 3d solids**: - All solids intersecting or touching solids in the BC_SUBTRACT (1.30.25) and BC_UNITE (1.30.25) layers of the component will be affected.

Procedures

Controlling the position of a window or door (2.5.19) Inserting windows or doors (2.5.19) Editing the parameters of an insert (2.5.19) Moving an insert (2.5.19) Copying inserts (2.5.19) Replacing an insert (2.5.19) Piping in Assembly Design (3.7.6)

Related Commands

BmDissolve (6.8.8) - dissolves a mechanical component inserted in the current drawing. BmForm (6.8.13) - creates a new mechanical component and inserts it into the current drawing. BmLink (6.8.15) - changes target 3D solids of component-based features. BmMech (6.8.19) - converts the current drawing into a mechanical main component. BmUnlink (6.8.37) - breaks the connection between a component insert (e.g. a Window) and a 3D solid (e.g. a Wall) retaining the opening. LibraryPanelOpen (6.20.23) - opens the Library panel. DmCopyFaces (6.12.12) - copies a set of 3D solid faces forming a feature (e.g. hole, rib or protrusion) to a new position on the same or another 3D solid. SmReplace (6.28.26) - replaces form features (including recognized ones) in sheet metal parts with form features from the built-in or user library. SmRibCreate (6.28.27) - creates associative Rib form features on sheet metal parts from 2D profiles.

6.8.17 BmLocalize

(6.2673 on page 5786) Converts external components to local components.

Accessing the Command

command bar: **bmlocalize** menu bar: **Assembly | Switch Component to Local** toolbar: **Assembly | Switch Component to Local** ribbon: **Assembly | Modify | Switch Component to Local** Quad cursor menu: **Model | Switch Component to Local** : **bmlocalize Prompts you in the command bar:** Select component instances [Entire model] <Entire model>: **(Select an external component.)** Entities in set: 1 Select component instances [Entire model] <Entire model>: **(Select an external component or press Enter to convert the selected component(s) to local components.)** If multiple inserts of the same external component exist in the model, all inserts are converted to local components.

Command Options

Option	Description
Entire model	Converts all external components in the model to local components.

Procedures

Working with components and component inserts (1.30.25)

Related Commands

BmDissolve (6.8.8) - dissolves a mechanical component inserted in the current drawing. BmExternalize (6.8.11) - converts local components to external components. BmReplace (6.8.31) - replaces a component insert.

Figure 6.613

6.8.18 BmMassProp

(6.624 on page 3887) Computes mass properties for the current model using densities of materials assigned to its the components. The density values used for the mass property calculations are taken from materials defined by the **Material** property of the components and subcomponents, which can be either inherited from the main component of the assembly or set explicitly. The density of the main component is defined by the materials set in the **Material** field in the Mechanical Browser (3.3.2) dialog. If a material does not have an assigned density, or its density is less or equal to zero, an error message displays, and the mass properties will not be computed. All materials involved in the assembly must have non-zero non-negative densities.

Accessing the Command

command bar: **bmmassprop** menu bar: **Assembly | Mass Properties** toolbar: **Assembly | Mass Properties** ribbon:

- **Assembly | Inquire | Mass Properties**
- **Home | Assembly | Mass Properties**

: **bmmassprop Prompts you in the command bar:** Select 3D solids and subcomponents or [Entire model] <Entire model>: **(Select an item.)** Entities in set: 1 Select 3D solids and subcomponents or [Entire model] <Entire model>: **(Select more items or right click.)** Reports in the Prompt History window: ---------- Component ---------- Mass: 17.61 kg Volume: 6522.94 cm³ Centroid: X= 22.59 mm Y= 235.71 mm Z= 201.09 mm Moments of inertia: X= 2.30 kg·m² Y= 0.95 kg·m² Z= 1.39 kg·m² Products of inertia: XY: 0.09 kg·m² YZ: 0.87 kg·m² ZX: 0.11 kg·m² Radii of gyration: X= 361.23 mm Y= 231.76 mm Z= 281.19 mm Principal moments and X-Y-Z directions about centroid: I: 0.22 kg·m² along X= -0.0022 Y= 0.9819 Z= 0.1891 J: 0.41 kg·m² along X= 0.1346 Y= -0.1871 Z= 0.9731 K: 0.61 kg·m² along X= 0.9909 Y= 0.0276 Z= -0.1318 Keep UCS aligned with principal moment axes? [Yes/No] <No>: (Press Enter or right click to keep the current UCS)

NOTE	BmMassProp will format the values of mass, volume and linear nature with their corresponding units only if the PROPUNITS (1.17.10) system variable has the corresponding bits set to 1, or the corresponding flag in the Settings dialog (1.17.10) for the Property units field is checked. See To set the Mass Units (3.7.5).

Command Options

Option	Description
Keep UCS aligned with principal moment axes? Yes / No	(6.614 on the next page) Yes: Aligns the UCS with the principal moment axes. (6.615 on page 3878) No: Keeps the current UCS.

Related Commands

BmBom (6.8.3) - inserts a Bill of Materials (BOM) table in the current drawing. MechanicalBrowserOpen (6.8.32) - displays the Mechanical Browser.

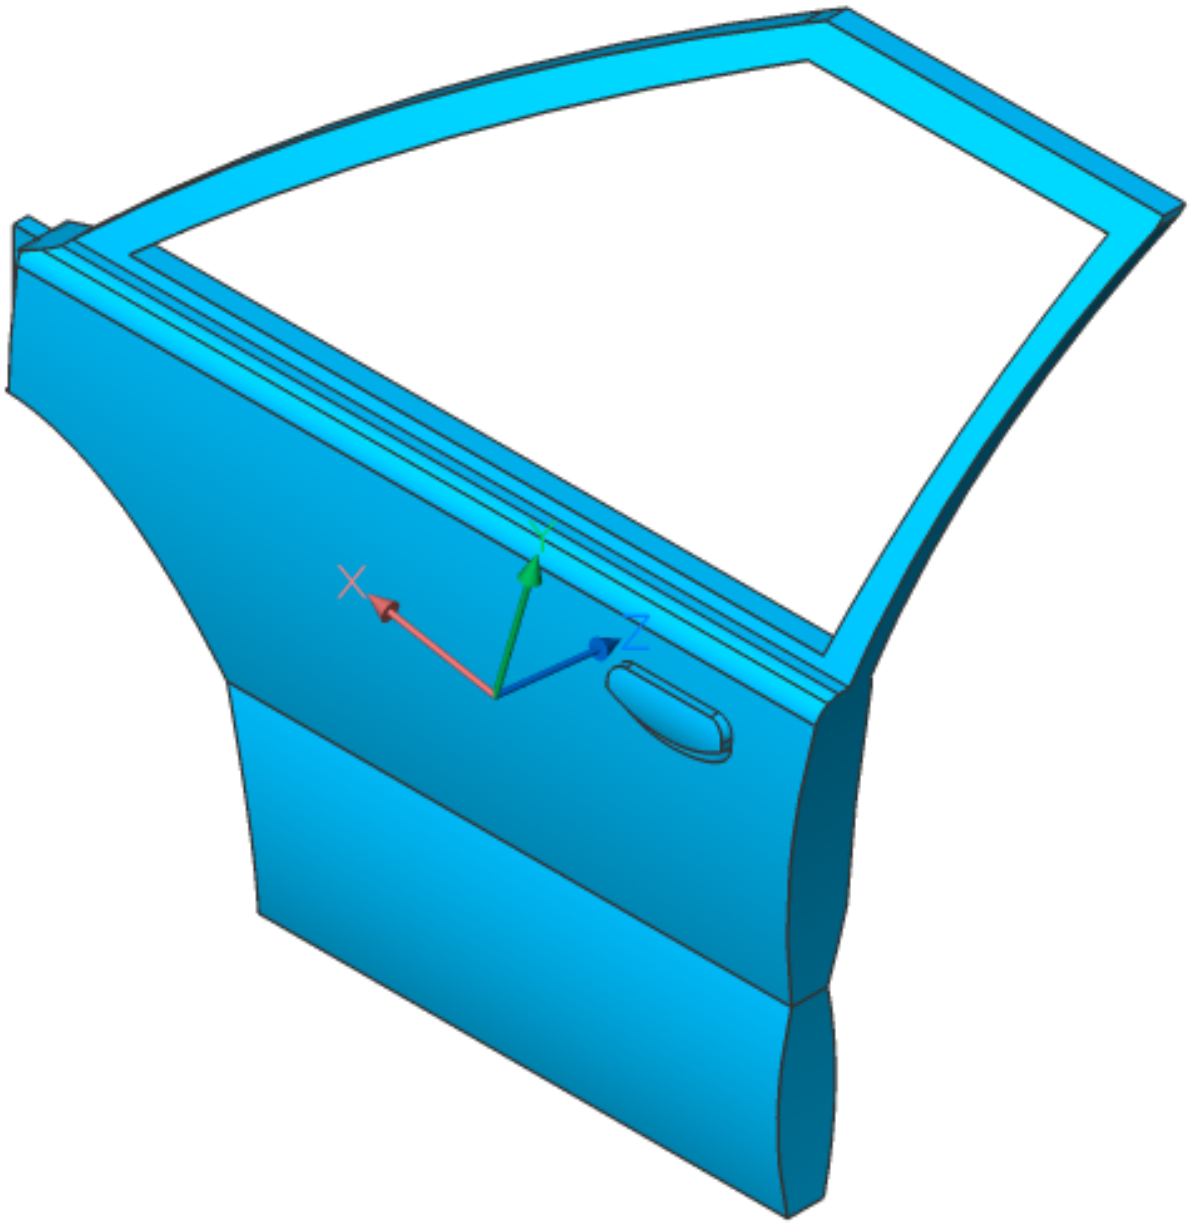

Figure 6.615

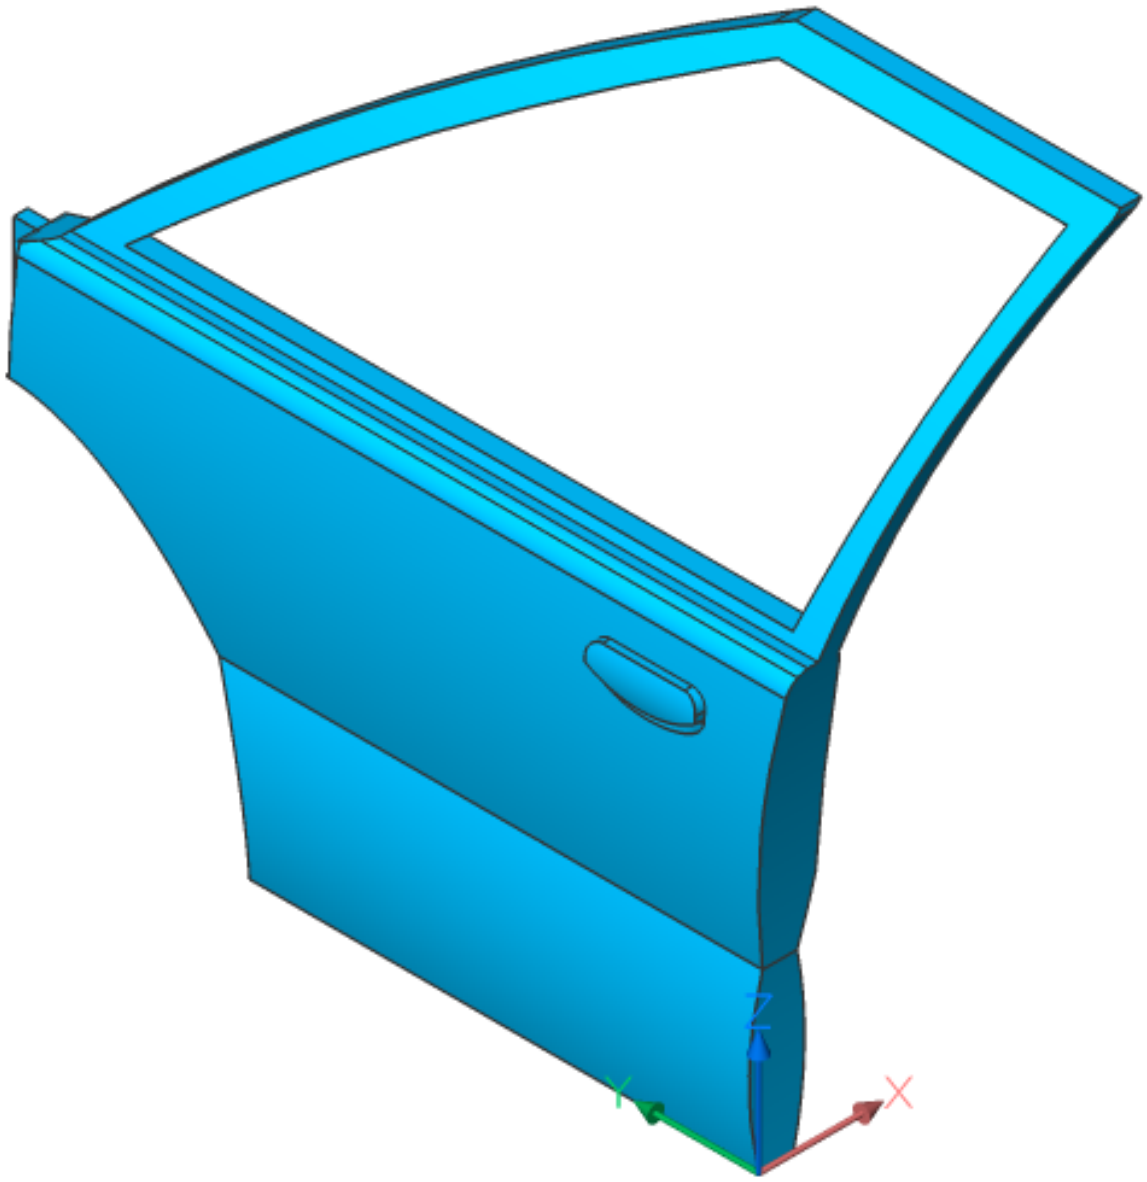

Figure 6.616

6.8.19 BmMech

(6.2673 on page 5786) BmMech converts the current drawing into a mechanical component. If the drawing contains block references or external references, they can also be converted into inserts of local and external components. If the drawing is a mechanical component already BmMech does nothing.

Access the Command

command bar: **bmmech** menu bar: **Assembly | Initialize Mechanical Structure** toolbar: **Assembly | Initialize Mechanical Structure** ribbon:

- **Home| Assembly | Initialize Mechanical Structure**
- **Assembly | Create | Initialize Mechanical Structure**

: **bmmech Prompts you in the command bar:** Name for new mechanical component <CurrentDrawingName>: **(Press Enter to accept the current name or type a new name if you want to keep the original. If the drawing was not yet saved before, a default name, Component_1, is suggested.)** Select blocks and external references to convert to components or [Yes - to convert all/No - to skip conversion] <Yes - to convert all>: **(Press Enter or choose an option.)**

Command Options

Option	Description
Yes	If the drawing contains block references or external references, blocks are converted to internal components and external references are converted to external components. Blocks are not available in the INSERT (6.17.13) command. Use BMINSERT (6.8.16) to insert blocks as internal components.
No	The mechanical structure is initialized but blocks and external references are not converted.

Related Commands

BmExternalize (6.8.11) - converts local components to external components. BmInsert (6.8.16) - inserts an existing mechanical component into the current drawing. BmLocalize (6.8.17) - converts external components to local components. BmNew (6.8.20) - creates a new mechanical component as a new drawing file. BmUnmech (6.8.28) - converts the current mechanical component into a plain drawing.

Figure 6.617

6.8.20 BmNew

(6.2673 on page 5786) Creates a mechanical component as a new drawing file.

Accessing the Command

command bar: **bmnew** menu bar: **Assembly | New Component** toolbar: **Assembly | New Component** ribbon: **Assembly | Create | New Component** : **bmnew Prompts you in the command bar:** Name for new mechanical component <Component_x>: **(Type a name for the new component or press Enter to accept the default name.)**

Command Options

No options.

- **Home | Assembly | Open Component Copy**
- **Assembly | Modify | Open Component Copy**

Quad cursor menu: **Model | Open Component Copy** : **bmopencopy Prompts you in the command bar:** Select insert: **(Select an external component in the model or the Mechanical Browser (3.3.2).)** A new drawing: <component_name>1 is created. Use the SAVE (6.27.1) command to rename and save the drawing.

Command Options

No options.

Related Commands

BmOpen (6.8.21) - opens the source drawing of an external mechanical component.

Figure 6.620

6.8.23 -BmHardware

(6.2582 on page 5709) -BmHardware Inserts a standard hardware part as a mechanical component in the current drawing. If necessary, run the BmMech (6.8.19) command to initialize the mechanical structure in the current drawing.

NOTE	This command is obsolete and creates non-parametric standard hardware parts. To insert parametric standard hardware, use the Components panel (6.9.26). This contains parametric Standard Mechanical Components (3.7.4).

Access the command

command bar: **-bmhardware** : **-bmhardware Prompts you in the command bar:** Input a category (? to list available categories) <ALL>: **(Enter a category name.)** Input a type (? to list available types) <ACORN-RVT>: **(Specify a type.)** Input a size (? to list available sizes) <.500>: **(Specify the size.)** Input a length (? to list available lengths) <1.0>: **(Specify the length.)** Select insertion point or [Edit inserted entity/Rotate component/set Base point/Name/insertion Type/Flip/mUltiple/Change target 3d solids] <0, 0, 0>: **(Specify a point in the drawing.)**

Command Options

Option	Description
Edit inserted entity	Allows you to edit the parameters of the selected insert. Prompts you: **Enter the parameter name or press ENTER to finish: - Type the name of a parameter. Press F2 to open the Prompt History (6.29.16) window.** (6.621 on the following page) **Enter expression < 30.00 >: - Type a value, then hit Enter. Enter the parameter name or press ENTER to finish: - Type the name of a parameter or hit Enter.** The insert is updated.
Rotate component	Allows you to specify a rotation angle. Prompts you: **Specify rotation angle of the insert: - Type a value or choose an option.**
set Base point	Allows you to specify a new base point for the insert. Prompts you: **New base point** <0,0,0>: - **Specify a point.**
Name	Allows you to rename the insert. Prompts you: **Component insert name <current_name>: -Type a name.**
insertion Type	Allows you to specify the insertion type: Local or External. Prompts you: **Specify component type [Local/External] <Local>: - Choose an option.**
Flip	Inserts the selected insert in the opposite face of the solid.

Multiple	Allows you to insert multiple copies. Prompts you for each copy: **Select insertion point or [Edit inserted entity/Rotate component/set Base point/Name/insertion Type/Flip/Array/Change target 3d solids]:** (Optional): choose an option and do one of the following: • Select multiple insertion points. Hit Enter to stop. • **Array** : creates an associative array of components. Prompts you: **Specify base point for the linear array:** - Specify a point. **Enter the distance between columns or set [Direction]:** - Specify a distance or choose a direction. **Enter the distance between rows or set [Single row/Rectangular/Direction]:** - Specify a distance or choose an option. **Select an end point for creating the array:** - Move the cursor to dynamically define the extents of the array, then click a point. **Accept resulting array or edit [Base point/Columns/Rows] <Accept>:** - Press Enter to accept the array or choose an option.
Change target 3d solids	Allows you to choose the new set of target solids. Any current component-based features will be removed and new ones will be created for the selected solids. Prompts you: **Select target 3D solids or [cleaR/Select all affected 3d solids] <Select all affected 3d solids>: - (Select target solids, choose an option or hit Enter.)** • **cleaR** : Allows you to remove the existed component-based features with their geometry (see BmUnlink (6.8.37)) • **Select all affected 3d solids** : This mode is similar to 'Change target 3D solids' but solids will be chosen automatically. A solid will be chosen if any solids from BC_SUBTRACT (1.30.25) layer intersects it or if any other solids, from the BC_UNITE (1.30.25) layer, touches or intersects it.

Related Commands

BmInsert (6.8.16) - inserts a mechanical component into the current drawing. ComponentsPanelOpen (6.9.26) - opens the Components panel and allows you to insert standard parts, items, and components supplied with BricsCAD, as well as, components from your library.

Figure 6.621

```

Related Commands

BmDependencies (6.8.9) - lists all files, containing component definitions inserted in the assembly, in the command window. BmUpdate (6.8.29) - reloads all referenced components from external files and updates BOM tables.

Figure 6.624

6.8.25 -BmParameters

(6.624) Allows to list and edit the parameters of inserted components and associative array. Parameters of components nested inside an array can be changed or assigned to an expression via the -BMPARAMETERS command.

Accessing the Command

command bar: **-bmparameters** : **-bmparameters Prompts you in the command bar:** Select component instances or arrays: **(Select a component or an associative array.)** Entities in set 1 Select component instances or arrays: **(Select more components or associative arrays, or press Enter.)** Enter an option to change parameter expression [Edit/Delete/Link to parameter/**?**] <?>: **(Press Enter to list the parameters of the selected components in the Prompt History window.)**

Command Options

Option	Description
Edit	Allows to edit the value of a parameter. Prompts you: **Enter parameter name:** Type the name of a parameter. Enter expression: Type a value in the command bar.
Delete	Allows to reset a previously edited parameter to its default value. Prompts you: **Enter parameter name:** Type the name of a parameter.
Link to parameter	Assigning parameters as an expression for a parameter of a dimensional constraint (both 2D and 3D) associated with an entity which has been put into an associative array. Prompts you: **Enter parameter name** ('*' to link all) <*>: Type the name of a parameter.
?	Lists the parameters of the selected components in the Prompt History window (6.29.16). Press the F2 function key to display the Prompt History window.

Related Commands

ArrayPath (6.4.26) - associatively distributes entity copies evenly along a path into multiple rows, and levels. ArrayPolar (6.4.41) - associatively distributes entity copies evenly in a circular pattern about a center point or axis of rotation, using multiple rows, and levels. ArrayRect (6.4.28) - associatively distributes entity copies into any number of rows, columns, and levels. -DesignTableEdit (6.10.27) - allows to edit design tables. DesignTable (6.10.31) - creates or imports .csv files containing sets of parameter values. Drop-down lists with the parameters values from the tables are added to the Mechanical Browser (3.3.2) and parametric component properties. -Parameters (6.24.6) - manages dimensional constraint parameters in the current drawing.

Figure 6.625

6.8.26 BmShow

(6.2673 on page 5786) Shows previously hidden mechanical components inserted in the current drawing.

Accessing the Command

 command bar: **bmshow** menu bar: **Assembly Visualization | Show** toolbar: **Assembly Visualization | Show** ribbon: **Assembly | Modify | Show** Quad cursor menu: **Model | Show** : **bmshow Prompts you in the command bar:** Select insert or enter an option [show ALl/COmponent name/Insert name] <show ALl>: **(Select a component of which some inserts are currently hidden or choose an option.)**

Command Options

Option	Description
show ALl	Shows all component inserts.
COmponent name	Prompts you: **Component name, all its inserts will be shown: - Type the component name of the component insert(s) you want to show.** This affects all inserts of the specified component.
Insert name	Prompts you: **Component insert name, use / to separate names of nested inserts: - Type the insert name of the component insert you want to show.** If you want to show a nested component insert (subcomponent insert) first type the insert name of the parent component insert, then the component insert name separated by a slash (/).

Related Commands

MechanicalBrowserOpen (6.8.32) - displays the Mechanical Browser. BmHide (6.8.14) - hides a mechanical component or subcomponent in the current drawing. BmVStyle (6.8.30) - applies a visual style to a mechanical component.

Figure 6.626

6.8.27 BmTrailingLines

(6.2582 on page 5709) Creates all necessary trailing lines (3.7.8) for selected parts.

Accessing the Command

 command bar: **bmtrailinglines** menu bar: **Assembly | Trailing Lines** toolbar: **Assembly | Trailing Lines** ribbon:

- **Home | Assembly | Trailing Lines**
- **Assembly | Tools | Trailing Lines**

: **bmtrailinglines Prompts you in the command bar:** Select entities to place automatic trailing lines or [use Origin points/use Center points/Entire model] <Entire model>: **(Select parts to add trailing lines or choose an option)**

Command options

Option	Description
use Origin points	Switches the mode used to choose the reference point for parts to the origin (insertion point) of the component. Displays message: **Origins of components will be used as reference points** Prompts you: **Select entities to place automatic trailing lines or [use Origin points/use Center points/Entire model] <Entire model>:**
use Center points	Switches the mode used to choose the reference point for parts to the center point of the bounding box of the component. Displays message: Centers of components will be used as reference points Prompts you: **Select entities to place automatic trailing lines or [use Origin points/use Center points/Entire model] <Entire model>:**
Entire model	Selects the entire model and starts the processing.

Related commands

BmBalloon (6.8.2) - creates associative balloon entities for assembly components in Model Space and for their generated views in a Paper Space layout. BmBom (6.8.3) - inserts a Bill of Materials (BOM) table in the current drawing. BmExplode (6.8.10) - creates a block with an exploded representation of the current assembly and allows to insert this block at a user defined location. BmExplodeMove (6.8.12) - creates a block with an exploded representation of the current assembly and allows to insert this block at a user defined location.

Figure 6.627

6.8.28 BmUnmech

(6.2673 on page 5786) Converts the current mechanical component into a plain drawing. The command applies to drawings that are a mechanical component only.

Accessing the Command

command bar: **bmunmech** menu bar: **Assembly | Remove Structure** toolbar: **Assembly | Remove Structure** ribbon:

- **Home | Assembly | Remove Structure**
- **Assembly | Tools | Remove Structure**

: **bmunmech Prompts you in the command bar:**
Warning: this command removes all mechanical structure from the current document. Proceed? [Yes/No] <Yes>:
(Press Enter or choose an option)

Command Options

Option	Description
Yes	Removes the mechanical structure from the drawing, thus turning it into a plain drawing. Inserts of local components are converted to block references (the component name becomes the block name); inserts of external components are converted to external references.
No	Aborts the command.

Related Commands

BmDissolve (6.8.8) - dissolves a mechanical component inserted in the current drawing. BmMech (6.8.19) - converts the current drawing into a mechanical component. BmNew (6.8.20) - creates a mechanical component as a new drawing file.

Figure 6.628

6.8.29 BmUpdate

(6.2673 on page 5786) Reloads all referenced components from external files and updates BOM tables. Use this command to

- Reload referenced components from external files (BmInsert (6.8.16));
- Rebuild component based features, sheet metal form features and BIM windows/doors components (see about BC_SUBTRACT (1.30.25) layer, Form Features (3.6.19), BmInsert (6.8.16));
- Update the Bill Of Material (BmBom (6.8.3));
- Regenerate drawing views produced out of 3D model (ViewBase (6.31.4)).

NOTE	If the BMAUTOUPDATE (1.17.10) system variable is ON, external assembly components are reloaded on opening the file.

Accessing the Command

===ERROR WITH DOWNLOADED IMAGE=== **Update**  **Update Selected** command bar: **bmupdate** menu bar: **Assembly | Update** and **Update Selected** ribbon:

- **Home | Assembly | Update**
- **Assembly | Tools | Update** and **Update Selected**

toolbar: **Assembly | Update** and **Update Selected** Quad cursor menu: **Model | Update Selected** : **bmupdate Prompts you in the command bar:** Select entities to update or [MOde/Entire model] <Entire model>: **(Select a component insert or generated drawing view; or select one of the faces of the component based or sheet metal form feature; or press Enter to select the entire model.)** Entities in set: 1 Select entities to update or [MOde/Entire model] <Entire model>: **(Select more objects.)** Updated xx definitions.

Command Options

Option	Description
Mode	Allows to change the way how the new placement face is defined. Each inserted component-based feature or BIM Window component has an associated placement face of the correspondent 3D solid the feature is attached to. This is the face which was used for feature placement in the BmInsert (6.8.16) command. The associated placement face of the feature can be lost in modeling or copying operations or it can be absent if the feature has been inserted in an empty area. The **BmUpdate** command allows to re-associate the feature with its placement face in one of two modes. Prompts you: **Select placement face [Automatic/Manual] <Automatic>:** • **Automatic** - the placement face for the feature is detected automatically • **Manual** - prompts you to select the new placement face
Entire model ===ERROR WITH DOWNLOADED IMAGE===	Updates the entire model.

Related Commands

BmBom (6.8.3) - inserts a Bill of Materials (BOM) table in the current drawing. MechanicalBrowserOpen (6.8.32) - displays the Mechanical Browser. BmDependencies (6.8.9) - lists all files, containing component definitions inserted in the assembly, in the command window. BmInsert (6.8.16) - inserts an existing mechanical component or sheet metal form feature into the current drawing. BimInsert (6.7.22) - inserts a window or door in a solid. Inserts a copy of a window or door in a solid.

Figure 6.629

6.8.30 BmVStyle

(6.2673 on page 5786) Applies a visual style to a mechanical component insert.

Accessing the Command

 command bar: **bmvstyle** menu bar: **Assembly Visualization | Visual Style** ribbon: **Assembly | Modify | Visual Style** toolbar: **Assembly | Visual Style** Quad cursor menu: **Model | Visual Style** : **bmvstyle Prompts you in the command bar:** Select visual style [by Viewport/Wireframe/Hidden/Realistic/Conceptual/Modeling/by Name] <Wireframe>: **(Choose an option.)** Select insert or enter an option [All/Insert name] <All>: **(Select an option or select a component insert - press Enter to select all components.)** Component insert name, use / to separate names of nested inserts: **(Type the names of one or more component inserts separated by slashes (/). Component insert names are case sensitive.)**

Command Options

Option	Description
by Viewport	Applies the current visual style of the viewport.
Wireframe	Applies the **3D Wireframe** visual style. (6.630 on the next page)
Hidden	Applies the **Hidden** visual style. (6.631 on the following page)
Realistic	Applies the **Realistic** visual style. (6.632 on the next page)
Conceptual	Applies the **Conceptual** visual style. (6.633 on page 3895)
Mechanical	Applies the **Mechanical** visual style. (6.634 on page 3895)
Modeling	Applies the **Modeling** visual style. (6.635 on page 3896)
High Quality	Applies the **High Quality** visual style. (6.636 on page 3896)
By Name	Applies a named visual style.

Related Commands

Hide (6.16.9) - removes hidden lines from 3D entities. 6.8.31 BmReplace

(6.2673 on page 5786) Replaces a component insert.

Accessing the Command

 command bar: **bmreplace** menu bar: **Assembly | Replace Component** toolbar: **Assembly | Replace Component** ribbon:

- **Home | Assembly | Replace Component**
- **Assembly | Modify | Replace Component**

Quad cursor menu: **Model | Replace Component** : **bmreplace Prompts you in the command bar.** Select component inserts to be replaced: **(Select an insert in the drawing.)** Entities in set: 1 Select component inserts [SIMilar inserts/component Type]: **(Select an insert in the drawing or press Enter.)** Select component insert to use as a replacement [SIMilar inserts/component Type/Parameter changes/from FIle] <from FIle>: **(Select component insert, an option, or press Enter.)** A File dialog displays: ===ERROR WITH DOWNLOADED IMAGE=== Select a file, then double click or click the Open button.

Command Options

Option	Description
SIMilar inserts	Allows to replace similar inserts automatically. Prompts you: **Replace file for all similar inserts** [Yes/No] <Yes>: • Yes: Replaces all similar inserts of the selected mechanical component(s) in assembly. • No: Replaces the selected component(s) only.
component Type	Allows to choose the insertion type for a replacement component. See External and local components (1.30.25) in the User Guide. Prompts you: **Component type** [Local/External/Keep as is/component Default] <component Default>: - Choose an option or press Enter. • Local: the new component will be local. • External: the new component will be external. • Keep as is: the new component inherits the insertion type from the replaced component. • Component Default: the new component will be linked as specified in its source file.

Parameter changes	Allows to control which parameter values will be used after the replacement is complete. Prompts you: **Reapply changes of parameters for the component being replaced?** [Yes-reapply/No-use replacement as is] <Yes-reapply>: - Choose an option or press Enter. • Yes-reapply: parameter values of the replaced component are applied. • No-use replacement as is: parameter values of the replacement component are applied.
from FIle	Allows to select a .dwg file for the replacement component.

Related Commands

BmExternalize (6.8.11) - converts local components to external components. BmOpen (6.8.21) - opens the source drawing of an external mechanical component.

6.9 C

6.9.1 Camera

(7.3 on page 6132) Places camera glyphs in drawings that point at target points, and creates named views.

Figure 6.645

Accessing the Command

 command bar: **camera** menu bar: **View | Camera** toolbar: **View |** ribbon: **View | View | Viewpoint | Camera :camera You are prompted:** Specify camera location: **(Enter a point to specify the location of the camera)** Specify target location: **(Enter a point to specify the location of the target, the point at which the camera looks)** Enter an option [?/Name/LOcation/Height/Target/LEns/CLipping/View/eXit] <eXit>: **(Enter an option, or else press Enter to conclude the command)** A camera glyph displays in the drawing to indicate the position of the

camera. Named views are saved with the drawing, named after the cameras, which are accessed by the **View (6.31.2)** command.

Command Options

Option	Description
?	Displays a list of existing cameras. Prompts you: **Enter camera name(s) to list <*> - (do one of the following)**: • Press Enter to list all existing cameras. • Use wildcards to (* or ?) list a selection of cameras. For example, Cam* lists all cameras names that start with 'cam' and ?a* lists all camera names of which the second letter is 'a'
Name	Names the new camera; prompts you: **Enter name for new camera <Camera1> - (type a name for the saved view, or else press Enter to accept the default name).**
Location	Positions the camera. Prompts you: **Specify camera location <x,y,z> - (do one of the following):** • Pick a point in the drawing • Type the x, y, z coordinates in the command bar, then press Enter.
Height	Sets the height (z coordinate) of the camera; prompts you: **Specify camera height <current height> - (enter a value).**
Target	Positions the target, the point at which the camera looks. Prompts you: **Specify target location <x,y,z> - (one of the following):** • Pick a point in the drawing. • Type the x-, y- and z-coordinates in the command bar, then press Enter.
Lens	Defines the lens length. Prompts you: **Specify lens length in mm <50.00> - (Enter a value).** A smaller number, such as 20, provides a wider field of view, while a higher number, such as 200, provides a closer look, like a zoom lens on a camera.

Clipping	Defines the front and back clipping planes, which cut off the view. Prompts you: 1. **Enable front clipping plane? Yes/<No> - (type Y to define the front clipping plane)**. Prompts you: 2. **Specify front clipping plane offset from target plane <0.00> -(do one of the following):** • Pick a point in the drawing. • Type a value in the command bar, then press Enter 3. **Enable back clipping plane? Yes/<No> - (type Y to define the back clipping plane).** Prompts you: 4. **Specify back clipping plane offset from target plane <0.00> - (do one of the following)**: • Pick to point in the drawing. • Type a value in the command bar, then press Enter
View	Sets the camera view current. Prompts you: **Switch to camera view? Yes/<No> - (type Y , then press Enter).**
Exit	Exits the command, and then creates the camera.

Editing a Camera

Properties of a camera view can be edited:

- In the dialog box displayed by the View (6.31.2) command. (6.646 on the next page)
- In the Properties (6.24.54) bar: Select the camera glyph in the drawing. (6.647 on the following page)

Figure 6.646

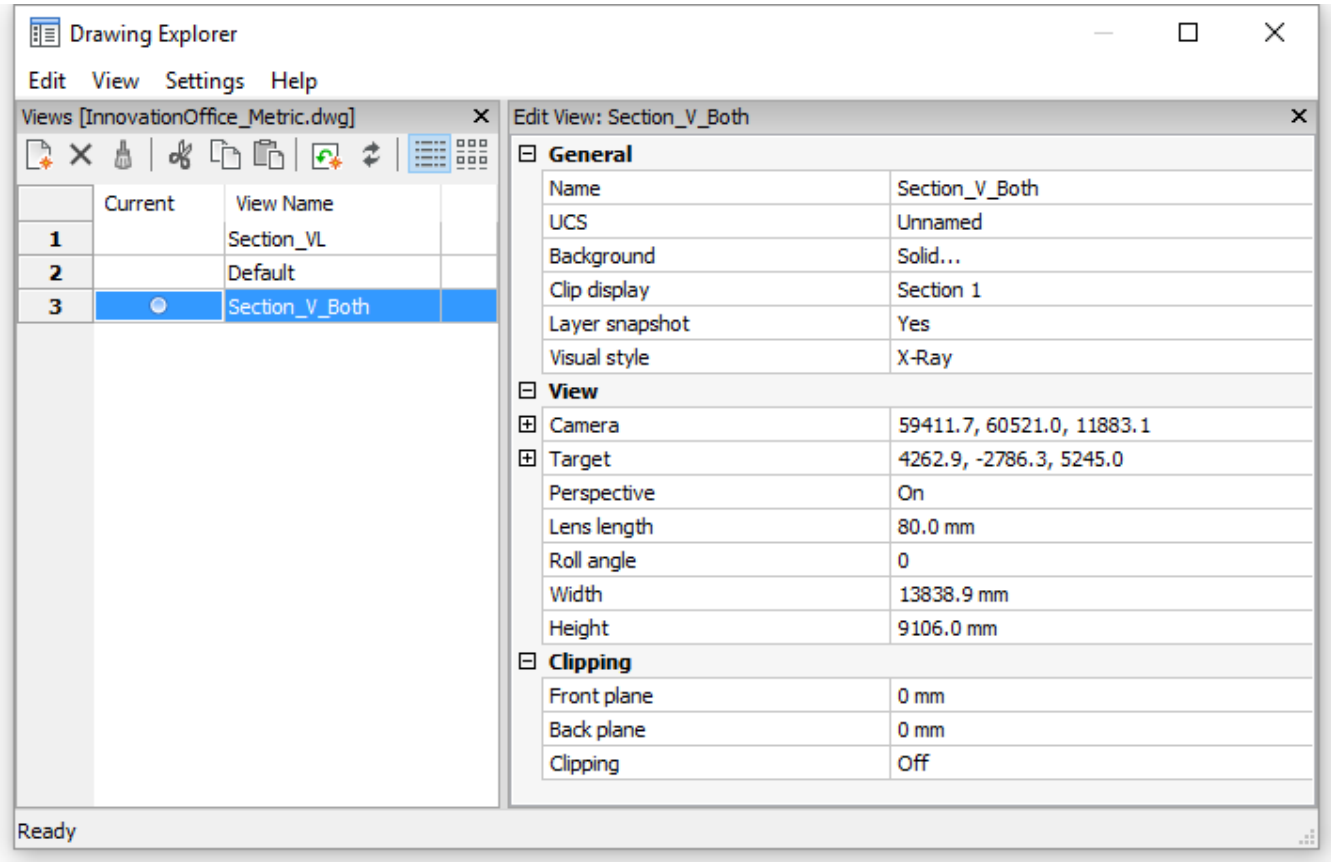

Figure 6.647

Camera	
Name	Camera 1
Camera	-422.40, -2318.27, 0.00
X	-422.40
Y	-2318.27
Z	0.00
Target	5551.65, -2396.75, 0.00
X	5551.65
Y	-2396.75
Z	0.00
Lens Length	50.00
Field of view	38°34'48"
Roll angle	0°0'0"
Plot glyph	No
Clipping	
Front plane	4500.00
Back plane	1000.00
Clipping	Front and back on

Grips Editing

Cameras can be edited directly through grips:

1. Select the camera glyph in the drawing. Notice that it has three grips. Front (F) and back (B) clipping planes display in a blue dotted line.
2. Drag the grips to perform the following actions:
   - Position the camera (1).
   - Move the camera definition as a whole (2).
   - Position the target (3).

(6.648 on the next page)

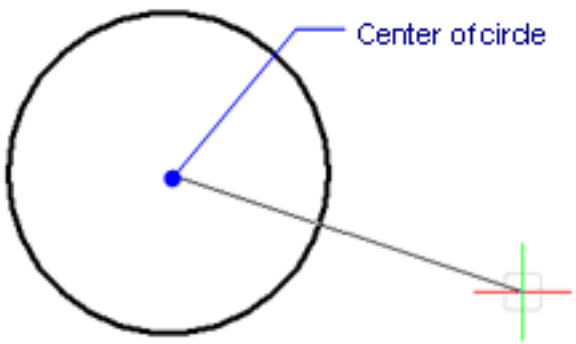
6.9.3 Center

(6.2981 on page 6079) Toggles Center entity snap; snaps to the center of circles, arcs, and other entities with a circular curve.

Accessing the Command

command bar: **center** transparent: **cen** toolbar: **Entity Snaps |** ribbon: **Home | Entity Snaps | Snap to Center : center** Displays no prompts in the command bar. Each time you enter the command, the program toggles the Center entity snap mode between on and off. (6.1788 on page 5005) When center entity snap is on, the cursor snaps to the center points of curved entities, such as circles, arcs, and polyarcs.

Figure 6.653



Command Options

Option	Description
Center	Entering the command toggles Center entity snap. This command can be entered transparently during commands, but must be entered without the apostrophe prefix (').

Related Commands

OSnap (6.23.16) - toggles entity snap modes in the Settings dialog box. -OSnap (6.23.13) - toggles entity snap modes in the command bar. Aperture (6.4.14) - sizes the aperture cursor for entity snaps. 2dIntersection (6.2.1) - toggles apparent intersection snap mode. 3dIntersection (6.3.7) - toggles intersection snap mode. Apparent (6.4.16) - toggles apparent intersection snap mode. Endpoint (6.13.7) - toggles endpoint snap mode. Extension (6.13.22) - toggles extension snap mode. From (6.14.13) - allows to enter relative coordinates with respect to a reference point. GCenter (6.15.5) - toggles Geometric Center (GCenter) entity snap. Insertion (6.17.18) - toggles insertion snap mode. Intersection (6.17.19) - toggles intersection snap mode. Midpoint (6.21.16) - toggles midpoint snap mode. Mtp (6.21.35) - allows to specify a point as the midpoint between two points. Nearest (6.22.2) - toggles nearest snap mode. Node (6.22.7) - toggles node (point) snap mode. None (6.22.8) - turns off all entity snap modes. Parallel (6.24.5) - toggles parallel snap mode. Perpendicular (6.24.25) - toggles perpendicular snap mode. Quadrant (6.25.7) - toggles quadrant snap mode. Tangent (6.29.10) - toggles tangent snap mode.

Figure 6.654

6.9.4 CenterDisassociate

(6.2981 on page 6079) Breaks the association of centerline and center mark entities with the associated entities, such as lines, arcs, and circles.

Accessing the Command

command bar: **centerdisassociate** menu bar: **Dimension | Center Marks and Lines | Center Disassociate** toolbar: **Dimensions | Center Marks and Lines | Center Disassociate** ribbon: **Annotate | Dimensions | Center Disassociate : centerdisassociate You are prompted in the command bar:** Select a center mark or centerline to disassociate: **(Select a center mark or centerline entity)** Entities in set: 1 Select a center mark or centerline to disassociate: **(Select a center mark or centerline entity, or else press Enter)**

Command Options

Option	Description
Select a center mark or centerline to disassociate	Selects a center mark or centerline to disassociate from the associated entity(ies), such as circles, arcs, or lines The command repeats automatically, so press Enter to end it.

Related Commands

CenterLine (6.9.5) - creates a centerline entity associated with two selected lines. CenterMark (6.9.6) - creates a center mark entity associated with a selected circle or arc. CenterReassociate (6.9.7) - recreates the association between a centerline entity and two selected lines, or between a center mark and a selected circle or arc. CenterReset (6.9.8) - resets centerline and center mark entities.

Figure 6.655

6.9.5 CenterLine

(6.2981 on page 6079) Creates a centerline associated with two selected lines or polyline segments.

Accessing the Command

command bar: **centerline** alias: **cl** menu bar: **Dimension | Center Marks and Lines | Centerline** toolbar: **Dimensions | Center Marks and Lines | Centerline** ribbon:

- **Home | Annotate | Centerline**
- **Annotate | Dimensions | Centerline**

: centerline You are prompted in the command bar: Select first line: **(Select a line entity)** Select second line: **(Select another line entity)** (6.656) When applying a centerline to the intersection of two lines, the location of the picked points determine the direction of the centerline. (6.657 on the facing page)

Figure 6.656

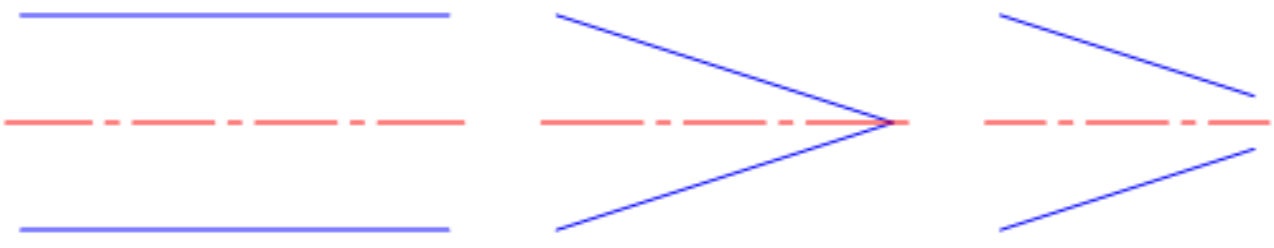


Figure 6.657

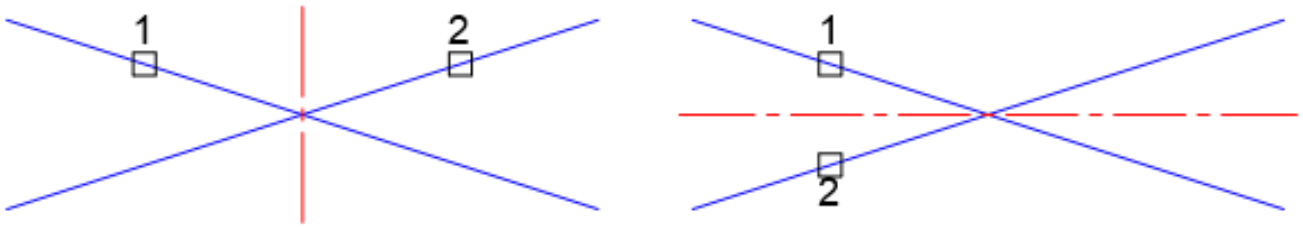

Command Options

Option	Description
Select first line	Select a line or polyline segment
Select second line	Select another line or polyline segment

The lines and polyline segments can be selected inside blocks and in drawing view viewports. You can pick two segments of the same polyline. The centerline is associative, so when one or both lines are moved, the centerline repositions itself.

Procedures

Center lines and center marks (1.29.10)

Grips Editing

Centerlines can be edited through grips. (6.658)

- 1: Overshoot grips: drag the grip to lengthen the centerline
- 2: Midpoint grip: drag the grip to move the centerline*.

When an extension is applied to one or both ends of the centerline by dragging an overshoot grip, four grips display. (6.659 on the following page)

- 3: Overshoot grips: drag the grip to lengthen the centerline
- 4: Midpoint of the original centerline; drag the grip to move the centerline*.
- 5: Midpoint of the extended centerline; drag the grip to move the centerline*.

*Use the CenterReset (6.9.8) command to reset the centerline.

Figure 6.658

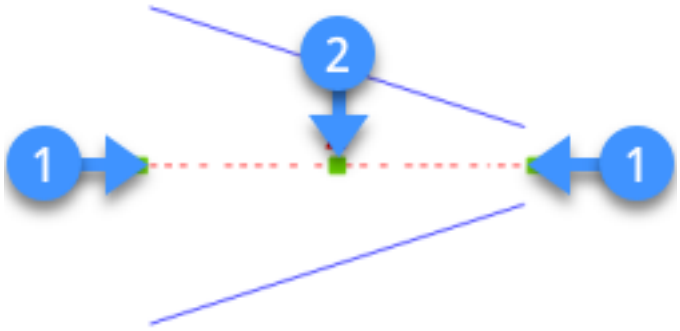

Figure 6.659

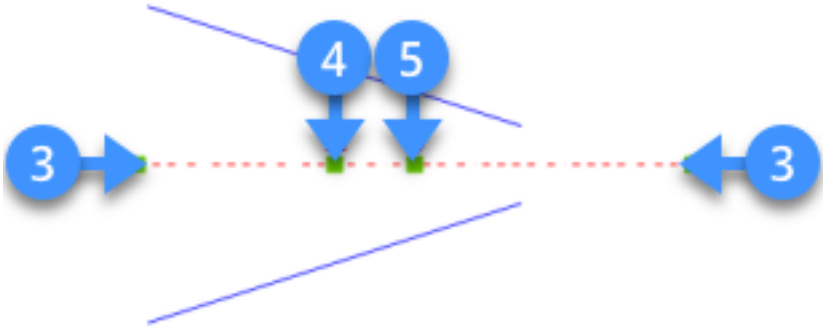


Related Commands

CenterDisassociate (6.9.4) - breaks the association of centerline and a center mark entities. CenterMark (6.9.6) - creates a center mark entity associated with a selected circle or arc. CenterReassociate (6.9.7) - recreates the association between a centerline entity and two selected lines, or between a center mark and a selected circle or arc. CenterReset (6.9.8) - resets centerline and center mark entities.

Figure 6.660

6.9.6 CenterMark

(6.2981 on page 6079) Creates a center mark entity associated with a selected circle, arc, or polyline arc.

Accessing the Command

command bar: **centermark** alias: **cm** menu bar: **Dimension | Center Marks and Lines | Center Mark** toolbar: **Dimensions | Center Marks and Lines | Center Mark** ribbon:

- **Home | Annotate | Center Mark**
- **Annotate | Dimensions | Center Mark**

: centermark You are prompted in the command bar: Select circle or arc: **(Select a circle or a circular arc.)** Depending on the current value of the CENTERMARKEXE system variable, the center mark is drawn with or without extension lines.

(6.662 on the following page)
Center mark only (CENTERMARKEXE = OFF)
(6.663 on page 3925)
Center mark with extension lines (CENTERMARKEXE = ON)

Command Options

Option	Description
Select circle or arc	Select a circle, an arc, or a polyarc segment, which can be selected inside blocks and in drawing view viewports.

The centermark is associative, so when the arc or circle is moved, the centermark repositions itself.

Procedures

- Center lines and center marks (1.29.10)

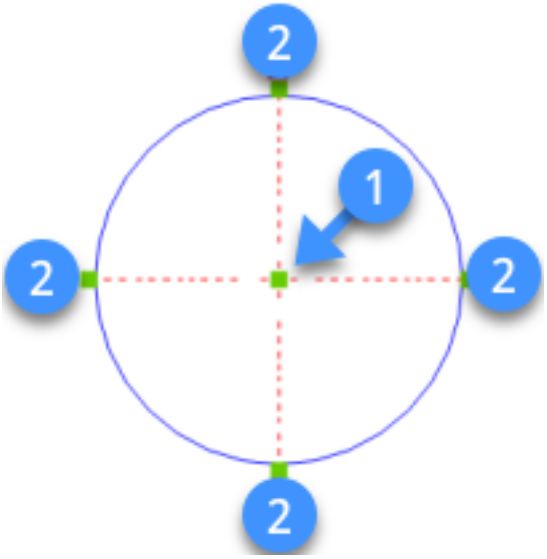
Grips Editing

Center marks can be edited through grips. (6.661 on the following page)

1. Center grip: drag the grip to move the center mark*.
2. Overshoot grips: drag the grip to lengthen the extension line**.

*Use the CenterReset (6.9.8) command to reset the centerline. **If you lengthen an extension line, it loses its associativity, and so changing the diameter does not adjust the changed extension line. It will, however, still moved along with a circle.

Figure 6.661



Related Commands

DimCenter (6.11.7) - places non-associative center marks at the center points of circles and arcs. CenterDisassociate (6.9.4) - breaks the association of centerline and a center mark entities. CenterLine (6.9.5) - creates a centerline entity associated with two selected lines. CenterReassociate (6.9.7) - recreates the association between a centerline entity and two selected lines, or between a center mark and a selected circle or arc. CenterReset (6.9.8) - resets centerline and center mark entities.

Figure 6.662

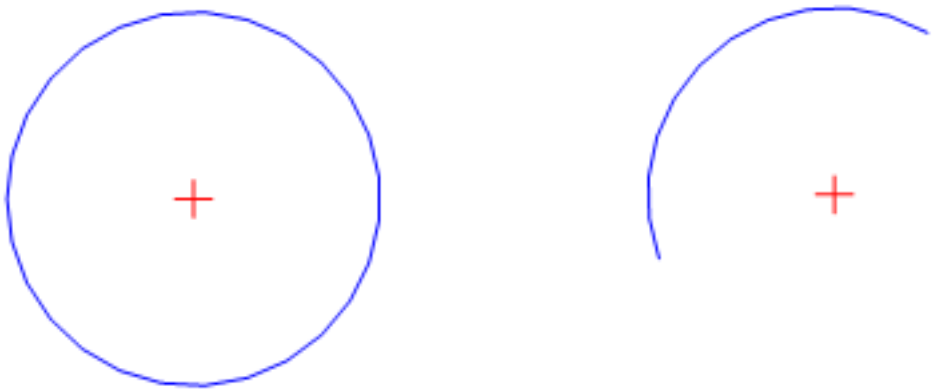


Figure 6.663

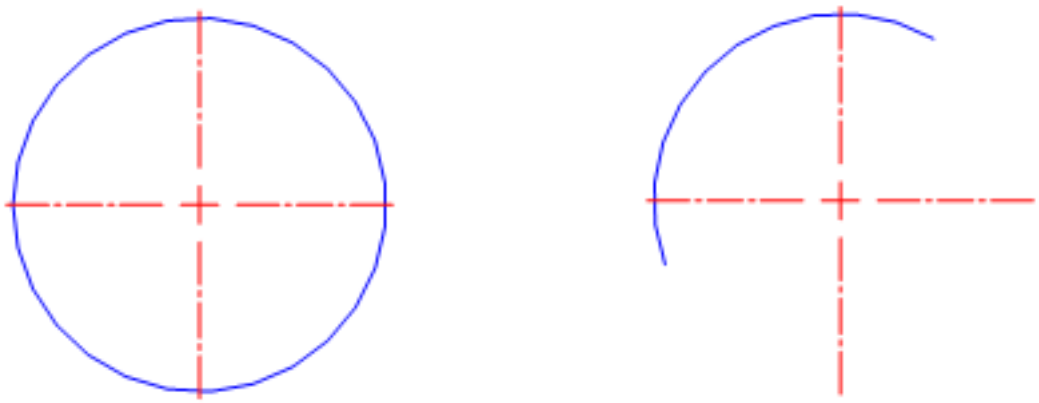

Figure 6.664

6.9.7 CenterReassociate

(6.2981 on page 6079) Associates a centerline entity with two selected lines, or else a center mark with a circle, arc, or polyarc.

Accessing the Command

command bar: **centerreassociate** menu bar: **Dimension | Center Marks and Lines | Center Reassociate** toolbar: **Dimensions | Center Marks and Lines | Center Reassociate** ribbon: **Annotate | Dimensions | Center Reassociate : centerreassociate You are prompted:** Select a center mark or centerline to reassociate: **(Select a center mark or centerline entity)** When you select a center mark, **prompts you:** Select circle or arc: **(Select a circle, circular arc, or polyarc)** When you select a centerline, **prompts you instead:** Select first line: **(Select a line entity)** Select second line: **(Select another line entity)**

Command Options

Option	Description
Select a center mark or centerline to reassociate	Selects the center mark or a centerline to associate with entities; prompts you: • When you select a center mark, prompts you, **Select circle or arc** - **(select a circle, circular arc, or polyarc)** • When you select a centerline, prompts you instead **Select first line** - **(select a line entity)**, and then prompts you **Select second line:** - **(select another line entity)**

Related Commands

CenterDisassociate (6.9.4) - breaks the association of centerline and a center mark entities. CenterLine (6.9.5) - creates a centerline entity associated with two selected lines. CenterMark (6.9.6) - creates a center mark entity associated with a selected circle or arc. CenterReset (6.9.8) - resets centerline and center mark entities.

Figure 6.665

6.9.8 CenterReset

(6.2981 on page 6079) Resets centerline and center mark entities.

Accessing the Command

command bar: **centerreset** menu bar: **Dimension | Center Marks and Lines | Center Reset** toolbar: **Dimensions | Center Marks and Lines | Center Reset** ribbon: **Annotate | Dimensions | Center Reset : centerreset You are prompted in the command bar:** Select a center mark or centerline to reset: **(Select a center mark or centerline entity)** Entities in set: 1 Select a center mark or centerline to reset: **(Select a center mark or centerline entity, or else press Enter)**

Command Options

Option	Description
Select a center mark or centerline to reset	Select a center mark or centerline entity, or else press Enter to end the command

Centerlines are reset by the program when one of the associated lines is moved. Center marks are reset automatically when the associated circle or arc is moved or when the their radius or diameter is modified.

Related Commands

CenterDisassociate (6.9.4) - breaks the association of centerline and a center mark entities. CenterLine (6.9.5) - creates a centerline entity associated with two selected lines. CenterMark (6.9.6) - creates a center mark entity associated with a selected circle or arc. CenterReassociate (6.9.7) - recreates the association between a centerline entity and two selected lines, or between a center mark and a selected circle or arc.

Figure 6.666

Shape Classic Pro Platinum Mechanical BIM

6.9.9 Chamfer

(7.3 on page 6132) Creates chamfers at intersections, defined by two lengths, or a length and an angle.

Accessing the Command

command bar: **chamfer** alias: **cha** menu bar: **Modify | Chamfer** toolbar: **Modify |**  ribbon: **Change | Modify | Chamfer : chamfer You are prompted:** Chamfer (dist1=0, dist2=0) Select first entity [Chamfer Settings... /Polyline/ Angle/ Distance/ mEthod/Trim/Undo/Multiple]: **(Select an entity, or else enter an option)** Select second entity (select with pressed SHIFT to make corner): **(Select another entity)** Chamfered intersection: (6.667) Chamfered polyline: (6.668 on the next page)

Figure 6.667

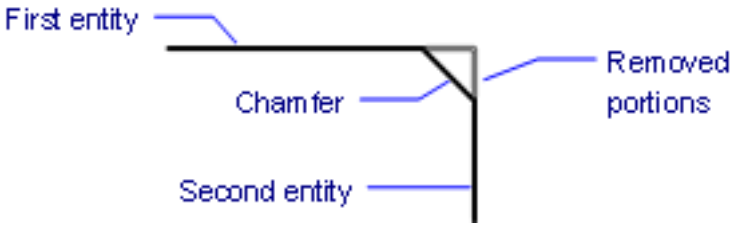

Figure 6.668

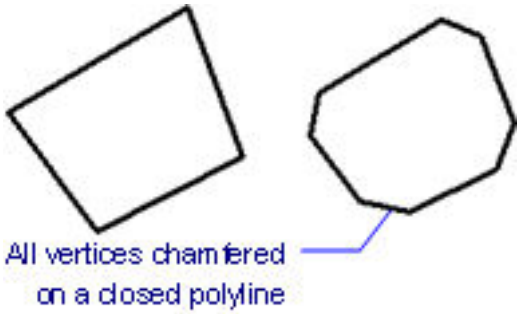


Command Options

Option	Description
Select first entity	Selects the first entity to be chamfered. Only open entities can be chamfered, with one exception: vertices of closed polylines can be chamfered with the **Polyline** option. This command cannot place a chamfer between two polylines,but it can place a chamfer between a line and a polyline, even a closed polyline.
Select second entity	Selects the second entity. The two entities need not meet, but cannot be parallel to each other. To connect connect both entities without creating a chamfer, hold the **Shift** key when selecting the second entity; this acts like a combined Trim-Extend command.
Settings	Displays the Settings (1.17.10) dialog box for setting chamfer parameters.
Polyline	Chamfers the vertices of a polyline; prompts you: **Select 2D polyline to chamfer** - **(Select a polyline with at least one vertex)**
Angle	Changes to the Length-Angle method of determining the chamfer line; prompts you: 1. **Length on first entity <0>** - **(specify a length, or pick two points, or else press Enter to accept the default)** 2. **Angle relative to first entity <0>** - **(specify an angle, or pick two points, or else press Enter to accept the default)** When you pick two points to specify the angle, the program measures the angle from 0 degrees, the x axis.
Distance	Changes to the Distance-Distance method of determining the chamfer line; prompts you: 1. **Chamfer distance on first entity <0>** - **(specify a length, or pick two points, or else press Enter to accept the default)** 2. **Chamfer distance on second entity <0>** - **(specify an length, or pick two points, or else press Enter to accept the default)**

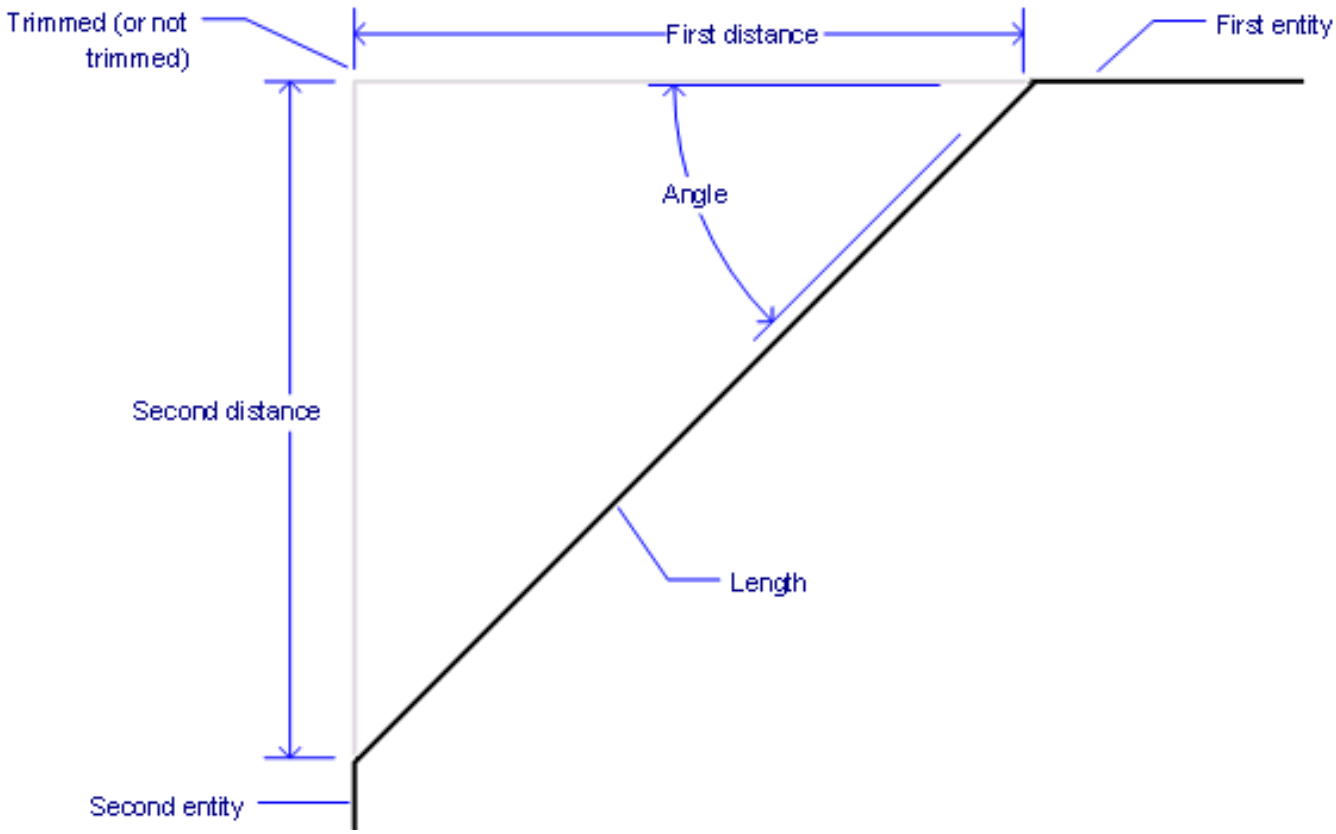
Method	Switches between Length-Angle and Distance-Distance modes; remember to enter an **e** for the this option's abbreviation, and not an **m**. Prompts you: Chamfer using [Angle/Distance] <Distance> - **(enter an option)**: • **Angle** - changes to the Length-Angle method of determining the chamfer line • **Distance** - changes to the Distance-Distance method of determining the chamfer line The program will keep using the same method for determining the chamfer until you change it again.
Trim	Determines if the program trims the entities; prompts you: **[Trim/No] <Trim>** - **(choose an option or press Enter to keep the current mode):** • **Trim** - trims or extends the selected entities to meet the chamfer line • **No** - creates the chamfer and leaves the selected entities unchanged
Undo	Undoes the last chamfer when in Multiple mode.
Multiple	Lets you create multiple chamfers using the same settings over and over again; press **Esc** to exit the command.

Settings

(6.669 on the facing page)

Setting	**Description**
Chamfer Mode	Determines how the chamfer is created: • **Distance-Distance** - specify two distances. • **Length-Angle** - specify a length and an angle.
Chamfer First Distance	Specifies the default value of the first chamfer distance.
Chamfer Second Distance	Specifies the default value of the second distance.
Chamfer Length	Specifies the default length of the chamfer.
Chamfer Angle	Specifies the default angle of the chamfer.
Trim Mode	Toggles whether intersecting entities are trimmed: • **Yes** - trims or extends entities to the chamfer line. • **No** - does not trim intersecting entities.

Figure 6.669



Procedures

- Chamfering using the distance-distance method (1.32.27)
- Chamfering using the length-angle method (1.32.27)
- Chamfering all vertices of a polyline (1.32.27)

Related Commands

Break (6.6.21) - cuts parts out of entities. dmChamfer (6.12.4) - creates an equal distance chamfer between adjacent faces sharing a sharp edge. dmFillet (6.12.13) - creates a smooth fillet between adjacent faces sharing a sharp edge. Extend (6.13.21) - extends open entities to a boundary. Fillet (6.14.6) - fillets intersections. Settings (6.27.25) - specifies parameters for chamfers. SolidEdit (6.27.42) - edits faces, edges, and bodies of solid models. Trim (6.29.35) - trims entities where they cross other entities.

Figure 6.670

6.9.10 Change

(7.3 on page 6132) Changes the properties of entities, through the command bar. This command has largely been superseded by the Properties panel.

Accessing the Command

command bar: **change** alias: **-ch : change You are prompted:** Select entities to change: **(Choose one or more entities)** Entities in set: xx Select entities to change: **(Press Enter to end entity selection)** Change point [special Entities/Properties...]: **(Enter an option, or specify a new endpoint)** When you enter **P** at the prompt: Property to change [Color/Elevation/LAyer/LineType/linetype Scale/Line Weight/Thickness/TRansparency/Material/Annotative]: **(Enter an option, or press Enter to exit the command)**

Command Options

Option	Description
Select entities to change	Choose one or more entities in the drawing.
Special Entities	Specifies options for changing the properties of rays and infinite lines (xlines): **Point change for Rays and Infinite Lines affects [Angles/Points/None] <No change>** - **(enter an option)**: • **Angles** - changes the angle. • **Points** - changes the location of the points defining the rays and infinite lines. • **None** - leaves entities unchanged.
Properties Options	
Color	Changes the color of the entity; prompts you: **New color** - **(enter the name or number of a color.)** See **Color (6.9.19)** command.
Elevation	Changes the elevation (z coordinate); prompts you: **New elevation** - **(enter a positive or negative number change the elevation above the x,y-plane)**. See **Elev (6.13.4)** command.
LAyer	Changes the layer to which the entities are assigned; layer name must exist in the drawing. Prompts you: **New layer** - **(enter the name of a layer).** See **Layer (6.13.17)** command.
LType	Changes the linetype; linetype must be loaded into the drawing. Prompts you: **New linetype** - **(enter the name of a linetype).** See **Linetype (6.20.32)** command.
ltScale	Changes the linetype scale; prompts you: **New linetype scale** - **(enter a number)**. See **LtScale** system variable.
LWeight	Changes the lineweight; prompts you: **Enter new lineweight** - **(enter a lineweight unit)**. See **LWeight (6.20.42)** command.
Thickness	Changes the thickness; prompts you: **New thickness** - **(enter a positive or negative number.)** See Elev (6.13.4) command.

Transparency	Changes the transparency; prompts you: **New transparency <ByLayer>** - **(enter a value between 0 and 90)**
Material	Applies a material; prompts you: **New material <ByLayer>** - **(enter the name of a material).** See the Material (6.21.10) command.
Annotative	Sets the annotative property; prompts you: **Make Annotative?[Yes/No] <No>** - **(enter Yes or No).**
Change Point	Changes the size of the entity, depending on what the entity is: • **Lines** - moves the endpoint closest to the pick point • **Arcs** - changes the length closest to the pick point • **Circles** - changes the diameter • **Text** - moves the text • **Blocks** - moves the block This option has no effect on polylines.

Procedures

- To change text entities (1.32.16)
- To relocate blocks (1.32.16)

Related Commands

ChProp (6.9.11) - changes the properties of entities in the command bar. LayCur (6.20.2) - moves the selected entities to the current layer. Properties (6.24.54) - changes the properties and sizes of entities in a palette.

Figure 6.671

6.9.11 ChProp

(7.3 on page 6132) Changes the properties of entities, with fewer options than the Change command (short for "change properties.") This command is largely superseded by the Properties panel.

Accessing the Command

command bar: **chprop : chprop You are prompted:** Select entities to change: **(Choose one or more entities)** Select entities to change: **(Press Enter to end entity selection)** Property to change [Color/LAyer/LType/ltScale/LWeight/Thickness/T **(Enter an option, or else press Enter to exit the command)**

Command Options

Option	Description
Select entities to change	Choose one or more entities in the drawing.
Color	Changes the color of the entity; prompts you: **New color - (enter the name or number of a color)**. See **Color (6.9.19)** command.
Elevation	Changes the elevation (z coordinate); prompts you: **New elevation - (enter a positive or negative number change the elevation above the x,y-plane)**. See **Elev (6.13.4)** command.
LAyer	Changes the layer to which the entities are assigned; layer name must exist in the drawing. Prompts you: **New layer - (enter the name of a layer).** See **Layer (6.13.17)** command.
LType	Changes the linetype; linetype must be loaded into the drawing. Prompts you: **New linetype - (enter the name of a linetype).** See **Linetype (6.20.32)** command.
ltScale	Changes the linetype scale; prompts you: **New linetype scale - (enter a number)**. See **LtScale** system variable.
LWeight	Changes the lineweight; prompts you: **Enter new lineweight - (enter a lineweight unit).** See **LWeight (6.20.42)** command.
Thickness	Changes the thickness; prompts you: **New thickness - (enter a positive or negative number)**. See Elev (6.13.4) command.
Transparency	Changes the transparency; prompts you: **New transparency <ByLayer> - (enter a value between 0 and 90)**
Material	Applies a material; prompts you: **New material <ByLayer> - (enter the name of a material)**. See the Material (6.21.10) command.
Annotative	Sets the annotative property; prompts you: **Make Annotative?[Yes/No] <No> - (enter Yes or No)**.

Related Commands

Change (6.9.10) - changes the properties and sizes of entities in the command bar. LayCur (6.20.2) - moves the selected entities to the current layer. Properties (6.24.54) - changes the properties and sizes of entities in a palette.

Figure 6.672

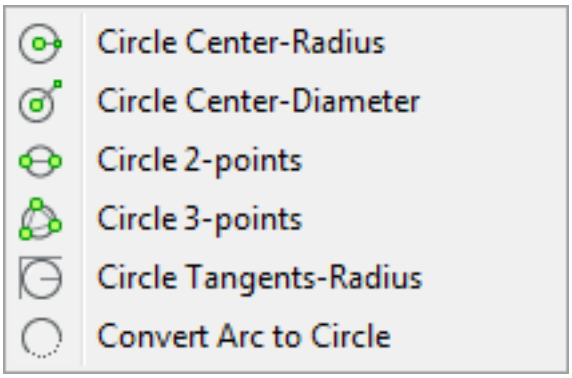
6.9.12 Circle

(7.3 on page 6132) This command draws circles by two points, three points, and by tangent, tangent, and radius; it also converts arcs to circles.

Accessing the Command

command bar: **circle** alias: **c** menu bar: **Draw | Circle** toolbar: **Draw |** ribbon: **Draw | Draw | Circles** : **circle** **You are prompted:** Select center of circle or [2Point/3Point/TTR/Arc/Multiple]: **(Pick a point, or enter an option)** Set Radius or [Diameter] <x.xx>: **(Pick a point, enter a distance, or type D to define the diameter)** The complete list of circle drawing methods is summarized by the Draw | Circle menu: (6.673) In the icons, the larger green dot indicates the starting point, the smaller green dots the additional pick points. When an icon has all small dots, then the pick order does not matter.

Figure 6.673



Command Options

Option	Description
Select center of circle (6.675 on page 3938)	**Specifies the center of the circle:** • Enter x,y,z coordinates • Pick a point in the drawing The z coordinate is rarely entered, so most often you enter x,y coordinates.
Diameter	After you pick the center point, this prompt asks you to specifies the diameter of the circle: **Diameter of circle - (enter a distance, coordinates, or pick a point)**
Set Radius	After you pick the center point, this prompt asks you to specify the radius of the circle: **Radius of circle - (enter a distance, coordinates, or pick a point)**
2Point (6.676 on page 3939)	Defines the circle by two points that you pick on its circumference; prompts you: 1. **First point on diameter - (enter coordinates, or pick a point)** 2. **Second point on diameter - (enter coordinates, or pick another point)** The abbreviation for this option is 2P.
3Point (6.677 on page 3939)	Defines the circle by three points that you pick on its circumference; prompts you: 1. **First point on circle - (enter coordinates, or pick a point)** 2. **Second point - (enter coordinates, or pick another point)** 3. **Third point - (enter coordinates, or pick another point)** The abbreviation for this option is 3P.
RadTanTan (6.678 on page 3939)	Defines the circle by two points that are tangent to other entities, along with the radius. A **tangent** is where a circle touches another entity. The **Tangent (6.29.10)** entity snap is activated automatically during the first two prompts: 1. **Select first tangent point - (enter coordinates, or pick an entity)** 2. **Select second tangent point - (enter coordinates, or pick another entity)** 3. **Radius of circle - (specify a distance, or pick two points)** The abbreviation for this option is RTT.
Arc	Converts arcs to circles by closing them; prompts you: **Select arc to convert to circle - (Choose an arc)**
Multiple	Repeats the command until you press **Esc**.

Procedures

- General procedure to draw a circle (1.25.14)

- Editing a circle (1.25.14)

Grips Editing

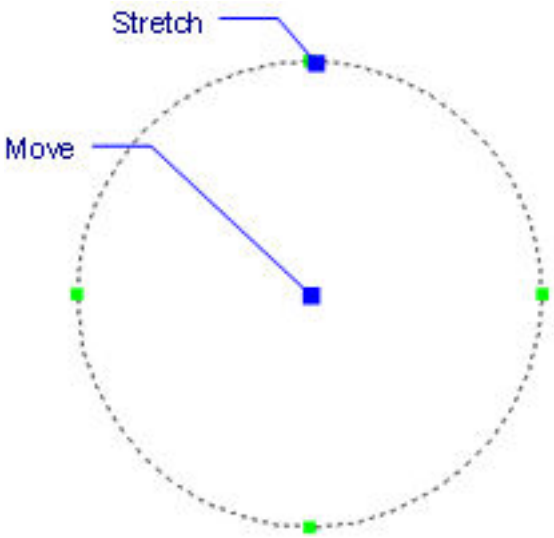
Circles can be edited directly through grips:

1. Select the circle. Notice that it has five grips.
2. Drag the grips to perform the following actions:

- Drag the quadrant grips to stretch the circle (increase and decrease the radius).
- Drag the center point grip to move the circle.

(6.674 on the next page)

Figure 6.674



Related Commands

Ai_CircTan (6.5.2) - draws a circle tangent to three entities. Arc (6.4.21) - draws arcs. Change (6.9.10) - changes the diameter of circles. Ellipse (6.13.5) - draws ellipses. Join (6.18.1) - joins arcs to create circles. Donut (6.10.37) - draws fat circles from polyline arcs. DimRadius (6.11.16) and DimDiameter (6.11.9) - dimensions circles. Center (6.9.3) - snaps to the center of circles. Quadrant (6.25.7) - snaps to the 90-degree points on the circumference of circles. Tangent (6.29.10) - snaps to the tangency of circles.

6.9.13 ChSpace

(6.2981 on page 6079) Moves entities from paper space to model space and vice versa (short for "change space").

Accessing the Command

The command applies to layouts only. command bar: **chspace** menu: **Modify | Change Space** **Note:** This command can only be used in a Layout Tab ('Paper Space'). This command operates in two modes:

Moving Entities from Paper Space to Model Space

Select the layout that contains the entities to be moved, and then enter the command: **: chspace You are prompted:** Select entities: **(Select an entity)** Entities in set: 1 Select entities: **(Select more entities, or else press Enter)** Select TARGET viewport and press ENTER to continue: **(Click inside a viewport, or press Enter to accept the currently selected viewport)** <number of objects> objects were moved from PAPER space to MODEL space. Objects were scaled to maintain visual appearance by a factor of <scale factor>. **Note:** The scale factor is the inverse of custom scale of the selected target viewport. For example, if the custom scale = 1/2 (0.5), then the scale factor = 2.

Moving Entities from Model Space to Paper Space

When in a layout, double-click a viewport in which the entities are that need to be moved, and then enter the command: **: chspace You are prompted:** Select entities: **(Select one or more entities)** Entities in set: 1 Select entities: **(Select more entities, or else press Enter to continue)** Select SOURCE viewport and press ENTER to continue: **(Click inside a viewport, or else press Enter to accept the currently selected viewport.)** <number of objects> objects were moved from MODEL space to PAPER space. Objects were scaled to maintain visual appearance by a factor of <scale factor> **Note:** The scale factor equals the custom scale of the selected source viewport.

Command Options

Option	Description
Select entities	Selects one or more entities to be moved from one space to the other. Press Enter to end entity selection.
Select TARGET viewport	Start in the source viewport in paper space, and then click the target in model space
Select SOURCE viewport	Start in the target viewport in model space, and then click the target in paper space

Related Commands

CopyClip (6.9.36) - copies entities to the Clipboard. CutClip (6.9.48) - copies entities to the Clipboard, and then erases them from the drawing. MSpace (6.21.32) - switches to model space. PasteClip (6.24.13) - pastes entities from the Clipboard into the drawing (short for "paste clipboard"). PSpace (6.24.59) - switches to paper space.

Figure 6.680

6.9.14 CleanScreenOff

(7.3 on page 6132) Displays user interface elements that were hidden by the **CleanScreenOn (6.9.17)** command.

Accessing the Command

command bar: **cleanscreenoff** keyboard:Ctrl + 0 (zero) menu bar: **View | Clean Screen** toolbar: **Standard |** quad: **General | Clean Screen**
Note: Do not use the numeric keypad. On AZERTY-keyboards: do not press the **Shift** key when hitting the number key. : **cleanscreenoff** Displays no prompts in the command bar.

Related Commands

CleanScreenOn (6.9.17) - hides elements of the user interface. CommandLine (6.9.25) - displays the command bar. CommandLineHide (6.9.21) - hides the command bar. Ribbon (6.26.32) - displays the ribbon. RibbonClose (6.26.49) - hides the ribbon. StatBar (6.27.51) - toggles the display of the status bar.

Figure 6.681

6.9.15 CleanUnusedVariables

(7.3 on page 6132) Purges parametric variables not used by constraint expressions and not linked to dimensions.

Accessing the Command

 command bar: **cleanunusedvariables** menu bar: **Parametric | Delete Unused Parameters** toolbar: **Parameters |**  ribbon: **Solids | 3D Constraints | Delete Parameter** : **cleanunusedvariables** When used parametric variables are cleaned, reports: **** 9 unused variables were removed** When no unused variables exist in the drawing, this message is displayed: **** No unused variables detected**

Related Commands

Parameters (6.24.6) - manages dimensional constraint parameters and user variables in the current drawing. Dimconstraint (6.10.30) - applies a dimensional constraint to an entity or between constraint points on entities; converts associative dimensions to dynamic dimensions. DcAligned (6.10.6) - constrains the distance between two points. DcAngular (6.10.7) - constrains the angle between two lines or linear polyline segments; the total angle of an arc or an arc polyline segment; or the angle between three points on entities. DcConvert (6.10.18) - converts an associative dimension to a dimensional constraint. DcDiameter (6.10.8) - constrains the diameter of a circle or an arc. DcHorizontal (6.10.10) - constrains the horizontal distance (X-distance) between two points with respect to the current coordinate system. DcLinear (6.10.12) - constrains the horizontal distance (X-distance) or vertical distance (Y-distance) between two points with respect to the current coordinate system. DcRadius (6.10.11) - constrains the radius of a circle or an arc. DcVertical (6.10.15) - constrains the vertical distance (Y-distance) between two points with respect to the current coordinate system. Delconstraint (6.10.26) - removes all dimensional and geometrical constraints from an entity.

Figure 6.682

6.9.16 Civil3DImport

(6.2880 on page 5977) Creates BricsCAD civil entities from an Autodesk® Civil 3D drawing.

Accessing the Command

Commandline: **CIVIL3DIMPORT : CIVIL3DIMPORT** Opens the Select Civil 3D files dialog box for you to select DWG files from which to import Civil 3D entities.

Related Commands

TinEdit (1.26.8) - Allows to add/remove boundaries, breaklines, and points to a surface. TinExtract (6.29.18) - Creates a mesh or 3D solid between TIN surfaces or between a TIN surface and elevation or vertical offset. TinMerge (6.29.22) - Combines two or more TIN surfaces (or gradings) into a new TIN surface. Tin Modify (6.29.23) - Easily deforms or smoothens a selected TIN surface. TinVolume (6.29.24) - Creates a TIN volume surface between a base and comparison TIN surfaces or an elevation.

Figure 6.683

6.9.17 CleanScreenOn

(7.3 on page 6132) Makes the drawing area larger by hiding elements of the user interface, as specified by the CLEANSCREENOPTIONS system variable.

Accessing the Command

 command bar: **cleanscreenoff** keyboard: Ctrl + 0 (zero) menu bar: **View | Clean Screen** toolbar: **Standard |** quad: **General | Clean Screen** Do not use the numeric keypad. On AZERTY-keyboards: do not press the Shift-key when hitting the number key. **: cleanscreenon** Displays no prompts in the command bar: Elements in the user interface are hidden according to the values of the Clean Screen Options section of the Settings dialog box: (6.684)

2	☑ Hide dockable panels
4	☑ Hide toolbars
8	☑ Hide ribbon
16	☑ Hide command line panel
32	☑ Hide status bar
64	☑ Hide menu bar

CleanScreenOptions Variable Options

Option	Description
Hide document tabs	The display of document tabs is controlled by the ShowDocTabs user preference. See Working with document tabs (1.15.2) in the User Guide.
Hide dockable panels	Hides all dockable panels, such as the Command Bar, BIM Compositions, Content Browser, Layers, Mechanical Browser, Properties Bar, Render Materials, Ribbon, Sheet Sets, Structure, Tool Palettes. These can be toggled independently of the ClearScreenOn command by the +Toolbars command. See the Dockable Panels (1.15.7) topic in the User Guide.
Hide toolbars	Hides all toolbars. See the Toolbars (1.15.7) topic in the User Guide.
Hide ribbon	Hides the ribbon, which can be turned on and off independently by the RIBBON (6.26.32) and RIBBONCLOSE (6.26.49) commands.
Hide command line panel	Hides the command bar, which can be turned on and off independently by the COMMANDLINE (6.9.25) and COMMANDLINEHIDE (6.9.21) commands.
Hide status bar	Hides the status bar, which can be turned on and off independently by the STATBAR (6.27.51) command. The current status of the status bar is saved through the WNDLSTAT system variable.
Hide menu bar	Hides the menu bar, which can be turned on and off independently by the MENUBAR system variable.

Related Commands

CleanScreenOff (6.9.14) - displays user interface elements that were hidden by the CleanScreenOn (6.9.17) command. CommandLine (6.9.25) - displays the command bar. CommandLineHide (6.9.21) - hides the command bar. Ribbon (6.26.32) - displays the ribbon. RibbonClose (6.26.49) - hides the ribbon. StatBar (6.27.51) - toggles the display of the status bar.

Figure 6.685

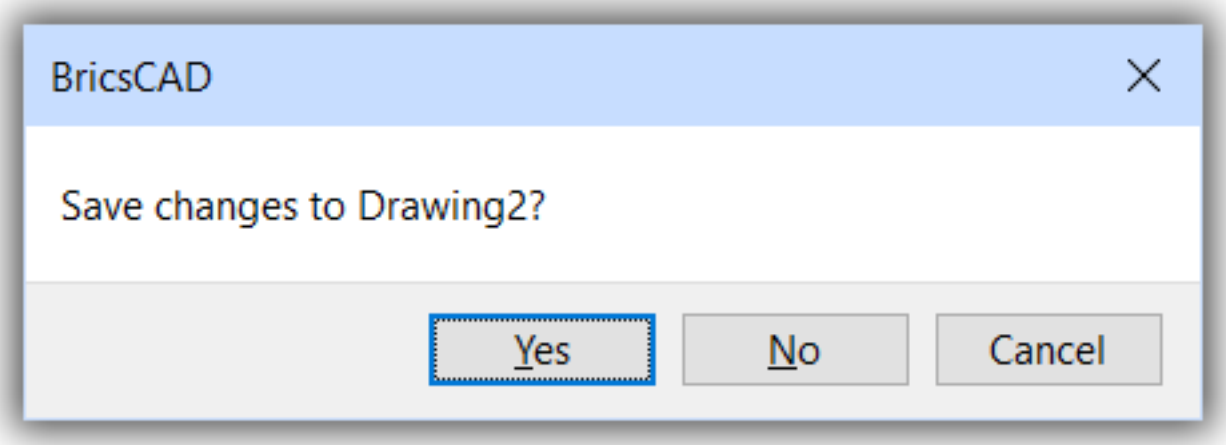
6.9.18 Close

(7.3 on page 6132) Closes the current drawing.

Accessing the Command

command bar: **close** keyboard shortcut: **Ctrl+F4** menu bar: **File | Close** : **close** If the drawing needs to be saved before closing, displays a dialog box: (6.686) Click the Yes, No, or Cancel button.

Figure 6.686



Command Options

Option	Description
Yes	Saves the drawing before closing it.
No	Does not save the drawing, and then closes it.
Cancel	Cancels the command and returns to the drawing.

Procedures

- Working with document tabs (1.15.2)

Related Commands

Open (6.23.8) - opens drawing files. WClose (6.33.7) - closes the current window. Quit (6.25.8) - exits BricsCAD after closing open drawings.

Figure 6.687

6.9.19 Color

(7.3 on page 6132) Specifies the current working color, through a dialog box.

Accessing the Command

 command bar: **color** transparent: **'color** aliases: **col, color, ddcolor, ddcolour, setcolor** menu bar: **Settings | Color | Select Color** toolbar: **Settings |**  status bar: **Color** field (**ByLayer or** ) ribbon: **Settings | Set Color** : **color** Displays a dialog box: (6.688 on the next page) Choose a color, and then click **OK**.

Command Options

Option	Description
Index Color tab	(6.691 on page 3952)
ByBlock	Sets the color to ByBlock, in which entities take on the color defined by their block.
ByLayer	Sets the color the ByLayer, in which entities take on the color defined by their layer's property.

Option	Description
True Color tab	(6.692 on page 3952)
Hue	Specifies the color's hue; range is from 0 to 240. (Hue is the color, ranging from red through green, blue, and pink.)
Saturation	Specifies the intensity of the color; range is from 0 to 240. (Saturation is the intensity of the color, where 0 = gray and 240 = full color.)
Luminosity	Specifies the brightness of the color; range is from 0 to 240. (Luminosity is the lightness or darkness, where 0 = black and 240 = white. Hue, saturation, and luminosity work together, while red, green, and blue work separately.)
Red	Specifies the amount of red in the color; range is from 0 (no red) to 255 (full red).
Green	Specifies the amount of green in the color; range is from 0 (no green) to 255 (full green).
Blue	Specifies the amount of blue in the color; range is from 0 (no blue) to 255 (full blue).

Status Bar Menu

Right-click ByLayer (or other color name) on the status bar for the shortcut menu: (6.2741 on page 5846) (6.695 on page 3954)

Option	Description
ByLayer, ByBlock, Red, et cetera	Chooses the default color.
Properties	Opens the Select Color dialog box.

Procedures

- To edit plot style tables (1.33.3)
- To manage plot styles (1.33.5)

Related Commands

ConvertPStyles (6.9.38) - converts drawings from CTB to STB plot styles. Layer (6.13.17) - assigns plot styles to layers. PageSetup (6.24.2) - assigns plot style to drawings. PlotStyle (6.24.28) - sets the current plot style. Print (6.25.2) - plots drawings with plot styles. Properties (6.24.54) - changes plot styles assigned to entities. StylesManager (6.27.57) - creates and attaches plot styles to drawings.

Figure 6.711

6.9.29 ConvertOldLights

(7.3 on page 6132) Converts the definitions old lights to that of the current format.

Accessing the Command

command bar: **convertoldlights : convertoldlights** The drawing is searched for old light definitions, which are then converted to the current format automatically. It may be necessary to check their properties (in case some may have changed) by editing the converted lights with the **LightList (6.20.36)** command.

Related Commands

Light (6.20.30) - creates a new light in the drawing. LightList (6.20.36) - displays the Drawing Explorer - Lights dialog window.

Figure 6.712

6.9.30 ConvertOldMaterials

(7.3 on page 6132) Converts old definitions of material to the that of the current format.

Accessing the Command

command bar: **convertoldmaterials : convertoldmaterials** The drawing is searched for old material definitions, which are then converted to the current format automatically. It might be necessary to edit the converted materials to check their settings with the **Materials (6.21.10)** command.

Related commands

Materials (6.21.10) - creates materials and edits their properties through the Drawing Explorer.

Figure 6.713

6.9.31 ConvertPoly

(6.2981 on page 6079) Converts 2D and 3D polylines between modern lightweight and classic polylines (heavyweight) definitions.

Accessing the Command

command bar: **convertpoly** transparent: **'convertpoly** menu bar: **Modify | Convert Polyline : convertpoly You are prompted:** Enter polyline conversion option [Heavy/Light/3dPoly] <Light>**: (Enter an option)** Select entities: **(Select one or more polylines in the drawing)** Entities in set: 2 Select entities: **(Select more polylines, or press else Enter to convert the selection)** 2 polyline objects converted.

Command Options

Option	Description
Light	Converts lightweight 2D polylines to classic, heavyweight polylines. This may be needed to make drawings compatible with certain software.
Heavy	Converts classic 2D polylines to lightweight ones.
3dPoly	Converts 3D polylines (The abbreviation for this option is 3P.)
Select entities	Select one or more polylines. The program ignores ineligible entities.

The primary benefit to using this command is to reduce the drawing file size by using lightweight polyline definitions. This command does not convert the following kinds of polylines:

- Curve-fit
- Splined polylines
- Polylines with extended object data stored on their vertices .

You may not need to use this command in the following situations:

- Editing commands apply to both classic and lightweight polylines.
- The PlineType system variable specifies whether classic polylines are converted to lightweight polylines automatically when an older drawing is opened. You can use this system variable to determine which style of polyline is created in new drawings.

Related Commands

PLine (6.24.27) - draws polyline lines, arcs, and splines. PEdit (6.24.24) - edits polylines, 3D polylines, and 3D meshes.

Figure 6.714

6.9.32 ContentBrowserOpen

(6.2981 on page 6079) Opens the Content Browser panel.

Accessing the Command

command bar: **contentbrowseropen** context menu*: **Content Browser** (6.715 on the facing page) * Place the cursor over a toolbar or a ribbon panel, then right click. : **contentbrowseropen** Displays the Content Browser panel: (6.716 on page 3974)

Command Options

Option	Description
Add Folder...	Adds a folder to the **Local Folders** tree. Do one of the following: • Click the **Add Folder...** button. • Right click on the **Local Folders** node, then choose **Add folder** in the context menu.
Remove Folder	Removes a folder from the **Local Folders** tree. Right click the folder you want to remove and choose **Remove folder** in the context menu.
Open Drawing	Opens a drawing in one of the folders in the **Local Folders** tree. Do one of the following: • Double click the drawing name. • Right click the drawing name and choose **Open drawing** in the context menu.
Insert Block	Executes the -Insert (6.17.14) command. Do the following: • Expand the source drawing in the **Local Folders** tree. • Click **Blocks** . • Select the block, then do one of the following: • Drag the block onto the current drawing. • Right click and choose **Insert Block** in the context menu.
Copy Dimension Style	Copies the selected dimension style(s) to the current drawing. Do the following: • Expand the source drawing in the **Local Folders** tree. • Click **Dimension Styles** . • Select the style(s)*, then do one of the following: • Drag the selected style(s) onto the current drawing. • Right click and choose **Add Dimstyle(s)** in the context menu. * Press and hold the Ctrl-key to select multiple dimension styles.

Place View	Executes the PlaceView (6.24.34) command. Places a model view selected from a source drawing into a paper space layout of the current drawing. Do the following: • Switch to the layout where you want to place the model view in the target drawing. • Expand the source drawing in the **Local Folders** tree. • Click **Model Views** . (6.717 on the facing page) • Drag a model view from the **Content Browser** panel onto the paper space layout of the target drawing.* Prompts you: **Enter file name: (D:\BricsCAD Training\Bricscad\TrainingCD\EN\Exercises\House.dwg) Enter view name to place or [?]: (Garage (Option) right click to select scale.) Enter view origin point:** • (option) Right click and choose a scale in the Scale List • Click a point to place the view. The source drawing is inserted as an Xref drawing in the model space of the current drawing, on a layer with the same name as the source drawing A paper space viewport is added looking onto the xref according to a newly added view that matches the source view. In this new viewport, only the layers of the xref are set visible, so the view is not disturbed by other drawing content. If the current drawing belongs to a sheetset, a matching sheetset view is created and a view label block is added. * If the current layout does not belong to an open sheet set an alert box displays: (6.718 on the next page)

Procedures

To open or close a panel (1.15.7) To dock a panel (1.15.7) To dock a panel with respect to another docked panel (1.15.7) To stack panels in a tabbed panel (1.15.7)

Related Commands

ContentBrowserclose (6.9.39) - closes the Content Browser panel. -Insert (6.17.14) - inserts blocks, by prompting in the command bar and prompts for attribute values through the command bar or a dialog box. MView (6.21.37) - creates one or more viewports in layout tabs. PlaceView (6.24.34) - places a model view selected from a source drawing into a paper space layout of the current drawing.

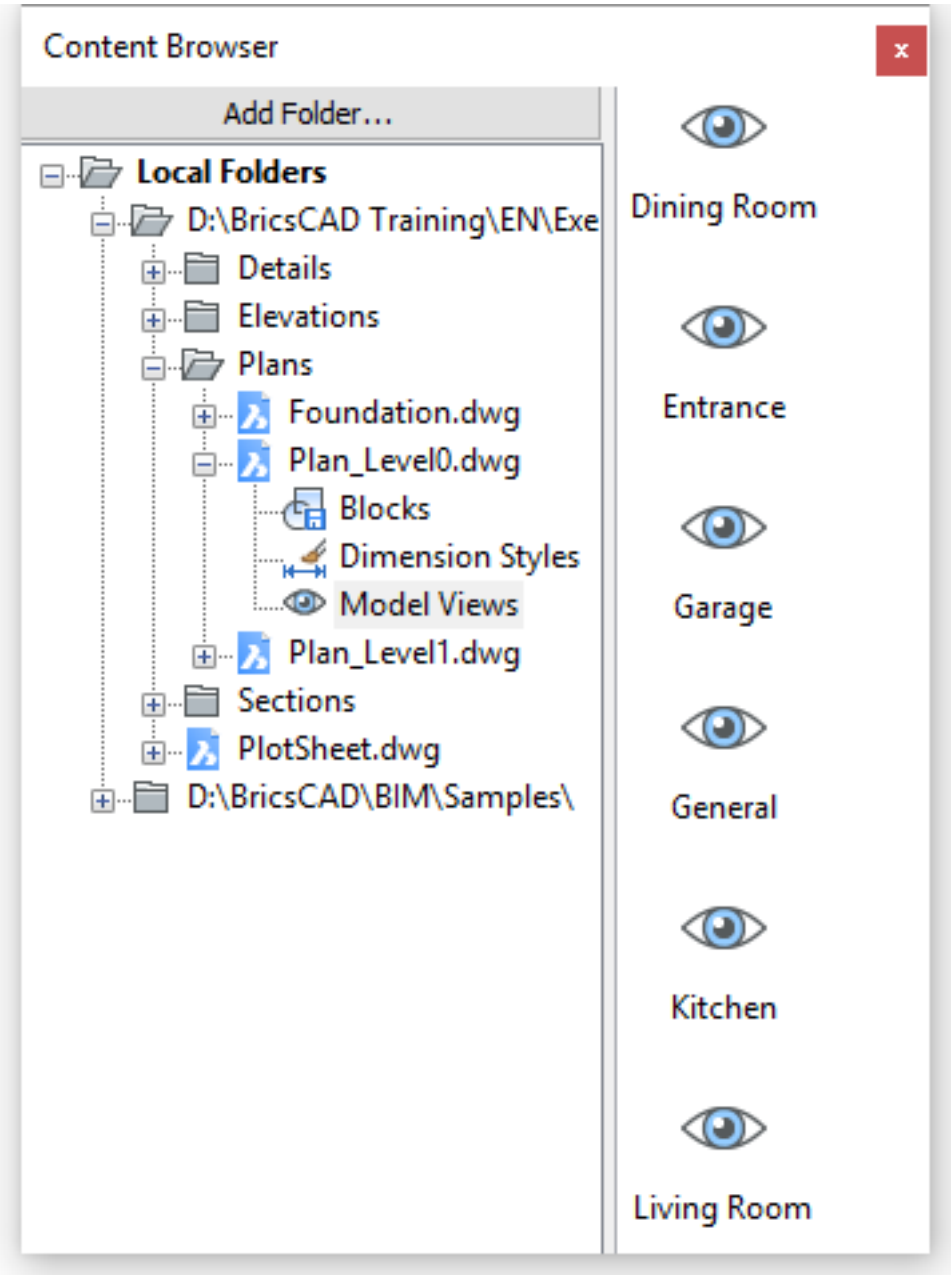

Figure 6.718

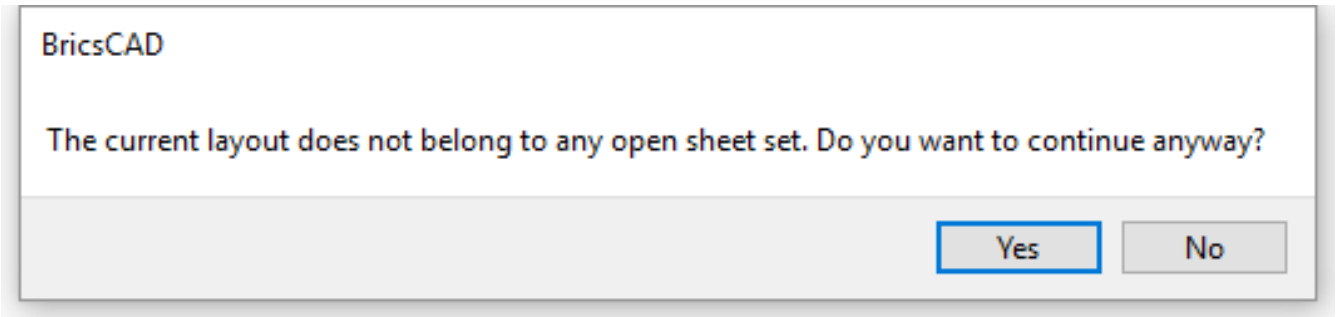

Figure 6.719

6.9.33 ConvToMesh

(7.3 on page 6132) Converts the following 2D and 3D entities to 3D meshes: 3D solids, 3D surfaces, 3D faces, polyface and polygon meshes (legacy), regions, and closed polylines.

Accessing the Command

Keyboard: **convtomesh :ConvToMesh You are prompted:** Select entities: **(Select one or more valid entities; see list below)** Entities in set: 1 Select entities: **(Press Enter to finish selecting entities and execute command)** BricsCAD converts the entities into meshes.

Command Options

Option	Description
Select entities:	Select one or more of the following entities: • 3D solids • 3D surfaces • 3D faces • Polyface and polygon meshes (legacy) • Regions • Closed polylines

The **Smoothness** property allows to control the 'roundness' of mesh entities in the Properties panel. (6.720) From left to right: None, Level 1, Level 2, Level 3, Level 4. (6.721 on the facing page)

Figure 6.720

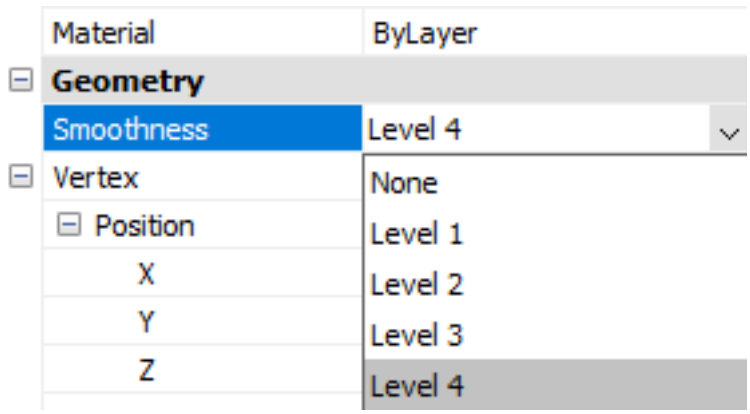

Figure 6.721

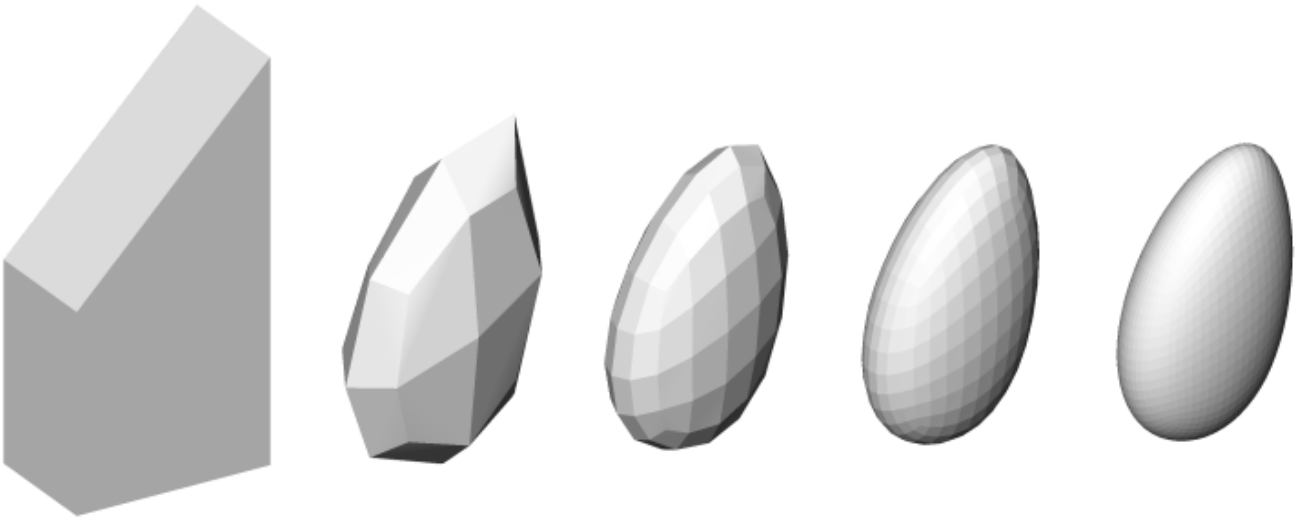


Related Commands

ConvToSolid (6.9.34) - converts entities to 3D solids. ConvToSurface (6.9.53) - converts entities to 3D surfaces

Figure 6.722

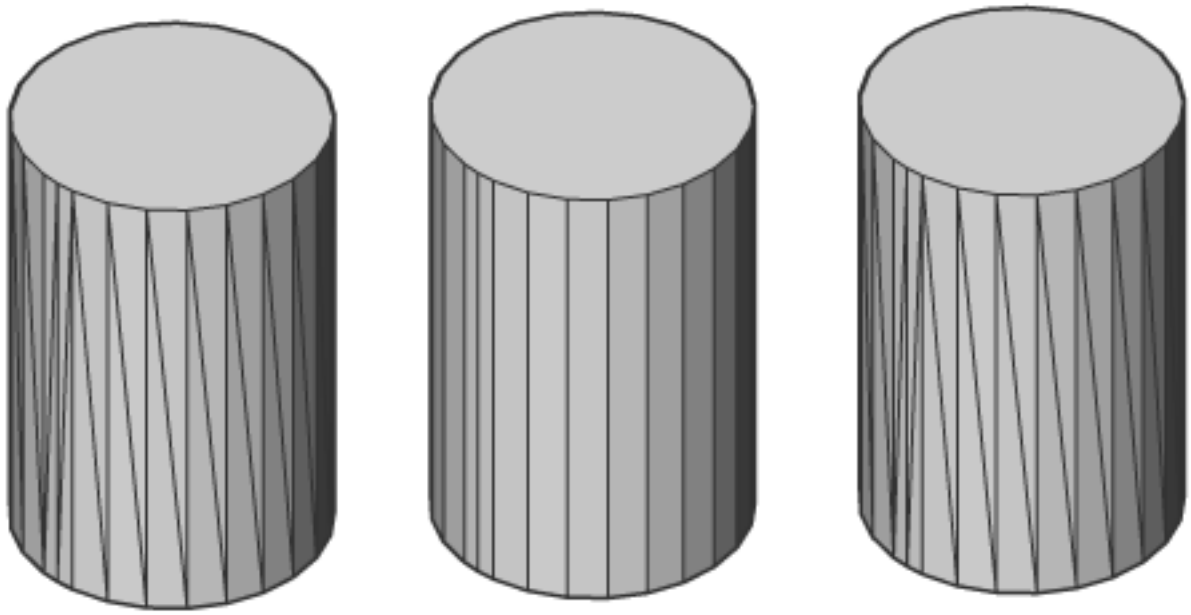
6.9.34 ConvToSolid

(7.3 on page 6132) Converts the following 2D and 3D entities to 3D solids: watertight 3D meshes and 3D surfaces; 3D polygon and polyface meshes; circles with thickness; and closed polylines of non-zero thickness and uniform width.

Accessing the Command

Keyboard: **convtosolid** : **ConvToSolid You are prompted:** Select entities [selection options (?)]: **(Select one or more valid entities, as listed below)** Entities in set: 1 Select entities [selection options (?)]: **(Press Enter to finish selecting entities and execute command)** BricsCAD converts the entities into 3D solids. Depending on the value of the SMOOTHMESHCONVERT system variable, the resulting faceted 3D solid is optipized or not. (6.723 on the facing page) From left to right: original mesh entity, faceted optimized solid, faceted non-optimized solid.

Figure 6.723



Command Options

Option	Description
Select entities:	Select one or more of the following entities: • Watertight 3D meshes and 3D surfaces • 3D polygon and polyface meshes • Circles with thickness • Closed polylines of non-zero thickness and uniform width ("Watertight" means a mesh or surface that is completely enclosed, with no gaps or other openings.)
selection options (?)	Allows to choose a selection method. See the SELECT (6.27.16) command.

Related Commands

ConvToMesh (6.9.33) - converts entities to 3D meshes. ConvToSurface (6.9.53) - converts entities to 3D surfaces.

Figure 6.724

Shape Classic Pro Platinum Mechanical BIM

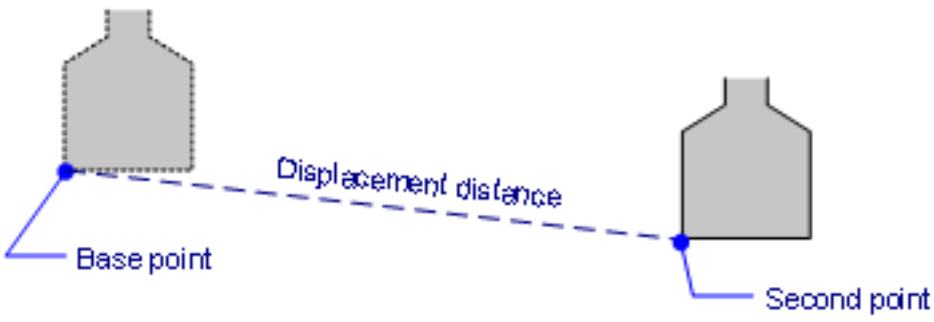
6.9.35 COPY

(7.3 on page 6132) Makes copies of entities, including repeating ones.

Accessing the Command

command bar: **copy** aliases: **co, cp** menu bar: **Modify | Copy** toolbar: **Modify |** ribbon: **Change | Arrange | Copy** Quad cursor menu: **Custom | : copy You are prompted:** Select entities to copy: **(Select one or more entities)** Select entities to copy: **(Select more entities, or else press Enter to end entity selection)** Current copy mode: Multiple Enter base point [Displacement/mOde] <Displacement>: **(Pick a point, or enter an option.)** Enter second point or [Array] <Use base point as displacement>: **(Pick another point, or press Enter)** Enter second point [Undo/Array/Repeat/Exit]: **(Pick another point, or enter an option)** (6.725)

Figure 6.725



Command Options

Option	Description
Select entities to copy	Use any selection mode to choose the entities to be copied.
Enter base point	Specifies the point from which to copy. Use entity snaps to pick the starting point accurately.
mOde	Toggles between single and multiple copying modes; prompts you: **Enter a copy mode [Single/Multiple] <Multiple>** - **(enter S or M)**: • **Single** - makes one copy, and then exits the command • **Multiple** - repeats the 'Enter second point' prompt until you enter the Exit option
Array	Specifies the number of copies to create and the distance between each copy or the distance between the first and last copies.
Displacement	Specifies the displacement (the distance at which to position the copy); prompts you: **Enter displacement point <0.0000,0.0000,0.0000>** - **(enter x,y,z coordinates, or pick a point)**
Enter second point	Specifies the destination of the copied entities by entering coordinates or picking a point When you use x,y,z coordinates, you copy objects in 3D space. Hold down the **Shift** key to copy entities in a horizontal or vertical direction
Use Base Point As Displacement	Determines the displacement distance from the coordinates of the base point.
Multiple	In single-copy mode only: Switches to multiple-copy mode.
Undo	In multiple-copy mode only: Undoes the last copy operation.
Repeat	Repeats the copy using the same displacement; prompts you: **Select end point (<ENTER> to key in number of repeats)** - **(specify a point or press Enter.)** • **Specify a point** - move the cursor in the displacement direction. The further you move away from the source entity, the more copies are created. Click when the desired number of copies displays. • **Enter number of repeats <1>** - press Enter to accept the previous number of repeats or type a number, then press Enter.
Exit	In multiple-copy mode only: Exits this command.

Procedures

- Using Copy and Paste to copy entities between drawings (1.32.18)
- Using Copy and Pasteorig to copy entities between drawings (1.32.18)
- Using Copybase and Paste to copy entities between drawings (1.32.18)
- Paste a selection as a block in the target drawing (1.32.18)
- To copy entities using grips (1.32.3)

Related Commands

3dArray (6.3.2) - creates arrayed copies of entities in 3D rectangular and polar patterns. Array (6.4.19) - creates arrayed copies of entities in 2D linear, rectangular, and polar patterns. CopyBase (6.9.58)- copies selected entities to the Clipboard with a base point, for pasting at an insertion point. CopyClip (6.9.36) - copies selected entities to the Clipboard, which can then be pasted in the same or other drawings. CopyGuided (6.9.50) - after selecting the entities, the relation to their guide curves will automatically guide you to inserting the copy in similar locations. CopyToLayer (6.9.40) - creates duplicates of selected entities on a layer specified by the user. MInsert (6.21.15) - inserts arrayed copies of blocks. Offset (6.23.3) - creates parallel copies of entities.

Figure 6.726

6.9.36 CopyClip

(7.3 on page 6132) Copies entities to the Clipboard for pasting into drawings and other documents. 

Accessing the Command

command bar: **copyclip** keyboard shortcut: **Ctrl+C** menu bar: **Edit | Copy** toolbar: **Standard |**  ribbon: **Home | Edit | Copy : copyclip You are prompted:** Select entities to copy to the clipboard: **(Choose one or more entities, or press Ctrl+A to sleet all of them)** Select entities to copy to the clipboard: **(Choose more entities, or press else Enter to exit entity selection)**

Command Options

Option	Description
Select entities to copy to the clipboard	Choose the entities to be copied; use any entity selection method. Once in the Clipboard, the entities can be pasted **Ctrl+V** into the same drawing, into other drawings, and into other documents.

The **PictureExportScale** user preference sets the resolution of the image when the exported geometry is pasted in bitmap format, such as in a Word document.

Procedures

- Using Copy and Paste to copy entities between drawings (1.32.18)
- Using Copy and Pasteorig to copy entities between drawings (1.32.18)

Related Commands

Copy (6.9.35) - makes copies entities, including repeating ones. ChSpace (6.9.13) - moves entities from paper space to model space and vice versa. CopyBase (6.9.58)- copies selected entities to the Clipboard with a base point. CopyHist (6.9.59) - copies all text from the Text window to the Clipboard. CutClip (6.9.48) - cuts (moves) selected entities to the Clipboard. PasteBlock (6.24.11) - pasted entities from the Clipboard as a block at an insertion point. PasteClip (6.24.13) - pastes entities from the Clipboard into the current drawing. PasteOrig (6.24.12) - pastes entities from the Clipboard at the original coordinates. PasteSpec (6.24.14) - displays the Paste Special dialog box for controlling the format of pasted entities.

Figure 6.727

6.9.37 CopyEData

(6.2981 on page 6079) Copies extended entity data from one entity to others.

Accessing the Command

command bar: **copyedata** transparent: **'Copyedata** menu bar: **Tools | Entity Data | Copy Entity Data** toolbar: **Entity Data |** **: copyedata You are prompted:** Copy Entity Data: Name of application or [?]: **(Enter the name of the application to which the entity data belongs, or else type ? to list the names of application)** Select entity from which to copy Entity Data: **(Choose a single entity.)** Select entity to which to copy Entity Data: **(Choose another entity)** Select entity to which to copy Entity Data: **(Choose another entity, or else press Enter to exit the command)**

Command Options

Option	Description
Name of Application	Specifies the name of the application that generated the extended entity data.
?	Lists the names of registered applications.
Select Entity From Which to Copy Entity Data	Selects the entity from which to copy edata. The entity must contain edata, which can be created with the EditEData command.
Select Entity To Which to Copy Entity Data	Specifies the entity to receive the edata.

Related Commands

DelEData (6.10.28) - erases extended entity data from entities. EditEData (6.13.3) - creates and edits extended entity data. MoveEData (6.21.39) - moves extended entity data to other entities. ReAssocApp (6.26.2) - associates applications with entities.

Figure 6.728

6.9.38 ConvertPStyles

(6.2981 on page 6079) Converts the plotting method in drawings to from CTB (using color tables) to STB (using named plot styles).

Accessing the Command

command bar: **convertpstyles** : **convertpstyles** Displays a dialog box: (6.729 on the following page) Click **OK**. The next dialog box appears: (6.730 on the next page) Choose an STB file, and then click **Open**. **BricsCAD reports in the command bar:** Drawing converted from Color Dependent mode to Named plot style mode. **(To convert CTB files to STB format, use the ConvertCtb (6.9.28) command.)**

Figure 6.729

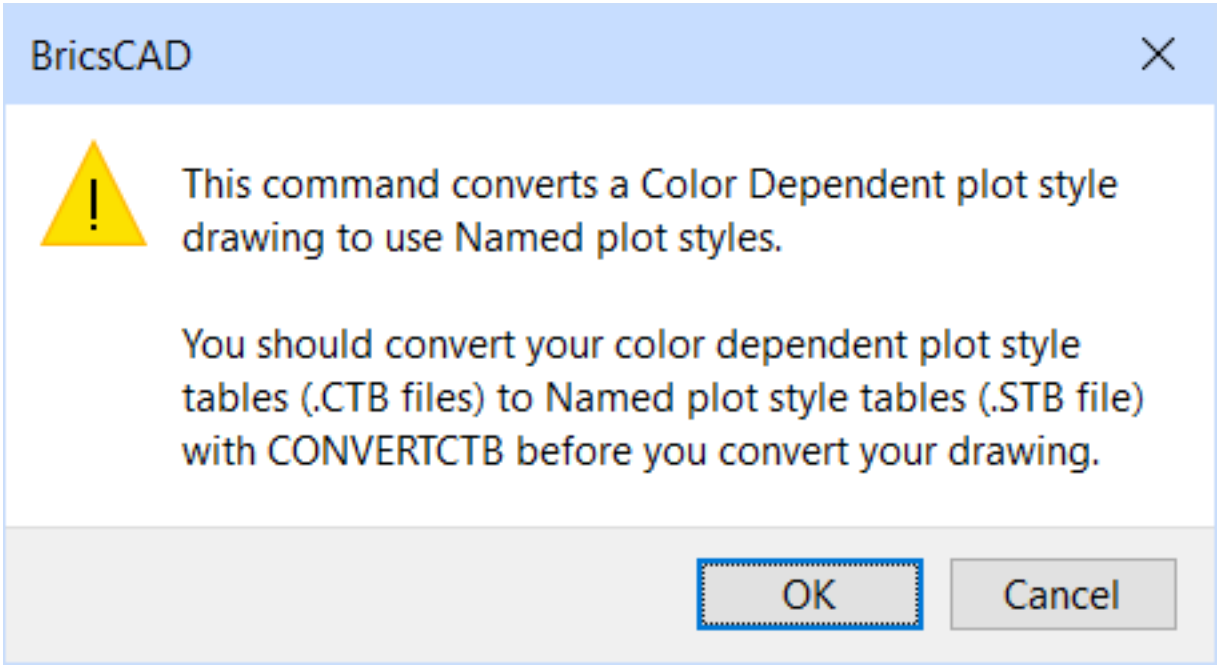


Figure 6.730

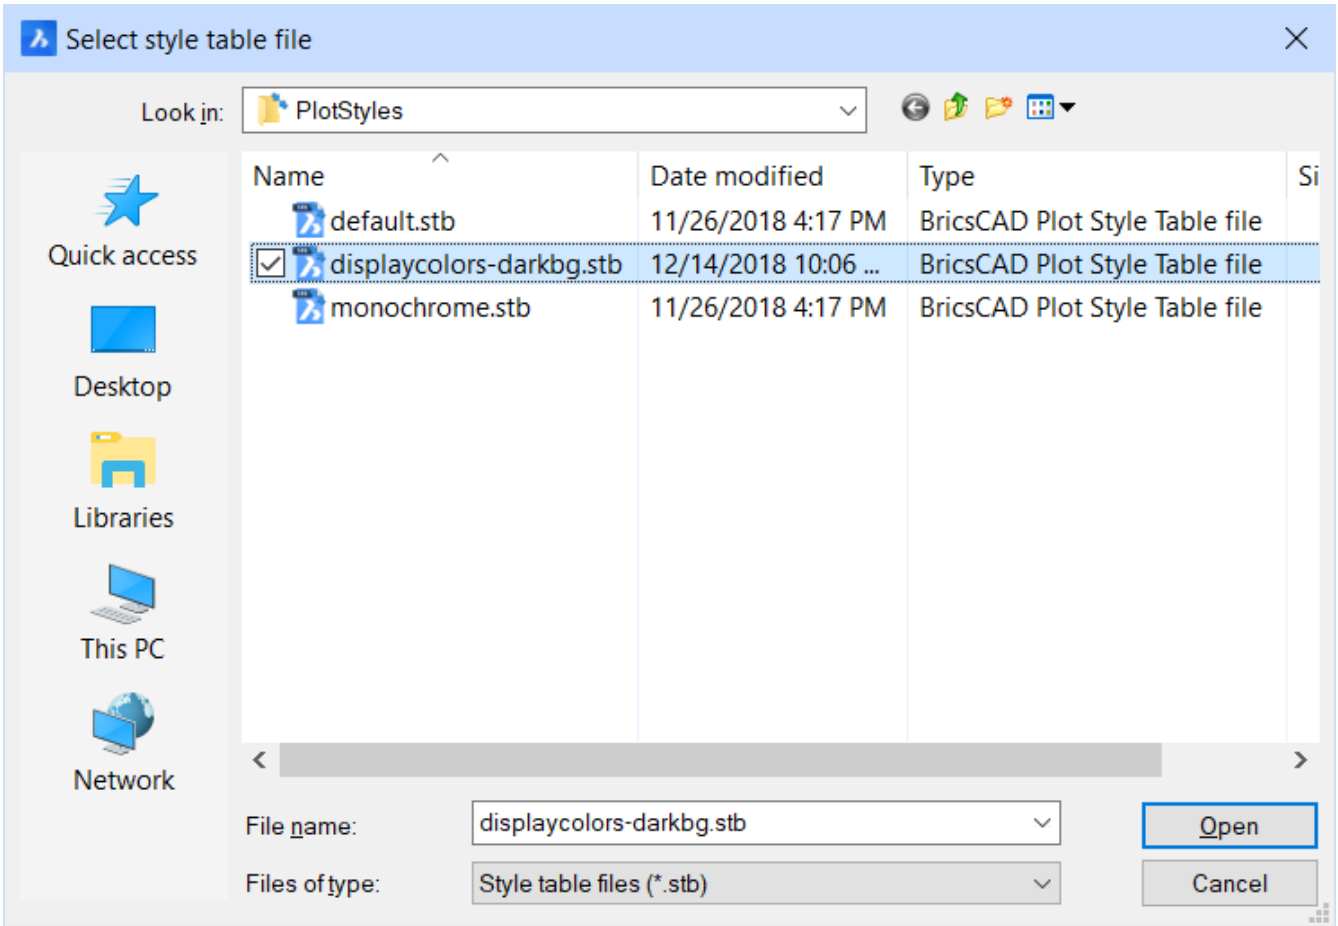

Procedures

- To edit plot style tables (1.33.3)
- To manage plot styles (1.33.5)

Related Commands

ConvertCtb (6.9.28) - converts CTB plot style files to STB files. Layer (6.13.17) - assigns plot styles to layers. PageSetup (6.24.2) - assigns plot style to drawings. PlotStyle (6.24.28) - sets the current plot style. Print (6.25.2) - plots drawings with plot styles. Properties (6.24.54) - changes plot styles assigned to entities. StylesManager (6.27.57) - creates and attaches plot styles to drawings.

Figure 6.731

6.9.39 ContentBrowserClose

(6.2981 on page 6079) Closes the Content Browser panel.

Accessing the Command

command bar: **contentbrowserclose : contentbrowserclose**

Related Commands

ContentBrowserOpen (6.9.32) - opens the Content Browser panel.

Figure 6.732

6.9.40 CopyToLayer

(7.3 on page 6132) Creates duplicates of selected entities on a layer specified by the user.

Accessing the Command

Keyboard: **copytolayer : copytolayer Prompts you:** Select entities to copy [selection options (?)]: **(Select entities or type ?.)** Entities in set: 1 Select entities to copy [selection options (?)]: **(Select more entities or type ? or press Enter.)** Select object on target layer or [Name] <Name>: **(Select an entity or press Enter.)** Enter base point [Displacement/Exit] <Exit>: **(Specify a point or choose an option.)** Enter second point <Use base point as displacement>: **(Specify a point or press Enter.)**

Command Options

Title	Description
Selection options (?)	Prompts you to choose a selection method. See the Select (6.27.16) command.
Select object on target layer	Select an entity on the layer you want the selection to be copied to.
Name	Lets you choose the target layer in a dialog box: (6.733 on the following page) Select a layer, then click the **OK** button.
Enter base point Enter second point	Specifies the start and end point of the displacement. Prompts you: **Enter base point [Displacement/Exit] <Exit>: (Specify a point or choose an option.) Enter second point <Use base point as displacement>:** • **Enter second point**: Specify a point or enter a distance and angle in the dynamic input fields when Dynamic Input Mode (DYN) is active. • **Use base point**: Copies the selection at the same location on the target layer.
Displacement	Prompts you: **Enter displacement vector <0.00, 0.00, 0.00>:** Do one of the following: • Enter x,y,z coordinate values to specify a relative distance and direction. • When Dynamic Input Mode (DYN) is active, type a distance and angle in the dynamic input fields.
Exit	Exits the command without copying the selection.

Related Commands

Copy (6.9.35) - makes copies entities, including repeating ones.

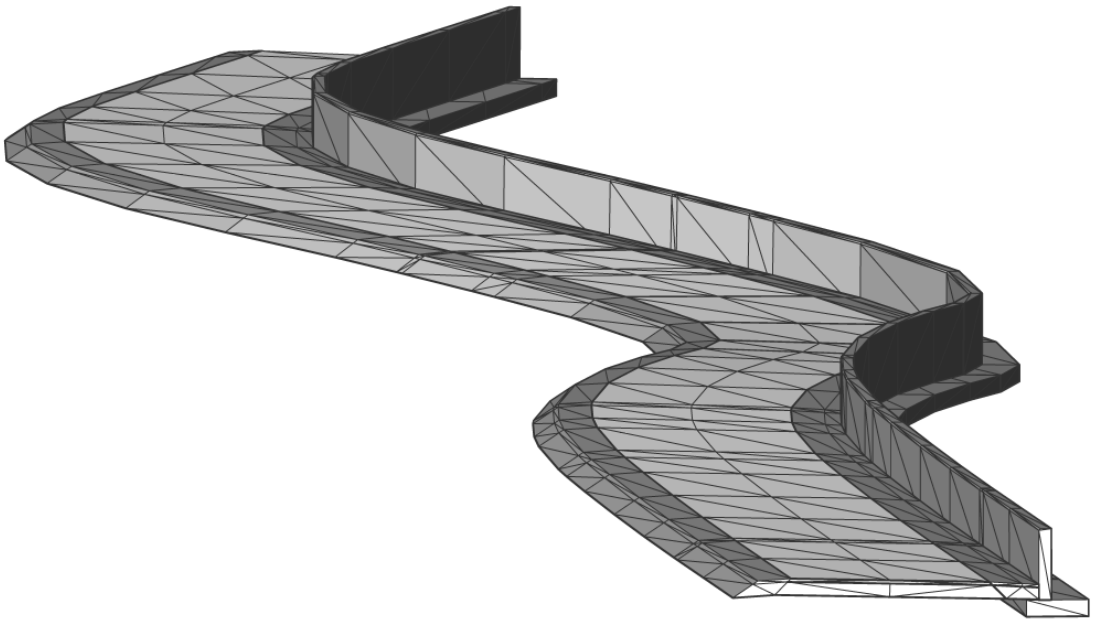
6.9.41 Corridor

(6.2880 on page 5977) Creates a corridor from a corridor template, 3D alignment and/or TIN Surface.

Accessing the Command

Commandline: **CORRIDOR** Quad: **Model | Corridor** Ribbon: **Civil | Create | Corridor : Corridor Prompts you:** Select 3d alignment used as a corridor baseline: **(select a 3D alignment)** Select corridor template: **(select a corridor template)** Enter region start station: **(enter the start station for the selected corridor template)** Enter region end station: **(enter the end station for the selected corridor template)** (6.735 on the following page)

Figure 6.735



Procedures

Creating a road corridor (1.26.12) Displaying the properties of a Corridor (1.26.12) Creating a template of road cross-section with asphalt layer and left and right kerb (1.26.12) Creating a template element of kerb (1.26.12)

Related Commands

CorridorTemplateElement (6.9.44) - Creates a corridor template element from closed polylines. CorridorTemplate (6.9.43) - Creates a corridor template from template elements. CorridorEdit (6.9.42) - Adds or removes regions for a selected corridor. CorridorExtract (6.9.52) - Extracts a 3D solid, 3D mesh, or 3D polyline from a corridor. Tin (6.29.14) - Creates a topographical surface from an imported points file or placing new points. Alignment (6.4.5) - Creates horizontal, vertical and 3D alignments to represent a reference system used to position linear objects in space.

Figure 6.736

6.9.42 CorridorEdit

(6.2880 on page 5977) Adds or removes regions for a selected corridor.

Accessing the Command

Commandline: **CORRIDOREDIT** Ribbon: **Civil | Modify | Edit Corridor : CorridorEdit Prompts you:** Select corridor: **(select a corridor to edit)** Select option [Add Region/Remove Region]: **(Choose Add or Remove region then select the corridor template you wish to add or the region you wish to remove)**

Procedures

Creating a road corridor (1.26.12) Editing a corridor (1.26.12) Creating a template of road cross-section with asphalt layer and left and right kerb (1.26.12) Creating a template element of kerb (1.26.12)

Related Commands

Corridor (6.9.41) - Creates a corridor from a corridor template, 3D alignment and/or TIN Surface. CorridorTemplateElement (6.9.44) - Creates a corridor template element from closed polylines. CorridorTemplate (6.9.43) - Creates a corridor template from template elements. CorridorExtract (6.9.52) - Extracts a 3D solid, 3D mesh, or 3D polyline from a corridor. Tin (6.29.14) - Creates a topographical surface from an imported points file or placing new points. Alignment (6.4.5) - Creates horizontal, vertical and 3D alignments to represent a reference system used to position linear objects in space.

Figure 6.737

6.9.43 CorridorTemplate

(6.2880 on page 5977) Creates a corridor template from template elements.

Accessing the Command

Commandline: **CORRIDORTEMPLATE** Ribbon: **Civil | Create | Corridor Template : CorridorTemplate Prompts you:** Pick point to create corridor template or [Add template element]: **(pick a point or choose Add to add a template element)** (6.738)

(6.2880 on page 5977) Creates a corridor template element from closed polylines.

Accessing the Command

Commandline: **CORRIDORTEMPLATEELEMENT** Ribbon: **Civil | Create | Corridor Template Element : CorridorTemplateElement Prompts you:** Select polylines representing the corridor template element [selection options (?)]: **(select the polylines)** Pick corridor template element base point: **(pick the basepoint)** (6.740)

Figure 6.740

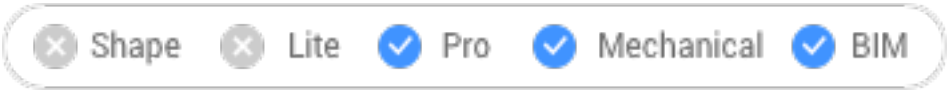
Procedures

Creating a template of road cross-section with asphalt layer and left and right kerb (1.26.12) Creating a template element of kerb (1.26.12) Creating a road corridor (1.26.12)

Related Commands

CorridorTemplate (6.9.43) - Creates a corridor template from template elements. Corridor (6.9.41) - Creates a corridor from a corridor template, 3D alignment and/or TIN Surface. CorridorEdit (6.9.42) - Adds or removes regions for a selected corridor. CorridorExtract (6.9.52) - Extracts a 3D solid, 3D mesh, or 3D polyline from a corridor. Tin (6.29.14) - Creates a topographical surface from an imported points file or placing new points. Alignment (6.4.5) - Creates horizontal, vertical and 3D alignments to represent a reference system used to position linear objects in space.

Figure 6.741



6.9.45 -CreateLibraryBlock

(6.1951 on page 5150) Creates library blocks from a selection set or an entire drawing and adds them to the library; prompts you in the command line.

Accessing the Command

Keyboard: **-createlibraryblock** Alias: **-bmcreatecomponent : -createlibraryblock Prompts you:** Select entities to create component from or use [selection options (?)] <Drawing>: **(Select entities or press Enter to select the entire drawing.)** Entities in set: 1 Select entities to create component from or use [selection options (?)] <Drawing>: **(Select more entities or press Enter to stop selecting.)** Specify component category: [1 - All/ 2 - Building/ ... - 0 - Add new category/] <rootCat (current category)>: **(Type the number of a category or press Enter to add the component to the current category.)** Specify the component name: **(Type a name for the new component.)** Enter component base point :<0, 0, 0>: **(Specify the base point or press Enter to accept the WCS origin.)** Enter thumbnail position [Top Front Left/Top Front Right/Top Back Left/Top Back Right/Top] <Top Front Left>: **(Choose an option.)** Generating thumbnails... done.

Command Options

Option	Description
Select entities	Do one of the following: • Select the entities to be included in the component. Press Enter to stop selecting. • Press Enter at the first prompt to include all entities in the drawing.
Specify component category	The options are: • **Current**: The currently selected category in the Components Panel (6.9.26). • **1 - All/ 2 - Building/ 3 - Doors/ 4 ...**: All subcategories of the currently selected category are listed. Enter the number of a category. • **0 - Add new category/**: creates a new category as a subcategory of the currently selected category in the Library panel. Type 0. Prompts you: **Specify new category name: Type a name.** The name is added to the available categories list. Type the number of the newly created category.
Base point	Defines the base point of the component. Do one of the following: • Press Enter to accept the origin of the WCS (0,0,0). • Type the x,y,z coordinates. • Pick a point in the drawing.

Thumbnail position	Defines the view orientation of the thumbnail image. The options are: • Four isometric views: Top Front Left, Top Front Right, Top Back Left and Top Back Right • Top

Related Commands

CreateLibraryBlock (6.9.55) - Creates library blocks from a selection set or an entire drawing and adds them to the library through a dialog box. LIbrayPanelOpen (6.20.23) - Opens the Library panel.

Figure 6.742

6.9.46 Cone

(7.3 on page 6132) Creates cones and truncated cones:

- Classic: cone is drawn from a 3D polyface mesh (see the Ai_Cone (6.5.8) command).
- Other license levels: cone is drawn as a 3D solid

Accessing the Command

 command bar: **cone** menu bar: **Model | 3D Solids | Cone** toolbar: **3D Solids |**  ribbon: **Solid | Create | Primitive | Cone : cone You are prompted:** Select center point or [3Point/2Point/Ttr/Elliptical]: **(Pick a point, or enter an option)** Radius of base of cone or Diameter <xx.xx>: **(type a value, or pick a point to define the base radius, press Enter to accept the default value, or else type D to define the diameter)** Specify height or [2Point/Axis/Top] <xx.xx>: **(Type a value, pick a point, press Enter to accept the default value, or else enter an option)** (6.743 on the facing page) When Dynamic Dimensions (1.21.9) are active, you can enter the dimensions in the dynamic dimensions entry fields. (6.744 on the next page)

Figure 6.743

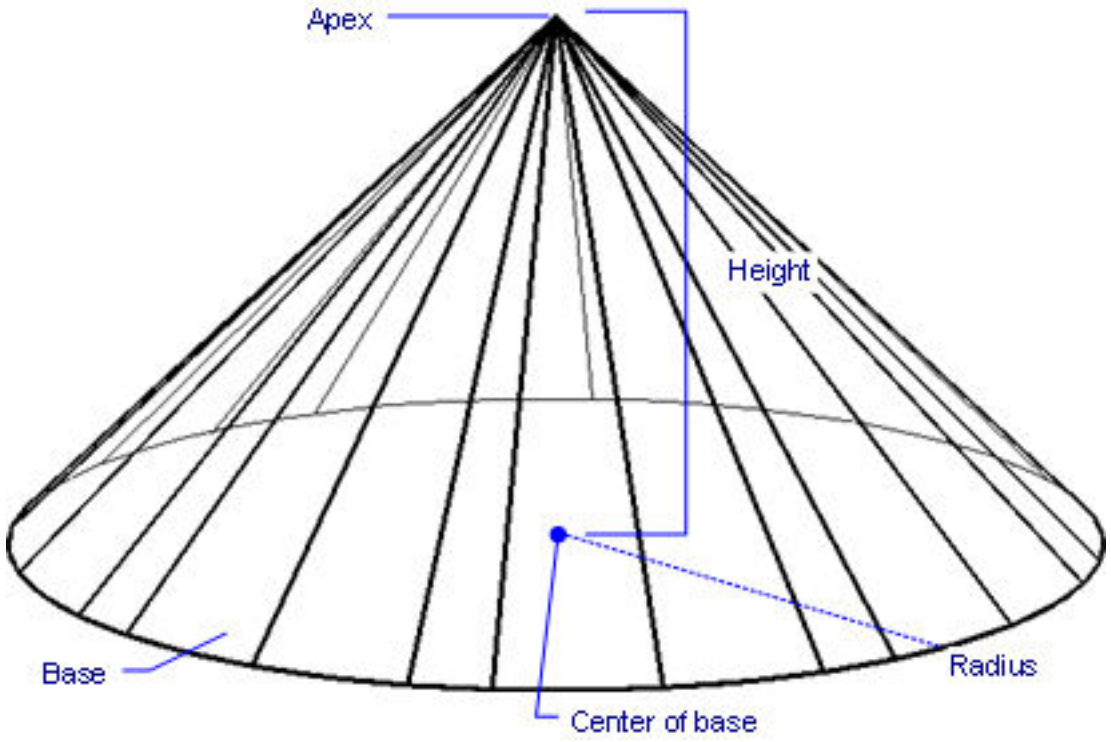


Figure 6.744

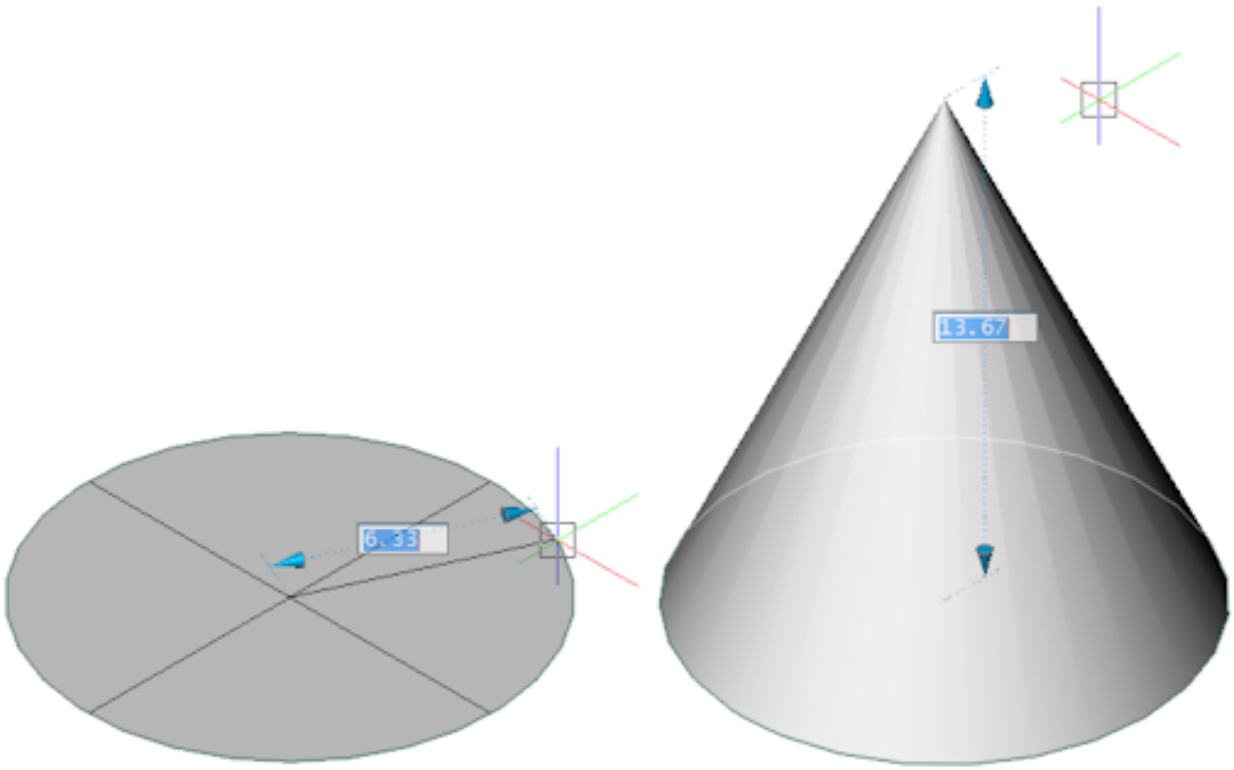


Command Options

Base Options	Description
3Point	Defines a circular base through three points that indicate the circumference. Prompts you: 1. **First point** - **(specify a point)** 2. **Second point** - **(specify a point)** 3. **Third point** - **(specify a point)** 4. **Specify height or [2Point/Axis/Top] <xx.xx>** - **(type a value or choose an option)**
2Point	Defines a circular base through two points that indicate the diameter). Prompts you: 1. **First end of diameter** - **(specify a point)** 2. **Second end of diameter** - **(specify a point)** 3. **Specify height or [2Point/Axis/Top] <xx.xx>** - **(type a value or choose an option)**
TTR (Tangent Tangent Radius)	Defines the diameter of the circular base as tangent to two entities and a radius. Prompts you: 1. **Specify point on object for first tangent** - **(select a point on a circle, arc, line or polyline segment)**; the Tangent (6.29.10) entity snap turns on automatically. 2. **Specify point on object for second tangent** - **(select a point on a circle, arc, line or polyline segment)**; the Tangent entity snap turns on automatically. 3. **Radius of circle** - **(type a value or specify two points)** 4. **Specify height or [2Point/Axis/Top] <xx.xx>** - **(type a value, or else choose an option)**
Elliptical	Defines an base that is elliptical. Prompts you: 1. **Set first end of ellipse or [Center]** - **(specify the first end of the major axis of the ellipse.)** 2. **Second end of ellipse axis** - **(specify the second end of the major axis of the ellipse.)** 3. **Other end of ellipse axis** - **(specify the endpoint of the minor axis of the ellipse.)** 4. **Specify height or [2Point/Axis/Top] <xx.xx>** - **(type a value or choose an option.)**

Height options	Description

2Point	Specifies the height of the cone as the distance between any two points; prompts you: 1. **Specify first point - (pick a point or else enter x,y,z coordinates)** 2. **Specify second point - (pick a point or else enter x,y,z coordinates)**
Axis	Specifies the height of the cone by picking a point for the cone's tip, rotating the cone as necessary. Prompts you: **Specify axis endpoint - (pick a point or else enter x,y,z coordinates)**
Top	Create a truncated cone, where the top is flat. Prompts you: 1. **Radius of top of cone <0> - (specify the radius of the top face of the truncated cone)** 2. **Specify height or [2Point/Axis/Top] <xx.xx> - (press Enter to accept the default value, type a value, or pick a point, or enter an option)**

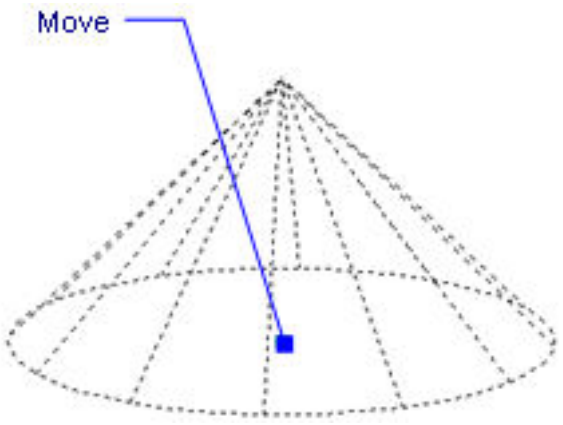
Grips Editing

Cone can be edited directly through grips:

1. Select the Cone. Notice that it has one grip.
2. Drag the grip to move the cone.

(6.745)

Figure 6.745



Related Commands

Box (6.6.18) - creates 3D boxes as solid models. Cylinder (6.9.49) - creates 3D cylinders as solid models. Dish (6.10.42) - creates the lower half of 3D balls as solid models. Dome (6.10.35) - creates the upper half of 3D balls as solid models. Extrude (6.13.25) - extrudes 2D entities into 3D solid models. Interfere (6.17.17) - creates 3D volumes of intersecting 3D solid models. Intersect (6.17.20) - removes volumes not in common between two solid models. MassProp (6.21.2) - reports the mass properties of 3D solid models and 2D regions. Pyramid (6.24.64) - creates a pyramid as a 3D solid (Pro and Platinum). Creates a pyramid as a polygon mesh (Classic) Revolve (6.26.45) - revolves 2D entities into 3D solid models. Section (6.27.11) - creates 2D regions from 3D models. Slice (6.27.40) - cuts 3D solids into two parts. SolidEdit (6.27.42) - edits the bodies, faces, and edges of 3D models. Sphere (6.27.50) - creates 3D balls as solid models. Subtract (6.27.58) - removes one solid model from a second. Torus (6.29.29) - creates 3D donuts as solid models. Union (6.30.6) - joins two or more solid models into a single entity. Wedge (6.33.6) - creates 3D wedges as solid models.
